

MySQL 5.1 Reference Manual

Including MySQL Cluster NDB 6.X/7.X Reference Guide

MySQL 5.1 Reference Manual: Including MySQL Cluster NDB 6.X/7.X Reference Guide

Abstract

This is the MySQL™ Reference Manual. It documents MySQL 5.1 through 5.1.52, as well as MySQL Cluster releases based on versions 6.1, 6.2, 6.3, 7.0, and 7.1 of **NDBCLUSTER** through 5.1.15-ndb-6.1.23, 5.1.47-ndb-6.2.19, 5.1.47-ndb-6.3.38, 5.1.47-ndb-7.0.19, and 5.1.47-ndb-7.1.8.

MySQL 5.1 features. This manual describes features that are not included in every edition of MySQL 5.1; such features may not be included in the edition of MySQL 5.1 licensed to you. If you have any questions about the features included in your edition of MySQL 5.1, refer to your MySQL 5.1 license agreement or contact your Oracle sales representative.

Your access to and use of this material is subject to the terms and conditions of your Oracle Software License and Service Agreement, which has been executed and with which you agree to comply. This document and information contained herein may not be disclosed, copied, reproduced, or distributed to anyone outside Oracle without prior written consent of Oracle or as specifically provided below. This document is not part of your license agreement nor can it be incorporated into any contractual agreement with Oracle or its subsidiaries or affiliates.

This documentation is NOT distributed under a GPL license. Use of this documentation is subject to the following terms:

You may create a printed copy of this documentation solely for your own personal use. Conversion to other formats is allowed as long as the actual content is not altered or edited in any way. You shall not publish or distribute this documentation in any form or on any media, except if you distribute the documentation in a manner similar to how Oracle disseminates it (that is, electronically for download on a Web site with the software) or on a CD-ROM or similar medium, provided however that the documentation is disseminated together with the software on the same medium. Any other use, such as any dissemination of printed copies or use of this documentation, in whole or in part, in another publication, requires the prior written consent from an authorized representative of Oracle. Oracle and/or its affiliates reserve any and all rights to this documentation not expressly granted above.

For more information on the terms of this license, for details on how the MySQL documentation is built and produced, or if you are interested in doing a translation, please visit [MySQL Contact & Questions](#).

For additional licensing information, including licenses for libraries used by MySQL products, see [Preface, Notes, Licenses](#).

If you want help with using MySQL, please visit either the [MySQL Forums](#) or [MySQL Mailing Lists](#) where you can discuss your issues with other MySQL users.

For additional documentation on MySQL products, including translations of the documentation into other languages, and downloadable versions in variety of formats, including HTML and PDF formats, see the [MySQL Documentation Library](#).

Table of Contents

Preface, Notes, Licenses	xxxii
1. Licenses for Third-Party Components	xxxii
1.1. <code>FindGTest.cmake</code> License	xxxiii
1.2. <code>LPEG</code> Library License	xxxiv
1.3. <code>LuaFileSystem</code> Library License	xxxiv
1.4. <code>getarg</code> License	xxxiv
1.5. <code>libedit</code> License	xxxv
1.6. <code>libevent</code> License	xxxvi
1.7. <code>zlib</code> License	xxxvi
1.8. ASM	xxxvi
1.9. Apache Commons Collections	xxxvii
1.10. Apache Commons DBCP	xxxvii
1.11. Apache Commons FileUpload	xxxvii
1.12. Apache Commons IO	xxxvii
1.13. Apache Commons Lang	xxxviii
1.14. Apache Commons Logging	xxxviii
1.15. Apache Commons Pool	xxxviii
1.16. Apache Commons Validator	xxxviii
1.17. Apache License Version 2.0, January 2004	xxxviii
1.18. Apache Tomcat	xli
1.19. Apache log4j	xli
1.20. Apache log4j Version 1.2.9	xli
1.21. Boost Library License	xlii
1.22. Fred Fish's Dbug Library License	xlii
1.23. JDOM Project	xliii
1.24. OpenSSL v0.9.8o and later	xliii
1.25. RegEX-Spencer Library License	xliv
1.26. Richard A. O'Keefe String Library License	xliv
1.27. SHA-1 in C License	xliv
1.28. Spring Framework	xlv
1.29. StringTemplate Template Engine	xlv
1.30. cURL (<code>libcurl</code>) License	xlv
1.31. jQuery	xlvii
1.32. jQuery UI	xlvii
1.33. md5 (Message-Digest Algorithm 5) License	xlvii
1.34. nt_servc (Windows NT Service class library) License	xlvii
1. General Information	1
1.1. About This Manual	1
1.2. Typographical and Syntax Conventions	2
1.3. Overview of the MySQL Database Management System	3
1.3.1. What is MySQL?	3
1.3.2. History of MySQL	4
1.3.3. The Main Features of MySQL	4
1.4. MySQL Development History	7
1.5. What Is New in MySQL 5.1	7
1.6. MySQL Information Sources	9
1.6.1. MySQL Mailing Lists	9
1.6.2. MySQL Community Support at the MySQL Forums	11
1.6.3. MySQL Community Support on Internet Relay Chat (IRC)	11
1.6.4. MySQL Enterprise	11
1.7. How to Report Bugs or Problems	12
1.8. MySQL Standards Compliance	15
1.8.1. What Standards MySQL Follows	15
1.8.2. Selecting SQL Modes	15
1.8.3. Running MySQL in ANSI Mode	16
1.8.4. MySQL Extensions to Standard SQL	16
1.8.5. MySQL Differences from Standard SQL	18
1.8.6. How MySQL Deals with Constraints	22
1.9. Credits	24
1.9.1. Contributors to MySQL	24
1.9.2. Documenters and translators	28
1.9.3. Packages that support MySQL	29
1.9.4. Tools that were used to create MySQL	30
1.9.5. Supporters of MySQL	30

2. Installing and Upgrading MySQL	32
2.1. General Installation Guidance	33
2.1.1. Operating Systems Supported by MySQL Community Server	33
2.1.2. Choosing Which MySQL Distribution to Install	34
2.1.3. How to Get MySQL	37
2.1.4. Verifying Package Integrity Using MD5 Checksums or GnuPG	37
2.1.5. Installation Layouts	39
2.1.6. Compiler-Specific Build Characteristics	39
2.2. Installing MySQL from Generic Binaries on Unix/Linux	40
2.3. Installing MySQL Using a Source Distribution	43
2.3.1. MySQL Installation Layout for Source Installation	44
2.3.2. Source Installation Overview	44
2.3.3. Typical <code>configure</code> Options	46
2.3.4. Installing from the Development Source Tree	53
2.3.5. Dealing with Problems Compiling MySQL	55
2.4. Installing MySQL on Microsoft Windows	57
2.4.1. MySQL Installation Layout on Microsoft Windows	59
2.4.2. Choosing the Installation Package for Microsoft Windows	59
2.4.3. Installing MySQL on Windows Using the MSI Package	62
2.4.4. Using the MySQL Server Instance Config Wizard	67
2.4.5. Installing MySQL on Microsoft Windows from a <code>noinstall</code> Zip Archive	81
2.4.6. Troubleshooting a Microsoft Windows MySQL Server Installation	87
2.4.7. Upgrading MySQL Server on Microsoft Windows	89
2.4.8. MySQL Server on Microsoft Windows Post-Installation Procedures	89
2.4.9. Installing MySQL from Source on Windows	91
2.4.10. Compiling MySQL Clients on Microsoft Windows	94
2.5. Installing MySQL on Mac OS X	94
2.5.1. General Notes on Installing MySQL on Mac OS X	95
2.5.2. Installing MySQL on Mac OS X Using Native Packages	95
2.5.3. Installing the MySQL Startup Item	98
2.5.4. Installing and Using the MySQL Preference Pane	101
2.5.5. Using the Bundled MySQL on Mac OS X Server	102
2.6. Installing MySQL on Linux	103
2.6.1. Installing MySQL from RPM Packages on Linux	104
2.6.2. Installing MySQL on Linux using Native Package Manager	107
2.7. Installing MySQL on Solaris and OpenSolaris	110
2.7.1. Installing MySQL on Solaris using a Solaris PKG	111
2.7.2. Installing MySQL on OpenSolaris using IPS	111
2.7.3. Notes on Installing MySQL on Solaris from Source	112
2.8. Installing MySQL on IBM AIX	113
2.8.1. General Notes on Installing MySQL on AIX	113
2.8.2. Notes on Installing MySQL on AIX from Source	114
2.9. Installing MySQL on HP-UX	114
2.9.1. General Notes on Installing MySQL on HP-UX	114
2.9.2. Notes on Installing MySQL on HP-UX from Source	115
2.9.3. Installing MySQL on HP-UX using DEPOT	115
2.10. Installing MySQL on FreeBSD	116
2.11. Installing MySQL on i5/OS	116
2.12. Upgrading or Downgrading MySQL	120
2.12.1. Upgrading MySQL	120
2.12.2. Downgrading MySQL	128
2.12.3. Checking Whether Tables or Indexes Must Be Rebuilt	130
2.12.4. Rebuilding or Repairing Tables or Indexes	131
2.12.5. Copying MySQL Databases to Another Machine	132
2.13. Post-Installation Setup and Testing	133
2.13.1. Unix Post-Installation Procedures	133
2.13.2. Securing the Initial MySQL Accounts	141
2.14. Environment Variables	144
2.15. Perl Installation Notes	145
2.15.1. Installing Perl on Unix	146
2.15.2. Installing ActiveState Perl on Windows	146
2.15.3. Problems Using the Perl DBI/DBD Interface	147
3. Tutorial	149
3.1. Connecting to and Disconnecting from the Server	149
3.2. Entering Queries	150
3.3. Creating and Using a Database	152
3.3.1. Creating and Selecting a Database	153
3.3.2. Creating a Table	153
3.3.3. Loading Data into a Table	154
3.3.4. Retrieving Information from a Table	155

3.4. Getting Information About Databases and Tables	165
3.5. Using <code>mysql</code> in Batch Mode	166
3.6. Examples of Common Queries	167
3.6.1. The Maximum Value for a Column	168
3.6.2. The Row Holding the Maximum of a Certain Column	168
3.6.3. Maximum of Column per Group	168
3.6.4. The Rows Holding the Group-wise Maximum of a Certain Column	169
3.6.5. Using User-Defined Variables	169
3.6.6. Using Foreign Keys	169
3.6.7. Searching on Two Keys	171
3.6.8. Calculating Visits Per Day	171
3.6.9. Using <code>AUTO_INCREMENT</code>	171
3.7. Queries from the Twin Project	173
3.7.1. Find All Nondistributed Twins	173
3.7.2. Show a Table of Twin Pair Status	174
3.8. Using MySQL with Apache	175
4. MySQL Programs	176
4.1. Overview of MySQL Programs	176
4.2. Using MySQL Programs	180
4.2.1. Invoking MySQL Programs	180
4.2.2. Connecting to the MySQL Server	180
4.2.3. Specifying Program Options	183
4.2.4. Setting Environment Variables	192
4.3. MySQL Server and Server-Startup Programs	193
4.3.1. <code>mysqld</code> — The MySQL Server	193
4.3.2. <code>mysqld_safe</code> — MySQL Server Startup Script	193
4.3.3. <code>mysql.server</code> — MySQL Server Startup Script	198
4.3.4. <code>mysqld_multi</code> — Manage Multiple MySQL Servers	199
4.4. MySQL Installation-Related Programs	202
4.4.1. <code>comp_err</code> — Compile MySQL Error Message File	202
4.4.2. <code>make_win_bin_dist</code> — Package MySQL Distribution as ZIP Archive	203
4.4.3. <code>mysqlbug</code> — Generate Bug Report	204
4.4.4. <code>mysql_fix_privilege_tables</code> — Upgrade MySQL System Tables	204
4.4.5. <code>mysql_install_db</code> — Initialize MySQL Data Directory	205
4.4.6. <code>mysql_secure_installation</code> — Improve MySQL Installation Security	206
4.4.7. <code>mysql_tzinfo_to_sql</code> — Load the Time Zone Tables	206
4.4.8. <code>mysql_upgrade</code> — Check Tables for MySQL Upgrade	206
4.5. MySQL Client Programs	208
4.5.1. <code>mysql</code> — The MySQL Command-Line Tool	208
4.5.2. <code>mysqladmin</code> — Client for Administering a MySQL Server	224
4.5.3. <code>mysqlcheck</code> — A Table Maintenance Program	230
4.5.4. <code>mysqldump</code> — A Database Backup Program	235
4.5.5. <code>mysqlimport</code> — A Data Import Program	248
4.5.6. <code>mysqlshow</code> — Display Database, Table, and Column Information	252
4.5.7. <code>mysqlslap</code> — Load Emulation Client	255
4.6. MySQL Administrative and Utility Programs	262
4.6.1. <code>innodbchecksum</code> — Offline InnoDB File Checksum Utility	262
4.6.2. <code>myisam_ftdump</code> — Display Full-Text Index information	262
4.6.3. <code>myisamchk</code> — MyISAM Table-Maintenance Utility	263
4.6.4. <code>myisamlog</code> — Display MyISAM Log File Contents	277
4.6.5. <code>myisampack</code> — Generate Compressed, Read-Only MyISAM Tables	277
4.6.6. <code>mysqlaccess</code> — Client for Checking Access Privileges	282
4.6.7. <code>mysqlbinlog</code> — Utility for Processing Binary Log Files	284
4.6.8. <code>mysqldumpslow</code> — Summarize Slow Query Log Files	295
4.6.9. <code>mysqlhotcopy</code> — A Database Backup Program	297
4.6.10. <code>mysqlmanager</code> — The MySQL Instance Manager	299
4.6.11. <code>mysql_convert_table_format</code> — Convert Tables to Use a Given Storage Engine	310
4.6.12. <code>mysql_find_rows</code> — Extract SQL Statements from Files	311
4.6.13. <code>mysql_fix_extensions</code> — Normalize Table File Name Extensions	312
4.6.14. <code>mysql_setpermission</code> — Interactively Set Permissions in Grant Tables	312
4.6.15. <code>mysql_waitpid</code> — Kill Process and Wait for Its Termination	313
4.6.16. <code>mysql_zap</code> — Kill Processes That Match a Pattern	313
4.7. MySQL Program Development Utilities	314
4.7.1. <code>msql2mysql</code> — Convert mSQL Programs for Use with MySQL	314
4.7.2. <code>mysql_config</code> — Get Compile Options for Compiling Clients	314
4.7.3. <code>my_print_defaults</code> — Display Options from Option Files	315
4.7.4. <code>resolve_stack_dump</code> — Resolve Numeric Stack Trace Dump to Symbols	316
4.8. Miscellaneous Programs	316
4.8.1. <code>perror</code> — Explain Error Codes	316
4.8.2. <code>replace</code> — A String-Replacement Utility	317

4.8.3. <code>resolveip</code> — Resolve Host name to IP Address or Vice Versa	318
5. MySQL Server Administration	319
5.1. The MySQL Server	319
5.1.1. Server Option and Variable Reference	319
5.1.2. Server Command Options	341
5.1.3. Server Options for Loading Plugins	368
5.1.4. Server System Variables	369
5.1.5. Using System Variables	445
5.1.6. Server Status Variables	454
5.1.7. Server SQL Modes	471
5.1.8. Server-Side Help	476
5.1.9. Server Response to Signals	477
5.1.10. The Shutdown Process	477
5.2. MySQL Server Logs	478
5.2.1. Selecting General Query and Slow Query Log Output Destinations	479
5.2.2. The Error Log	481
5.2.3. The General Query Log	482
5.2.4. The Binary Log	483
5.2.5. The Slow Query Log	490
5.2.6. Server Log Maintenance	491
5.3. General Security Issues	492
5.3.1. General Security Guidelines	492
5.3.2. Password Security in MySQL	494
5.3.3. Making MySQL Secure Against Attackers	499
5.3.4. Security-Related <code>mysqld</code> Options	500
5.3.5. Security Issues with <code>LOAD DATA LOCAL</code>	502
5.3.6. How to Run MySQL as a Normal User	502
5.4. The MySQL Access Privilege System	503
5.4.1. Privileges Provided by MySQL	504
5.4.2. Privilege System Grant Tables	507
5.4.3. Specifying Account Names	510
5.4.4. Access Control, Stage 1: Connection Verification	512
5.4.5. Access Control, Stage 2: Request Verification	514
5.4.6. When Privilege Changes Take Effect	515
5.4.7. Causes of Access-Denied Errors	516
5.5. MySQL User Account Management	519
5.5.1. User Names and Passwords	520
5.5.2. Adding User Accounts	521
5.5.3. Removing User Accounts	523
5.5.4. Setting Account Resource Limits	523
5.5.5. Assigning Account Passwords	525
5.5.6. Using SSL for Secure Connections	526
5.5.7. Connecting to MySQL Remotely from Windows with SSH	534
5.5.8. Auditing MySQL Account Activity	534
5.6. Running Multiple MySQL Servers on the Same Machine	535
5.6.1. Running Multiple Servers on Windows	537
5.6.2. Running Multiple Servers on Unix	539
5.6.3. Using Client Programs in a Multiple-Server Environment	540
6. Backup and Recovery	542
6.1. Backup and Recovery Types	542
6.2. Database Backup Methods	544
6.3. Example Backup and Recovery Strategy	546
6.3.1. Establishing a Backup Policy	546
6.3.2. Using Backups for Recovery	548
6.3.3. Backup Strategy Summary	548
6.4. Using <code>mysqldump</code> for Backups	548
6.4.1. Dumping Data in SQL Format with <code>mysqldump</code>	549
6.4.2. Reloading SQL-Format Backups	549
6.4.3. Dumping Data in Delimited-Text Format with <code>mysqldump</code>	550
6.4.4. Reloading Delimited-Text Format Backups	551
6.4.5. <code>mysqldump</code> Tips	551
6.5. Point-in-Time (Incremental) Recovery Using the Binary Log	553
6.5.1. Point-in-Time Recovery Using Event Times	554
6.5.2. Point-in-Time Recovery Using Event Positions	555
6.6. <code>MyISAM</code> Table Maintenance and Crash Recovery	555
6.6.1. Using <code>myisamchk</code> for Crash Recovery	555
6.6.2. How to Check <code>MyISAM</code> Tables for Errors	556
6.6.3. How to Repair <code>MyISAM</code> Tables	556
6.6.4. <code>MyISAM</code> Table Optimization	558
6.6.5. Setting Up a <code>MyISAM</code> Table Maintenance Schedule	559

7.	Optimization	560
7.1.	Optimization Overview	560
7.1.1.	MySQL Design Limitations and Tradeoffs	560
7.1.2.	Designing Applications for Portability	560
7.1.3.	The MySQL Benchmark Suite	561
7.1.4.	Using Your Own Benchmarks	562
7.2.	Obtaining Query Execution Plan Information	562
7.2.1.	Optimizing Queries with <code>EXPLAIN</code>	562
7.2.2.	<code>EXPLAIN</code> Output Format	563
7.2.3.	Estimating Query Performance	570
7.3.	Optimizing SQL Statements	570
7.3.1.	Optimizing <code>SELECT</code> Statements	570
7.3.2.	Optimizing Non- <code>SELECT</code> Statements	596
7.3.3.	<code>INFORMATION_SCHEMA</code> Optimization	599
7.3.4.	Other Optimization Tips	603
7.4.	Controlling the Query Optimizer	605
7.4.1.	Controlling Query Plan Evaluation	605
7.4.2.	Controlling Switchable Optimizations	606
7.5.	Optimization and Indexes	607
7.5.1.	Column Indexes	607
7.5.2.	Multiple-Column Indexes	607
7.5.3.	How MySQL Uses Indexes	608
7.5.4.	<code>MyISAM</code> Index Statistics Collection	610
7.6.	Buffering and Caching	611
7.6.1.	The <code>MyISAM</code> Key Cache	611
7.6.2.	The <code>InnoDB</code> Buffer Pool	615
7.6.3.	The MySQL Query Cache	617
7.7.	Locking Issues	621
7.7.1.	Internal Locking Methods	622
7.7.2.	Table Locking Issues	623
7.7.3.	Concurrent Inserts	625
7.7.4.	External Locking	625
7.8.	Optimizing Database Structure	626
7.8.1.	Make Your Data as Small as Possible	626
7.8.2.	How MySQL Opens and Closes Tables	627
7.8.3.	Disadvantages of Creating Many Tables in the Same Database	628
7.8.4.	How MySQL Uses Internal Temporary Tables	628
7.9.	Optimizing the MySQL Server	629
7.9.1.	How Compiling and Linking Affects the Speed of MySQL	629
7.9.2.	System Factors and Startup Parameter Tuning	630
7.9.3.	Tuning Server Parameters	630
7.9.4.	How MySQL Uses Threads for Client Connections	634
7.9.5.	How MySQL Uses Memory	635
7.9.6.	Disk Issues	636
7.9.7.	Using Symbolic Links	636
7.9.8.	Enabling Large Page Support	639
7.9.9.	How MySQL Uses DNS	640
7.10.	Examining Thread Information	640
7.10.1.	Thread Command Values	641
7.10.2.	General Thread States	643
7.10.3.	Delayed-Insert Thread States	647
7.10.4.	Query Cache Thread States	648
7.10.5.	Replication Master Thread States	648
7.10.6.	Replication Slave I/O Thread States	649
7.10.7.	Replication Slave SQL Thread States	650
7.10.8.	Replication Slave Connection Thread States	650
7.10.9.	MySQL Cluster Thread States	651
7.10.10.	Event Scheduler Thread States	651
8.	Language Structure	653
8.1.	Literal Values	653
8.1.1.	Strings	653
8.1.2.	Numbers	655
8.1.3.	Date and Time Values	655
8.1.4.	Hexadecimal Values	655
8.1.5.	Boolean Values	656
8.1.6.	Bit-Field Values	656
8.1.7.	<code>NULL</code> Values	656
8.2.	Schema Object Names	656
8.2.1.	Identifier Qualifiers	658
8.2.2.	Identifier Case Sensitivity	658

8.2.3. Mapping of Identifiers to File Names	659
8.2.4. Function Name Parsing and Resolution	661
8.3. Reserved Words	664
8.4. User-Defined Variables	666

11.6.1. Arithmetic Operators	779

11.6.2. Mathematical Functions	781
11.7. Date and Time Functions	788
11.8. What Calendar Is Used By MySQL?	804
11.9. Full-Text Search Functions	804
11.9.1. Natural Language Full-Text Searches	805
11.9.2. Boolean Full-Text Searches	807
11.9.3. Full-Text Searches with Query Expansion	809
11.9.4. Full-Text Stopwords	810
11.9.5. Full-Text Restrictions	812
11.9.6. Fine-Tuning MySQL Full-Text Search	813
11.9.7. Adding a Collation for Full-Text Indexing	814
11.10. Cast Functions and Operators	815
11.11. XML Functions	818
11.12. Bit Functions	826
11.13. Encryption and Compression Functions	827
11.14. Information Functions	831
11.15. Miscellaneous Functions	838
11.16. Functions and Modifiers for Use with <code>GROUP BY</code> Clauses	841
11.16.1. <code>GROUP BY</code> (Aggregate) Functions	841
11.16.2. <code>GROUP BY</code> Modifiers	845
11.16.3. <code>GROUP BY</code> and <code>HAVING</code> with Hidden Columns	847
11.17. Spatial Extensions	848
11.17.1. Introduction to MySQL Spatial Support	848
11.17.2. The OpenGIS Geometry Model	849
11.17.3. Supported Spatial Data Formats	854
11.17.4. Creating a Spatially Enabled MySQL Database	855
11.17.5. Analyzing Spatial Information	860
11.17.6. Optimizing Spatial Analysis	868
11.17.7. MySQL Conformance and Compatibility	870
11.18. Precision Math	871
11.18.1. Types of Numeric Values	871
11.18.2. <code>DECIMAL</code> Data Type Changes	871
11.18.3. Expression Handling	872
11.18.4. Rounding Behavior	874
11.18.5. Precision Math Examples	874
12. SQL Statement Syntax	878
12.1. Data Definition Statements	878
12.1.1. <code>ALTER DATABASE</code> Syntax	878
12.1.2. <code>ALTER EVENT</code> Syntax	878
12.1.3. <code>ALTER LOGFILE GROUP</code> Syntax	880
12.1.4. <code>ALTER FUNCTION</code> Syntax	881
12.1.5. <code>ALTER PROCEDURE</code> Syntax	881
12.1.6. <code>ALTER SERVER</code> Syntax	881
12.1.7. <code>ALTER TABLE</code> Syntax	881
12.1.8. <code>ALTER TABLESPACE</code> Syntax	893
12.1.9. <code>ALTER VIEW</code> Syntax	894
12.1.10. <code>CREATE DATABASE</code> Syntax	894
12.1.11. <code>CREATE EVENT</code> Syntax	894
12.1.12. <code>CREATE FUNCTION</code> Syntax	898
12.1.13. <code>CREATE INDEX</code> Syntax	898
12.1.14. <code>CREATE LOGFILE GROUP</code> Syntax	901
12.1.15. <code>CREATE PROCEDURE</code> and <code>CREATE FUNCTION</code> Syntax	902
12.1.16. <code>CREATE SERVER</code> Syntax	906
12.1.17. <code>CREATE TABLE</code> Syntax	906
12.1.18. <code>CREATE TABLESPACE</code> Syntax	922
12.1.19. <code>CREATE TRIGGER</code> Syntax	923
12.1.20. <code>CREATE VIEW</code> Syntax	926
12.1.21. <code>DROP DATABASE</code> Syntax	929
12.1.22. <code>DROP EVENT</code> Syntax	930
12.1.23. <code>DROP FUNCTION</code> Syntax	930
12.1.24. <code>DROP INDEX</code> Syntax	930
12.1.25. <code>DROP LOGFILE GROUP</code> Syntax	931
12.1.26. <code>DROP PROCEDURE</code> and <code>DROP FUNCTION</code> Syntax	931
12.1.27. <code>DROP SERVER</code> Syntax	931
12.1.28. <code>DROP TABLE</code> Syntax	931
12.1.29. <code>DROP TABLESPACE</code> Syntax	932
12.1.30. <code>DROP TRIGGER</code> Syntax	932
12.1.31. <code>DROP VIEW</code> Syntax	932
12.1.32. <code>RENAME DATABASE</code> Syntax	933
12.1.33. <code>RENAME TABLE</code> Syntax	933

12.2. Data Manipulation Statements	933
12.2.1. <code>CALL</code> Syntax	933
12.2.2. <code>DELETE</code> Syntax	935
12.2.3. <code>DO</code> Syntax	938
12.2.4. <code>HANDLER</code> Syntax	938
12.2.5. <code>INSERT</code> Syntax	939
12.2.6. <code>LOAD DATA INFILE</code> Syntax	945
12.2.7. <code>REPLACE</code> Syntax	952
12.2.8. <code>SELECT</code> Syntax	953
12.2.9. Subquery Syntax	967
12.2.10. <code>TRUNCATE TABLE</code> Syntax	976
12.2.11. <code>UPDATE</code> Syntax	977
12.3. MySQL Transactional and Locking Statements	978
12.3.1. <code>START TRANSACTION</code> , <code>COMMIT</code> , and <code>ROLLBACK</code> Syntax	978
12.3.2. Statements That Cannot Be Rolled Back	980
12.3.3. Statements That Cause an Implicit Commit	980
12.3.4. <code>SAVEPOINT</code> and <code>ROLLBACK TO SAVEPOINT</code> Syntax	981
12.3.5. <code>LOCK TABLES</code> and <code>UNLOCK TABLES</code> Syntax	981
12.3.6. <code>SET TRANSACTION</code> Syntax	986
12.3.7. XA Transactions	987
12.4. Database Administration Statements	990
12.4.1. Account Management Statements	990
12.4.2. Table Maintenance Statements	999
12.4.3. Plugin and User-Defined Function Statements	1005
12.4.4. <code>SET</code> Syntax	1008
12.4.5. <code>SHOW</code> Syntax	1011
12.4.6. Other Administrative Statements	1042
12.5. Replication Statements	1046
12.5.1. SQL Statements for Controlling Master Servers	1046
12.5.2. SQL Statements for Controlling Slave Servers	1048
12.6. SQL Syntax for Prepared Statements	1053
12.6.1. <code>PREPARE</code> Syntax	1055
12.6.2. <code>EXECUTE</code> Syntax	1056
12.6.3. <code>DEALLOCATE PREPARE</code> Syntax	1056
12.6.4. Automatic Prepared Statement Repreparation	1056
12.7. MySQL Compound-Statement Syntax	1056
12.7.1. <code>BEGIN ... END</code> Compound Statement Syntax	1057
12.7.2. <code>DECLARE</code> Syntax	1057
12.7.3. Variables in Stored Programs	1057
12.7.4. Conditions and Handlers	1058
12.7.5. Cursors	1061
12.7.6. Flow Control Constructs	1062
12.7.7. <code>RETURN</code> Syntax	1065
12.8. MySQL Utility Statements	1065
12.8.1. <code>DESCRIBE</code> Syntax	1065
12.8.2. <code>EXPLAIN</code> Syntax	1065
12.8.3. <code>HELP</code> Syntax	1066
12.8.4. <code>USE</code> Syntax	1067
13. Storage Engines	1069
13.1. Comparing Transaction and Nontransaction Engines	1071
13.2. Other Storage Engines	1071
13.3. Setting the Storage Engine	1072
13.4. Overview of MySQL Storage Engine Architecture	1073
13.4.1. Pluggable Storage Engine Architecture	1073
13.4.2. The Common Database Server Layer	1074
13.5. The <code>MyISAM</code> Storage Engine	1075
13.5.1. <code>MyISAM</code> Startup Options	1076
13.5.2. Space Needed for Keys	1078
13.5.3. <code>MyISAM</code> Table Storage Formats	1078
13.5.4. <code>MyISAM</code> Table Problems	1080
13.6. The <code>InnoDB</code> Storage Engine	1081
13.6.1. <code>InnoDB</code> Contact Information	1083
13.6.2. <code>InnoDB</code> Configuration	1083

C.3.16. Changes in MySQL Connector/ODBC 5.0.6 (03 November 2006)	3347
C.3.17. Changes in MySQL Connector/ODBC 5.0.5 (17 October 2006)	3348
C.3.18. Changes in Connector/ODBC 5.0.3 (Connector/ODBC 5.0 Alpha 3) (20 June 2006)	3348
C.3.19. Changes in Connector/ODBC 5.0.2 (Never released)	3348
C.3.20. Changes in Connector/ODBC 5.0.1 (Connector/ODBC 5.0 Alpha 2) (05 June 2006)	3348
C.3.21. Changes in MySQL Connector/ODBC 3.51.28 (Not yet released)	3349
C.3.22. Changes in MySQL Connector/ODBC 3.51.27 (20 November 2008)	3350
C.3.23. Changes in MySQL Connector/ODBC 3.51.26 (07 July 2008)	3350
C.3.24. Changes in MySQL Connector/ODBC 3.51.25 (11 April 2008)	3350
C.3.25. Changes in MySQL Connector/ODBC 3.51.24 (14 March 2008)	3351
C.3.26. Changes in MySQL Connector/ODBC 3.51.23 (09 January 2008)	3351
C.3.27. Changes in MySQL Connector/ODBC 3.51.22 (13 November 2007)	3352
C.3.28. Changes in MySQL Connector/ODBC 3.51.21 (08 October 2007)	3352
C.3.29. Changes in MySQL Connector/ODBC 3.51.20 (10 September 2007)	3353
C.3.30. Changes in MySQL Connector/ODBC 3.51.19 (10 August 2007)	3353
C.3.31. Changes in MySQL Connector/ODBC 3.51.18 (08 August 2007)	3353
C.3.32. Changes in MySQL Connector/ODBC 3.51.17 (14 July 2007)	3355
C.3.33. Changes in MySQL Connector/ODBC 3.51.16 (14 June 2007)	3356
C.3.34. Changes in MySQL Connector/ODBC 3.51.15 (07 May 2007)	3356
C.3.35. Changes in MySQL Connector/ODBC 3.51.14 (08 March 2007)	3357
C.3.36. Changes in MySQL Connector/ODBC 3.51.13 (Never released)	3357
C.3.37. Changes in MySQL Connector/ODBC 3.51.12 (11 February 2005)	3357
C.3.38. Changes in MySQL Connector/ODBC 3.51.11 (28 January 2005)	3358
C.4. MySQL Connector/.NET Change History	3358

C.4.1. Changes in MySQL Connector/NET Version 6.3.x	3358
C.4.2. Changes in MySQL Connector/NET Version 6.2.x	3362
C.4.3. Changes in MySQL Connector/NET Version 6.1.x	3368
C.4.4. Changes in MySQL Connector/NET Version 6.0.x	3376
C.4.5. Changes in MySQL Connector/NET Version 5.3.x	3385
C.4.6. Changes in MySQL Connector/NET Version 5.2.x	3385
C.4.7. Changes in MySQL Connector/NET Version 5.1.x	3394
C.4.8. Changes in MySQL Connector/NET Version 5.0.x	3398
C.4.9. Changes in MySQL Connector/NET Version 1.0.x	3405
C.4.10. Changes in MySQL Connector/NET Version 0.9.0 (30 August 2004)	3412
C.4.11. Changes in MySQL Connector/NET Version 0.76	3415
C.4.12. Changes in MySQL Connector/NET Version 0.75	3415
C.4.13. Changes in MySQL Connector/NET Version 0.74	3416
C.4.14. Changes in MySQL Connector/NET Version 0.71	3417
C.4.15. Changes in MySQL Connector/NET Version 0.70	3418
C.4.16. Changes in MySQL Connector/NET Version 0.68	3419
C.4.17. Changes in MySQL Connector/NET Version 0.65	3420
C.4.18. Changes in MySQL Connector/NET Version 0.60	3420
C.4.19. Changes in MySQL Connector/NET Version 0.50	3420
C.5. MySQL Visual Studio Plugin Change History	3420
C.5.1. Changes in MySQL Visual Studio Plugin 1.0.3 (Not yet released)	3420
C.5.2. Changes in MySQL Visual Studio Plugin 1.0.2 (Not yet released)	3420
C.5.3. Changes in MySQL Visual Studio Plugin 1.0.1 (4 October 2006)	3421
C.5.4. Changes in MySQL Visual Studio Plugin 1.0.0 (4 October 2006)	3421
C.6. MySQL Connector/J Change History	3421
C.6.1. Changes in MySQL Connector/J 5.1.x	3421
C.6.2. Changes in MySQL Connector/J 5.0.x	3437
C.6.3. Changes in MySQL Connector/J 3.1.x	3446
C.6.4. Changes in MySQL Connector/J 3.0.x	3462
C.6.5. Changes in MySQL Connector/J 2.0.x	3473
C.6.6. Changes in MySQL Connector/J 1.2b (04 July 1999)	3478
C.6.7. Changes in MySQL Connector/J 1.2.x and lower	3478
C.7. MySQL Connector/MXJ Change History	3481
C.7.1. Changes in MySQL Connector/MXJ 5.0.11 (24th November 2009)	3481
C.7.2. Changes in MySQL Connector/MXJ 5.0.10 (Never released)	3482
C.7.3. Changes in MySQL Connector/MXJ 5.0.9 (19 August 2008)	3482
C.7.4. Changes in MySQL Connector/MXJ 5.0.8 (06 August 2007)	3482
C.7.5. Changes in MySQL Connector/MXJ 5.0.7 (27 May 2007)	3482
C.7.6. Changes in MySQL Connector/MXJ 5.0.6 (04 May 2007)	3483
C.7.7. Changes in MySQL Connector/MXJ 5.0.5 (14 March 2007)	3484
C.7.8. Changes in MySQL Connector/MXJ 5.0.4 (28 January 2007)	3485
C.7.9. Changes in MySQL Connector/MXJ 5.0.3 (24 June 2006)	3485
C.7.10. Changes in MySQL Connector/MXJ 5.0.2 (15 June 2006)	3485
C.7.11. Changes in MySQL Connector/MXJ 5.0.1 (Never released)	3486
C.7.12. Changes in MySQL Connector/MXJ 5.0.0 (09 December 2005)	3486
C.8. MySQL Connector/C++ Change History	3486
C.8.1. Changes in MySQL Connector/C++ 1.1.x	3486
C.8.2. Changes in MySQL Connector/C++ 1.0.x	3487
C.9. MySQL Proxy Change History	3492
C.9.1. Changes in MySQL Proxy 0.8.1 (Not yet released)	3492
C.9.2. Changes in MySQL Proxy 0.8.0 (21 Jan 2010)	3492
C.9.3. Changes in MySQL Proxy 0.7.2 (30 June 2009)	3493
C.9.4. Changes in MySQL Proxy 0.7.1 (15 May 2009)	3493
C.9.5. Changes in MySQL Proxy 0.7.0 (Never Released)	3493
C.9.6. Changes in MySQL Proxy 0.6.1 (06 February 2008)	3495
C.9.7. Changes in MySQL Proxy 0.6.0 (11 September 2007)	3495
C.9.8. Changes in MySQL Proxy 0.5.1 (30 June 2007)	3496
C.9.9. Changes in MySQL Proxy 0.5.0 (19 June 2007)	3496
D. Restrictions and Limits	3497
D.1. Restrictions on Stored Routines, Triggers, and Events	3497
D.2. Restrictions on Server-Side Cursors	3500
D.3. Restrictions on Subqueries	3501
D.4. Restrictions on Views	3503
D.5. Restrictions on XA Transactions	3505
D.6. Restrictions on Character Sets	3505
D.7. Limits in MySQL	3505
D.7.1. Limits of Joins	3505
D.7.2. The Maximum Number of Columns Per Table	3505
D.7.3. Windows Platform Limitations	3507
Index	3509

17.13. <code>ndbd redo log reader</code> Command Line Options	1745
17.14. <code>ndb_restore</code> Command Line Options	1746
17.15. <code>ndb show tables</code> Command Line Options	1756
17.16. <code>ndb size .pl</code> Command Line Options	1757
17.17. Common MySQL Cluster Command Line Options	1763
21.1. MySQL APIs and Interfaces	2175
21.2. MySQL Connector Versions and MySQL Server Versions	2175
21.3. Mapping of MySQL Error Numbers to SQLStates	2476
21.4. MySQL Configuration Options	2668
21.5. MySQL client constants	2669
21.6. MySQL fetch constants	2669
21.7. MySQLi Configuration Options	2728
21.8. Possible <code>mysqli_info</code> return values	2771
21.9. Valid options	2779
21.10. Supported flags	2788
21.11. Attribute values	2814
21.12. Type specification chars	2816
21.13. Return Values	2827
21.14. Object attributes	2852
21.15. Object properties	2854
21.16. Object properties	2856
21.17. Supported flags	2880
21.18. MySQL Native Driver Configuration Options	2885

List of Examples

21.1. Connector/J: Obtaining a connection from the <code>DriverManager</code>	2486
21.2. Connector/J: Using <code>java.sql.Statement</code> to execute a <code>SELECT</code> query	2487
21.3. Connector/J: Calling Stored Procedures	2488
21.4. Connector/J: Using <code>Connection.prepareStatement()</code>	2488
21.5. Connector/J: Registering output parameters	2489
21.6. Connector/J: Setting <code>CallableStatement</code> input parameters	2489
21.7. Connector/J: Retrieving results and output parameter values	2490
21.8. Connector/J: Retrieving <code>AUTO_INCREMENT</code> column values using <code>Statement.getGeneratedKeys()</code>	2490
21.9. Connector/J: Retrieving <code>AUTO_INCREMENT</code> column values using <code>SELECT LAST_INSERT_ID()</code>	2491
21.10. Connector/J: Retrieving <code>AUTO_INCREMENT</code> column values in <code>Updatable ResultSets</code>	2492
21.11. Connector/J: Using a connection pool with a J2EE application server	2494
21.12. Connector/J: Example of transaction with retry logic	2507
21.13. <code>insertdata.jsp</code>	2525
21.14. <code>response.jsp</code>	2526
21.15. MySQL extension overview example	2670
21.16. <code>mysql_affected_rows</code> example	2671
21.17. <code>mysql_affected_rows</code> example using transactions	2671
21.18. <code>mysql_client_encoding</code> example	2672
21.19. <code>mysql_close</code> example	2673
21.20. <code>mysql_connect</code> example	2675
21.21. <code>mysql_connect</code> example using <code>hostname:port</code> syntax	2675
21.22. <code>mysql_connect</code> example using <code>"/path/to/socket"</code> syntax	2675
21.23. <code>mysql_create_db</code> alternative example	2676
21.24. <code>mysql_data_seek</code> example	2678
21.25. <code>mysql_db_name</code> example	2679
21.26. <code>mysql_db_query</code> alternative example	2680
21.27. <code>mysql_drop_db</code> alternative example	2681
21.28. <code>mysql_errno</code> example	2682
21.29. <code>mysql_error</code> example	2683
21.30. <code>mysql_escape_string</code> example	2684
21.31. Query with aliased duplicate field names	2685
21.32. <code>mysql_fetch_array</code> with <code>MYSQL_NUM</code>	2685
21.33. <code>mysql_fetch_array</code> with <code>MYSQL_ASSOC</code>	2686
21.34. <code>mysql_fetch_array</code> with <code>MYSQL_BOTH</code>	2686
21.35. An expanded <code>mysql_fetch_assoc</code> example	2687
21.36. <code>mysql_fetch_field</code> example	2689
21.37. A <code>mysql_fetch_lengths</code> example	2690
21.38. <code>mysql_fetch_object</code> example	2691
21.39. <code>mysql_fetch_object</code> example	2691
21.40. Fetching one row with <code>mysql_fetch_row</code>	2692
21.41. A <code>mysql_field_flags</code> example	2693
21.42. <code>mysql_field_len</code> example	2694
21.43. <code>mysql_field_name</code> example	2695
21.44. A <code>mysql_field_table</code> example	2697
21.45. <code>mysql_field_type</code> example	2698
21.46. A <code>mysql_free_result</code> example	2699
21.47. <code>mysql_get_client_info</code> example	2700
21.48. <code>mysql_get_host_info</code> example	2701
21.49. <code>mysql_get_proto_info</code> example	2701
21.50. <code>mysql_get_server_info</code> example	2702
21.51. Relevant MySQL Statements	2703
21.52. <code>mysql_insert_id</code> example	2704
21.53. <code>mysql_list_dbs</code> example	2705
21.54. Alternate to deprecated <code>mysql_list_fields</code>	2706
21.55. <code>mysql_list_processes</code> example	2707
21.56. <code>mysql_list_tables</code> alternative example	2709
21.57. A <code>mysql_num_fields</code> example	2710
21.58. <code>mysql_num_rows</code> example	2710
21.59. A <code>mysql_ping</code> example	2713
21.60. Invalid Query	2714
21.61. Valid Query	2714
21.62. Simple <code>mysql_real_escape_string</code> example	2715
21.63. An example SQL Injection Attack	2715
21.64. <code>mysql_result</code> example	2717

21.65. <code>mysql_select_db</code> example	2718
21.66. <code>mysql_stat</code> example	2719
21.67. Alternative <code>mysql_stat</code> example	2720
21.68. <code>mysql_tablename</code> example	2721
21.69. <code>mysql_thread_id</code> example	2722
21.70. <code>mysqli->affected_rows</code> example	2739
21.71. <code>mysqli::autocommit</code> example	2741
21.72. <code>mysqli::change_user</code> example	2743
21.73. <code>mysqli::character_set_name</code> example	2745
21.74. <code>mysqli_get_client_info</code>	2746
21.75. <code>mysqli_get_client_version</code>	2747
21.76. <code>mysqli::commit</code> example	2748
21.77. <code>mysqli->connect_errno</code> example	2750
21.78. <code>mysqli->connect_error</code> example	2751
21.79. <code>mysqli::__construct</code> example	2752
21.80. Generating a Trace File	2754
21.81. <code>mysqli->errno</code> example	2756
21.82. <code>mysqli->error</code> example	2757
21.83. <code>mysqli->field_count</code> example	2759
21.84. <code>mysqli::get_charset</code> example	2760
21.85. <code>mysqli_get_client_info</code>	2761
21.86. <code>mysqli_get_client_version</code>	2762
21.87. A <code>mysqli_get_connection_stats</code> example	2763
21.88. <code>mysqli->host_info</code> example	2765
21.89. <code>mysqli->protocol_version</code> example	2766
21.90. <code>mysqli->server_info</code> example	2768
21.91. <code>mysqli->server_version</code> example	2769
21.92. <code>mysqli->info</code> example	2771
21.93. <code>mysqli->insert_id</code> example	2773
21.94. <code>mysqli::kill</code> example	2775
21.95. <code>mysqli::multi_query</code> example	2777
21.96. <code>mysqli::ping</code> example	2780
21.97. A <code>mysqli_poll</code> example	2782
21.98. <code>mysqli::prepare</code> example	2783
21.99. <code>mysqli::query</code> example	2785
21.100. <code>mysqli::real_connect</code> example	2788
21.101. <code>mysqli::real_escape_string</code> example	2790
21.102. <code>mysqli::rollback</code> example	2793
21.103. <code>mysqli::select_db</code> example	2795
21.104. <code>mysqli::set_charset</code> example	2797
21.105. <code>mysqli::set_local_infile_handler</code> example	2799
21.106. <code>mysqli->sqlstate</code> example	2801
21.107. <code>mysqli::stat</code> example	2803
21.108. <code>mysqli->thread_id</code> example	2806
21.109. <code>mysqli::use_result</code> example	2808
21.110. <code>mysqli->warning_count</code> example	2809
21.111. Object oriented style	2812
21.112. Procedural style	2813

21.155. PDO_MYSQL DSN examples	2901

Preface, Notes, Licenses

This is the Reference Manual for the MySQL Database System, version 5.1, through release 5.1.52. For license information, see the [legal notice](#). Differences between minor versions of MySQL 5.1 are noted in the present text with reference to release numbers (5.1.*x*).

This manual is not intended for use with older versions of the MySQL software due to the many functional and other differences between MySQL 5.1 and previous versions. If you are using an earlier release of the MySQL software, please refer to the appropriate manual. For example, [MySQL 5.0 Reference Manual](#), covers the 5.0 series of MySQL software releases.

If you are using MySQL 5.5, please refer to the [MySQL 5.5 Reference Manual](#).

The following is a list of the libraries we have included with the MySQL Server source and components used to test MySQL. We are thankful to all individuals that have created these. Some of the components require that their licensing terms be included in the documentation of products that include them. Cross references to these licensing terms are given with the applicable items in the list.

- Bjorn Benson

For his safe_malloc (memory checker) package which is used in when you build MySQL using one of the [BUILD/com-pile-*--debug](#) scripts or by manually setting the `-DSAFEMALLOC` flag.

- Free Software Foundation

The `readline` library, used by the `mysql` command-line client.

- The NetBSD Foundation

The `libedit` library, optionally used by the `mysql` command-line client. `libedit` is used for commercial builds because `readline` is covered under the GPL. License: [Section 1.5, “libedit License”](#)

- GroupLens Research Project

The MySQL Quality Assurance team would like to acknowledge the use of the MovieLens Data Sets (10 million ratings and 100,000 tags for 10681 movies by 71567 users) to help test MySQL products and to thank the GroupLens Research Project at the University of Minnesota for making the data sets available.

1. Licenses for Third-Party Components

MySQL 5.1

- [Section 1.22, “Fred Fish's Dbug Library License”](#)
- [Section 1.1, “FindGTest.cmake License”](#)
- [Section 1.4, “getarg License”](#)
- [Section 1.5, “libedit License”](#)
- [Section 1.26, “Richard A. O'Keefe String Library License”](#)
- [Section 1.33, “md5 \(Message-Digest Algorithm 5\) License”](#)
- [Section 1.34, “nt_servc \(Windows NT Service class library\) License”](#)
- [Section 1.25, “RegEX-Spencer Library License”](#)
- [Section 1.7, “zlib License”](#)

MySQL Cluster

- [Section 1.22, “Fred Fish's Dbug Library License”](#)
- [Section 1.1, “FindGTest.cmake License”](#)

- [Section 1.6, “libevent License”](#)
- [Section 1.26, “Richard A. O’Keefe String Library License”](#)
- [Section 1.33, “md5 \(Message-Digest Algorithm 5\) License”](#)
- [Section 1.34, “nt_servc \(Windows NT Service class library\) License”](#)
- [Section 1.25, “RegEX-Spencer Library License”](#)
- [Section 1.27, “SHA-1 in C License”](#)
- [Section 1.7, “ zlib License”](#)

MySQL Connector/C

- [Section 1.22, “Fred Fish’s Dbug Library License”](#)
- [Section 1.25, “RegEX-Spencer Library License”](#)
- [Section 1.7, “ zlib License”](#)

MySQL Connector/CPP

- [Section 1.21, “Boost Library License”](#)

MySQL Connector/J

- [Section 1.17, “Apache License Version 2.0, January 2004”](#)
- [Section 1.14, “Apache Commons Logging”](#)
- [Section 1.20, “Apache log4j Version 1.2.9”](#)

MySQL Connector/.NET

- [Section 1.7, “ zlib License”](#)

MySQL Enterprise Monitor 2.1

- [Section 1.17, “Apache License Version 2.0, January 2004”](#)
- [Section 1.9, “Apache Commons Collections”](#)

This product includes software developed by
The Apache Software Foundation (http://www.apache.org/).
```

This component is licensed under [Section 1.17, “Apache License Version 2.0, January 2004”](#).

## 1.16. Apache Commons Validator

The following software may be included in this product:

```
Apache Commons Validator

Component's NOTICE.txt file:
This product includes software developed by
The Apache Software Foundation (http://www.apache.org/).
```

This component is licensed under [Section 1.17, “Apache License Version 2.0, January 2004”](#).

## 1.17. Apache License Version 2.0, January 2004

The following applies to all products licensed under the Apache 2.0 License: You may not use the identified files except in compliance with the Apache License, Version 2.0 (the "License.") You may obtain a copy of the License at <http://www.apache.org/licenses/LICENSE-2.0>. A copy of the license is also reproduced below. Unless required by applicable law or agreed to in writing, software distributed under the License is distributed on an "AS IS" BASIS, WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied. See the License for the specific language governing permissions and limitations under the License.

```
Apache License Version 2.0, January 2004 http://www.apache.org/licenses/
TERMS AND CONDITIONS FOR USE, REPRODUCTION, AND DISTRIBUTION
```

1. Definitions.

"License" shall mean the terms and conditions for use, reproduction, and distribution as defined by Sections 1 through 9 of this document.

"Licensor" shall mean the copyright owner or entity authorized by the copyright owner that is granting the License.

"Legal Entity" shall mean the union of the acting entity and all other entities that control, are controlled by, or are under common control with that entity. For the purposes of this definition, "control" means (i) the power, direct or indirect, to cause the direction or management of such entity, whether by contract or otherwise, or (ii) ownership of fifty percent (50%) or more of the outstanding shares, or (iii) beneficial ownership of such entity.

"You" (or "Your") shall mean an individual or Legal Entity exercising permissions granted by this License.

"Source" form shall mean the preferred form for making modifications, including but not limited to software source code, documentation source, and configuration files.

"Object" form shall mean any form resulting from mechanical transformation or translation of a Source form, including but not limited to compiled object code, generated documentation, and conversions to other media types.

"Work" shall mean the work of authorship, whether in Source or Object form, made available under the License, as indicated by a copyright notice that is included in or attached to the work (an example is provided in the Appendix below).

"Derivative Works" shall mean any work, whether in Source or Object form, that is based on (or derived from) the Work and for which the editorial revisions, annotations, elaborations, or other modifications represent, as a whole, an original work of authorship. For the purposes of this License, Derivative Works shall not include works that remain separable from, or merely link (or bind by name) to the interfaces of, the Work and Derivative Works thereof.

"Contribution" shall mean any work of authorship, including the original version of the Work and any modifications or additions to that Work or Derivative Works thereof, that is intentionally submitted to Licensor for inclusion in the Work by the copyright owner or by an individual or Legal Entity authorized to submit on behalf of the copyright owner. For the purposes of this definition, "submitted" means any form of electronic, verbal, or written communication sent to the Licensor or its representatives, including but not limited to communication on electronic mailing lists, source code control systems, and issue tracking systems that are managed by, or on behalf of, the Licensor for the purpose of discussing and improving the Work, but excluding communication that is conspicuously marked or otherwise designated in writing by the copyright owner as "Not a Contribution."

"Contributor" shall mean Licensor and any individual or Legal Entity on behalf of whom a Contribution has been received by Licensor and subsequently incorporated within the Work.

2. Grant of Copyright License. Subject to the terms and conditions of this License, each Contributor hereby grants to You a perpetual, worldwide, non-exclusive, no-charge, royalty-free, irrevocable copyright license to reproduce, prepare Derivative Works of, publicly display, publicly perform, sublicense, and distribute the Work and such Derivative Works in Source or Object form.

3. Grant of Patent License. Subject to the terms and conditions of this License, each Contributor hereby grants to You a perpetual, worldwide, non-exclusive, no-charge, royalty-free, irrevocable (except as stated in this section) patent license to make, have made, use, offer to sell, sell, import, and otherwise transfer the Work, where such license applies only to those patent claims licensable by such Contributor that are necessarily infringed by their Contribution(s) alone or by combination of their Contribution(s) with the Work to which such Contribution(s) was submitted. If You institute patent litigation against any entity (including a cross-claim or counterclaim in a lawsuit) alleging that the Work or a Contribution incorporated within the Work constitutes direct or contributory patent infringement, then any patent licenses granted to You under this License for that Work shall terminate as of the date such litigation is filed.

4. Redistribution. You may reproduce and distribute copies of the Work or Derivative Works thereof in any medium, with or without modifications, and in Source or Object form, provided that You meet the following conditions:

(a) You must give any other recipients of the Work or Derivative Works a copy of this License; and

(b) You must cause any modified files to carry prominent notices stating that You changed the files; and

(c) You must retain, in the Source form of any Derivative Works that You distribute, all copyright, patent, trademark, and attribution notices from the Source form of the Work, excluding those notices that

do not pertain to any part of the Derivative Works; and

(d) If the Work includes a "NOTICE" text file as part of its distribution, then any Derivative Works that You distribute must include a readable copy of the attribution notices contained

within such NOTICE file, excluding those notices that do not pertain to any part of the Derivative Works, in at least one of the following places: within a NOTICE text file distributed as part of the Derivative Works; within the Source form or documentation, if provided along with the Derivative Works; or, within a display generated by the Derivative Works, if and wherever such third-party notices normally appear. The contents of the NOTICE file are for informational purposes only and do not modify the License. You may add Your own attribution notices within Derivative Works that You distribute, alongside or as an addendum to the NOTICE text from the Work, provided that such additional attribution notices cannot be construed as modifying the License.

You may add Your own copyright statement to Your modifications and may provide additional or different license terms and conditions for use, reproduction, or distribution of Your modifications, or for any such Derivative Works as a whole, provided Your use, reproduction, and distribution of the Work otherwise complies with the conditions stated in this License.

5. Submission of Contributions. Unless You explicitly state otherwise, any Contribution intentionally submitted for inclusion in the Work by You to the Licensor shall be under the terms and conditions of this License, without any additional terms or conditions. Notwithstanding the above, nothing herein shall supersede or modify the terms of any separate license agreement you may have executed with Licensor regarding such Contributions.

6. Trademarks. This License does not grant permission to use the trade names, trademarks, service marks, or product names of the Licensor, except as required for reasonable and customary use in describing the origin of the Work and reproducing the content of the NOTICE file.

7. Disclaimer of Warranty. Unless required by applicable law or agreed to in writing, Licensor provides the Work (and each Contributor provides its Contributions) on an "AS IS" BASIS, WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied, including, without limitation, any warranties or conditions of TITLE, NON-INFRINGEMENT, MERCHANTABILITY, or FITNESS FOR A PARTICULAR PURPOSE. You are solely responsible for determining the appropriateness of using or redistributing the Work and assume any risks associated with Your exercise of permissions under this License.

8. Limitation of Liability. In no event and under no legal theory, whether in tort (including negligence), contract, or otherwise, unless required by applicable law (such as deliberate and grossly negligent acts) or agreed to in writing, shall any Contributor be liable to You for damages, including any direct, indirect, special, incidental, or consequential damages of any character arising as a result of this License or out of the use or inability to use the Work (including but not limited to damages for loss of goodwill, work stoppage, computer failure or malfunction, or any and all other commercial damages or losses), even if such Contributor has been advised of the possibility of such damages.

9. Accepting Warranty or Additional Liability. While redistributing the Work or Derivative Works thereof, You may choose to offer, and charge a fee for, acceptance of support, warranty, indemnity, or other liability obligations and/or rights consistent with this License. However, in accepting such obligations, You may act only on Your own behalf and on Your sole responsibility, not on behalf of any other Contributor, and only if You agree to indemnify, defend, and hold each Contributor harmless for any liability incurred by, or claims asserted against, such Contributor by reason of your accepting any such warranty or additional liability.

#### END OF TERMS AND CONDITIONS

#### APPENDIX: How to apply the Apache License to your work

To apply the Apache License to your work, attach the following boilerplate notice, with the fields enclosed by brackets "[]" replaced with your own identifying information. (Don't include the brackets!) The text should be enclosed in the appropriate comment syntax for the file format. We also recommend that a file or class name and description of purpose be included on the same "printed page" as the copyright notice for easier identification within third-party archives.

Copyright [yyyy] [name of copyright owner]

Licensed under the Apache License, Version 2.0 (the "License");  
you may not use this file except in compliance with the License.  
You may obtain a copy of the License at  
<http://www.apache.org/licenses/LICENSE-2.0>

Unless required by applicable law or agreed to in writing, software distributed under the License is distributed on an "AS IS" BASIS, WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied. See the License for the specific language governing permissions and limitations under the License.

## 1.18. Apache Tomcat

The following software may be included in this product:

```
Apache Tomcat
Component's NOTICE.txt file:

## 1.22. Fred Fish's Dbug Library License

The following software may be included in this product:

### Fred Fish's Dbug Library

#### N O T I C E

Copyright Abandoned, 1987, Fred Fish

This previously copyrighted work has been placed into the public domain by the author and may be freely used for any purpose, private or commercial.

Because of the number of inquiries I was receiving about the use of this product in commercially developed works I have decided to simply make it public domain to further its unrestricted use. I specifically would be most happy to see this material become a part of the standard Unix distributions by AT&T and the Berkeley Computer Science Research Group, and a standard part of the GNU system from the Free Software Foundation.

I would appreciate it, as a courtesy, if this notice is left in all copies and derivative works. Thank you.

The author makes no warranty of any kind with respect to this

product and explicitly disclaims any implied warranties of merchantability or fitness for any particular purpose.

The dbug\_analyze.c file is subject to the following notice:

Copyright June 1987, Binayak Banerjee  
All rights reserved.

This program may be freely distributed under the same terms and conditions as Fred Fish's Dbug package.

## 1.23. JDOM Project

The following software may be included in this product:

JDOM

This product includes software developed by the JDOM Project (<http://www.jdom.org/>).

Copyright (C) 2000-2004 Jason Hunter & Brett McLaughlin.  
All rights reserved.

Redistribution and use in source and binary forms, with or without modification, are permitted provided that the following conditions are met:

1. Redistributions of source code must retain the above copyright notice, this list of conditions, and the following disclaimer.
2. Redistributions in binary form must reproduce the above copyright notice, this list of conditions, and the disclaimer that follows these conditions in the documentation and/or other materials provided with the distribution.
3. The name "JDOM" must not be used to endorse or promote products derived from this software without prior written permission. For written permission, please contact <[request\\_AT\\_jdom\\_DOT\\_org](mailto:request_AT_jdom_DOT_org)>.
4. Products derived from this software may not be called "JDOM", nor may "JDOM" appear in their name, without prior written permission from the JDOM Project Management <[request\\_AT\\_jdom\\_DOT\\_org](mailto:request_AT_jdom_DOT_org)>.

In addition, we request (but do not require) that you include in the end-user documentation provided with the redistribution and/or in the software itself an acknowledgement equivalent to the following:

"This product includes software developed by the JDOM Project (<http://www.jdom.org/>)."

Alternatively, the acknowledgment may be graphical using the logos available at <http://www.jdom.org/images/logos>.

THIS SOFTWARE IS PROVIDED "AS IS" AND ANY EXPRESSED OR IMPLIED WARRANTIES, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE ARE DISCLAIMED. IN NO EVENT SHALL THE JDOM AUTHORS OR THE PROJECT CONTRIBUTORS BE LIABLE FOR ANY DIRECT, INDIRECT, INCIDENTAL, SPECIAL, EXEMPLARY, OR CONSEQUENTIAL DAMAGES (INCLUDING, BUT NOT LIMITED TO, PROCUREMENT OF SUBSTITUTE GOODS OR SERVICES; LOSS OF USE, DATA, OR PROFITS; OR BUSINESS INTERRUPTION) HOWEVER CAUSED AND ON ANY THEORY OF LIABILITY, WHETHER IN CONTRACT, STRICT LIABILITY, OR TORT (INCLUDING NEGLIGENCE OR OTHERWISE) ARISING IN ANY WAY OUT OF THE USE OF THIS SOFTWARE, EVEN IF ADVISED OF THE POSSIBILITY OF SUCH DAMAGE.

This software consists of voluntary contributions made by many individuals on behalf of the JDOM Project and was originally created by Jason Hunter and Brett McLaughlin. For more information on the JDOM Project, please see <<http://www.jdom.org/>>."

## 1.24. OpenSSL v0.9.8o and later

The following software may be included in this product:

OpenSSL v0.9.8o and later

Copyright (c) 1998-2008 The OpenSSL Project.  
All rights reserved.

Redistribution and use in source and binary forms, with or without modification, are permitted provided that the following conditions are met:

1. Redistributions of source code must retain the above copyright notice, this list of conditions and the following disclaimer.
2. Redistributions in binary form must reproduce the above copyright notice, this list of conditions and the following disclaimer in the documentation and/or other materials provided with the distribution.
3. All advertising materials mentioning features or use of this software must display the following acknowledgment:  
"This product includes software developed by the OpenSSL Project for use in the OpenSSL Toolkit.  
(<http://www.openssl.org/>)"
4. The names "OpenSSL Toolkit" and "OpenSSL Project" must not be used to endorse or promote products derived from this software without prior written permission. For written permission, please contact [openssl-core@openssl.org](mailto:openssl-core@openssl.org).
5. Products derived from this software may not be called "OpenSSL"

nor may "OpenSSL" appear in their names without prior written permission of the OpenSSL Project.

6. Redistributions of any form whatsoever must retain the following acknowledgment:

"This product includes software developed by the OpenSSL Project for use in the OpenSSL Toolkit (<http://www.openssl.org/>)"

THIS SOFTWARE IS PROVIDED BY THE OpenSSL PROJECT ``AS IS'' AND ANY EXPRESSED OR IMPLIED WARRANTIES, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE ARE DISCLAIMED. IN NO EVENT SHALL THE OpenSSL PROJECT OR ITS CONTRIBUTORS BE LIABLE FOR ANY DIRECT, INDIRECT, INCIDENTAL, SPECIAL, EXEMPLARY, OR CONSEQUENTIAL DAMAGES (INCLUDING, BUT NOT LIMITED TO, PROCUREMENT OF SUBSTITUTE GOODS OR SERVICES; LOSS OF USE, DATA, OR PROFITS; OR BUSINESS INTERRUPTION) HOWEVER CAUSED AND ON ANY THEORY OF LIABILITY, WHETHER IN CONTRACT, STRICT LIABILITY, OR TORT (INCLUDING NEGLIGENCE OR OTHERWISE) ARISING IN ANY WAY OUT OF THE USE OF THIS SOFTWARE, EVEN IF ADVISED OF THE POSSIBILITY OF SUCH DAMAGE.

This product includes cryptographic software written by Eric Young (eay@cryptsoft.com). This product includes software written by Tim Hudson (tjh@cryptsoft.com).

## 1.25. RegEX-Spencer Library License

The following software may be included in this product: Henry Spencer's Regular-Expression Library (RegEX-Spencer)

Copyright 1992, 1993, 1994 Henry Spencer. All rights reserved.  
This software is not subject to any license of the American Telephone and Telegraph Company or of the Regents of the University of California.

Permission is granted to anyone to use this software for any purpose on any computer system, and to alter it and redistribute it, subject to the following restrictions:

1. The author is not responsible for the consequences of use of this software, no matter how awful, even if they arise from flaws in it.
2. The origin of this software must not be misrepresented, either by explicit claim or by omission. Since few users ever read sources, credits must appear in the documentation.
3. Altered versions must be plainly marked as such, and must not be misrepresented as being the original software. Since few users ever read sources, credits must appear in the documentation.
4. This notice may not be removed or altered.

## 1.26. Richard A. O'Keefe String Library License

The following software may be included in this product:

Richard A. O'Keefe String Library

The Richard O'Keefe String Library is subject to the following notice:

These files are in the public domain. This includes getopt.c, which is the work of Henry Spencer, University of Toronto Zoology, who says of it "None of this software is derived from Bell software. I had no access to the source for Bell's versions at the time I wrote it. This software is hereby explicitly placed in the public domain. It may be used for any purpose on any machine by anyone." I would greatly prefer it if \*my\* material received no military use.

The t\_ctype.h file is subject to the following notice:

Copyright (C) 1998, 1999 by Pruet Boonma, all rights reserved.  
Copyright (C) 1998 by Theppitak Karoonboonyanan, all rights reserved.

Permission to use, copy, modify, distribute and sell this software and its documentation for any purpose is hereby granted without fee, provided that the above copyright notice appear in all copies.

Smaphan Raruenrom and Pruet Boonma makes no representations about the suitability of this software for any purpose. It is provided "as is" without express or implied warranty.

## 1.27. SHA-1 in C License

The following software may be included in this product:

SHA-1 in C

SHA-1 in C  
By Steve Reid <steve@edmweb.com>

100% Public Domain

## 1.28. Spring Framework

The following software may be included in this product:

```
Spring Framework
```

```

Except as contained in this notice, the name of a copyright holder shall not be used in advertising or otherwise to promote the sale, use or other dealings in this Software without prior written authorization of the copyright holder.

## 1.31. jQuery

The following software may be included in this product:

jQuery

Copyright (c) 2009 John Resig.

Permission is hereby granted, free of charge, to any person obtaining a copy of this software and associated documentation files (the "Software"), to deal in the Software without restriction, including without limitation the rights to use, copy, modify, merge, publish, distribute, sublicense, and/or sell copies of the Software, and to permit persons to whom the Software is furnished to do so, subject to the following conditions:

The above copyright notice and this permission notice shall be included in all copies or substantial portions of the Software.

THE SOFTWARE IS PROVIDED "AS IS", WITHOUT WARRANTY OF ANY KIND, EXPRESS OR IMPLIED, INCLUDING BUT NOT LIMITED TO THE WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE AND NONINFRINGEMENT. IN NO EVENT SHALL THE AUTHORS OR COPYRIGHT HOLDERS BE LIABLE FOR ANY CLAIM, DAMAGES OR OTHER LIABILITY, WHETHER IN AN ACTION OF CONTRACT, TORT OR OTHERWISE, ARISING FROM, OUT OF OR IN CONNECTION WITH THE SOFTWARE OR THE USE OR OTHER DEALINGS IN THE SOFTWARE.

## 1.32. jQuery UI

The following software may be included in this product:

jQuery UI

Copyright (c) 2009 Paul Bakaus, <http://jqueryui.com>

This software consists of voluntary contributions made by many individuals (AUTHORS.txt, <http://jqueryui.com/about>) For exact contribution history, see the revision history and logs, available at <http://jquery-ui.googlecode.com/svn/>

Permission is hereby granted, free of charge, to any person obtaining a copy of this software and associated documentation files (the "Software"), to deal in the Software without restriction, including without limitation the rights to use, copy, modify, merge, publish, distribute, sublicense, and/or sell copies of the Software, and to permit persons to whom the Software is furnished to do so, subject to the following conditions:

The above copyright notice and this permission notice shall be included in all copies or substantial portions of the Software.

THE SOFTWARE IS PROVIDED "AS IS", WITHOUT WARRANTY OF ANY KIND, EXPRESS OR IMPLIED, INCLUDING BUT NOT LIMITED TO THE WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE AND NONINFRINGEMENT. IN NO EVENT SHALL THE AUTHORS OR COPYRIGHT HOLDERS BE LIABLE FOR ANY CLAIM, DAMAGES OR OTHER LIABILITY, WHETHER IN AN ACTION OF CONTRACT, TORT OR OTHERWISE, ARISING FROM, OUT OF OR IN CONNECTION WITH THE SOFTWARE OR THE USE OR OTHER DEALINGS IN THE SOFTWARE.

## 1.33. md5 (Message-Digest Algorithm 5) License

The following software may be included in this product:

md5 (Message-Digest Algorithm 5)

This code implements the MD5 message-digest algorithm.  
The algorithm is due to Ron Rivest. This code was  
written by Colin Plumb in 1993, no copyright is claimed.  
This code is in the public domain; do with it what you wish.

Equivalent code is available from RSA Data Security, Inc.  
This code has been tested against that, and is equivalent,

except that you don't need to include two pages of legalese with every copy.

The code has been modified by Mikael Ronstroem to handle calculating a hash value of a key that is always a multiple of 4 bytes long. Word 0 of the calculated 4-word hash value is returned as the hash value.

## 1.34. nt\_servc (Windows NT Service class library) License

The following software may be included in this product:

nt\_servc (Windows NT Service class library)

```
Windows NT Service class library
Copyright Abandoned 1998 Irena Pancirov - Irinet Snc
This file is public domain and comes with NO WARRANTY of any kind
```

---

# Chapter 1. General Information

The MySQL™ software delivers a very fast, multi-threaded, multi-user, and robust SQL (Structured Query Language) database server. MySQL Server is intended for mission-critical, heavy-load production systems as well as for embedding into mass-deployed software. Oracle is a registered trademark of Oracle Corporation and/or its affiliates. MySQL is a trademark of Oracle Corporation and/or its affiliates, and shall not be used by Customer without Oracle's express written authorization. Other names may be trademarks of their respective owners.

The MySQL software is Dual Licensed. Users can choose to use the MySQL software as an Open Source product under the terms of the GNU General Public License (<http://www.fsf.org/licenses/>) or can purchase a standard commercial license from Oracle. See <http://www.mysql.com/company/legal/licensing/> for more information on our licensing policies.

The following list describes some sections of particular interest in this manual:

- For a discussion about the capabilities of the MySQL Database Server, see [Section 1.3.3, “The Main Features of MySQL”](#).
- For development history, see [Section 1.4, “MySQL Development History”](#).
- For installation instructions, see [Chapter 2, \*Installing and Upgrading MySQL\*](#). For information about upgrading MySQL, see [Section 2.12.1, “Upgrading MySQL”](#), and the change notes at [Appendix C, MySQL Change History](#).
- For a tutorial introduction to the MySQL Database Server, see [Chapter 3, \*Tutorial\*](#).
- For information about configuring and administering MySQL Server, see [Chapter 5, MySQL Server Administration](#).
- For information about setting up replication servers, see [Chapter 16, \*Replication\*](#).
- For answers to a number of questions that are often asked concerning the MySQL Database Server and its capabilities, see [Appendix A, MySQL 5.1 Frequently Asked Questions](#).
- For a list of currently known bugs and misfeatures, see [Section B.5.8, “Known Issues in MySQL”](#).
- For a list of all the contributors to this project, see [Section 1.9, “Credits”](#).
- For a history of new features and bugfixes, see [Appendix C, MySQL Change History](#).
- For tips on porting the MySQL Database Software to new architectures or operating systems, see [MySQL Internals: Porting](#).
- For benchmarking information, see the `sql-bench` benchmarking directory in your MySQL distribution.

## Important

To report errors (often called “bugs”), please use the instructions at [Section 1.7, “How to Report Bugs or Problems”](#).

If you have found a sensitive security bug in MySQL Server, please let us know immediately by sending an email message to [<security@mysql.com>](mailto:<security@mysql.com>).

## 1.1. About This Manual

This is the Reference Manual for the MySQL Database System, version 5.1, through release 5.1.52. Differences between minor versions of MySQL 5.1 are noted in the present text with reference to release numbers (5.1.*x*).

This manual is not intended for use with older versions of the MySQL software due to the many functional and other differences between MySQL 5.1 and previous versions. If you are using an earlier release of the MySQL software, please refer to the appropriate manual. For example, [MySQL 5.0 Reference Manual](#), covers the 5.0 series of MySQL software releases.

If you are using MySQL 5.5, please refer to the [MySQL 5.5 Reference Manual](#).

Because this manual serves as a reference, it does not provide general instruction on SQL or relational database concepts. It also does not teach you how to use your operating system or command-line interpreter.

The MySQL Database Software is under constant development, and the Reference Manual is updated frequently as well. The most recent version of the manual is available online in searchable form at <http://dev.mysql.com/doc/>. Other formats also are available there, including HTML, PDF, and Windows CHM versions.

The Reference Manual source files are written in DocBook XML format. The HTML version and other formats are produced automatically, primarily using the DocBook XSL stylesheets. For information about DocBook, see <http://docbook.org/>

The DocBook XML sources of this manual are available from <http://dev.mysql.com/tech-resources/sources.html>. You can check out a copy of the documentation repository with this command:

```
svn checkout http://svn.mysql.com/svnpublic/mysql/doc/
```

If you have questions about using MySQL, you can ask them using our mailing lists or forums. See [Section 1.6.1, “MySQL Mailing Lists”](#), and [Section 1.6.2, “MySQL Community Support at the MySQL Forums”](#). If you have suggestions concerning additions or corrections to the manual itself, please send them to the <http://www.mysql.com/company/contact/>.

This manual was originally written by David Axmark and Michael “Monty” Widenius. It is maintained by the MySQL Documentation Team, consisting of Paul DuBois, Stefan Hinz, Jon Stephens, Martin MC Brown, and Tony Bedford.

## 1.2. Typographical and Syntax Conventions

This manual uses certain typographical conventions:

- **Text in this style** is used for SQL statements; database, table, and column names; program listings and source code; and environment variables. Example: “To reload the grant tables, use the `FLUSH PRIVILEGES` statement.”
- **Text in this style** indicates input that you type in examples.
- **Text in this style** indicates the names of executable programs and scripts, examples being `mysql` (the MySQL command line client program) and `mysqld` (the MySQL server executable).
- **Text in this style** is used for variable input for which you should substitute a value of your own choosing.
- **Text in this style** is used for emphasis.
- **Text in this style** is used in table headings and to convey especially strong emphasis.
- **Text in this style** is used to indicate a program option that affects how the program is executed, or that supplies information that is needed for the program to function in a certain way. *Example:* “The `--host` option (short form `-h`) tells the `mysql` client program the hostname or IP address of the MySQL server that it should connect to”.
- File names and directory names are written like this: “The global `my.cnf` file is located in the `/etc` directory.”
- Character sequences are written like this: “To specify a wildcard, use the ‘%’ character.”

When commands are shown that are meant to be executed from within a particular program, the prompt shown preceding the command indicates which command to use. For example, `shell>` indicates a command that you execute from your login shell, `root-shell>` is similar but should be executed as `root`, and `mysql>` indicates a statement that you execute from the `mysql` client program:

```
shell> type a shell command here
root-shell> type a shell command as root here
mysql> type a mysql statement here
```

In some areas different systems may be distinguished from each other to show that commands should be executed in two different environments. For example, while working with replication the commands might be prefixed with `master` and `slave`:

```
master> type a mysql command on the replication master here
slave> type a mysql command on the replication slave here
```

The “shell” is your command interpreter. On Unix, this is typically a program such as `sh`, `csh`, or `bash`. On Windows, the equivalent program is `command.com` or `cmd.exe`, typically run in a console window.

When you enter a command or statement shown in an example, do not type the prompt shown in the example.

Database, table, and column names must often be substituted into statements. To indicate that such substitution is necessary, this manual uses `db_name`, `tbl_name`, and `col_name`. For example, you might see a statement like this:

```
mysql> SELECT col_name FROM db_name.tbl_name;
```

This means that if you were to enter a similar statement, you would supply your own database, table, and column names, perhaps like this:

```
mysql> SELECT author_name FROM biblio_db.author_list;
```

SQL keywords are not case sensitive and may be written in any lettercase. This manual uses uppercase.

In syntax descriptions, square brackets ("[" and "]") indicate optional words or clauses. For example, in the following statement, `IF EXISTS` is optional:

```
DROP TABLE [IF EXISTS] tbl_name
```

When a syntax element consists of a number of alternatives, the alternatives are separated by vertical bars ("|"). When one member from a set of choices *may* be chosen, the alternatives are listed within square brackets ("[" and "]"):

```
TRIM([[BOTH | LEADING | TRAILING] [remstr] FROM] str)
```

When one member from a set of choices *must* be chosen, the alternatives are listed within braces ("{" and "}"):

```
{DESCRIBE | DESC} tbl_name [col_name | wild]
```

An ellipsis (...) indicates the omission of a section of a statement, typically to provide a shorter version of more complex syntax. For example, `SELECT ... INTO OUTFILE` is shorthand for the form of `SELECT` statement that has an `INTO OUTFILE` clause following other parts of the statement.

An ellipsis can also indicate that the preceding syntax element of a statement may be repeated. In the following example, multiple `reset_option` values may be given, with each of those after the first preceded by commas:

```
RESET reset_option [,reset_option] ...
```

Commands for setting shell variables are shown using Bourne shell syntax. For example, the sequence to set the `CC` environment variable and run the `configure` command looks like this in Bourne shell syntax:

```
shell> CC=gcc ./configure
```

If you are using `csh` or `tcsh`, you must issue commands somewhat differently:

```
shell> setenv CC gcc
shell> ./configure
```

## 1.3. Overview of the MySQL Database Management System

### 1.3.1. What is MySQL?

MySQL, the most popular Open Source SQL database management system, is developed, distributed, and supported by Oracle Corporation.

The MySQL Web site (<http://www.mysql.com/>) provides the latest information about MySQL software.

- MySQL is a database management system.

A database is a structured collection of data. It may be anything from a simple shopping list to a picture gallery or the vast amounts of information in a corporate network. To add, access, and process data stored in a computer database, you need a database management system such as MySQL Server. Since computers are very good at handling large amounts of data, database management systems play a central role in computing, as standalone utilities, or as parts of other applications.

- MySQL is a relational database management system.

A relational database stores data in separate tables rather than putting all the data in one big storeroom. This adds speed and flexibility. The SQL part of "MySQL" stands for "Structured Query Language." SQL is the most common standardized language used to access databases and is defined by the ANSI/ISO SQL Standard. The SQL standard has been evolving since 1986 and several versions exist. In this manual, "SQL-92" refers to the standard released in 1992, "SQL:1999" refers to the standard released in 1999, and "SQL:2003" refers to the current version of the standard. We use the phrase "the SQL standard" to mean the current version of the SQL Standard at any time.

- MySQL software is Open Source.

Open Source means that it is possible for anyone to use and modify the software. Anybody can download the MySQL software from the Internet and use it without paying anything. If you wish, you may study the source code and change it to suit your needs. The MySQL software uses the GPL (GNU General Public License), <http://www.fsf.org/licenses/>, to define what you may and may not do with the software in different situations. If you feel uncomfortable with the GPL or need to embed MySQL

code into a commercial application, you can buy a commercially licensed version from us. See the MySQL Licensing Overview for more information (<http://www.mysql.com/company/legal/licensing/>).

- The MySQL Database Server is very fast, reliable, and easy to use.

If that is what you are looking for, you should give it a try. MySQL Server also has a practical set of features developed in close cooperation with our users. You can find a performance comparison of MySQL Server with other database managers on our benchmark page. See [Section 7.1.3, “The MySQL Benchmark Suite”](#).

MySQL Server was originally developed to handle large databases much faster than existing solutions and has been successfully used in highly demanding production environments for several years. Although under constant development, MySQL Server today offers a rich and useful set of functions. Its connectivity, speed, and security make MySQL Server highly suited for accessing databases on the Internet.

- MySQL Server works in client/server or embedded systems.

The MySQL Database Software is a client/server system that consists of a multi-threaded SQL server that supports different backends, several different client programs and libraries, administrative tools, and a wide range of application programming interfaces (APIs).

We also provide MySQL Server as an embedded multi-threaded library that you can link into your application to get a smaller, faster, easier-to-manage standalone product.

- A large amount of contributed MySQL software is available.

It is very likely that your favorite application or language supports the MySQL Database Server.

The official way to pronounce “MySQL” is “My Ess Que Ell” (not “my sequel”), but we do not mind if you pronounce it as “my sequel” or in some other localized way.

### 1.3.2. History of MySQL

We started out with the intention of using the [mSQL](#) database system to connect to our tables using our own fast low-level (ISAM) routines. However, after some testing, we came to the conclusion that [mSQL](#) was not fast enough or flexible enough for our needs. This resulted in a new SQL interface to our database but with almost the same API interface as [mSQL](#). This API was designed to enable third-party code that was written for use with [mSQL](#) to be ported easily for use with MySQL.

MySQL is named after co-founder Monty Widenius's daughter, My.

The name of the MySQL Dolphin (our logo) is “Sakila,” which was chosen from a huge list of names suggested by users in our “Name the Dolphin” contest. The winning name was submitted by Ambrose Twebaze, an Open Source software developer from Swaziland, Africa. According to Ambrose, the feminine name Sakila has its roots in SiSwati, the local language of Swaziland. Sakila is also the name of a town in Arusha, Tanzania, near Ambrose’s country of origin, Uganda.

### 1.3.3. The Main Features of MySQL

This section describes some of the important characteristics of the MySQL Database Software. See also [Section 1.4, “MySQL Development History”](#). In most respects, the roadmap applies to all versions of MySQL. For information about features as they are introduced into MySQL on a series-specific basis, see the “In a Nutshell” section of the appropriate Manual:

- MySQL 4.0: [MySQL 4.0 in a Nutshell](#)
- MySQL 4.1: [MySQL 4.1 in a Nutshell](#)
- MySQL 5.0: [MySQL 5.0 in a Nutshell](#)
- MySQL 5.1: [MySQL 5.1 in a Nutshell](#)
- MySQL 5.5: [MySQL 5.5 in a Nutshell](#)
- MySQL 5.6: [MySQL 5.6 in a Nutshell](#)

Internals and Portability:

- Written in C and C++.

- Tested with a broad range of different compilers.
- Works on many different platforms. See [Operating Systems Supported by MySQL Community Server](#).
- Uses GNU Automake, Autoconf, and Libtool for portability.
- Tested with Purify (a commercial memory leakage detector) as well as with Valgrind, a GPL tool (<http://developer.kde.org/~sewardj/>).
- Uses multi-layered server design with independent modules.
- Designed to be fully multi-threaded using kernel threads, to easily use multiple CPUs if they are available.
- Provides transactional and nontransactional storage engines.
- Uses very fast B-tree disk tables ([MyISAM](#)) with index compression.
- Designed to make it relatively easy to add other storage engines. This is useful if you want to provide an SQL interface for an in-house database.
- Uses a very fast thread-based memory allocation system.
- Executes very fast joins using an optimized nested-loop join.
- Implements in-memory hash tables, which are used as temporary tables.
- Implements SQL functions using a highly optimized class library that should be as fast as possible. Usually there is no memory allocation at all after query initialization.
- Provides the server as a separate program for use in a client/server networked environment, and as a library that can be embedded (linked) into standalone applications. Such applications can be used in isolation or in environments where no network is available.

Data Types:

- Many data types: signed/unsigned integers 1, 2, 3, 4, and 8 bytes long, [FLOAT](#), [DOUBLE](#), [CHAR](#), [VARCHAR](#), [BINARY](#), [VARBINARY](#), [TEXT](#), [BLOB](#), [DATE](#), [TIME](#), [DATETIME](#), [TIMESTAMP](#), [YEAR](#), [SET](#), [ENUM](#), and OpenGIS spatial types. See [Chapter 10, Data Types](#).
- Fixed-length and variable-length string types.

Statements and Functions:

- Full operator and function support in the [SELECT](#) list and [WHERE](#) clause of queries. For example:

```
mysql> SELECT CONCAT(first_name, ' ', last_name)
-> FROM citizen
-> WHERE income/dependents > 10000 AND age > 30;
```
- Full support for SQL [GROUP BY](#) and [ORDER BY](#) clauses. Support for group functions ([COUNT\(\)](#), [AVG\(\)](#), [STD\(\)](#), [SUM\(\)](#), [MAX\(\)](#), [MIN\(\)](#), and [GROUP\\_CONCAT\(\)](#)).
- Support for [LEFT OUTER JOIN](#) and [RIGHT OUTER JOIN](#) with both standard SQL and ODBC syntax.
- Support for aliases on tables and columns as required by standard SQL.
- Support for [DELETE](#), [INSERT](#), [REPLACE](#), and [UPDATE](#) to return the number of rows that were changed (affected), or to return the number of rows matched instead by setting a flag when connecting to the server.
- Support for MySQL-specific [SHOW](#) statements that retrieve information about databases, storage engines, tables, and indexes. MySQL 5.0 adds support for the [INFORMATION\\_SCHEMA](#) database, implemented according to standard SQL.
- An [EXPLAIN](#) statement to show how the optimizer resolves a query.
- Independence of function names from table or column names. For example, [ABS](#) is a valid column name. The only restriction is that for a function call, no spaces are permitted between the function name and the “(” that follows it. See [Section 8.3, “Reserved Words”](#).

- You can refer to tables from different databases in the same statement.

Security:

- A privilege and password system that is very flexible and secure, and that enables host-based verification.
- Password security by encryption of all password traffic when you connect to a server.

Scalability and Limits:

- Support for large databases. We use MySQL Server with databases that contain 50 million records. We also know of users who use MySQL Server with 200,000 tables and about 5,000,000,000 rows.
- Support for up to 64 indexes per table (32 before MySQL 4.1.2). Each index may consist of 1 to 16 columns or parts of columns. The maximum index width is 1000 bytes (767 for `InnoDB`); before MySQL 4.1.2, the limit is 500 bytes. An index may use a prefix of a column for `CHAR`, `VARCHAR`, `BLOB`, or `TEXT` column types.

Connectivity:

- Clients can connect to MySQL Server using several protocols:
  - Clients can connect using TCP/IP sockets on any platform.
  - On Windows systems in the NT family (NT, 2000, XP, 2003, or Vista), clients can connect using named pipes if the server is started with the `--enable-named-pipe` option. In MySQL 4.1 and higher, Windows servers also support shared-memory connections if started with the `--shared-memory` option. Clients can connect through shared memory by using the `--protocol=memory` option.
  - On Unix systems, clients can connect using Unix domain socket files.
- MySQL client programs can be written in many languages. A client library written in C is available for clients written in C or C++, or for any language that provides C bindings.
- APIs for C, C++, Eiffel, Java, Perl, PHP, Python, Ruby, and Tcl are available, enabling MySQL clients to be written in many languages. See [Chapter 21, “Connectors and APIs](#).
- The Connector/ODBC (MyODBC) interface provides MySQL support for client programs that use ODBC (Open Database Connectivity) connections. For example, you can use MS Access to connect to your MySQL server. Clients can be run on Windows or Unix. MyODBC source is available. All ODBC 2.5 functions are supported, as are many others. See [Section 21.1, “MySQL Connector/ODBC”](#).
- The Connector/J interface provides MySQL support for Java client programs that use JDBC connections. Clients can be run on Windows or Unix. Connector/J source is available. See [Section 21.3, “MySQL Connector/J”](#).
- MySQL Connector/.NET enables developers to easily create .NET applications that require secure, high-performance data connectivity with MySQL. It implements the required ADO.NET interfaces and integrates into ADO.NET aware tools. Developers can build applications using their choice of .NET languages. MySQL Connector/.NET is a fully managed ADO.NET driver written in 100% pure C#. See [Section 21.2, “MySQL Connector/.NET”](#).

Localization:

- The server can provide error messages to clients in many languages. See [Section 9.2, “Setting the Error Message Language”](#).
- Full support for several different character sets, including `latin1` (`cp1252`), `german`, `big5`, `ujis`, and more. For example, the Scandinavian characters “å”, “ä” and “ö” are permitted in table and column names. Unicode support is available as of MySQL 4.1.
- All data is saved in the chosen character set.
- Sorting and comparisons are done according to the chosen character set and collation (using `latin1` and Swedish collation by default). It is possible to change this when the MySQL server is started. To see an example of very advanced sorting, look at the Czech sorting code. MySQL Server supports many different character sets that can be specified at compile time and runtime.
- As of MySQL 4.1, the server time zone can be changed dynamically, and individual clients can specify their own time zone.

[Section 9.6, “MySQL Server Time Zone Support”.](#)

Clients and Tools:

- MySQL includes several client and utility programs. These include both command-line programs such as `mysqldump` and `mysqladmin`, and graphical programs such as MySQL Administrator and MySQL Query Browser.
- MySQL Server has built-in support for SQL statements to check, optimize, and repair tables. These statements are available from the command line through the `mysqlcheck` client. MySQL also includes `myisamchk`, a very fast command-line utility for performing these operations on MyISAM tables. See [Chapter 4, MySQL Programs](#).
- MySQL programs can be invoked with the `--help` or `-?` option to obtain online assistance.

## 1.4. MySQL Development History

This section describes the general MySQL development history, provides an overview about features that have been implemented in previous series and that are new in MySQL 5.1, the release series covered in this manual. The maturity level this release series is general availability. Information about maturity levels can be found in [Section 2.1.2.1, “Choosing Which Version of MySQL to Install”](#).

Before upgrading from one release series to the next, please see the notes in [Section 2.12.1, “Upgrading MySQL”](#).

The most requested features and the versions in which they were implemented are summarized in the following table.

| Feature                         | MySQL Series                        |
|---------------------------------|-------------------------------------|
| Unions                          | 4.0                                 |
| Subqueries                      | 4.1                                 |
| R-trees                         | 4.1 (for the MyISAM storage engine) |
| Stored procedures and functions | 5.0                                 |
| Views                           | 5.0                                 |
| Cursors                         | 5.0                                 |
| XA transactions                 | 5.0                                 |
| Triggers                        | 5.0 and 5.1                         |
| Event scheduler                 | 5.1                                 |

## 1.5. What Is New in MySQL 5.1

The following features have been added to MySQL 5.1:

- **Partitioning.** This capability enables distributing portions of individual tables across a file system, according to rules which can be set when the table is created. In effect, different portions of a table are stored as separate tables in different locations, but from the user point of view, the partitioned table is still a single table. Syntactically, this implements a number of new extensions to the `CREATE TABLE`, `ALTER TABLE`, and `EXPLAIN ... SELECT` statements. As of MySQL 5.1.6, queries against partitioned tables can take advantage of *partition pruning*. In some cases, this can result in query execution that is an order of magnitude faster than the same query against a nonpartitioned version of the same table. See [Chapter 18, Partitioning](#), for further information on this functionality. (Author: Mikael Ronström)
- **Row-based replication.** Replication capabilities in MySQL originally were based on propagation of SQL statements from master to slave. This is called *statement-based replication*. As of MySQL 5.1.5, another basis for replication is available. This is called *row-based replication*. Instead of sending SQL statements to the slave, the master writes events to its binary log that indicate how individual table rows are effected. As of MySQL 5.1.8, a third option is available: *mixed*. This will use statement-based replication by default, and only switch to row-based replication in particular cases. See [Section 16.1.2, “Replication](#)

[Formats](#). (Authors: Lars Thalmann, Guilhem Bichot, Mats Kindahl)

- **Plugin API.** MySQL 5.1 adds support for a very flexible plugin API that enables loading and unloading of various components at runtime, without restarting the server. Although the work on this is not finished yet, *plugin full-text parsers* are a first step in this direction. This permits users to implement their own input filter on the indexed text, enabling full-text search capability on arbitrary data such as PDF files or other document formats. A pre-parser full-text plugin performs the actual parsing and extraction of the text and hands it over to the built-in MySQL full-text search. See [Section 22.2, “The MySQL Plugin API”](#). (Author: Sergey Vojtovich)
- **Event scheduler.** MySQL Events are tasks that run according to a schedule. When you create an event, you are creating a named database object containing one or more SQL statements to be executed at one or more regular intervals, beginning and ending at a specific date and time. Conceptually, this is similar to the idea of the Unix `cron` (also known as a “cron job”) or the Windows Task Scheduler. See [Section 19.4, “Using the Event Scheduler”](#). (Author: Andrey Hristov)
- **Server log tables.** Before MySQL 5.1, the server writes general query log and slow query log entries to log files. As of MySQL 5.1, the server's logging capabilities for these logs are more flexible. Log entries can be written to log files (as before) or to the `general_log` and `slow_log` tables in the `mysql` database. If logging is enabled, either or both destinations can be selected. The `--log-output` option controls the destination or destinations of log output. See [Section 5.2.1, “Selecting General Query and Slow Query Log Output Destinations”](#). (Author: Petr Chardin)
- **Upgrade program.** The `mysql_upgrade` program (available as of MySQL 5.1.7) checks all existing tables for incompatibilities with the current version of MySQL Server and repairs them if necessary. This program should be run for each MySQL upgrade. See [Section 4.4.8, “`mysql\_upgrade` — Check Tables for MySQL Upgrade”](#). (Authors: Alexey Botchkov, Mikael Widenius)
- **MySQL Cluster.** MySQL Cluster is now released as a separate product, based on MySQL 5.1 but with the addition of the `NDBCLUSTER` storage engine. Clustering support is no longer available in mainline MySQL 5.1 releases. MySQL Cluster releases are identified by a 3-part NDB version number; currently, the MySQL Cluster NDB 6.3, MySQL Cluster NDB 7.0, and MySQL Cluster NDB 7.1 release series are available for production use.

Some of the changes in MySQL Cluster since MySQL 5.0 are listed here:

- **MySQL Cluster replication.** Replication between MySQL Clusters is now supported. It is now also possible to replicate between a MySQL Cluster and a noncluster database. See [Section 17.6, “MySQL Cluster Replication”](#).
- **MySQL Cluster disk data storage.** Formerly, the `NDBCLUSTER` storage engine was strictly in-memory; now, it is possible to store Cluster data (but not indexes) on disk. This enables MySQL Cluster to scale upward with fewer hardware (RAM) requirements than previously. In addition, the Disk Data implementation includes a new “no-steal” restoration algorithm for fast node restarts when storing very large amounts of data (terabyte range). See [Section 17.5.10, “MySQL Cluster Disk Data Tables”](#), for more information.
- **Improved backups for MySQL Cluster.** A fault arising in a single data node during a Cluster backup no longer causes the entire backup to be aborted, as occurred in previous versions of MySQL Cluster.

Many other new features and improvements have been made to the `NDBCLUSTER` storage engine in MySQL Cluster NDB 6.3 and MySQL Cluster NDB 7.0; for more information about these, see [Section 17.1.4, “MySQL Cluster Development History”](#).

- **Backup of tablespaces.** The `mysqldump` utility now supports an option for dumping tablespaces. Use `-Y` or `-all-tablespaces` to enable this functionality.
- **Improvements to INFORMATION\_SCHEMA.** MySQL 5.1 provides much more information in its metadata database than was available in MySQL 5.0. New tables in the `INFORMATION_SCHEMA` database include `FILES`, `EVENTS`, `PARTITIONS`, `PROCESSLIST`, `ENGINES`, and `PLUGINS`.
- **XML functions with XPath support.** `ExtractValue()` returns the content of a fragment of XML matching a given XPath expression. `UpdateXML()` replaces the element selected from a fragment of XML by an XPath expression supplied by the user with a second XML fragment (also user-supplied), and returns the modified XML. See [Section 11.11, “XML Functions”](#). (Author: Alexander Barkov)
- **Load emulator.** The `mysqlslap` program is designed to emulate client load for a MySQL server and report the timing of each stage. It works as if multiple clients were accessing the server. See [Section 4.5.7, “`mysqlslap` — Load Emulation Client”](#). (Authors: Patrick Galbraith, Brian Aker)

The following constructs are deprecated and are removed as of MySQL 5.5. Where alternatives are shown, applications should be updated to use them.

- The `log_bin_trust_routine_creators` system variable (use `log_bin_trust_function_creators`).
- The `table_type` system variable (use `storage_engine`).

- The `TYPE` table option to specify the storage engine for `CREATE TABLE` or `ALTER TABLE` (use `ENGINE`).
- The `SHOW TABLE TYPES` SQL statement (use `SHOW ENGINES`).
- The `SHOW INNODB STATUS` and `SHOW MUTEX STATUS` SQL statements (use `SHOW ENGINE INNODB STATUS SHOW ENGINE INNODB MUTEX`).
- The `SHOW PLUGIN` SQL statement (use `SHOW PLUGINS`).
- The `LOAD TABLE ... FROM MASTER` and `LOAD DATA FROM MASTER` SQL statements (use `mysqldump` or `mysqlhotcopy` to dump tables and `mysql` to reload dump files).
- The `BACKUP TABLE` and `RESTORE TABLE` SQL statements (use `mysqldump` or `mysqlhotcopy` to dump tables and `mysql` to reload dump files).
- `TIMESTAMP(N)` data type: The ability to specify a display width of `N` (use without `N`).
- The `--master-xxx` server options to set replication parameters (use the `CHANGE MASTER TO` statement instead): `--master-host`, `--master-user`, `--master-password`, `--master-port`, `--master-connect-retry`, `--master-ssl`, `--master-ssl-ca`, `--master-ssl-capath`, `--master-ssl-cert`, `--master-ssl-cipher`, `--master-ssl-key`.

## 1.6. MySQL Information Sources

This section lists sources of additional information that you may find helpful, such as the MySQL mailing lists and user forums, and Internet Relay Chat.

### 1.6.1. MySQL Mailing Lists

This section introduces the MySQL mailing lists and provides guidelines as to how the lists should be used. When you subscribe to a mailing list, you receive all postings to the list as email messages. You can also send your own questions and answers to the list.

To subscribe to or unsubscribe from any of the mailing lists described in this section, visit <http://lists.mysql.com/>. For most of them, you can select the regular version of the list where you get individual messages, or a digest version where you get one large message per day.

Please *do not* send messages about subscribing or unsubscribing to any of the mailing lists, because such messages are distributed automatically to thousands of other users.

Your local site may have many subscribers to a MySQL mailing list. If so, the site may have a local mailing list, so that messages sent from `lists.mysql.com` to your site are propagated to the local list. In such cases, please contact your system administrator to be added to or dropped from the local MySQL list.

If you wish to have traffic for a mailing list go to a separate mailbox in your mail program, set up a filter based on the message headers. You can use either the `List-ID:` or `Delivered-To:` headers to identify list messages.

The MySQL mailing lists are as follows:

- `announce`

The list for announcements of new versions of MySQL and related programs. This is a low-volume list to which all MySQL users should subscribe.

- `mysql`

The main list for general MySQL discussion. Please note that some topics are better discussed on the more-specialized lists. If you post to the wrong list, you may not get an answer.

- `bugs`

The list for people who want to stay informed about issues reported since the last release of MySQL or who want to be actively involved in the process of bug hunting and fixing. See [Section 1.7, “How to Report Bugs or Problems”](#).

- `internals`

The list for people who work on the MySQL code. This is also the forum for discussions on MySQL development and for posting patches.

- [mysqldoc](#)

The list for people who work on the MySQL documentation.

- [benchmarks](#)

The list for anyone interested in performance issues. Discussions concentrate on database performance (not limited to MySQL), but also include broader categories such as performance of the kernel, file system, disk system, and so on.

- [packagers](#)

The list for discussions on packaging and distributing MySQL. This is the forum used by distribution maintainers to exchange ideas on packaging MySQL and on ensuring that MySQL looks and feels as similar as possible on all supported platforms and operating systems.

- [java](#)

The list for discussions about the MySQL server and Java. It is mostly used to discuss JDBC drivers such as MySQL Connector/J.

- [win32](#)

The list for all topics concerning the MySQL software on Microsoft operating systems, such as Windows 9x, Me, NT, 2000, XP, and 2003.

- [myodbc](#)

The list for all topics concerning connecting to the MySQL server with ODBC.

- [gui-tools](#)

The list for all topics concerning MySQL graphical user interface tools such as [MySQL Administrator](#) and [MySQL Query Browser](#).

- [cluster](#)

The list for discussion of MySQL Cluster.

- [dotnet](#)

The list for discussion of the MySQL server and the .NET platform. It is mostly related to MySQL Connector/Net.

- [plusplus](#)

The list for all topics concerning programming with the C++ API for MySQL.

- [perl](#)

The list for all topics concerning Perl support for MySQL with [DBD::mysql](#).

If you're unable to get an answer to your questions from a MySQL mailing list or forum, one option is to purchase support from Oracle. This puts you in direct contact with MySQL developers.

The following MySQL mailing lists are in languages other than English. These lists are not operated by Oracle.

- <[mysql-france-subscribe@yahoogroups.com](mailto:mysql-france-subscribe@yahoogroups.com)>

A French mailing list.

- <[list@tinc.net](mailto:list@tinc.net)>

A Korean mailing list. To subscribe, email `subscribe mysql your@email.address` to this list.

- <[mysql-de-request@lists.4t2.com](mailto:mysql-de-request@lists.4t2.com)>

A German mailing list. To subscribe, email `subscribe mysql-de your@email.address` to this list. You can find information about this mailing list at <http://www.4t2.com/mysql/>.

- <[mysql-br-request@listas.linkway.com.br](mailto:mysql-br-request@listas.linkway.com.br)>

A Portuguese mailing list. To subscribe, email `subscribe mysql-br your@email.address` to this list.

- <[mysql-alta@elistas.net](mailto:mysql-alta@elistas.net)>

A Spanish mailing list. To subscribe, email `subscribe mysql your@email.address` to this list.

### 1.6.1.1. Guidelines for Using the Mailing Lists

Please do not post mail messages from your browser with HTML mode turned on. Many users do not read mail with a browser.

When you answer a question sent to a mailing list, if you consider your answer to have broad interest, you may want to post it to the list instead of replying directly to the individual who asked. Try to make your answer general enough that people other than the original poster may benefit from it. When you post to the list, please make sure that your answer is not a duplication of a previous answer.

Try to summarize the essential part of the question in your reply. Do not feel obliged to quote the entire original message.

When answers are sent to you individually and not to the mailing list, it is considered good etiquette to summarize the answers and send the summary to the mailing list so that others may have the benefit of responses you received that helped you solve your problem.

### 1.6.2. MySQL Community Support at the MySQL Forums

The forums at <http://forums.mysql.com> are an important community resource. Many forums are available, grouped into these general categories:

- Migration
- MySQL Usage
- MySQL Connectors
- Programming Languages
- Tools
- 3rd-Party Applications
- Storage Engines
- MySQL Technology
- SQL Standards
- Business

### 1.6.3. MySQL Community Support on Internet Relay Chat (IRC)

In addition to the various MySQL mailing lists and forums, you can find experienced community people on Internet Relay Chat (IRC). These are the best networks/channels currently known to us:

**freenode** (see <http://www.freenode.net/> for servers)

- `#mysql` is primarily for MySQL questions, but other database and general SQL questions are welcome. Questions about PHP, Perl, or C in combination with MySQL are also common.

If you are looking for IRC client software to connect to an IRC network, take a look at **xChat** (<http://www.xchat.org/>). X-Chat (GPL licensed) is available for Unix as well as for Windows platforms (a free Windows build of X-Chat is available at <http://www.silverex.org/download/>).

### 1.6.4. MySQL Enterprise

Oracle offers technical support in the form of MySQL Enterprise. For organizations that rely on the MySQL DBMS for business-critical production applications, MySQL Enterprise is a commercial subscription offering which includes:

- MySQL Enterprise Server
- MySQL Enterprise Monitor
- Monthly Rapid Updates and Quarterly Service Packs
- MySQL Knowledge Base
- 24x7 Technical and Consultative Support

MySQL Enterprise is available in multiple tiers, giving you the flexibility to choose the level of service that best matches your needs. For more information, see [MySQL Enterprise](#).

## 1.7. How to Report Bugs or Problems

Before posting a bug report about a problem, please try to verify that it is a bug and that it has not been reported already:

- Start by searching the MySQL online manual at <http://dev.mysql.com/doc/>. We try to keep the manual up to date by updating it frequently with solutions to newly found problems. The change history (<http://dev.mysql.com/doc/mysql/en/news.html>) can be particularly useful since it is quite possible that a newer version contains a solution to your problem.
- If you get a parse error for an SQL statement, please check your syntax closely. If you cannot find something wrong with it, it is extremely likely that your current version of MySQL Server doesn't support the syntax you are using. If you are using the current version and the manual doesn't cover the syntax that you are using, MySQL Server doesn't support your statement. In this case, your options are to implement the syntax yourself or email <[licensing@mysql.com](mailto:licensing@mysql.com)> and ask for an offer to implement it.

If the manual covers the syntax you are using, but you have an older version of MySQL Server, you should check the MySQL change history to see when the syntax was implemented. In this case, you have the option of upgrading to a newer version of MySQL Server.

- For solutions to some common problems, see [Section B.5, “Problems and Common Errors”](#).
- Search the bugs database at <http://bugs.mysql.com/> to see whether the bug has been reported and fixed.
- Search the MySQL mailing list archives at <http://lists.mysql.com/>. See [Section 1.6.1, “MySQL Mailing Lists”](#).
- You can also use <http://www.mysql.com/search/> to search all the Web pages (including the manual) that are located at the MySQL Web site.

If you cannot find an answer in the manual, the bugs database, or the mailing list archives, check with your local MySQL expert. If you still cannot find an answer to your question, please use the following guidelines for reporting the bug.

The normal way to report bugs is to visit <http://bugs.mysql.com/>, which is the address for our bugs database. This database is public and can be browsed and searched by anyone. If you log in to the system, you can enter new reports. If you have no Web access, you can generate a bug report by using the `mysqlbug` script described at the end of this section.

Bugs posted in the bugs database at <http://bugs.mysql.com/> that are corrected for a given release are noted in the change history.

If you have found a sensitive security bug in MySQL, you can send email to <[security@mysql.com](mailto:security@mysql.com)>.

To discuss problems with other users, you can use one of the MySQL mailing lists. [Section 1.6.1, “MySQL Mailing Lists”](#).

Writing a good bug report takes patience, but doing it right the first time saves time both for us and for yourself. A good bug report, containing a full test case for the bug, makes it very likely that we will fix the bug in the next release. This section helps you write your report correctly so that you do not waste your time doing things that may not help us much or at all. Please read this section carefully and make sure that all the information described here is included in your report.

Preferably, you should test the problem using the latest production or development version of MySQL Server before posting. Any one should be able to repeat the bug by just using `mysql test < script_file` on your test case or by running the shell or Perl script that you include in the bug report. Any bug that we are able to repeat has a high chance of being fixed in the next MySQL release.

It is most helpful when a good description of the problem is included in the bug report. That is, give a good example of everything you did that led to the problem and describe, in exact detail, the problem itself. The best reports are those that include a full example showing how to reproduce the bug or problem. See [MySQL Internals: Porting](#).

Remember that it is possible for us to respond to a report containing too much information, but not to one containing too little.

People often omit facts because they think they know the cause of a problem and assume that some details do not matter. A good principle to follow is that if you are in doubt about stating something, state it. It is faster and less troublesome to write a couple more lines in your report than to wait longer for the answer if we must ask you to provide information that was missing from the initial report.

The most common errors made in bug reports are (a) not including the version number of the MySQL distribution that you use, and (b) not fully describing the platform on which the MySQL server is installed (including the platform type and version number). These are highly relevant pieces of information, and in 99 cases out of 100, the bug report is useless without them. Very often we get questions like, “Why doesn’t this work for me?” Then we find that the feature requested wasn’t implemented in that MySQL version, or that a bug described in a report has been fixed in newer MySQL versions. Errors often are platform-dependent. In such cases, it is next to impossible for us to fix anything without knowing the operating system and the version number of the platform.

If you compiled MySQL from source, remember also to provide information about your compiler if it is related to the problem. Often people find bugs in compilers and think the problem is MySQL-related. Most compilers are under development all the time and become better version by version. To determine whether your problem depends on your compiler, we need to know what compiler you used. Note that every compiling problem should be regarded as a bug and reported accordingly.

If a program produces an error message, it is very important to include the message in your report. If we try to search for something from the archives, it is better that the error message reported exactly matches the one that the program produces. (Even the letter-case should be observed.) It is best to copy and paste the entire error message into your report. You should never try to reproduce the message from memory.

If you have a problem with Connector/ODBC (MyODBC), please try to generate a trace file and send it with your report. See the MyODBC section of [Chapter 21, Connectors and APIs](#).

If your report includes long query output lines from test cases that you run with the `mysql` command-line tool, you can make the output more readable by using the `--vertical` option or the `\G` statement terminator. The `EXPLAIN SELECT` example later in this section demonstrates the use of `\G`.

Please include the following information in your report:

- The version number of the MySQL distribution you are using (for example, MySQL 5.0.19). You can find out which version you are running by executing `mysqladmin version`. The `mysqladmin` program can be found in the `bin` directory under your MySQL installation directory.
- The manufacturer and model of the machine on which you experience the problem.
- The operating system name and version. If you work with Windows, you can usually get the name and version number by double-clicking your My Computer icon and pulling down the “Help/About Windows” menu. For most Unix-like operating systems, you can get this information by executing the command `uname -a`.
- Sometimes the amount of memory (real and virtual) is relevant. If in doubt, include these values.
- If you are using a source distribution of the MySQL software, include the name and version number of the compiler that you used. If you have a binary distribution, include the distribution name.
- If the problem occurs during compilation, include the exact error messages and also a few lines of context around the offending code in the file where the error occurs.
- If `mysqld` died, you should also report the statement that crashed `mysqld`. You can usually get this information by running `mysqld` with query logging enabled, and then looking in the log after `mysqld` crashes. See [MySQL Internals: Porting](#).
- If a database table is related to the problem, include the output from the `SHOW CREATE TABLE db_name.tbl_name` statement in the bug report. This is a very easy way to get the definition of any table in a database. The information helps us create a situation matching the one that you have experienced.
- The SQL mode in effect when the problem occurred can be significant, so please report the value of the `sql_mode` system variable. For stored procedure, stored function, and trigger objects, the relevant `sql_mode` value is the one in effect when the object was created. For a stored procedure or function, the `SHOW CREATE PROCEDURE` or `SHOW CREATE FUNCTION` statement shows the relevant SQL mode, or you can query `INFORMATION_SCHEMA` for the information:

```
SELECT ROUTINE_SCHEMA, ROUTINE_NAME, SQL_MODE
FROM INFORMATION_SCHEMA.ROUTINES;
```

For triggers, you can use this statement:

```
SELECT EVENT_OBJECT_SCHEMA, EVENT_OBJECT_TABLE, TRIGGER_NAME, SQL_MODE
FROM INFORMATION_SCHEMA.TRIGGERS;
```

- For performance-related bugs or problems with `SELECT` statements, you should always include the output of `EXPLAIN SELECT ...`, and at least the number of rows that the `SELECT` statement produces. You should also include the output from `SHOW CREATE TABLE tbl_name` for each table that is involved. The more information you provide about your situation, the more likely it is that someone can help you.

The following is an example of a very good bug report. The statements are run using the `mysql` command-line tool. Note the use of the `\G` statement terminator for statements that would otherwise provide very long output lines that are difficult to read.

```
mysql> SHOW VARIABLES;
mysql> SHOW COLUMNS FROM ... \G
<output from SHOW COLUMNS>
mysql> EXPLAIN SELECT ... \G
<output from EXPLAIN>
mysql> FLUSH STATUS;
mysql> SELECT ...;
<A short version of the output from SELECT,
including the time taken to run the query>
mysql> SHOW STATUS;
<output from SHOW STATUS>
```

- If a bug or problem occurs while running `mysqld`, try to provide an input script that reproduces the anomaly. This script should include any necessary source files. The more closely the script can reproduce your situation, the better. If you can make a reproducible test case, you should upload it to be attached to the bug report.

If you cannot provide a script, you should at least include the output from `mysqladmin variables extended-status processlist` in your report to provide some information on how your system is performing.

- If you cannot produce a test case with only a few rows, or if the test table is too big to be included in the bug report (more than 10 rows), you should dump your tables using `mysqldump` and create a `README` file that describes your problem. Create a compressed archive of your files using `tar` and `gzip` or `zip`, and use FTP to transfer the archive to <ftp://ftp.mysql.com/pub/mysql/upload/>. Then enter the problem into our bugs database at <http://bugs.mysql.com/>.
- If you believe that the MySQL server produces a strange result from a statement, include not only the result, but also your opinion of what the result should be, and an explanation describing the basis for your opinion.
- When you provide an example of the problem, it is better to use the table names, variable names, and so forth that exist in your actual situation than to come up with new names. The problem could be related to the name of a table or variable. These cases are rare, perhaps, but it is better to be safe than sorry. After all, it should be easier for you to provide an example that uses your actual situation, and it is by all means better for us. If you have data that you do not want to be visible to others in the bug report, you can use FTP to transfer it to <ftp://ftp.mysql.com/pub/mysql/upload/>. If the information is really top secret and you do not want to show it even to us, go ahead and provide an example using other names, but please regard this as the last choice.
- Include all the options given to the relevant programs, if possible. For example, indicate the options that you use when you start the `mysqld` server, as well as the options that you use to run any MySQL client programs. The options to programs such as `mysqld` and `mysql`, and to the `configure` script, are often key to resolving problems and are very relevant. It is never a bad idea to include them. If your problem involves a program written in a language such as Perl or PHP, please include the language processor's version number, as well as the version for any modules that the program uses. For example, if you have a Perl script that uses the `DBI` and `DBD::mysql` modules, include the version numbers for Perl, `DBI`, and `DBD::mysql`.
- If your question is related to the privilege system, please include the output of `mysqlaccess`, the output of `mysqladmin reload`, and all the error messages you get when trying to connect. When you test your privileges, you should first run `mysqlaccess`. After this, execute `mysqladmin reload version` and try to connect with the program that gives you trouble. `mysqlaccess` can be found in the `bin` directory under your MySQL installation directory.
- If you have a patch for a bug, do include it. But do not assume that the patch is all we need, or that we can use it, if you do not provide some necessary information such as test cases showing the bug that your patch fixes. We might find problems with your patch or we might not understand it at all. If so, we cannot use it.

If we cannot verify the exact purpose of the patch, we will not use it. Test cases help us here. Show that the patch handles all the situations that may occur. If we find a borderline case (even a rare one) where the patch will not work, it may be useless.

- Guesses about what the bug is, why it occurs, or what it depends on are usually wrong. Even the MySQL team cannot guess such things without first using a debugger to determine the real cause of a bug.
- Indicate in your bug report that you have checked the reference manual and mail archive so that others know you have tried to solve the problem yourself.
- If the problem is that your data appears corrupt or you get errors when you access a particular table, you should first check your tables and then try to repair them with `CHECK TABLE` and `REPAIR TABLE` or with `myisamchk`. See [Chapter 5, MySQL Server Administration](#).

If you are running Windows, please verify the value of `lower_case_table_names` using the `SHOW VARIABLES LIKE 'lower_case_table_names'` statement. This variable affects how the server handles lettercase of database and table

names. Its effect for a given value should be as described in [Section 8.2.2, “Identifier Case Sensitivity”](#).

- If you often get corrupted tables, you should try to find out when and why this happens. In this case, the error log in the MySQL data directory may contain some information about what happened. (This is the file with the `.err` suffix in the name.) See [Section 5.2.2, “The Error Log”](#). Please include any relevant information from this file in your bug report. Normally `mysqld` should *never* crash a table if nothing killed it in the middle of an update. If you can find the cause of `mysqld` dying, it is much easier for us to provide you with a fix for the problem. See [Section B.5.1, “How to Determine What Is Causing a Problem”](#).
- If possible, download and install the most recent version of MySQL Server and check whether it solves your problem. All versions of the MySQL software thoroughly tested and should work without problems. We believe in making everything as backward-compatible as possible, and you should be able to switch MySQL versions without difficulty. See [Section 2.1.2, “Choosing Which MySQL Distribution to Install”](#).

If you have no Web access and cannot report a bug by visiting <http://bugs.mysql.com/>, you can use the `mysqlbug` script to generate a bug report (or a report about any problem). `mysqlbug` helps you generate a report by determining much of the following information automatically, but if something important is missing, please include it with your message. `mysqlbug` can be found in the `scripts` directory (source distribution) and in the `bin` directory under your MySQL installation directory (binary distribution).

## 1.8. MySQL Standards Compliance

This section describes how MySQL relates to the ANSI/ISO SQL standards. MySQL Server has many extensions to the SQL standard, and here you can find out what they are and how to use them. You can also find information about functionality missing from MySQL Server, and how to work around some of the differences.

The SQL standard has been evolving since 1986 and several versions exist. In this manual, “SQL-92” refers to the standard released in 1992, “SQL:1999” refers to the standard released in 1999, “SQL:2003” refers to the standard released in 2003, and “SQL:2008” refers to the most recent version of the standard, released in 2008. We use the phrase “the SQL standard” or “standard SQL” to mean the current version of the SQL Standard at any time.

One of our main goals with the product is to continue to work toward compliance with the SQL standard, but without sacrificing speed or reliability. We are not afraid to add extensions to SQL or support for non-SQL features if this greatly increases the usability of MySQL Server for a large segment of our user base. The `HANDLER` interface is an example of this strategy. See [Section 12.2.4, “HANDLER Syntax”](#).

We continue to support transactional and nontransactional databases to satisfy both mission-critical 24/7 usage and heavy Web or logging usage.

MySQL Server was originally designed to work with medium-sized databases (10-100 million rows, or about 100MB per table) on small computer systems. Today MySQL Server handles terabyte-sized databases, but the code can also be compiled in a reduced version suitable for hand-held and embedded devices. The compact design of the MySQL server makes development in both directions possible without any conflicts in the source tree.

Currently, we are not targeting real-time support, although MySQL replication capabilities offer significant functionality.

MySQL supports high-availability database clustering using the `NDBCLUSTER` storage engine. See [Chapter 17, MySQL Cluster NDB 6.X/7.X](#).

We are implementing XML functionality beginning in MySQL 5.1, which supports most of the W3C XPath standard. We plan to increase support for XML as part of future MySQL development. See [Section 11.11, “XML Functions”](#).

### 1.8.1. What Standards MySQL Follows

Our aim is to support the full ANSI/ISO SQL standard, but without making concessions to speed and quality of the code.

ODBC levels 0 to 3.51.

### 1.8.2. Selecting SQL Modes

The MySQL server can operate in different SQL modes, and can apply these modes differentially for different clients. This capability enables each application to tailor the server's operating mode to its own requirements.

SQL modes control aspects of server operation such as what SQL syntax MySQL should support and what kind of data validation checks it should perform. This makes it easier to use MySQL in different environments and to use MySQL together with other database servers.

You can set the default SQL mode by starting `mysqld` with the `--sql-mode="mode_value"` option. You can also change

the mode at runtime by setting the `sql_mode` system variable with a `SET [GLOBAL|SESSION] sql_mode='mode_value'` statement.

For more information on setting the SQL mode, see [Section 5.1.7, “Server SQL Modes”](#).

### 1.8.3. Running MySQL in ANSI Mode

You can tell `mysqld` to run in ANSI mode with the `--ansi` startup option. Running the server in ANSI mode is the same as starting it with the following options:

```
--transaction-isolation=SERIALIZABLE --sql-mode=ANSI
```

You can achieve the same effect at runtime by executing these two statements:

```
SET GLOBAL TRANSACTION ISOLATION LEVEL SERIALIZABLE;
SET GLOBAL sql_mode = 'ANSI';
```

You can see that setting the `sql_mode` system variable to '`ANSI`' enables all SQL mode options that are relevant for ANSI mode as follows:

```
mysql> SET GLOBAL sql_mode='ANSI';
mysql> SELECT @@global.sql_mode;
 -> 'REAL_AS_FLOAT,PIPES_AS_CONCAT,ANSI_QUOTES,IGNORE_SPACE,ANSI'
```

Running the server in ANSI mode with `--ansi` is not quite the same as setting the SQL mode to '`ANSI`'. The `--ansi` option affects the SQL mode and also sets the transaction isolation level. Setting the SQL mode to '`ANSI`' has no effect on the isolation level.

See [Section 5.1.2, “Server Command Options”](#), and [Section 1.8.2, “Selecting SQL Modes”](#).

### 1.8.4. MySQL Extensions to Standard SQL

MySQL Server supports some extensions that you probably won't find in other SQL DBMSs. Be warned that if you use them, your code won't be portable to other SQL servers. In some cases, you can write code that includes MySQL extensions, but is still portable, by using comments of the following form:

```
/*! MySQL-specific code */
```

In this case, MySQL Server parses and executes the code within the comment as it would any other SQL statement, but other SQL servers will ignore the extensions. For example, MySQL Server recognizes the `STRAIGHT_JOIN` keyword in the following statement, but other servers will not:

```
SELECT /*! STRAIGHT_JOIN */ col1 FROM table1,table2 WHERE ...
```

If you add a version number after the “`!`” character, the syntax within the comment is executed only if the MySQL version is greater than or equal to the specified version number. The `TEMPORARY` keyword in the following comment is executed only by servers from MySQL 3.23.02 or higher:

```
CREATE /*! 3.23.02 TEMPORARY */ TABLE t (a INT);
```

The following descriptions list MySQL extensions, organized by category.

- Organization of data on disk

MySQL Server maps each database to a directory under the MySQL data directory, and maps tables within a database to file names in the database directory. This has a few implications:

- Database and table names are case sensitive in MySQL Server on operating systems that have case-sensitive file names (such as most Unix systems). See [Section 8.2.2, “Identifier Case Sensitivity”](#).
- You can use standard system commands to back up, rename, move, delete, and copy tables that are managed by the `MyISAM` storage engine. For example, it is possible to rename a `MyISAM` table by renaming the `.MYD`, `.MYI`, and `.frm` files to which the table corresponds. (Nevertheless, it is preferable to use `RENAME TABLE` or `ALTER TABLE ... RENAME` and let the server rename the files.)

Prior to MySQL 5.1.6, database and table names cannot contain path name separator characters (“`/`”, “`\`”).

- General language syntax

- By default, strings can be enclosed by either “`”` or “`‘`”, not just by “`‘`”. (If the `ANSI_QUOTES` SQL mode is enabled, strings can be enclosed only by “`‘`” and the server interprets strings enclosed by “`”` as identifiers.)
- “`\`” is the escape character in strings.
- In SQL statements, you can access tables from different databases with the `db_name.tbl_name` syntax. Some SQL servers provide the same functionality but call this `User space`. MySQL Server doesn't support tablespaces such as used in statements like this: `CREATE TABLE ralph.my_table ... IN my_tablespace`.
- SQL statement syntax
  - The `ANALYZE TABLE`, `CHECK TABLE`, `OPTIMIZE TABLE`, and `REPAIR TABLE` statements.
  - The `CREATE DATABASE`, `DROP DATABASE`, and `ALTER DATABASE` statements. See [Section 12.1.10, “CREATE DATABASE Syntax”](#), [Section 12.1.21, “DROP DATABASE Syntax”](#), and [Section 12.1.1, “ALTER DATABASE Syntax”](#).
  - The `DO` statement.
  - `EXPLAIN SELECT` to obtain a description of how tables are processed by the query optimizer.
  - The `FLUSH` and `RESET` statements.
  - The `SET` statement. See [Section 12.4.4, “SET Syntax”](#).
  - The `SHOW` statement. See [Section 12.4.5, “SHOW Syntax”](#). The information produced by many of the MySQL-specific `SHOW` statements can be obtained in more standard fashion by using `SELECT` to query `INFORMATION_SCHEMA`. See [Chapter 20, INFORMATION\\_SCHEMA Tables](#).
  - Use of `LOAD DATA INFILE`. In many cases, this syntax is compatible with Oracle's `LOAD DATA INFILE`. See [Section 12.2.6, “LOAD DATA INFILE Syntax”](#).
  - Use of `RENAME TABLE`. See [Section 12.1.33, “RENAME TABLE Syntax”](#).
  - Use of `REPLACE` instead of `DELETE` plus `INSERT`. See [Section 12.2.7, “REPLACE Syntax”](#).
  - Use of `CHANGE col_name`, `DROP col_name`, or `DROP INDEX`, `IGNORE` or `RENAME` in `ALTER TABLE` statements. Use of multiple `ADD`, `ALTER`, `DROP`, or `CHANGE` clauses in an `ALTER TABLE` statement. See [Section 12.1.7, “ALTER TABLE Syntax”](#).
  - Use of index names, indexes on a prefix of a column, and use of `INDEX` or `KEY` in `CREATE TABLE` statements. See [Section 12.1.17, “CREATE TABLE Syntax”](#).
  - Use of `TEMPORARY` or `IF NOT EXISTS` with `CREATE TABLE`.
  - Use of `IF EXISTS` with `DROP TABLE` and `DROP DATABASE`.
  - The capability of dropping multiple tables with a single `DROP TABLE` statement.
  - The `ORDER BY` and `LIMIT` clauses of the `UPDATE` and `DELETE` statements.
  - `INSERT INTO tbl_name SET col_name = ...` syntax.
  - The `DELAYED` clause of the `INSERT` and `REPLACE` statements.
  - The `LOW_PRIORITY` clause of the `INSERT`, `REPLACE`, `DELETE`, and `UPDATE` statements.
  - Use of `INTO OUTFILE` or `INTO DUMPFILE` in `SELECT` statements. See [Section 12.2.8, “SELECT Syntax”](#).
  - Options such as `STRAIGHT_JOIN` or `SQL_SMALL_RESULT` in `SELECT` statements.
  - You don't need to name all selected columns in the `GROUP BY` clause. This gives better performance for some very specific, but quite normal queries. See [Section 11.16, “Functions and Modifiers for Use with GROUP BY Clauses”](#).
  - You can specify `ASC` and `DESC` with `GROUP BY`, not just with `ORDER BY`.
  - The ability to set variables in a statement with the `:=` assignment operator:

```
mysql> SELECT @a:=SUM(total),@b:=COUNT(*),@a/@b AS avg
-> FROM test_table;
mysql> SELECT @t1:=(@t2:=1)+@t3:=4,@t1,@t2,@t3;
```

- Data types
  - The `MEDIUMINT`, `SET`, and `ENUM` data types, and the various `BLOB` and `TEXT` data types.
  - The `AUTO_INCREMENT`, `BINARY`, `NULL`, `UNSIGNED`, and `ZEROFILL` data type attributes.
- Functions and operators
  - To make it easier for users who migrate from other SQL environments, MySQL Server supports aliases for many functions. For example, all string functions support both standard SQL syntax and ODBC syntax.
  - MySQL Server understands the `||` and `&&` operators to mean logical OR and AND, as in the C programming language. In MySQL Server, `||` and `OR` are synonyms, as are `&&` and `AND`. Because of this nice syntax, MySQL Server doesn't support the standard SQL `||` operator for string concatenation; use `CONCAT()` instead. Because `CONCAT()` takes any number of arguments, it is easy to convert use of the `||` operator to MySQL Server.
  - Use of `COUNT(DISTINCT value_list)` where `value_list` has more than one element.
  - String comparisons are case-insensitive by default, with sort ordering determined by the collation of the current character set, which is `latin1` (cp1252 West European) by default. If you don't like this, you should declare your columns with the `BINARY` attribute or use the `BINARY` cast, which causes comparisons to be done using the underlying character code values rather than a lexical ordering.
  - The `%` operator is a synonym for `MOD()`. That is, `N % M` is equivalent to `MOD(N,M)`. `%` is supported for C programmers and for compatibility with PostgreSQL.
  - The `=, <>, <=, <, >=, >, <<, >>, <=>`, `AND`, `OR`, or `LIKE` operators may be used in expressions in the output column list (to the left of the `FROM`) in `SELECT` statements. For example:

```
mysql> SELECT col1=1 AND col2=2 FROM my_table;
```

- The `LAST_INSERT_ID()` function returns the most recent `AUTO_INCREMENT` value. See [Section 11.14, “Information Functions”](#).
- `LIKE` is permitted on numeric values.
- The `REGEXP` and `NOT REGEXP` extended regular expression operators.
- `CONCAT()` or `CHAR()` with one argument or more than two arguments. (In MySQL Server, these functions can take a variable number of arguments.)
- The `BIT_COUNT()`, `CASE`, `ELT()`, `FROM_DAYS()`, `FORMAT()`, `IF()`, `PASSWORD()`, `ENCRYPT()`, `MD5()`, `ENCODE()`, `DECODE()`, `PERIOD_ADD()`, `PERIOD_DIFF()`, `TO_DAYS()`, and `WEEKDAY()` functions.
- Use of `TRIM()` to trim substrings. Standard SQL supports removal of single characters only.
- The `GROUP BY` functions `STD()`, `BIT_OR()`, `BIT_AND()`, `BIT_XOR()`, and `GROUP_CONCAT()`. See [Section 11.16, “Functions and Modifiers for Use with GROUP BY Clauses”](#).

## 1.8.5. MySQL Differences from Standard SQL

We try to make MySQL Server follow the ANSI SQL standard and the ODBC SQL standard, but MySQL Server performs operations differently in some cases:

- There are several differences between the MySQL and standard SQL privilege systems. For example, in MySQL, privileges for a table are not automatically revoked when you delete a table. You must explicitly issue a `REVOKE` statement to revoke privileges for a table. For more information, see [Section 12.4.1.5, “REVOKE Syntax”](#).
- The `CAST()` function does not support cast to `REAL` or `BIGINT`. See [Section 11.10, “Cast Functions and Operators”](#).

### 1.8.5.1. `SELECT INTO TABLE`

MySQL Server doesn't support the `SELECT ... INTO TABLE` Sybase SQL extension. Instead, MySQL Server supports the `INSERT INTO ... SELECT` standard SQL syntax, which is basically the same thing. See [Section 12.2.5.1, “`INSERT ... SELECT` Syntax”](#). For example:

```
INSERT INTO tbl_temp2 (fld_id)
 SELECT tbl_temp1.fld_order_id
```

```
FROM tbl_temp1 WHERE tbl_temp1.fld_order_id > 100;
```

Alternatively, you can use `SELECT ... INTO OUTFILE` or `CREATE TABLE ... SELECT`.

You can use `SELECT ... INTO` with user-defined variables. The same syntax can also be used inside stored routines using cursors and local variables. See [Section 12.7.3.3, “SELECT ... INTO Statement”](#).

### 1.8.5.2. UPDATE

If you access a column from the table to be updated in an expression, `UPDATE` uses the current value of the column. The second assignment in the following statement sets `col2` to the current (updated) `col1` value, not the original `col1` value. The result is that `col1` and `col2` have the same value. This behavior differs from standard SQL.

```
UPDATE t1 SET col1 = col1 + 1, col2 = col1;
```

### 1.8.5.3. Transactions and Atomic Operations

MySQL Server (version 3.23-max and all versions 4.0 and above) supports transactions with the `InnoDB` transactional storage engine. `InnoDB` provides *full* ACID compliance. See [Chapter 13, “Storage Engines”](#). For information about `InnoDB` differences from standard SQL with regard to treatment of transaction errors, see [Section 13.6.12, “InnoDB Error Handling”](#).

The other nontransactional storage engines in MySQL Server (such as `MyISAM`) follow a different paradigm for data integrity called “atomic operations.” In transactional terms, `MyISAM` tables effectively always operate in `autocommit = 1` mode. Atomic operations often offer comparable integrity with higher performance.

Because MySQL Server supports both paradigms, you can decide whether your applications are best served by the speed of atomic operations or the use of transactional features. This choice can be made on a per-table basis.

As noted, the tradeoff for transactional versus nontransactional storage engines lies mostly in performance. Transactional tables have significantly higher memory and disk space requirements, and more CPU overhead. On the other hand, transactional storage engines such as `InnoDB` also offer many significant features. MySQL Server's modular design enables the concurrent use of different storage engines to suit different requirements and deliver optimum performance in all situations.

But how do you use the features of MySQL Server to maintain rigorous integrity even with the nontransactional `MyISAM` tables, and how do these features compare with the transactional storage engines?

- If your applications are written in a way that is dependent on being able to call `ROLLBACK` rather than `COMMIT` in critical situations, transactions are more convenient. Transactions also ensure that unfinished updates or corrupting activities are not committed to the database; the server is given the opportunity to do an automatic rollback and your database is saved.

If you use nontransactional tables, MySQL Server in almost all cases enables you to resolve potential problems by including simple checks before updates and by running simple scripts that check the databases for inconsistencies and automatically repair or warn if such an inconsistency occurs. You can normally fix tables perfectly with no data integrity loss just by using the MySQL log or even adding one extra log.

- More often than not, critical transactional updates can be rewritten to be atomic. Generally speaking, all integrity problems that transactions solve can be done with `LOCK TABLES` or atomic updates, ensuring that there are no automatic aborts from the server, which is a common problem with transactional database systems.
- To be safe with MySQL Server, regardless of whether you use transactional tables, you only need to have backups and have binary logging turned on. When that is true, you can recover from any situation that you could with any other transactional database system. It is always good to have backups, regardless of which database system you use.

The transactional paradigm has its advantages and disadvantages. Many users and application developers depend on the ease with which they can code around problems where an abort appears to be necessary, or is necessary. However, even if you are new to the atomic operations paradigm, or more familiar with transactions, do consider the speed benefit that nontransactional tables can offer on the order of three to five times the speed of the fastest and most optimally tuned transactional tables.

In situations where integrity is of highest importance, MySQL Server offers transaction-level reliability and integrity even for nontransactional tables. If you lock tables with `LOCK TABLES`, all updates stall until integrity checks are made. If you obtain a `READ LOCAL` lock (as opposed to a write lock) for a table that enables concurrent inserts at the end of the table, reads are permitted, as are inserts by other clients. The newly inserted records are not be seen by the client that has the read lock until it releases the lock. With `INSERT DELAYED`, you can write inserts that go into a local queue until the locks are released, without having the client wait for the insert to complete. See [Section 7.7.3, “Concurrent Inserts”](#), and [Section 12.2.5.2, “INSERT DELAYED Syntax”](#).

“Atomic,” in the sense that we mean it, is nothing magical. It only means that you can be sure that while each specific update is running, no other user can interfere with it, and there can never be an automatic rollback (which can happen with transactional

tables if you are not very careful). MySQL Server also guarantees that there are no dirty reads.

Following are some techniques for working with nontransactional tables:

- Loops that need transactions normally can be coded with the help of `LOCK TABLES`, and you don't need cursors to update records on the fly.
- To avoid using `ROLLBACK`, you can employ the following strategy:
  1. Use `LOCK TABLES` to lock all the tables you want to access.
  2. Test the conditions that must be true before performing the update.
  3. Update if the conditions are satisfied.
  4. Use `UNLOCK TABLES` to release your locks.

This is usually a much faster method than using transactions with possible rollbacks, although not always. The only situation this solution doesn't handle is when someone kills the threads in the middle of an update. In that case, all locks are released but some of the updates may not have been executed.

- You can also use functions to update records in a single operation. You can get a very efficient application by using the following techniques:
  - Modify columns relative to their current value.
  - Update only those columns that actually have changed.

For example, when we are updating customer information, we update only the customer data that has changed and test only that none of the changed data, or data that depends on the changed data, has changed compared to the original row. The test for changed data is done with the `WHERE` clause in the `UPDATE` statement. If the record wasn't updated, we give the client a message: "Some of the data you have changed has been changed by another user." Then we show the old row versus the new row in a window so that the user can decide which version of the customer record to use.

This gives us something that is similar to column locking but is actually even better because we only update some of the columns, using values that are relative to their current values. This means that typical `UPDATE` statements look something like these:

```
UPDATE tablename SET pay_back=pay_back+125;
UPDATE customer
 SET
 customer_date='current_date',
 address='new address',
 phone='new phone',
 money_owed_to_us=money_owed_to_us-125
 WHERE
 customer_id=id AND address='old address' AND phone='old phone';
```

This is very efficient and works even if another client has changed the values in the `pay_back` or `money_owed_to_us` columns.

- In many cases, users have wanted `LOCK TABLES` or `ROLLBACK` for the purpose of managing unique identifiers. This can be handled much more efficiently without locking or rolling back by using an `AUTO_INCREMENT` column and either the `LAST_INSERT_ID()` SQL function or the `mysql_insert_id()` C API function. See [Section 11.14, “Information Functions”](#), and [Section 21.9.3.37, “mysql\\_insert\\_id\(\)”](#).

You can generally code around the need for row-level locking. Some situations really do need it, and `InnoDB` tables support row-level locking. Otherwise, with `MyISAM` tables, you can use a flag column in the table and do something like the following:

```
UPDATE tbl_name SET row_flag=1 WHERE id=ID;
```

MySQL returns `1` for the number of affected rows if the row was found and `row_flag` wasn't `1` in the original row. You can think of this as though MySQL Server changed the preceding statement to:

```
UPDATE tbl_name SET row_flag=1 WHERE id=ID AND row_flag <> 1;
```

#### 1.8.5.4. Foreign Keys

The `InnoDB` storage engine supports checking of foreign key constraints, including `CASCADE`, `ON DELETE`, and `ON UPDATE`.

See [Section 13.6.4.4, “FOREIGN KEY Constraints”](#).

For storage engines other than `InnoDB`, MySQL Server parses the `FOREIGN KEY` syntax in `CREATE TABLE` statements, but does not use or store it. In the future, the implementation will be extended to store this information in the table specification file so that it may be retrieved by `mysqldump` and ODBC. At a later stage, foreign key constraints will be implemented for `MyISAM` tables as well.

Foreign key enforcement offers several benefits to database developers:

- Assuming proper design of the relationships, foreign key constraints make it more difficult for a programmer to introduce an inconsistency into the database.
- Centralized checking of constraints by the database server makes it unnecessary to perform these checks on the application side. This eliminates the possibility that different applications may not all check the constraints in the same way.
- Using cascading updates and deletes can simplify the application code.
- Properly designed foreign key rules aid in documenting relationships between tables.

Do keep in mind that these benefits come at the cost of additional overhead for the database server to perform the necessary checks. Additional checking by the server affects performance, which for some applications may be sufficiently undesirable as to be avoided if possible. (Some major commercial applications have coded the foreign key logic at the application level for this reason.)

MySQL gives database developers the choice of which approach to use. If you don't need foreign keys and want to avoid the overhead associated with enforcing referential integrity, you can choose another storage engine instead, such as `MyISAM`. (For example, the `MyISAM` storage engine offers very fast performance for applications that perform only `INSERT` and `SELECT` operations. In this case, the table has no holes in the middle and the inserts can be performed concurrently with retrievals. See [Section 7.7.3, “Concurrent Inserts”](#).)

If you choose not to take advantage of referential integrity checks, keep the following considerations in mind:

- In the absence of server-side foreign key relationship checking, the application itself must handle relationship issues. For example, it must take care to insert rows into tables in the proper order, and to avoid creating orphaned child records. It must also be able to recover from errors that occur in the middle of multiple-record insert operations.
- If `ON DELETE` is the only referential integrity capability an application needs, you can achieve a similar effect as of MySQL Server 4.0 by using multiple-table `DELETE` statements to delete rows from many tables with a single statement. See [Section 12.2.2, “DELETE Syntax”](#).
- A workaround for the lack of `ON DELETE` is to add the appropriate `DELETE` statements to your application when you delete records from a table that has a foreign key. In practice, this is often as quick as using foreign keys and is more portable.

Be aware that the use of foreign keys can sometimes lead to problems:

- Foreign key support addresses many referential integrity issues, but it is still necessary to design key relationships carefully to avoid circular rules or incorrect combinations of cascading deletes.
- It is not uncommon for a DBA to create a topology of relationships that makes it difficult to restore individual tables from a backup. (MySQL alleviates this difficulty by enabling you to temporarily disable foreign key checks when reloading a table that depends on other tables. See [Section 13.6.4.4, “FOREIGN KEY Constraints”](#). As of MySQL 4.1.1, `mysqldump` generates dump files that take advantage of this capability automatically when they are reloaded.)

Foreign keys in SQL are used to check and enforce referential integrity, not to join tables. If you want to get results from multiple tables from a `SELECT` statement, you do this by performing a join between them:

```
SELECT * FROM t1 INNER JOIN t2 ON t1.id = t2.id;
```

See [Section 12.2.8.1, “JOIN Syntax”](#), and [Section 3.6.6, “Using Foreign Keys”](#).

The `FOREIGN KEY` syntax without `ON DELETE ...` is often used by ODBC applications to produce automatic `WHERE` clauses.

## 1.8.5.5. '--' as the Start of a Comment

Standard SQL uses the C syntax `/* this is a comment */` for comments, and MySQL Server supports this syntax as well. MySQL also support extensions to this syntax that enable MySQL-specific SQL to be embedded in the comment, as described in [Section 8.6, “Comment Syntax”](#).

Standard SQL uses “`--`” as a start-comment sequence. MySQL Server uses “`#`” as the start comment character. MySQL Server 3.23.3 and up also supports a variant of the “`--`” comment style. That is, the “`--`” start-comment sequence must be followed by a space (or by a control character such as a newline). The space is required to prevent problems with automatically generated SQL queries that use constructs such as the following, where we automatically insert the value of the payment for `payment`:

```
UPDATE account SET credit=credit-payment
```

Consider about what happens if `payment` has a negative value such as `-1`:

```
UPDATE account SET credit=credit--1
```

`credit--1` is a legal expression in SQL, but “`--`” is interpreted as the start of a comment, part of the expression is discarded. The result is a statement that has a completely different meaning than intended:

```
UPDATE account SET credit=credit
```

The statement produces no change in value at all. This illustrates that permitting comments to start with “`--`” can have serious consequences.

Using our implementation requires a space following the “`--`” for it to be recognized as a start-comment sequence in MySQL Server 3.23.3 and newer. Therefore, `credit--1` is safe to use.

Another safe feature is that the `mysql` command-line client ignores lines that start with “`--`”.

The following information is relevant only if you are running a MySQL version earlier than 3.23.3:

If you have an SQL script in a text file that contains “`--`” comments, you should use the `replace` utility as follows to convert the comments to use “`#`” characters before executing the script:

```
shell> replace " --" "#" < text-file-with-funny-comments.sql \
 | mysql db_name
```

That is safer than executing the script in the usual way:

```
shell> mysql db_name < text-file-with-funny-comments.sql
```

You can also edit the script file “in place” to change the “`--`” comments to “`#`” comments:

```
shell> replace " --" "#" -- text-file-with-funny-comments.sql
```

Change them back with this command:

```
shell> replace " #" " --" -- text-file-with-funny-comments.sql
```

See [Section 4.8.2, “replace — A String-Replacement Utility”](#).

## 1.8.6. How MySQL Deals with Constraints

MySQL enables you to work both with transactional tables that permit rollback and with nontransactional tables that do not. Because of this, constraint handling is a bit different in MySQL than in other DBMSs. We must handle the case when you have inserted or updated a lot of rows in a nontransactional table for which changes cannot be rolled back when an error occurs.

The basic philosophy is that MySQL Server tries to produce an error for anything that it can detect while parsing a statement to be executed, and tries to recover from any errors that occur while executing the statement. We do this in most cases, but not yet for all.

The options MySQL has when an error occurs are to stop the statement in the middle or to recover as well as possible from the problem and continue. By default, the server follows the latter course. This means, for example, that the server may coerce illegal values to the closest legal values.

Several SQL mode options are available to provide greater control over handling of bad data values and whether to continue statement execution or abort when errors occur. Using these options, you can configure MySQL Server to act in a more traditional fashion that is like other DBMSs that reject improper input. The SQL mode can be set globally at server startup to affect all clients. Individual clients can set the SQL mode at runtime, which enables each client to select the behavior most appropriate for its requirements. See [Section 5.1.7, “Server SQL Modes”](#).

The following sections describe how MySQL Server handles different types of constraints.

### 1.8.6.1. PRIMARY KEY and UNIQUE Index Constraints

Normally, errors occurs for data-change statements (such as `INSERT` or `UPDATE`) that would violate primary-key, unique-key, or foreign-key constraints. If you are using a transactional storage engine such as `InnoDB`, MySQL automatically rolls back the statement. If you are using a nontransactional storage engine, MySQL stops processing the statement at the row for which the error occurred and leaves any remaining rows unprocessed.

MySQL supports an `IGNORE` keyword for `INSERT`, `UPDATE`, and so forth. If you use it, MySQL ignores primary-key or unique-key violations and continues processing with the next row. See the section for the statement that you are using ([Section 12.2.5, “`INSERT` Syntax”](#), [Section 12.2.11, “`UPDATE` Syntax”](#), and so forth).

You can get information about the number of rows actually inserted or updated with the `mysql_info()` C API function. You can also use the `SHOW WARNINGS` statement. See [Section 21.9.3.35, “`mysql\_info\(\)`”](#), and [Section 12.4.5.42, “`SHOW WARNINGS` Syntax”](#).

Currently, only `InnoDB` tables support foreign keys. See [Section 13.6.4.4, “FOREIGN KEY Constraints”](#).

### 1.8.6.2. Constraints on Invalid Data

By default, MySQL is forgiving of illegal or improper data values and coerces them to legal values for data entry. However, you can change the server SQL mode to select more traditional treatment of bad values such that the server rejects them and aborts the statement in which they occur. See [Section 5.1.7, “Server SQL Modes”](#).

This section describes the default (forgiving) behavior of MySQL, as well as the strict SQL mode and how it differs.

If you are not using strict mode, then whenever you insert an “incorrect” value into a column, such as a `NULL` into a `NOT NULL` column or a too-large numeric value into a numeric column, MySQL sets the column to the “best possible value” instead of producing an error: The following rules describe in more detail how this works:

- If you try to store an out of range value into a numeric column, MySQL Server instead stores zero, the smallest possible value, or the largest possible value, whichever is closest to the invalid value.
- For strings, MySQL stores either the empty string or as much of the string as can be stored in the column.
- If you try to store a string that doesn't start with a number into a numeric column, MySQL Server stores 0.
- Invalid values for `ENUM` and `SET` columns are handled as described in [Section 1.8.6.3, “`ENUM` and `SET` Constraints”](#).
- MySQL enables you to store certain incorrect date values into `DATE` and `DATETIME` columns (such as `'2000-02-31'` or `'2000-02-00'`). The idea is that it is not the job of the SQL server to validate dates. If MySQL can store a date value and retrieve exactly the same value, MySQL stores it as given. If the date is totally wrong (outside the server's ability to store it), the special “zero” date value `'0000-00-00'` is stored in the column instead.
- If you try to store `NULL` into a column that doesn't take `NULL` values, an error occurs for single-row `INSERT` statements. For multiple-row `INSERT` statements or for `INSERT INTO ... SELECT` statements, MySQL Server stores the implicit default value for the column data type. In general, this is 0 for numeric types, the empty string (' ') for string types, and the “zero” value for date and time types. Implicit default values are discussed in [Section 10.1.4, “Data Type Default Values”](#).
- If an `INSERT` statement specifies no value for a column, MySQL inserts its default value if the column definition includes an explicit `DEFAULT` clause. If the definition has no such `DEFAULT` clause, MySQL inserts the implicit default value for the column data type.

The reason for using the preceding rules in nonstrict mode is that we can't check these conditions until the statement has begun executing. We can't just roll back if we encounter a problem after updating a few rows, because the storage engine may not support rollback. The option of terminating the statement is not that good; in this case, the update would be “half done,” which is probably the worst possible scenario. In this case, it is better to “do the best you can” and then continue as if nothing happened.

In MySQL 5.0.2 and up, you can select stricter treatment of input values by using the `STRICT_TRANS_TABLES` or `STRICT_ALL_TABLES` SQL modes:

```
SET sql_mode = 'STRICT_TRANS_TABLES';
SET sql_mode = 'STRICT_ALL_TABLES';
```

`STRICT_TRANS_TABLES` enables strict mode for transactional storage engines, and also to some extent for nontransactional engines. It works like this:

- For transactional storage engines, bad data values occurring anywhere in a statement cause the statement to abort and roll back.

- For nontransactional storage engines, a statement aborts if the error occurs in the first row to be inserted or updated. (When the error occurs in the first row, the statement can be aborted to leave the table unchanged, just as for a transactional table.) Errors in rows after the first do not abort the statement, because the table has already been changed by the first row. Instead, bad data values are adjusted and result in warnings rather than errors. In other words, with `STRICT_TRANS_TABLES`, a wrong value causes MySQL to roll back all updates done so far, if that can be done without changing the table. But once the table has been changed, further errors result in adjustments and warnings.

For even stricter checking, enable `STRICT_ALL_TABLES`. This is the same as `STRICT_TRANS_TABLES` except that for nontransactional storage engines, errors abort the statement even for bad data in rows following the first row. This means that if an error occurs partway through a multiple-row insert or update for a nontransactional table, a partial update results. Earlier rows are inserted or updated, but those from the point of the error on are not. To avoid this for nontransactional tables, either use single-row statements or else use `STRICT_TRANS_TABLES` if conversion warnings rather than errors are acceptable. To avoid problems in the first place, do not use MySQL to check column content. It is safest (and often faster) to let the application ensure that it passes only legal values to the database.

With either of the strict mode options, you can cause errors to be treated as warnings by using `INSERT IGNORE` or `UPDATE IGNORE` rather than `INSERT` or `UPDATE` without `IGNORE`.

### 1.8.6.3. `ENUM` and `SET` Constraints

`ENUM` and `SET` columns provide an efficient way to define columns that can contain only a given set of values. See [Section 10.4.4, “The `ENUM` Type”](#), and [Section 10.4.5, “The `SET` Type”](#). However, before MySQL 5.0.2, `ENUM` and `SET` columns do not provide true constraints on entry of invalid data:

- `ENUM` columns always have a default value. If you specify no default value, then it is `NULL` for columns that can have `NULL`, otherwise it is the first enumeration value in the column definition.
- If you insert an incorrect value into an `ENUM` column or if you force a value into an `ENUM` column with `IGNORE`, it is set to the reserved enumeration value of `0`, which is displayed as an empty string in string context.
- If you insert an incorrect value into a `SET` column, the incorrect value is ignored. For example, if the column can contain the values `'a'`, `'b'`, and `'c'`, an attempt to assign `'a,x,b,y'` results in a value of `'a,b'`.

As of MySQL 5.0.2, you can configure the server to use strict SQL mode. See [Section 5.1.7, “Server SQL Modes”](#). With strict mode enabled, the definition of a `ENUM` or `SET` column does act as a constraint on values entered into the column. An error occurs for values that do not satisfy these conditions:

- An `ENUM` value must be one of those listed in the column definition, or the internal numeric equivalent thereof. The value cannot be the error value (that is, 0 or the empty string). For a column defined as `ENUM('a','b','c')`, values such as `''`, `'d'`, or `'ax'` are illegal and are rejected.
- A `SET` value must be the empty string or a value consisting only of the values listed in the column definition separated by commas. For a column defined as `SET('a','b','c')`, values such as `'d'` or `'a,b,c,d'` are illegal and are rejected.

Errors for invalid values can be suppressed in strict mode if you use `INSERT IGNORE` or `UPDATE IGNORE`. In this case, a warning is generated rather than an error. For `ENUM`, the value is inserted as the error member (`0`). For `SET`, the value is inserted as given except that any invalid substrings are deleted. For example, `'a,x,b,y'` results in a value of `'a,b'`.

## 1.9. Credits

The following sections list developers, contributors, and supporters that have helped to make MySQL what it is today.

### 1.9.1. Contributors to MySQL

Although Oracle Corporation and/or its affiliates own all copyrights in the `MySQL server` and the `MySQL manual`, we wish to recognize those who have made contributions of one kind or another to the `MySQL distribution`. Contributors are listed here, in somewhat random order:

- Gianmassimo Vigazzola <[qwerg@mbox.vol.it](mailto:qwerg@mbox.vol.it)> or <[qwerg@tin.it](mailto:qwerg@tin.it)>

The initial port to Win32/NT.

- Per Eric Olsson

For constructive criticism and real testing of the dynamic record format.

- Irena Pancirov <[irena@mail.yacc.it](mailto:irena@mail.yacc.it)>

Win32 port with Borland compiler. `mysqlshutdown.exe` and `mysqlwatch.exe`.

- David J. Hughes

For the effort to make a shareware SQL database. At TcX, the predecessor of MySQL AB, we started with `mSQL`, but found that it couldn't satisfy our purposes so instead we wrote an SQL interface to our application builder Unireg. `mysqladmin` and `mysql` client are programs that were largely influenced by their `mSQL` counterparts. We have put a lot of effort into making the MySQL syntax a superset of `mSQL`. Many of the API's ideas are borrowed from `mSQL` to make it easy to port free `mSQL` programs to the MySQL API. The MySQL software doesn't contain any code from `mSQL`. Two files in the distribution (`client/insert_test.c` and `client/select_test.c`) are based on the corresponding (noncopyrighted) files in the `mSQL` distribution, but are modified as examples showing the changes necessary to convert code from `mSQL` to MySQL Server. (`mSQL` is copyrighted David J. Hughes.)

- Patrick Lynch

For helping us acquire <http://www.mysql.com/>.

- Fred Lindberg

For setting up qmail to handle the MySQL mailing list and for the incredible help we got in managing the MySQL mailing lists.

- Igor Romanenko <[igor@frog.kiev.ua](mailto:igor@frog.kiev.ua)>

`mysqldump` (previously `msqldump`, but ported and enhanced by Monty).

- Yuri Dario

For keeping up and extending the MySQL OS/2 port.

- Tim Bunce

Author of `mysqlhotcopy`.

- Zarko Mocnik <[zarko.mocnik@dem.si](mailto:zarko.mocnik@dem.si)>

Sorting for Slovenian language.

- "TAMITO" <[tommy@valley.ne.jp](mailto:tommy@valley.ne.jp)>

The `_MB` character set macros and the ujis and sjis character sets.

- Joshua Chamas <[joshua@chamas.com](mailto:joshua@chamas.com)>

Base for concurrent insert, extended date syntax, debugging on NT, and answering on the MySQL mailing list.

- Yves Carlier <[Yves.Carlier@rug.ac.be](mailto:Yves.Carlier@rug.ac.be)>

`mysqlaccess`, a program to show the access rights for a user.

- Rhys Jones <[rhyss@wales.com](mailto:rhyss@wales.com)> (And GWE Technologies Limited)

For one of the early JDBC drivers.

- Dr Xiaokun Kelvin ZHU <[X.Zhu@brad.ac.uk](mailto:X.Zhu@brad.ac.uk)>

Further development of one of the early JDBC drivers and other MySQL-related Java tools.

- James Cooper <[pixel@organic.com](mailto:pixel@organic.com)>

For setting up a searchable mailing list archive at his site.

- Rick Mehalick <[Rick\\_Mehalick@i-o.com](mailto:Rick_Mehalick@i-o.com)>

For `xmysql`, a graphical X client for MySQL Server.

- Doug Sisk <[sisk@wix.com](mailto:sisk@wix.com)>

For providing RPM packages of MySQL for Red Hat Linux.

- Diemand Alexander V. <[axeld@vial.ethz.ch](mailto:axeld@vial.ethz.ch)>

For providing RPM packages of MySQL for Red Hat Linux-Alpha.

- Antoni Pamies Olive <[toni@readysoft.es](mailto:toni@readysoft.es)>

For providing RPM versions of a lot of MySQL clients for Intel and SPARC.

- Jay Bloodworth <[jay@pathways.sde.state.sc.us](mailto:jay@pathways.sde.state.sc.us)>

For providing RPM versions for MySQL 3.21.

- David Sacerdote <[davids@secnet.com](mailto:davids@secnet.com)>

Ideas for secure checking of DNS host names.

- Wei-Jou Chen <[jou@nematic.ieo.nctu.edu.tw](mailto:jou@nematic.ieo.nctu.edu.tw)>

Some support for Chinese(BIG5) characters.

- Wei He <[hewei@mail.ied.ac.cn](mailto:hewei@mail.ied.ac.cn)>

A lot of functionality for the Chinese(GBK) character set.

- Jan Pazdziora <[adelton@fi.muni.cz](mailto:adelton@fi.muni.cz)>

Czech sorting order.

- Zeev Suraski <[bourbon@netvision.net.il](mailto:bourbon@netvision.net.il)>

`FROM_UNIXTIME()` time formatting, `ENCRYPT()` functions, and `bison` advisor. Active mailing list member.

- Luuk de Boer <[luuk@wxs.nl](mailto:luuk@wxs.nl)>

Ported (and extended) the benchmark suite to `DBI/DBD`. Have been of great help with `crash-me` and running benchmarks. Some new date functions. The `mysql_setpermission` script.

- Alexis Mikhailov <[root@medinf.chuvashia.su](mailto:root@medinf.chuvashia.su)>

User-defined functions (UDFs); `CREATE FUNCTION` and `DROP FUNCTION`.

- Andreas F. Bobak <[bobak@relog.ch](mailto:bobak@relog.ch)>

The `AGGREGATE` extension to user-defined functions.

- Ross Wakelin <[R.Wakelin@march.co.uk](mailto:R.Wakelin@march.co.uk)>

Help to set up InstallShield for MySQL-Win32.

- Jethro Wright III <[jetman@li.net](mailto:jetman@li.net)>

The `libmysql.dll` library.

- James Pereria <[jpereira@iafrica.com](mailto:jpereira@iafrica.com)>

Mysqlmanager, a Win32 GUI tool for administering MySQL Servers.

- Curt Sampson <[cjs@portal.ca](mailto:cjs@portal.ca)>

Porting of MIT-pthreads to NetBSD/Alpha and NetBSD 1.3/i386.

- Martin Ramsch <[m.ramsch@computer.org](mailto:m.ramsch@computer.org)>

Examples in the MySQL Tutorial.

- Steve Harvey

For making `mysqlaccess` more secure.

- Konark IA-64 Centre of Persistent Systems Private Limited  
<http://www.pspl.co.in/konark/>. Help with the Win64 port of the MySQL server.
- Albert Chin-A-Young.  
Configure updates for Tru64, large file support and better TCP wrappers support.
- John Birrell  
Emulation of `pthread_mutex()` for OS/2.
- Benjamin Pflugmann  
Extended `MERGE` tables to handle `INSERTS`. Active member on the MySQL mailing lists.
- Jocelyn Fournier  
Excellent spotting and reporting innumerable bugs (especially in the MySQL 4.1 subquery code).
- Marc Liyanage  
Maintaining the Mac OS X packages and providing invaluable feedback on how to create Mac OS X packages.
- Robert Rutherford  
Providing invaluable information and feedback about the QNX port.
- Previous developers of NDB Cluster  
Lots of people were involved in various ways summer students, master thesis students, employees. In total more than 100 people so too many to mention here. Notable name is Ataullah Dabaghi who up until 1999 contributed around a third of the code base. A special thanks also to developers of the AXE system which provided much of the architectural foundations for NDB Cluster with blocks, signals and crash tracing functionality. Also credit should be given to those who believed in the ideas enough to allocate of their budgets for its development from 1992 to present time.
- Google Inc.  
We wish to recognize Google Inc. for contributions to the MySQL distribution: Mark Callaghan's SMP Performance patches and other patches.

Other contributors, bugfinders, and testers: James H. Thompson, Maurizio Menghini, Wojciech Tryc, Luca Berra, Zarko Mocnik, Wim Bonis, Elmar Haneke, <[jehamby@lightside](mailto:jehamby@lightside)>, <[psmith@BayNetworks.com](mailto:psmith@BayNetworks.com)>, <[duane@connect.com.au](mailto:duane@connect.com.au)>, Ted Deppner <[ted@psyber.com](mailto:ted@psyber.com)>, Mike Simons, Jaakko Hyvatti.

And lots of bug report/patches from the folks on the mailing list.

A big tribute goes to those that help us answer questions on the MySQL mailing lists:

- Daniel Koch <[dkoch@amcity.com](mailto:dkoch@amcity.com)>  
Irix setup.
- Luuk de Boer <[luuk@wxs.nl](mailto:luuk@wxs.nl)>  
Benchmark questions.
- Tim Sailer <[tps@users.buoy.com](mailto:tps@users.buoy.com)>  
`DBD::mysql` questions.
- Boyd Lynn Gerber <[gerberb@zenez.com](mailto:gerberb@zenez.com)>  
SCO-related questions.
- Richard Mehalick <[RM186061@shellus.com](mailto:RM186061@shellus.com)>  
`xmysql`-related questions and basic installation questions.
- Zeev Suraski <[bourbon@netvision.net.il](mailto:bourbon@netvision.net.il)>

Apache module configuration questions (log & auth), PHP-related questions, SQL syntax-related questions and other general questions.

- Francesc Guasch <[frankie@citel.upc.es](mailto:frankie@citel.upc.es)>  
General questions.
- Jonathan J Smith <[jsmith@wtp.net](mailto:jsmith@wtp.net)>  
Questions pertaining to OS-specifics with Linux, SQL syntax, and other things that might need some work.
- David Sklar <[sklar@student.net](mailto:sklar@student.net)>  
Using MySQL from PHP and Perl.
- Alistair MacDonald <[A.MacDonald@uel.ac.uk](mailto:A.MacDonald@uel.ac.uk)>  
Is flexible and can handle Linux and perhaps HP-UX. Tries to get users to use [mysqlbug](#).
- John Lyon <[jlyon@imag.net](mailto:jlyon@imag.net)>  
Questions about installing MySQL on Linux systems, using either .rpm files or compiling from source.
- Lorvid Ltd. <[lorvid@WOLFENET.com](mailto:lorvid@WOLFENET.com)>  
Simple billing/license/support/copyright issues.
- Patrick Sherrill <[patrick@coconet.com](mailto:patrick@coconet.com)>  
ODBC and VisualC++ interface questions.
- Randy Harmon <[rjharmon@uptimecomputers.com](mailto:rjharmon@uptimecomputers.com)>  
[DBD](#), Linux, some SQL syntax questions.

## 1.9.2. Documenters and translators

The following people have helped us with writing the MySQL documentation and translating the documentation or error messages in MySQL.

- Paul DuBois  
Ongoing help with making this manual correct and understandable. That includes rewriting Monty's and David's attempts at English into English as other people know it.
- Kim Aldale  
Helped to rewrite Monty's and David's early attempts at English into English.
- Michael J. Miller Jr. <[mke@terrapin.turbolift.com](mailto:mke@terrapin.turbolift.com)>  
For the first MySQL manual. And a lot of spelling/language fixes for the FAQ (that turned into the MySQL manual a long time ago).
- Yan Cailin  
First translator of the MySQL Reference Manual into simplified Chinese in early 2000 on which the Big5 and HK coded (<http://mysql.hitstar.com/>) versions were based. [Personal home page at linuxdb.yeah.net](#).
- Jay Flaherty <[fty@mediapulse.com](mailto:fty@mediapulse.com)>  
Big parts of the Perl [DBI/DBD](#) section in the manual.
- Paul Southworth <[pauls@etext.org](mailto:pauls@etext.org)>, Ray Loyzaga <[yar@cs.su.oz.au](mailto:yar@cs.su.oz.au)>  
Proof-reading of the Reference Manual.
- Therrien Gilbert <[gilbert@ican.net](mailto:gilbert@ican.net)>, Jean-Marc Pouyet <[jmp@scalaire.fr](mailto:jmp@scalaire.fr)>

French error messages.

- Petr Snajdr, <[snajdr@pvt.net](mailto:snajdr@pvt.net)>

Czech error messages.

- Jaroslaw Lewandowski <[jotel@itnet.com.pl](mailto:jotel@itnet.com.pl)>

Polish error messages.

- Miguel Angel Fernandez Roiz

Spanish error messages.

- Roy-Magne Mo <[rmo@www.hivolda.no](mailto:rmo@www.hivolda.no)>

Norwegian error messages and testing of MySQL 3.21.xx.

- Timur I. Bakeyev <[root@timur.tatarstan.ru](mailto:root@timur.tatarstan.ru)>

Russian error messages.

- <[brenno@dewinter.com](mailto:brenno@dewinter.com)> & Filippo Grassilli <[phil@hyppo.com](mailto:phil@hyppo.com)>

Italian error messages.

- Dirk Munzinger <[dirk@trinity.saar.de](mailto:dirk@trinity.saar.de)>

German error messages.

- Billik Stefan <[billik@sun.uniag.sk](mailto:billik@sun.uniag.sk)>

Slovak error messages.

- Stefan Saroiu <[tzoompy@cs.washington.edu](mailto:tzoompy@cs.washington.edu)>

Romanian error messages.

- Peter Feher

Hungarian error messages.

- Roberto M. Serqueira

Portuguese error messages.

- Carsten H. Pedersen

Danish error messages.

- Arjen Lentz

Dutch error messages, completing earlier partial translation (also work on consistency and spelling).

### 1.9.3. Packages that support MySQL

The following is a list of creators/maintainers of some of the most important API/packages/applications that a lot of people use with MySQL.

We cannot list every possible package here because the list would then be way to hard to maintain. For other packages, please refer to the software portal at <http://solutions.mysql.com/software/>.

- Tim Bunce, Alligator Descartes

For the `DBD` (Perl) interface.

- Andreas Koenig <[a.koenig@mind.de](mailto:a.koenig@mind.de)>

For the Perl interface for MySQL Server.

- Jochen Wiedmann <[wiedmann@neckar-alb.de](mailto:wiedmann@neckar-alb.de)>  
For maintaining the Perl `DBD::mysql` module.
- Eugene Chan <[eugene@acenet.com.sg](mailto:eugene@acenet.com.sg)>  
For porting PHP for MySQL Server.
- Georg Richter  
MySQL 4.1 testing and bug hunting. New PHP 5.0 `mysqli` extension (API) for use with MySQL 4.1 and up.
- Giovanni Maruzzelli <[maruzz@matrice.it](mailto:maruzz@matrice.it)>  
For porting iODBC (Unix ODBC).
- Xavier Leroy <[Xavier.Leroy@inria.fr](mailto:Xavier.Leroy@inria.fr)>  
The author of LinuxThreads (used by the MySQL Server on Linux).

## 1.9.4. Tools that were used to create MySQL

The following is a list of some of the tools we have used to create MySQL. We use this to express our thanks to those that has created them as without these we could not have made MySQL what it is today.

- Free Software Foundation  
From whom we got an excellent compiler (`gcc`), an excellent debugger (`gdb` and the `libc` library (from which we have borrowed `strto.c` to get some code working in Linux)).
- Free Software Foundation & The XEmacs development team  
For a really great editor/environment.
- Julian Seward  
Author of `valgrind`, an excellent memory checker tool that has helped us find a lot of otherwise hard to find bugs in MySQL.
- Dorothea Lütkehaus and Andreas Zeller  
For `DDD` (The Data Display Debugger) which is an excellent graphical front end to `gdb`.

## 1.9.5. Supporters of MySQL

Although Oracle Corporation and/or its affiliates own all copyrights in the `MySQL server` and the `MySQL manual`, we wish to recognize the following companies, which helped us finance the development of the `MySQL server`, such as by paying us for developing a new feature or giving us hardware for development of the `MySQL server`.

- VA Linux / Andover.net  
Funded replication.
- NuSphere  
Editing of the MySQL manual.
- Stork Design studio  
The MySQL Web site in use between 1998-2000.
- Intel  
Contributed to development on Windows and Linux platforms.
- Compaq

Contributed to Development on Linux/Alpha.

- SWSOFT  
Development on the embedded `mysqld` version.
- FutureQuest  
The `--skip-show-database` option.

---

# Chapter 2. Installing and Upgrading MySQL

This chapter describes how to obtain and install MySQL. A summary of the procedure follows and later sections provide the details. If you plan to upgrade an existing version of MySQL to a newer version rather than install MySQL for the first time, see [Section 2.12.1, “Upgrading MySQL”](#), for information about upgrade procedures and about issues that you should consider before upgrading.

If you are interested in migrating to MySQL from another database system, you may wish to read [Section A.8, “MySQL 5.1 FAQ: Migration”](#), which contains answers to some common questions concerning migration issues.

1. **Determine whether MySQL runs and is supported on your platform.**

Please note that not all platforms are equally suitable for running MySQL, and that not all platforms on which MySQL is known to run are officially supported by Oracle Corporation:

2. **Choose which distribution to install.**

Several versions of MySQL are available, and most are available in several distribution formats. You can choose from pre-packaged distributions containing binary (precompiled) programs or source code. When in doubt, use a binary distribution. We also provide public access to our current source tree for those who want to see our most recent developments and help us test new code. To determine which version and type of distribution you should use, see [Section 2.1.2, “Choosing Which MySQL Distribution to Install”](#).

3. **Download the distribution that you want to install.**

For instructions, see [Section 2.1.3, “How to Get MySQL”](#). To verify the integrity of the distribution, use the instructions in [Section 2.1.4, “Verifying Package Integrity Using MD5 Checksums or GnuPG”](#).

4. **Install the distribution.**

To install MySQL from a binary distribution, use the instructions in [Section 2.2, “Installing MySQL from Generic Binaries on Unix/Linux”](#).

To install MySQL from a source distribution or from the current development source tree, use the instructions in [Section 2.3, “Installing MySQL Using a Source Distribution”](#).

5. **Perform any necessary post-installation setup.**

After installing MySQL, read [Section 2.13, “Post-Installation Setup and Testing”](#). This section contains important information about making sure the MySQL server is working properly. It also describes how to secure the initial MySQL user accounts, *which have no passwords* until you assign passwords. The section applies whether you install MySQL using a binary or source distribution.

6. If you want to run the MySQL benchmark scripts, Perl support for MySQL must be available. See [Section 2.15, “Perl Installation Notes”](#).

Instructions for installing MySQL on different platforms and environments is available on a platform by platform basis:

- **Unix, Linux, FreeBSD**

For instructions on installing MySQL on most Linux and Unix platforms using a generic binary (for example, a `tar.gz` package), see [Section 2.2, “Installing MySQL from Generic Binaries on Unix/Linux”](#).

For information on building MySQL entirely from the source code distributions or the source code repositories, see [Section 2.3, “Installing MySQL Using a Source Distribution”](#).

For specific platform help on installation, configuration, and building from source see the correspondingin platform section:

- Linux, including notes on distribution specific methods, see [Section 2.6, “Installing MySQL on Linux”](#).
- Solaris and OpenSolaris, including PKG and IPS formats, see [Section 2.7, “Installing MySQL on Solaris and OpenSolaris”](#).
- IBM AIX, see [Section 2.7, “Installing MySQL on Solaris and OpenSolaris”](#).
- Hewlett-Packard HP-UX, including the DEPOT package format, see [Section 2.9, “Installing MySQL on HP-UX”](#).
- FreeBSD, see [Section 2.10, “Installing MySQL on FreeBSD”](#).

- **Microsoft Windows**

For instructions on installing MySQL on Microsoft Windows, using either a Zipped binary or an MSI package, see [Section 2.4, “Installing MySQL on Microsoft Windows”](#).

For information on using the MySQL Server Instance Config Wizard, see [Section 2.4.4, “Using the MySQL Server Instance Config Wizard”](#).

For details and instructions on building MySQL from source code using Microsoft Visual Studio, see [Section 2.4.9, “Installing MySQL from Source on Windows”](#).

- **Mac OS X**

For installation on Mac OS X, including using both the binary package and native PKG formats, see [Section 2.5, “Installing MySQL on Mac OS X”](#).

For information on making use of the MySQL Startup Item to automatically start and stop MySQL, see [Section 2.5.3, “Installing the MySQL Startup Item”](#).

For information on the MySQL Preference Pane, see [Section 2.5.4, “Installing and Using the MySQL Preference Pane”](#).

- **IBM i5/OS**

For instructions on installing, starting, and stopping, MySQL on i5/OS, see [Section 2.11, “Installing MySQL on i5/OS”](#).

## 2.1. General Installation Guidance

The immediately following sections contain the information necessary to choose, download, and verify your distribution. The instructions in later sections of the chapter describe how to install the distribution that you choose. For binary distributions, see the instructions at [Section 2.2, “Installing MySQL from Generic Binaries on Unix/Linux”](#) or the corresponding section for your platform if available. To build MySQL from source, use the instructions in [Section 2.3, “Installing MySQL Using a Source Distribution”](#).

### 2.1.1. Operating Systems Supported by MySQL Community Server

This section lists the operating systems on which MySQL Community Server is known to run.

**Important**

Oracle Corporation does not necessarily provide official support for all the platforms listed in this section. For information about those platforms that are officially supported, see <http://www.mysql.com/support/supportedplatforms.html> on the MySQL Web site.

We use GNU Autoconf, so it is possible to port MySQL to all modern systems that have a C++ compiler and a working implementation of POSIX threads. (Thread support is needed for the server. To compile only the client code, the only requirement is a C++ compiler.)

MySQL has been reported to compile successfully on the following combinations of operating system and thread package.

- AIX 4.x, 5.x with native threads. See [Section 2.8, “Installing MySQL on IBM AIX”](#). AIX 5.3 should be upgraded to technology level 7 (5300-07).
- FreeBSD 5.x and up with native threads. See [Section 2.10, “Installing MySQL on FreeBSD”](#).
- HP-UX 11.x with the native threads. See [Section 2.9, “Installing MySQL on HP-UX”](#).
- Linux, builds on all fairly recent Linux distributions with `glibc` 2.3. See [Section 2.6, “Installing MySQL on Linux”](#).
- Mac OS X. See [Section 2.5, “Installing MySQL on Mac OS X”](#).
- Solaris 2.8 on SPARC and x86, including support for native threads. See [Section 2.7, “Installing MySQL on Solaris and OpenSolaris”](#).
- Windows 2000, Windows XP, Windows Vista, Windows Server 2003, and Windows Server 2008. See [Section 2.4, “Installing MySQL on Microsoft Windows”](#).

MySQL has also been known to run on other systems in the past. See [Section 2.1, “General Installation Guidance”](#). Some porting

effort might be required for current versions of MySQL on these systems.

Not all platforms are equally well-suited for running MySQL. How well a certain platform is suited for a high-load mission-critical MySQL server is determined by the following factors:

- General stability of the thread library. A platform may have an excellent reputation otherwise, but MySQL is only as stable as the thread library it calls, even if everything else is perfect.
- The capability of the kernel and the thread library to take advantage of symmetric multi-processor (SMP) systems. In other words, when a process creates a thread, it should be possible for that thread to run on a CPU different from the original process.
- The capability of the kernel and the thread library to run many threads that acquire and release a mutex over a short critical region frequently without excessive context switches. If the implementation of `pthread_mutex_lock()` is too anxious to yield CPU time, this hurts MySQL tremendously. If this issue is not taken care of, adding extra CPUs actually makes MySQL slower.
- General file system stability and performance.
- Table size. If your tables are large, performance is affected by the ability of the file system to deal with large files and dealing with them efficiently.
- Our level of expertise here at Oracle Corporation with the platform. If we know a platform well, we enable platform-specific optimizations and fixes at compile time. We can also provide advice on configuring your system optimally for MySQL.
- The amount of testing we have done internally for similar configurations.
- The number of users that have run MySQL successfully on the platform in similar configurations. If this number is high, the likelihood of encountering platform-specific surprises is much smaller.

## 2.1.2. Choosing Which MySQL Distribution to Install

When preparing to install MySQL, you should decide which version to use. MySQL development occurs in several release series, and you can pick the one that best fits your needs. After deciding which version to install, you can choose a distribution format. Releases are available in binary or source format.

### 2.1.2.1. Choosing Which Version of MySQL to Install

The first decision to make is whether you want to use a production (stable) release or a development release. In the MySQL development process, multiple release series co-exist, each at a different stage of maturity:

- MySQL 5.5 and 5.6 are the current development release series.
- MySQL 5.1 is the current General Availability (Production) release series. New releases are issued for bugfixes only; no new features are being added that could affect stability.
- MySQL 5.0 is the previous stable (production-quality) release series. MySQL 5.0 is now at the end of the product lifecycle. Active development and support for this version has ended.

Extended support for MySQL 5.0 remains available. According to the <http://www.mysql.com/about/legal/lifecycle/>, only Security and Severity Level 1 issues are still being fixed for MySQL 5.0.

- MySQL 4.1, 4.0, and 3.23 are old stable (production-quality) release series. Active development and support for these versions has ended.

We do not use a complete code freeze because this prevents us from making bugfixes and other fixes that must be done. We may add small things that should not affect anything that currently works in a production release. Naturally, relevant bugfixes from an earlier series propagate to later series.

Normally, if you are beginning to use MySQL for the first time or trying to port it to some system for which there is no binary distribution, go with the General Availability release series. Currently, this is MySQL 5.1. All MySQL releases, even those from development series, are checked with the MySQL benchmarks and an extensive test suite before being issued.

If you are running an older system and want to upgrade, but do not want to take the chance of having a nonseamless upgrade, you should upgrade to the latest version in the same release series you are using (where only the last part of the version number is newer than yours). We have tried to fix only fatal bugs and make only small, relatively “safe” changes to that version.

If you want to use new features not present in the production release series, you can use a version from a development series. Be

aware that development releases are not as stable as production releases.

If you want to use the very latest sources containing all current patches and bugfixes, you can use one of our source code repositories (see [Section 2.3.4, “Installing from the Development Source Tree”](#)). These are not “releases” as such, but are available as previews of the code on which future releases are to be based.

The naming scheme in MySQL 5.1 uses release names that consist of three numbers and a suffix; for example, **mysql-5.1.29-rc**. The numbers within the release name are interpreted as follows:

- The first number (**5**) is the major version and describes the file format. All MySQL 5 releases have the same file format.
- The second number (**1**) is the release level. Taken together, the major version and release level constitute the release series number.
- The third number (**29**) is the version number within the release series. This is incremented for each new release. Usually you want the latest version for the series you have chosen.

For each minor update, the last number in the version string is incremented. When there are major new features or minor incompatibilities with previous versions, the second number in the version string is incremented. When the file format changes, the first number is increased.

Release names also include a suffix to indicates the stability level of the release. Releases within a series progress through a set of suffixes to indicate how the stability level improves. The possible suffixes are:

- **alpha** indicates that the release is for preview purposes only. Known bugs should be documented in the News section (see [Appendix C, MySQL Change History](#)). Most alpha releases implement new commands and extensions. Active development that may involve major code changes can occur in an alpha release. However, we do conduct testing before issuing a release.
- **beta** indicates that the release is appropriate for use with new development. Within beta releases, the features and compatibility should remain consistent. However, beta releases may contain numerous and major unaddressed bugs.

All APIs, externally visible structures, and columns for SQL statements will not change during future beta, release candidate, or production releases.

- **rc** indicates a Release Candidate. Release candidates are believed to be stable, having passed all of MySQL's internal testing, and with all known fatal runtime bugs fixed. However, the release has not been in widespread use long enough to know for sure that all bugs have been identified. Only minor fixes are added. (A release candidate is what formerly was known as a gamma release.)
- If there is no suffix, it indicates that the release is a General Availability (GA) or Production release. GA releases are stable, having successfully passed through all earlier release stages and are believed to be reliable, free of serious bugs, and suitable for use in production systems. Only critical bugfixes are applied to the release.

All releases of MySQL are run through our standard tests and benchmarks to ensure that they are relatively safe to use. Because the standard tests are extended over time to check for all previously found bugs, the test suite keeps getting better.

All releases have been tested at least with these tools:

- **An internal test suite.** The `mysql-test` directory contains an extensive set of test cases. We run these tests for every server binary. See [Section 22.1.2, “MySQL Test Suite”](#), for more information about this test suite.
- **The MySQL benchmark suite.** This suite runs a range of common queries. It is also a test to determine whether the latest batch of optimizations actually made the code faster. See [Section 7.1.3, “The MySQL Benchmark Suite”](#).

We also perform additional integration and nonfunctional testing of the latest MySQL version in our internal production environment. Integration testing is done with different connectors, storage engines, replication modes, backup, partitioning, stored programs, and so forth in various combinations. Additional nonfunctional testing is done in areas of performance, concurrency, stress, high volume, upgrade and downgrade.

### 2.1.2.2. Choosing a Distribution Format

After choosing which version of MySQL to install, you should decide whether to use a binary distribution or a source distribution. In most cases, you should probably use a binary distribution, if one exists for your platform. Binary distributions are available in native format for many platforms, such as RPM files for Linux or PKG package installers for Mac OS X or Solaris. Distributions also are available as Zip archives or compressed `tar` files.

Reasons to choose a binary distribution include the following:

- Binary distributions generally are easier to install than source distributions.
- To satisfy different user requirements, we provide several servers in binary distributions. `mysqld` is an optimized server that is a smaller, faster binary. `mysqld-debug` is compiled with debugging support.

Each of these servers is compiled from the same source distribution, though with different configuration options. All native MySQL clients can connect to servers from either MySQL version.

Under some circumstances, you may be better off installing MySQL from a source distribution:

- You want to install MySQL at some explicit location. The standard binary distributions are ready to run at any installation location, but you might require even more flexibility to place MySQL components where you want.
- You want to configure `mysqld` to ensure that features are available that might not be included in the standard binary distributions. Here is a list of the most common extra options that you may want to use to ensure feature availability:
  - `--with-libwrap`
  - `--with-named-z-libs` (this is done for some of the binaries)
  - `--with-debug[=full]`
- You want to configure `mysqld` without some features that are included in the standard binary distributions. For example, distributions normally are compiled with support for all character sets. If you want a smaller MySQL server, you can recompile it with support for only the character sets you need.
- You have a special compiler (such as `pgcc`) or want to use compiler options that are better optimized for your processor. Binary distributions are compiled with options that should work on a variety of processors from the same processor family.
- You want to use the latest sources from one of the Bazaar repositories to have access to all current bugfixes. For example, if you have found a bug and reported it to the MySQL development team, the bugfix is committed to the source repository and you can access it there. The bugfix does not appear in a release until a release actually is issued.
- You want to read (or modify) the C and C++ code that makes up MySQL. For this purpose, you should get a source distribution, because the source code is always the ultimate manual.
- Source distributions contain more tests and examples than binary distributions.

### 2.1.2.3. How and When Updates Are Released

MySQL is evolving quite rapidly and we want to share new developments with other MySQL users. We try to produce a new release whenever we have new and useful features that others also seem to have a need for.

We also try to help users who request features that are easy to implement. We take note of what our licensed users want, and we especially take note of what our support customers want and try to help them in this regard.

No one is *required* to download a new release. The News section helps you determine whether the new release has something you really want. See [Appendix C, MySQL Change History](#).

We use the following policy when updating MySQL:

- Enterprise Server releases are meant to appear every 18 months, supplemented by quarterly service packs and monthly rapid updates. Community Server releases are meant to appear 2 to 3 times per year.
- Releases are issued within each series. For each release, the last number in the version is one more than the previous release within the same series.
- Binary distributions for some platforms are made by us for major releases. Other people may make binary distributions for other systems, but probably less frequently.
- We make fixes available as soon as we have identified and corrected small or noncritical but annoying bugs. The fixes are available in source form immediately from our public Bazaar repositories, and are included in the next release.
- If by any chance a security vulnerability or critical bug is found in a release, our policy is to fix it in a new release as soon as

possible. (We would like other companies to do this, too!)

### 2.1.3. How to Get MySQL

Check our downloads page at <http://dev.mysql.com/downloads/> for information about the current version of MySQL and for downloading instructions. For a complete up-to-date list of MySQL download mirror sites, see [ht-tp://dev.mysql.com/downloads/mirrors.html](http://dev.mysql.com/downloads/mirrors.html). You can also find information there about becoming a MySQL mirror site and how to report a bad or out-of-date mirror.

Our main mirror is located at <http://mirrors.sunsite.dk/mysql/>.

### 2.1.4. Verifying Package Integrity Using MD5 Checksums or GnuPG

After you have downloaded the MySQL package that suits your needs and before you attempt to install it, you should make sure that it is intact and has not been tampered with. There are three means of integrity checking:

- MD5 checksums
- Cryptographic signatures using [GnuPG](#), the GNU Privacy Guard
- For RPM packages, the built-in RPM integrity verification mechanism

The following sections describe how to use these methods.

If you notice that the MD5 checksum or GPG signatures do not match, first try to download the respective package one more time, perhaps from another mirror site. If you repeatedly cannot successfully verify the integrity of the package, please notify us about such incidents, including the full package name and the download site you have been using, at [<webmaster@mysql.com>](mailto:<webmaster@mysql.com>) or [<build@mysql.com>](mailto:<build@mysql.com>). Do not report downloading problems using the bug-reporting system.

#### 2.1.4.1. Verifying the MD5 Checksum

After you have downloaded a MySQL package, you should make sure that its MD5 checksum matches the one provided on the MySQL download pages. Each package has an individual checksum that you can verify with the following command, where *package\_name* is the name of the package you downloaded:

```
shell> md5sum package_name
```

Example:

```
shell> md5sum mysql-standard-5.1.52-linux-i686.tar.gz
aaab65abbec64d5e907cd41b8699945 mysql-standard-5.1.52-linux-i686.tar.gz
```

You should verify that the resulting checksum (the string of hexadecimal digits) matches the one displayed on the download page immediately below the respective package.

#### Note

Make sure to verify the checksum of the *archive file* (for example, the *.zip* or *.tar.gz* file) and not of the files that are contained inside of the archive.

Note that not all operating systems support the `md5sum` command. On some, it is simply called `md5`, and others do not ship it at all. On Linux, it is part of the **GNU Text Utilities** package, which is available for a wide range of platforms. You can download the source code from <http://www.gnu.org/software/textutils/> as well. If you have OpenSSL installed, you can use the command `openssl md5 package_name` instead. A Windows implementation of the `md5` command line utility is available from [ht-tp://www.fourmilab.ch/md5/](http://www.fourmilab.ch/md5/). `winMd5Sum` is a graphical MD5 checking tool that can be obtained from [ht-tp://www.nullriver.com/index/products/winmd5sum](http://www.nullriver.com/index/products/winmd5sum).

#### 2.1.4.2. Signature Checking Using GnuPG

Another method of verifying the integrity and authenticity of a package is to use cryptographic signatures. This is more reliable than using MD5 checksums, but requires more work.

We sign MySQL downloadable packages with [GnuPG](#) (GNU Privacy Guard). [GnuPG](#) is an Open Source alternative to the well-known Pretty Good Privacy ([PGP](#)) by Phil Zimmermann. See <http://www.gnupg.org/> for more information about [GnuPG](#) and how to obtain and install it on your system. Most Linux distributions ship with [GnuPG](#) installed by default. For more information about [GnuPG](#), see <http://www.openpgp.org/>.

To verify the signature for a specific package, you first need to obtain a copy of our public GPG build key, which you can download from <http://keyserver.pgp.com/>. The key that you want to obtain is named `build@mysql.com`. Alternatively, you can cut and paste the key directly from the following text:

```
-----BEGIN PGP PUBLIC KEY BLOCK-----
Version: GnuPG v1.4.5 (GNU/Linux)

n3r1QpVC9yhnW2cSAjq+kr72GX0eAJ4295k16NxYEuFApmr1+0uUq/SlsQ==
=Mski

-----END PGP PUBLIC KEY BLOCK-----
```

To import the build key into your personal public GPG keyring, use `gpg --import`. For example, if you have saved the key in a file named `mysql_pubkey.asc`, the import command looks like this:

```
shell> gpg --import mysql_pubkey.asc
gpg: key 5072E1F5: public key "MySQL Package signing key (www.mysql.com) <build@mysql.com>" imported
gpg: Total number processed: 1
gpg: imported: 1
gpg: no ultimately trusted keys found
```

You can also download the key from the public keyserver using the public key id, **5072E1F5**:

```
shell> gpg --recv-keys 5072E1F5
gpg: requesting key 5072E1F5 from hkp server subkeys.pgp.net
gpg: key 5072E1F5: "MySQL Package signing key (www.mysql.com) <build@mysql.com>" 2 new signatures
gpg: no ultimately trusted keys found
gpg: Total number processed: 1
gpg: new signatures: 2
```

If you want to import the key into your RPM configuration to validate RPM install packages, you should be able to import the key directly:

```
shell> rpm --import mysql_pubkey.asc
```

If you experience problems, try exporting the key from `gpg` and importing:

```
shell> gpg --export -a 5072e1f5 > 5072e1f5.asc
shell> rpm --import 5072e1f5.asc
```

Alternatively, `rpm` also supports loading the key directly from a URL, and you can use this manual page:

```
shell> rpm --import http://dev.mysql.com/doc/refman/5.1/en/checking-gpg-signature.html
```

After you have downloaded and imported the public build key, download your desired MySQL package and the corresponding signature, which also is available from the download page. The signature file has the same name as the distribution file with an `.asc` extension, as shown by the examples in the following table.

**Table 2.1. MySQL Package and Signature Files**

|                   |                                                      |
|-------------------|------------------------------------------------------|
| Distribution file | <code>mysql-standard-5.1.52-linux-i686.tar.gz</code> |
|-------------------|------------------------------------------------------|

|                |                                                          |
|----------------|----------------------------------------------------------|
| Signature file | <code>mysql-standard-5.1.52-linux-i686.tar.gz.asc</code> |
|----------------|----------------------------------------------------------|

Make sure that both files are stored in the same directory and then run the following command to verify the signature for the distribution file:

```
shell> gpg --verify package_name.asc
```

Example:

```
shell> gpg --verify mysql-standard-5.1.52-linux-i686.tar.gz.asc
gpg: Signature made Tue 12 Jul 2005 23:35:41 EST using DSA key ID 5072E1F5
gpg: Good signature from "MySQL Package signing key (www.mysql.com) <build@mysql.com>"
```

The `Good signature` message indicates that everything is all right. You can ignore any `insecure memory` warning you might obtain.

See the GPG documentation for more information on how to work with public keys.

### 2.1.4.3. Signature Checking Using RPM

For RPM packages, there is no separate signature. RPM packages have a built-in GPG signature and MD5 checksum. You can verify a package by running the following command:

```
shell> rpm --checksig package_name.rpm
```

Example:

```
shell> rpm --checksig MySQL-server-5.1.52-0.glibc23.i386.rpm
MySQL-server-5.1.52-0.glibc23.i386.rpm: md5 gpg OK
```

#### Note

If you are using RPM 4.1 and it complains about `(GPG) NOT OK (MISSING KEYS: GPG#5072e1f5)`, even though you have imported the MySQL public build key into your own GPG keyring, you need to import the key into the RPM keyring first. RPM 4.1 no longer uses your personal GPG keyring (or GPG itself). Rather, RPM maintains a separate keyring because it is a system-wide application and a user's GPG public keyring is a user-specific file. To import the MySQL public key into the RPM keyring, first obtain the key as described in [Section 2.1.4.2, “Signature Checking Using GnuPG”](#). Then use `rpm --import` to import the key. For example, if you have saved the public key in a file named `mysql_pubkey.asc`, import it using this command:

```
shell> rpm --import mysql_pubkey.asc
```

If you need to obtain the MySQL public key, see [Section 2.1.4.2, “Signature Checking Using GnuPG”](#).

## 2.1.5. Installation Layouts

The installation layout for different installation types (for example native packages, binary tarballs, and source tarballs) differs, which can lead to confusion when managing different systems or using different installation sources. Layouts for different installation types are provided below. Note that the layout of installations from vendors other than Oracle may differ from these layouts.

The individual are contained within the corresponding installation type or platform chapter:

- [Section 2.4.1, “MySQL Installation Layout on Microsoft Windows”](#)
- [Section 2.3.1, “MySQL Installation Layout for Source Installation”](#)
- [Table 2.2, “MySQL Installation Layout for generic Unix/Linux binary package”](#)
- [Table 2.17, “MySQL Installation Layout for Linux RPM”](#)
- [Table 2.14, “MySQL Directory Layout on Mac OS X”](#)

## 2.1.6. Compiler-Specific Build Characteristics

In some cases, the compiler used to build MySQL affects the features available for use. The notes in this section apply for binary distributions provided by Oracle Corporation or that you compile yourself from source.

### **icc (Intel C++ Compiler) Builds**

A server built with `icc` has these characteristics:

- SSL support is not included.
- `InnoDB Plugin` is not included.

## **2.2. Installing MySQL from Generic Binaries on Unix/Linux**

This section covers the installation of MySQL binary distributions that are provided for various platforms in the form of compressed `tar` files (files with a `.tar.gz` extension).

To obtain MySQL, see [Section 2.1.3, “How to Get MySQL”](#).

Oracle provides a set of binary distributions of MySQL. In addition to binaries provided in platform-specific package formats, we offer binary distributions for a number of platforms in the form of compressed `tar` files (`.tar.gz` files). For Windows distributions, see [Section 2.4, “Installing MySQL on Microsoft Windows”](#).

On Unix, a `tar` file binary distribution is installed by unpacking it at the installation location you choose (typically `/usr/local/mysql`) and creates the following directories in that location.

**Table 2.2. MySQL Installation Layout for generic Unix/Linux binary package**

| Directory                | Contents of Directory                                                                                            |
|--------------------------|------------------------------------------------------------------------------------------------------------------|
| <code>bin</code>         | Client programs and the <code>mysqld</code> server                                                               |
| <code>data</code>        | Log files, databases                                                                                             |
| <code>docs</code>        | Manual in Info format                                                                                            |
| <code>man</code>         | Unix manual pages                                                                                                |
| <code>include</code>     | Include (header) files                                                                                           |
| <code>lib</code>         | Libraries                                                                                                        |
| <code>scripts</code>     | <code>mysql_install_db</code>                                                                                    |

Debug versions of the `mysqld` binary are available as `mysqld-debug`. If you would like to compile a debug version of MySQL from a source distribution, you should add `--with-debug` or `--with-debug=full` to the `configure` command used to configure the distribution and remove any `-fomit-frame-pointer` options. For more information on compiling from source, see [Section 2.3, “Installing MySQL Using a Source Distribution”](#).

MySQL `tar` file binary distributions have names of the form `mysql-VERSION-OS.tar.gz`, where `VERSION` is a number (for example, `5.1.52`), and `OS` indicates the type of operating system for which the distribution is intended (for example, `pc-linux-i686`).

In addition to these generic packages, we also offer binaries in platform-specific package formats for selected platforms. See the platform specific sections for more information, for more information on how to install these.

You need the following tools to install a MySQL `tar` file binary distribution:

- GNU `gunzip` to uncompress the distribution.
- A reasonable `tar` to unpack the distribution. GNU `tar` is known to work. Some operating systems come with a preinstalled version of `tar` that is known to have problems. For example, the `tar` provided with early versions of Mac OS X, SunOS 4.x, Solaris 8, Solaris 9, Solaris 10 and OpenSolaris, and HP-UX are known to have problems with long file names.
  - On Mac OS X, you can use the preinstalled `gnutar` program.
  - On Solaris 10 and OpenSolaris you can use the preinstalled `gtar`.
  - On other systems with a deficient `tar`, you should install GNU `tar` first.

**Warning**

If you have previously installed a MySQL installation using your operating system native package management system, such as `yum` or `apt-get`, you may experience problems installing using a native binary. Make sure your previous MySQL previous installation has been removed entirely (using your package management system), and that any additional files, such as old versions of your data files, have also been removed. You should also check the existence of configuration files such as `/etc/my.cnf` or the `/etc/mysql` directory have been deleted.

If you run into problems and need to file a bug report, please use the instructions in [Section 1.7, “How to Report Bugs or Problems”](#).

The basic commands that you must execute to install and use a MySQL binary distribution are:

**Note**

The following process assumes that you have root (administrator) access to your system. Alternatively you can prefix each command using the `sudo` (Linux) or `pfexec` (OpenSolaris) command.

```
shell> groupadd mysql
shell> useradd -r -g mysql mysql
shell> cd /usr/local
shell> gunzip < /path/to/mysql-VERSION-OS.tar.gz | tar xvf -
shell> ln -s full-path-to-mysql-VERSION-OS mysql
shell> cd mysql
shell> chown -R mysql .
shell> chgrp -R mysql .
shell> scripts/mysql_install_db --user=mysql
shell> chown -R root .
shell> chown -R mysql data
shell> cp /usr/local/mysql/support-files/my-small/etc/my.cnf # Optional
shell> bin/mysqld_safe --user=mysql &
shell> cp /usr/local/mysql/support-files/mysql.server /etc/init.d/mysql.server # Optional
```

**Note**

This procedure does not set up any passwords for MySQL accounts. After following the procedure, proceed to [Section 2.13, “Post-Installation Setup and Testing”](#).

A more detailed version of the preceding description for installing a binary distribution follows:

**Note**

The following process assumes that you have root (administrator) access to your system. Alternatively you can prefix each command using the `sudo` (Linux) or `pfexec` (OpenSolaris) command.

1. If your system does not already have a user and group for `mysqld` to run as, you may need to create one.

```
shell> groupadd mysql
shell> useradd -r -g mysql mysql
```

**Note**

The above will create a user that has login permissions to your server. You may wish to disable the account, as the user is only required for ownership, not login, purposes. You can do this on Linux by using the `-r` command-line option.

These commands add the `mysql` group and the `mysql` user. The syntax for `useradd` and `groupadd` may differ slightly on different versions of Unix, or they may have different names such as `adduser` and `addgroup`.

You might want to call the user and group something else instead of `mysql`. If so, substitute the appropriate name in the following steps.

2. Pick the directory under which you want to unpack the distribution and change location into it. In the following example, we unpack the distribution under `/usr/local`. (The instructions, therefore, assume that you have permission to create files and directories in `/usr/local`. If that directory is protected, you must perform the installation as `root`.)

```
shell> cd /usr/local
```

3. Obtain a distribution file using the instructions in [Section 2.1.3, “How to Get MySQL”](#). For a given release, binary distributions for all platforms are built from the same MySQL source distribution.
4. Unpack the distribution, which creates the installation directory. Then create a symbolic link to that directory:

```
shell> gunzip < /path/to/mysql-VERSION-OS.tar.gz | tar xvf -
shell> ln -s full-path-to-mysql-VERSION-OS mysql
```

The `tar` command creates a directory named `mysql-VERSION-OS`. The `ln` command makes a symbolic link to that directory. This lets you refer more easily to the installation directory as `/usr/local/mysql`.

With GNU `tar`, no separate invocation of `gunzip` is necessary. You can replace the first line with the following alternative command to uncompress and extract the distribution:

```
shell> tar zxvf /path/to/mysql-VERSION-OS.tar.gz
```

5. Change location into the installation directory:

```
shell> cd mysql
```

You will find several files and subdirectories in the `mysql` directory. The most important for installation purposes are the `bin` and `scripts` subdirectories:

- The `bin` directory contains client programs and the server. You should add the full path name of this directory to your `PATH` environment variable so that your shell finds the MySQL programs properly. See [Section 2.14, “Environment Variables”](#).
  - The `scripts` directory contains the `mysql_install_db` script used to initialize the `mysql` database containing the grant tables that store the server access permissions.
6. Ensure that the distribution contents are accessible to `mysql`. If you unpacked the distribution as `mysql`, no further action is required. If you unpacked the distribution as `root`, its contents will be owned by `root`. Change its ownership to `mysql` by executing the following commands as `root` in the installation directory:

```
shell> chown -R mysql .
shell> chgrp -R mysql .
```

The first command changes the owner attribute of the files to the `mysql` user. The second changes the group attribute to the `mysql` group.

7. If you have not installed MySQL before, you must create the MySQL data directory and initialize the grant tables:

```
shell> scripts/mysql_install_db --user=mysql
```

If you run the command as `root`, include the `--user` option as shown. If you run the while logged in as that user, you can omit the `--user` option.

The command should create the data directory and its contents with `mysql` as the owner.

After creating or updating the grant tables, you need to restart the server manually.

8. Most of the MySQL installation can be owned by `root` if you like. The exception is that the data directory must be owned by `mysql`. To accomplish this, run the following commands as `root` in the installation directory:

```
shell> chown -R root .
shell> chown -R mysql data
```

9. You may want to optionally copy one of the provided configuration files from the `support-files` directory into your `/etc/` directory. There are different sample configuration files for different use cases, server types, and CPU and RAM configurations. If you want to use one of these standard files, you should copy it to `/etc/my.cnf`, or `/etc/mysql/my.cnf` and edit and check the configuration before starting your MySQL server for the first time.

If you do not copy one of the standard configuration files, the MySQL server will be started with the default settings.

10. If the plugin directory is writable by the server, it may be possible for a user to write executable code to a file in the directory using `SELECT ... INTO DUMPFILE`. This can be prevented by making `plugin_dir` read only to the server or by setting `--secure-file-priv` to a directory where `SELECT` writes can be made safely.
11. If you want MySQL to start automatically when you boot your machine, you can copy `support-files/mysql.server` to the location where your system has its startup files. More information can be found in the `support-files/mysql.server` script itself and in [Section 2.13.1.2, “Starting and Stopping MySQL Automatically”](#).
12. You can set up new accounts using the `bin/mysql_setpermission` script if you install the `DBI` and `DBD::mysql` Perl

modules. See [Section 4.6.14, “mysql\\_setpermission — Interactively Set Permissions in Grant Tables”](#). For Perl module installation instructions, see [Section 2.15, “Perl Installation Notes”](#).

13. If you would like to use `mysqlaccess` and have the MySQL distribution in some nonstandard location, you must change the location where `mysqlaccess` expects to find the `mysql` client. Edit the `bin/mysqlaccess` script at approximately line 18. Search for a line that looks like this:

```
$MYSQL = '/usr/local/bin/mysql'; # path to mysql executable
```

Change the path to reflect the location where `mysql` actually is stored on your system. If you do not do this, a `Broken pipe` error will occur when you run `mysqlaccess`.

After everything has been unpacked and installed, you should test your distribution. To start the MySQL server, use the following command:

```
shell> bin/mysqld_safe --user=mysql &
```

If you run the command as `root`, you must use the `--user` option as shown. The value of the option is the name of the login account that you created in the first step to use for running the server. If you run the command while logged in as `mysql`, you can omit the `--user` option.

If the command fails immediately and prints `mysqld ended`, you can find some information in the `host_name.err` file in the data directory.

More information about `mysqld_safe` is given in [Section 4.3.2, “mysqld\\_safe — MySQL Server Startup Script”](#).

#### Note

The accounts that are listed in the MySQL grant tables initially have no passwords. After starting the server, you should set up passwords for them using the instructions in [Section 2.13, “Post-Installation Setup and Testing”](#).

## 2.3. Installing MySQL Using a Source Distribution

Before you proceed with an installation from source, first check whether our binary is available for your platform and whether it works for you. We put a great deal of effort into ensuring that our binaries are built with the best possible options. Source builds allow you to customize the build parameters, compiler optimizations, and installation location.

This section documents the process for building MySQL from source on Unix-like systems, including Linux, commercial Unix, BSD, Mac OS X and others. If you want to build MySQL from source on Windows, see [Section 2.4.9, “Installing MySQL from Source on Windows”](#).

To obtain a source distribution for MySQL, [Section 2.1.3, “How to Get MySQL”](#). MySQL source distributions are provided as compressed `tar` archives and have names of the form `mysql-VERSION.tar.gz`, where `VERSION` is a number like `5.1.52`.

You need the following tools to build and install MySQL from source:

- GNU `gunzip` to uncompress the distribution.
- A reasonable `tar` to unpack the distribution.

The standard `tar` provided with some operating systems is not able to unpack the long file names in the MySQL distribution. You should download and install GNU `tar`, or if available, use a pre-installed version of GNU tar. Usually this is available as `gnutar`, `gtar`, or as `tar` within a GNU or Free Software directory, such as `/usr/sfw/bin` or `/usr/local/bin`.

- A working ANSI C++ compiler. GCC 3.2 or later, Sun Studio 10 or later, Visual Studio 2005 or later, and many current vendor-supplied compilers are known to work.
- A good `make` program. GNU `make` is always recommended and is sometimes required. If you have problems, use GNU `make` 3.75 or newer.
- `libtool` 1.5.24 or later is also recommended.

To complete an installation using the source code:

- To build using a `tar.gz` or RPM-based source code distribution, see [Section 2.3.2, “Source Installation Overview”](#).

- For information on building from one of our development trees, see [Section 2.3.4, “Installing from the Development Source Tree”](#).
- For information on using the `configure` command to specify the source build parameters, including links to platform specific parameters that you might need, see [Section 2.3.3, “Typical `configure` Options”](#).

You can create your own binary installation from a compiled source distribution by executing the `scripts/make_binary_distribution` script from the top directory of the source distribution.

If you run into problems and need to file a bug report, please use the instructions in [Section 1.7, “How to Report Bugs or Problems”](#).

### 2.3.1. MySQL Installation Layout for Source Installation

A source distribution is installed after you configure and compile it. By default, the installation step installs files under `/usr/local`, in the following subdirectories, although this can be changed during the configuration phase.

**Table 2.3. MySQL Installation Layout for Source Installation**

| Directory                  | Contents of Directory                                                                                            |
|----------------------------|------------------------------------------------------------------------------------------------------------------|
| <code>bin</code>           | Client programs and scripts                                                                                      |
| <code>include/mysql</code> | Include (header) files                                                                                           |
| <code>Docs</code>          | Manual in Info, CHM formats                                                                                      |
| <code>man</code>           | Unix manual pages                                                                                                |
| <code>lib/mysql</code>     | Libraries                                                                                                        |
| <code>libexec</code>       | The <code>mysqld</code> server                                                                                   |
| <code>share/mysql</code>   | Miscellaneous support files, including error messages, sample configuration files, SQL for database installation |
| <code>sql-bench</code>     | Benchmarks and <code>crash-me</code> test                                                                        |
| <code>var</code>           | Databases and log files                                                                                          |

Within its installation directory, the layout of a source installation differs from that of a binary installation in the following ways:

- The `mysqld` server is installed in the `libexec` directory rather than in the `bin` directory.
- The data directory is `var` rather than `data`.
- `mysql_install_db` is installed in the `bin` directory rather than in the `scripts` directory.
- The header file and library directories are `include/mysql` and `lib/mysql` rather than `include` and `lib`.

### 2.3.2. Source Installation Overview

The source installation first builds and then installs MySQL from the source packages, and then follows the same basic configuration and installation sequence for a binary installation.

If you start from a source RPM, do the following:

```
shell> rpmbuild --rebuild --clean MySQL-VERSION.src.rpm
```

#### Note

This makes a binary RPM that you can install. For older versions of RPM, you may have to replace the command `rpmbuild` with `rpm` instead.

The sequence for installation from a source distribution is similar to the process for installing from a generic binary distribution (as detailed in [Section 2.2, “Installing MySQL from Generic Binaries on Unix/Linux”](#)). The basic commands and sequence required to install using MySQL `.tar.gz` source distribution are:

```
shell> groupadd mysql
shell> useradd -g mysql mysql
Source-build specific instructions
```

```
shell> gunzip < mysql-VERSION.tar.gz | tar -xvf -
shell> cd mysql-VERSION
shell> ./configure --prefix=/usr/local/mysql
shell> make
shell> make install
End of Source-build specific instructions
shell> cd /usr/local/mysql
shell> chown -R mysql .
shell> chgrp -R mysql .
shell> bin/mysql_install_db --user=mysql
shell> chown -R root .
shell> chown -R mysql var
shell> cp support-files/my-medium.cnf /etc/my.cnf #optional
shell> bin/mysqld_safe --user=mysql &
shell> cp /usr/local/mysql/support-files/mysql.server /etc/init.d/mysql.server # Optional
```

### Note

The following procedure does not set up any passwords for MySQL accounts. After following the procedure, proceed to [Section 2.13, “Post-Installation Setup and Testing”](#), for post-installation setup and testing.

A more detailed version of the source-build specific instructions are shown below. Perform the following steps as the `mysql` user, except as noted.

1. Set up the `mysql` user and group that will be used to run and execute the MySQL server, and own the database file. For more detail, see [Creating mysql System user and group](#).
2. Pick the directory under which you want to unpack the distribution and change location into it.

Obtain a distribution file using the instructions in [Section 2.1.3, “How to Get MySQL”](#).

Unpack the distribution into the current directory:

```
shell> gunzip < /path/to/mysql-VERSION.tar.gz | tar xvf -
```

This command creates a directory named `mysql-VERSION`.

With GNU `tar`, no separate invocation of `gunzip` is necessary. You can use the following alternative command to uncompress and extract the distribution:

```
shell> tar zxvf /path/to/mysql-VERSION-OS.tar.gz
```

3. Change location into the top-level directory of the unpacked distribution:

```
shell> cd mysql-VERSION
```

4. Configure the source directory:

```
shell> ./configure --prefix=/usr/local/mysql
```

When you run `configure`, you might want to specify other options. Run `./configure --help` for a list of options. [Section 2.3.3, “Typical configure Options”](#), discusses some of the more useful options.

If `configure` fails and you are going to send mail to a MySQL mailing list to ask for assistance, please include any lines from `config.log` that you think can help solve the problem. Also include the last couple of lines of output from `configure`. To file a bug report, please use the instructions in [Section 1.7, “How to Report Bugs or Problems”](#).

5. Compile the source distribution:

```
shell> make
```

On systems where you are using GNU `make` and it has been installed as `gmake`:

```
shell> gmake
```

If the compile fails, see [Section 2.3.5, “Dealing with Problems Compiling MySQL”](#), for help.

6. Install the distribution:

```
shell> make install
```

You might need to run this command as `root`.

The remainder of the installation process, including setting up the configuration file, creating the core databases, and starting the MySQL server, are identical to the remainder of the process as shown in [Generic Binary Install](#).

After everything has been installed, you should test your distribution. To start the MySQL server, use the following command:

```
shell> /usr/local/mysql/bin/mysqld_safe --user=mysql &
```

If you run the command as `root`, you should use the `--user` option as shown. The value of the option is the name of the login account that you created in the first step to use for running the server. If you run the command while logged in as that user, you can omit the `--user` option.

If the command fails immediately and prints `mysqld ended`, you can find some information in the `host_name.err` file in the data directory.

More information about `mysqld_safe` is given in [Section 4.3.2, “mysqld\\_safe — MySQL Server Startup Script”](#).

#### Note

The accounts that are listed in the MySQL grant tables initially have no passwords. After starting the server, you should set up passwords for them using the instructions in [Section 2.13, “Post-Installation Setup and Testing”](#).

### 2.3.3. Typical `configure` Options

The `configure` script gives you a great deal of control over how you configure a MySQL source distribution. Typically you do this using options on the `configure` command line. You can also affect `configure` using certain environment variables. See [Section 2.14, “Environment Variables”](#). For a full list of options supported by `configure`, run this command:

```
shell> ./configure --help
```

A list of the available `configure` options is provided in the table below.

**Table 2.4. Build (`configure`) Reference**

| Formats                                      | Description                                                  | Default                   | Introduced | Removed |
|----------------------------------------------|--------------------------------------------------------------|---------------------------|------------|---------|
| <code>--bindir=DIR</code>                    | User executables                                             | <code>EPREFIX/bin</code>  |            |         |
| <code>--build=BUILD</code>                   | Configure for building on BUILD                              | <code>guessed</code>      |            |         |
| <code>--cache-file=FILE</code>               | Cache test results in FILE                                   | <code>disabled</code>     |            |         |
| <code>-C</code>                              | Alias for `--cache-file=config.cache'                        |                           |            |         |
| <code>--config-cache</code>                  |                                                              |                           |            |         |
| <code>--datadir=DIR</code>                   | Read-only architecture-independent data                      | <code>PREFIX/share</code> |            |         |
| <code>--disable-FEATURE</code>               | Do not include FEATURE                                       |                           |            |         |
| <code>- -dis-able-community-features</code>  | Disable additional features provided by the community        |                           | 5.1.28     |         |
| <code>- -dis-able-dependency-tracking</code> | Disable dependency tracking                                  |                           |            |         |
| <code>--disable-grant-options</code>         | Disable GRANT options                                        |                           |            |         |
| <code>--disable-largefile</code>             | Omit support for large files                                 |                           |            |         |
| <code>--disable-libtool-lock</code>          | Disable libtool lock                                         |                           |            |         |
| <code>- -dis-able-thread-safe-client</code>  | Compile the client without threads                           |                           | 5.1.7      |         |
| <code>--enable-FEATURE</code>                | Enable FEATURE                                               |                           |            |         |
| <code>--enable-assembler</code>              | Use assembler versions of some string functions if available |                           |            |         |
| <code>--enable-debug-sync</code>             | Compile in Debug Sync facility                               |                           | 5.1.41     |         |

| <b>Formats</b>                                | <b>Description</b>                                  | <b>Default</b>                         | <b>Introduced</b> | <b>Removed</b> |
|-----------------------------------------------|-----------------------------------------------------|----------------------------------------|-------------------|----------------|
| <code>--enable-dependency-tracking</code>     | Do not reject slow dependency extractors            |                                        |                   |                |
| <code>--enable-fast-install</code>            | Optimize for fast installation                      | <code>yes</code>                       |                   |                |
| <code>--enable-local-infile</code>            | Enable LOAD DATA LOCAL INFILE                       | <code>disabled</code>                  |                   |                |
| <code>--enable-profiling</code>               | Build a version with query profiling code           |                                        | 5.1.24            |                |
| <code>--enable-shared</code>                  | Build shared libraries                              | <code>yes</code>                       |                   |                |
| <code>--enable-static</code>                  | Build static libraries                              | <code>yes</code>                       |                   |                |
| <code>--enable-thread-safe-client</code>      | Compile the client with threads                     |                                        |                   | 5.1.6          |
| <code>--exec-prefix=EPREFIX</code>            | Install architecture-dependent files in EPREFIX     |                                        |                   |                |
| <code>-h</code>                               | Display this help and exit                          |                                        |                   |                |
| <code>--help</code>                           |                                                     |                                        |                   |                |
| <code>--help=short</code>                     | Display options specific to this package            |                                        |                   |                |
| <code>--help=recursive</code>                 | Display the short help of all the included packages |                                        |                   |                |
| <code>--host=HOST</code>                      | Cross-compile to build programs to run on HOST      |                                        |                   |                |
| <code>--includedir=DIR</code>                 | C header files                                      | <code>PREFIX/include</code>            |                   |                |
| <code>--infodir=DIR</code>                    | Info documentation                                  | <code>PREFIX/info</code>               |                   |                |
| <code>--libdir=DIR</code>                     | Object code libraries                               | <code>EPREFIX/lib</code>               |                   |                |
| <code>--libexecdir=DIR</code>                 | Program executables                                 | <code>EPREFIX/libexec</code>           |                   |                |
| <code>--localstatedir=DIR</code>              | Modifiable single-machine data                      | <code>PREFIX/var</code>                |                   |                |
| <code>--mandir=DIR</code>                     | man documentation                                   | <code>PREFIX/man</code>                |                   |                |
| <code>-n</code>                               | Do not create output files                          |                                        |                   |                |
| <code>--no-create</code>                      |                                                     |                                        |                   |                |
| <code>--oldincludedir=DIR</code>              | C header files for non-gcc                          | <code>/usr/include</code>              |                   |                |
| <code>--prefix=PREFIX</code>                  | Install architecture-independent files in PREFIX    |                                        |                   |                |
| <code>--program-prefix=PREFIX</code>          | Prepend PREFIX to installed program names           |                                        |                   |                |
| <code>--program-suffix=SUFFIX</code>          | Append SUFFIX to installed program names            |                                        |                   |                |
| <code>--program-transform-name=PROGRAM</code> | run sed PROGRAM on installed program names          |                                        |                   |                |
| <code>-q</code>                               | Do not print `checking...' messages                 |                                        |                   |                |
| <code>--quiet</code>                          |                                                     |                                        |                   |                |
| <code>--sbindir=DIR</code>                    | System administrative executables                   | <code>EPREFIX/sbin</code>              |                   |                |
| <code>--sharedstatedir=DIR</code>             | Modifiable architecture-independent data            | <code>PREFIX/com</code>                |                   |                |
| <code>--srcdir=DIR</code>                     | Find the sources in DIR                             | <code>configure directory or ..</code> |                   |                |
| <code>--sysconfdir=DIR</code>                 | Read-only single-machine data                       | <code>PREFIX/etc</code>                |                   |                |
| <code>--target=TARGET</code>                  | Configure for building compilers for TARGET         |                                        |                   |                |
| <code>-V</code>                               | Display version information and exit                |                                        |                   |                |
| <code>--version</code>                        |                                                     |                                        |                   |                |

| -<br>-<br>with-black-hole-storage-engine  | Enable the Blackhole Storage Engine                                                              | no             |                   | 5.1.9          |
| --with-charset                            | Default character set                                                                            |                |                   |                |
| --with-client-ldflags                     | Extra linking arguments for clients                                                              |                |                   |                |
| --with-collation                          | Default collation                                                                                |                |                   |                |
| --with-comment                            | Comment about compilation environment                                                            |                |                   |                |
| --with-csv-storage-engine                 | Enable the CSV Storage Engine                                                                    | yes            |                   | 5.1.9          |
| --with-darwin-mwcc                        | Use Metrowerks CodeWarrior wrappers on OS X/Darwin                                               |                |                   |                |
| --with-debug                              | Add debug code                                                                                   |                | 5.1.7             |                |
| --with-debug=full                         | Add debug code (adds memory checker, very slow)                                                  |                |                   |                |
| -<br>-<br>with-embedded-privilege-control | Build parts to check user's privileges (only affects embedded library)                           |                |                   |                |
| --with-embedded-server                    | Build the embedded server                                                                        |                |                   |                |
| --with-error-inject                       | Enable error injection in MySQL Server                                                           |                | 5.1.11            |                |
| -<br>-<br>with-example-storage-engine     | Enable the Example Storage Engine                                                                | no             |                   | 5.1.9          |
| --with-extra-Charsets                     | Use charsets in addition to default                                                              |                |                   |                |
| --with-fast-mutexes                       | Compile with fast mutexes                                                                        | enabled        | 5.1.5             |                |
| -<br>-<br>with-federated-storage-engine   | Enable federated storage engine                                                                  | no             | 5.1.3             | 5.1.9          |
| --with-gnu-ld                             | Assume the C compiler uses GNU ld                                                                | no             |                   |                |
| --with-innodb                             | Enable innobase storage engine                                                                   | no             | 5.1.3             | 5.1.9          |
| --with-lib-ccflags                        | Extra CC options for libraries                                                                   |                |                   |                |
| --with-libwrap=DIR                        | Compile in libwrap (tcp_wrappers) support                                                        |                |                   |                |
| --with-low-memory                         | Try to use less memory to compile to avoid memory limitations                                    |                |                   |                |
| --with-machine-type                       | Set the machine type, like "powerpc"                                                             |                |                   |                |
| --with-max-indexes=N                      | Sets the maximum number of indexes                                                               | 64             |                   |                |

| <b>Formats</b>                   | <b>Description</b>                                                                              | <b>Default</b>           | <b>Introduced</b> | <b>Removed</b> |
|----------------------------------|-------------------------------------------------------------------------------------------------|--------------------------|-------------------|----------------|
|                                  | per table                                                                                       |                          |                   |                |
| --with-mysqld-lfflags            | Extra linking arguments for mysqld                                                              |                          |                   |                |
| --with-mysqld-libs               | Extra libraries to link with for mysql                                                          |                          |                   |                |
| --with-mysqld-user               | What user the mysqld daemon shall be run as                                                     |                          |                   |                |
| --with-mysqlmanager              | Build the mysqlmanager binary                                                                   | Build if server is built |                   |                |
| --with-named-curses-libs         | Use specified curses libraries                                                                  |                          |                   |                |
| --with-named-thread-libs         | Use specified thread libraries                                                                  |                          |                   |                |
| --with-ndb-ccflags               | Extra CC options for ndb compile                                                                |                          |                   |                |
| --with-ndb-docs                  | Include the NDB Cluster ndbapi and mgmapi documentation                                         |                          |                   |                |
| --with-ndb-port                  | Port for NDB Cluster management server                                                          |                          |                   |                |
| --with-ndb-port-base             | Port for NDB Cluster management server                                                          |                          |                   |                |
| --with-ndb-sci=DIR               | Provide MySQL with a custom location of sci library                                             |                          |                   |                |
| --with-ndb-test                  | Include the NDB Cluster ndbapi test programs                                                    |                          |                   |                |
| --with-ndbcluster                | Include the NDB Cluster table handler                                                           | no                       |                   | 5.1.9          |
| --with-openssl=DIR               | Include the OpenSSL support                                                                     |                          |                   | 5.1.9          |
| --with-openssl-includes          | Find OpenSSL headers in DIR                                                                     |                          |                   | 5.1.9          |
| --with-openssl-libs              | Find OpenSSL libraries in DIR                                                                   |                          |                   | 5.1.9          |
| --with-other-libc=DIR            | Link against libc and other standard libraries installed in the specified non-standard location |                          |                   |                |
| --with-pic                       | Try to use only PIC/non-PIC objects                                                             | use both                 |                   |                |
| --with-plugin-PLUGIN             | Forces the named plugin to be linked into mysqld statically                                     |                          | 5.1.11            |                |
| --with-plugins                   | Plugins to include in mysqld                                                                    | none                     | 5.1.11            |                |
| --with-pstack                    | Use the pstack backtrace library                                                                |                          |                   |                |
| --with-pthread                   | Force use of pthread library                                                                    |                          |                   |                |
| - - with-row-based-replication   | Include row-based replication                                                                   |                          | 5.1.5             | 5.1.6          |
| --with-server-suffix             | Append value to the version string                                                              |                          |                   |                |
| --with-ssl=DIR                   | Include SSL support                                                                             |                          | 5.1.11            |                |
| --with-system-type               | Set the system type, like "sun-solaris10"                                                       |                          |                   |                |
| --with-tags                      | Include additional configurations                                                               | automatic                |                   |                |
| --with-tcp-port                  | Which port to use for MySQL services                                                            | 3306                     |                   |                |
| --with-unix-socket-path          | Where to put the unix-domain socket                                                             |                          |                   |                |
| --with-yassl                     | Include the yaSSL support                                                                       |                          |                   | 5.1.9          |
| - - with-zlib-dir=no bundled DIR | Provide MySQL with a custom location of compression library                                     |                          |                   |                |
| --without-PACKAGE                | Do not use PACKAGE                                                                              |                          |                   |                |
| --without-bench                  | Skip building of the benchmark suite                                                            |                          |                   | 5.1.11         |
| --without-debug                  | Build a production version without                                                              |                          |                   | 5.1.6          |

| Formats                                     | Description                                      | Default | Introduced | Removed |
|---------------------------------------------|--------------------------------------------------|---------|------------|---------|
|                                             | debugging code                                   |         |            |         |
| --without-docs                              | Skip building of the documentation               |         |            |         |
| --without-extra-tools                       | Skip building utilities in the tools directory   |         |            | 5.1.9   |
| --without-geometry                          | Do not build geometry-related parts              |         |            |         |
| --without-libedit                           | Use system libedit instead of bundled copy       |         |            |         |
| --without-man                               | Skip building of the man pages                   |         |            |         |
| --without-ndb-binlog                        | Disable ndb binlog                               |         | 5.1.6      |         |
| --without-ndb-debug                         | Disable special ndb debug features               |         |            |         |
| --without-plugin-PLUGIN                     | Exclude PLUGIN                                   |         | 5.1.11     |         |
| --without-query-cache                       | Do not build query cache                         |         |            |         |
| --without-readline                          | Use system readline instead of bundled copy      |         |            |         |
| -<br>-<br>without-<br>row-based-replication | Don't include row-based replication              |         | 5.1.7      | 5.1.14  |
| --without-server                            | Only build the client                            |         |            |         |
| --without-uca                               | Skip building of the national Unicode collations |         |            |         |

If you are using a version of `gcc` recent enough to understand the `-fno-exceptions` option, it is *very important* that you use this option. Otherwise, you may compile a binary that crashes randomly. Also use `-felide-constructors` and `-fno-rtti` along with `-fno-exceptions`. When in doubt, do the following:

```
CFLAGS="-O3" CXX=gcc CXXFLAGS="-O3 -felide-constructors \
-fno-exceptions -fno-rtti" ./configure \
--prefix=/usr/local/mysql --enable-assembler \
--with-mysqld-ldflags=-all-static
```

On most systems, this gives you a fast and stable binary.

When compiling from source, you should also be aware of any platform specific considerations that may influence and impact the build process. Knowing and applying this information will help to ensure you get the best performance and most stable binary for your chosen platform. For more information, use the following sections:

- [Section 2.8.2, “Notes on Installing MySQL on AIX from Source”](#)
- [Section 2.9.2, “Notes on Installing MySQL on HP-UX from Source”](#)
- [Section 2.7.3, “Notes on Installing MySQL on Solaris from Source”](#)

Some of the `configure` options available are described here. For options that may be of use if you have difficulties building MySQL, see [Section 2.3.5, “Dealing with Problems Compiling MySQL”](#).

- To compile just the MySQL client libraries and client programs and not the server, use the `--without-server` option:

```
shell> ./configure --without-server
```

If you have no C++ compiler, some client programs such as `mysql` cannot be compiled because they require C++. In this case, you can remove the code in `configure` that tests for the C++ compiler and then run `./configure` with the `--without-server` option. The compile step should still try to build all clients, but you can ignore any warnings about files such as `mysql.cc`. (If `make` stops, try `make -k` to tell it to continue with the rest of the build even if errors occur.)

- If you want to build the embedded MySQL library (`libmysqld.a`), use the `--with-embedded-server` option.
- If you do not want your log files and database directories located under `/usr/local/var`, use a `configure` command something like one of these:

```
shell> ./configure --prefix=/usr/local/mysql
shell> ./configure --prefix=/usr/local \
 --localstatedir=/usr/local/mysql/data
```

The first command changes the installation prefix so that everything is installed under `/usr/local/mysql` rather than the default of `/usr/local`. The second command preserves the default installation prefix, but overrides the default location for database directories (normally `/usr/local/var`) and changes it to `/usr/local/mysql/data`.

You can also specify the installation directory and data directory locations at server startup time by using the `--basedir` and `--datadir` options. These can be given on the command line or in an MySQL option file, although it is more common to use an option file. See [Section 4.2.3.3, “Using Option Files”](#).

- This option specifies the port number on which the server listens for TCP/IP connections. The default is port 3306. To listen on a different port, use a `configure` command like this:

```
shell> ./configure --with-tcp-port=3307
```

- If you are using Unix and you want the MySQL socket file location to be somewhere other than the default location (normally in the directory `/tmp` or `/var/run`), use a `configure` command like this:

```
shell> ./configure \
 --with-unix-socket-path=/usr/local/mysql/tmp/mysql.sock
```

The socket file name must be an absolute path name. You can also change the location of `mysql.sock` at server startup by using a MySQL option file. See [Section B.5.4.5, “How to Protect or Change the MySQL Unix Socket File”](#).

- If you want to compile statically linked programs (for example, to make a binary distribution, to get better performance, or to work around problems with some Red Hat Linux distributions), run `configure` like this:

```
shell> ./configure --with-client-ldflags=-all-static \
 --with-mysqld-ldflags=-all-static
```

- If you are using `gcc` and do not have `libg++` or `libstdc++` installed, you can tell `configure` to use `gcc` as your C++ compiler:

```
shell> CC=gcc CXX=gcc ./configure
```

When you use `gcc` as your C++ compiler, it does not attempt to link in `libg++` or `libstdc++`. This may be a good thing to do even if you have those libraries installed. Some versions of them have caused strange problems for MySQL users in the past.

The following list indicates some compilers and environment variable settings that are commonly used with each one.

In most cases, you can get a reasonably optimized MySQL binary by using the following options to the `configure` line:

```
--prefix=/usr/local/mysql --enable-assembler \
--with-mysqld-ldflags=-all-static
```

The full `configure` line would, in other words, be something like the following for all recent `gcc` versions:

```
CFLAGS="-O3 -mpentiumpro" CXX=gcc CXXFLAGS="-O3 -mpentiumpro \
-felide-constructors -fno-exceptions -fno-rtti" ./configure \
--prefix=/usr/local/mysql --enable-assembler \
--with-mysqld-ldflags=-all-static
```

The binaries we provide on the MySQL Web site at <http://dev.mysql.com/downloads/> are all compiled with full optimization and should be perfect for most users. See [Section 2.2, “Installing MySQL from Generic Binaries on Unix/Linux”](#). There are some configuration settings you can tweak to build an even faster binary, but these are only for advanced users. See [Section 7.9.1, “How Compiling and Linking Affects the Speed of MySQL”](#).

If the build fails and produces errors about your compiler or linker not being able to create the shared library `libmysqlclient.so.N` (where `N` is a version number), you can work around this problem by giving the `--disable-shared` option to `configure`. In this case, `configure` does not build a shared `libmysqlclient.so.N` library.

- By default, MySQL uses the `latin1` (cp1252 West European) character set. To change the default set, use the `--with-charset` option:

```
shell> ./configure --with-charset=CHARSET
```

`CHARSET` may be one of `binary, armSCII8, ascii, big5, cp1250, cp1251, cp1256, cp1257, cp850, cp852,`

`cp866, cp932, dec8, eucjpms, euckr, gb2312, gbk, geostd8, greek, hebrew, hp8, keybcs2, koi8r, koi8u, latin1, latin2, latin5, latin7, macce, macroman, sjis, swe7, tis620, ucs2, ujis, utf8`. (Additional character sets might be available. Check the output from `./configure --help` for the current list.)

The default collation may also be specified. MySQL uses the `latin1_swedish_ci` collation by default. To change this, use the `--with-collation` option:

```
shell> ./configure --with-collation=COLLATION
```

To change both the character set and the collation, use both the `--with-charset` and `--with-collation` options. The collation must be a legal collation for the character set. (Use the `SHOW COLLATION` statement to determine which collations are available for each character set.)

With the `configure` option `--with-extra-Charsets=LIST`, you can define which additional character sets should be compiled into the server. `LIST` is one of the following:

- A list of character set names separated by spaces
- `complex` to include all character sets that can't be dynamically loaded
- `all` to include all character sets into the binaries

Clients that want to convert characters between the server and the client should use the `SET NAMES` statement. See [Section 5.1.4, “Server System Variables”](#), and [Section 9.1.4, “Connection Character Sets and Collations”](#).

- To configure MySQL with debugging code, use the `--with-debug` option:

```
shell> ./configure --with-debug
```

This causes a safe memory allocator to be included that can find some errors and that provides output about what is happening. See [MySQL Internals: Porting](#).

As of MySQL 5.1.12, using `--with-debug` to configure MySQL with debugging support enables you to use the `-debug="d,parser_debug"` option when you start the server. This causes the Bison parser that is used to process SQL statements to dump a parser trace to the server's standard error output. Typically, this output is written to the error log.

- To cause the Debug Sync facility to be compiled into the server, use the `--enable-debug-sync` option. This facility is used for testing and debugging. When compiled in, Debug Sync is disabled by default. To enable it, start mysqld with the `-debug-sync-timeout=N` option, where `N` is a timeout value greater than 0. (The default value is 0, which disables Debug Sync.) `N` becomes the default timeout for individual synchronization points.

Debug Sync is also compiled in if you configure with the `--with-debug` option (which implies `--enable-debug-sync`), unless you also use the `--disable-debug-sync` option.

For a description of the Debug Sync facility and how to use synchronization points, see [MySQL Internals: Test Synchronization](#).

The `--enable-debug-sync` and `--disable-debug-sync` options were added in MySQL 5.1.41.

- If your client programs are using threads, you must compile a thread-safe version of the MySQL client library with the `--enable-thread-safe-client` configure option. This creates a `libmysqlclient_r` library with which you should link your threaded applications. See [Section 21.9.16.2, “How to Make a Threaded Client”](#).
- Some features require that the server be built with compression library support, such as the `COMPRESS()` and `UNCOMPRESS()` functions, and compression of the client/server protocol. The `--with-zlib-dir=no|bundled|DIR` option provides control over compression library support. The value `no` explicitly disables compression support. `bundled` causes the `zlib` library bundled in the MySQL sources to be used. A `DIR` path name specifies the directory in which to find the compression library sources.
- It is possible to build MySQL with large table support using the `--with-big-tables` option.

This option causes the variables that store table row counts to be declared as `unsigned long long` rather than `unsigned long`. This enables tables to hold up to approximately  $1.844E+19$  ( $(2^{32})^2$ ) rows rather than  $2^{32}$  (~ $4.295E+09$ ) rows. Previously it was necessary to pass `-DBIG_TABLES` to the compiler manually in order to enable this feature.

- Run `configure` with the `--disable-grant-options` option to cause the `--bootstrap`, `--skip-grant-tables`, and `--init-file` options for `mysqld` to be disabled. For Windows, the `configure.js` script recognizes the `DISABLE_GRANT_OPTIONS` flag, which has the same effect. The capability is available as of MySQL 5.1.15.

- This option allows MySQL Community Server features to be enabled. Additional options may be required for individual features, such as `--enable-profiling` to enable statement profiling. This option was added in MySQL 5.1.24. It is enabled by default as of MySQL 5.1.28; to disable it, use `--disable-community-features`.
- When given with `--enable-community-features`, the `--enable-profiling` option enables the statement profiling capability exposed by the `SHOW PROFILE` and `SHOW PROFILES` statements. (See [Section 12.4.5.33, “SHOW PROFILE Syntax”](#).) This option was added in MySQL 5.1.24. It is enabled by default as of MySQL 5.1.28; to disable it, use `--disable-profiling`.
- See [Section 2.1, “General Installation Guidance”](#), for options that pertain to particular operating systems.
- See [Section 5.5.6.2, “Using SSL Connections”](#), for options that pertain to configuring MySQL to support secure (encrypted) connections.
- Several `configure` options apply to plugin selection and building:

```
--with-plugins=PLUGIN[,PLUGIN]...
--with-plugins=GROUP
--with-plugin=PLUGIN
--without-plugin=PLUGIN
```

`PLUGIN` is an individual plugin name such as `csv` or `archive`.

As shorthand, `GROUP` is a configuration group name such as `none` (select no plugins) or `all` (select all plugins).

You can build a plugin as static (compiled into the server) or dynamic (built as a dynamic library that must be installed using the `INSTALL PLUGIN` statement before it can be used). Some plugins might not support static or dynamic build.

`configure --help` shows the following information pertaining to plugins:

- The plugin-related options
- The names of all available plugins
- For each plugin, a description of its purpose, which build types it supports (static or dynamic), and which plugin groups it is a part of.

`--with-plugins` can take a list of one or more plugin names separated by commas, or a plugin group name. The named plugins are configured to be built as static plugins.

`--with-plugin=PLUGIN` configures the given plugin to be built as a static plugin.

`--without-plugin=PLUGIN` disables the given plugin from being built.

If a plugin is named both with a `--with` and `--without` option, the result is undefined.

For any plugin that is not explicitly selected or disabled, it is selected to be built dynamically if it supports dynamic build, and not built if it does not support dynamic build. (Thus, in the case that no plugin options are given, all plugins that support dynamic build are selected to be built as dynamic plugins. Plugins that do not support dynamic build are not built.)

## 2.3.4. Installing from the Development Source Tree

### Caution

You should read this section only if you are interested in helping us test our new code. If you just want to get MySQL up and running on your system, you should use a standard release distribution (either a binary or source distribution).

To obtain the most recent development source tree, you must have Bazaar installed. You can obtain Bazaar from the [Bazaar VCS Web site](#). Bazaar is supported by any platform that supports Python, and is therefore compatible with any Linux, Unix, Windows or Mac OS X host. Instructions for downloading and installing Bazaar on the different platforms are available on the Bazaar Web site.

All MySQL projects are hosted on [Launchpad](#). MySQL projects, including MySQL server, MySQL Workbench, and others are available from the [Sun/MySQL Engineering](#) page. For the repositories related only to MySQL server, see the [MySQL Server](#) page.

To build under Unix/Linux, you must have the following tools installed:

- GNU `make`, available from <http://www.gnu.org/software/make/>. Although some platforms come with their own `make` implementations, it is highly recommended that you use GNU `make`. It may already be available on your system as `gmake`.

- `autoconf` 2.58 (or newer), available from <http://www.gnu.org/software/autoconf/>.
- `automake` 1.8.1, available from <http://www.gnu.org/software/automake/>.
- `libtool` 1.5, available from <http://www.gnu.org/software/libtool/>.
- `m4`, available from <http://www.gnu.org/software/m4/>.
- `bison`, available from <http://www.gnu.org/software/bison/>. You should use the latest version of bison where possible. Version 1.75 and version 2.1 are known to work. There have been reported problems with `bison` 1.875. If you experience problems, upgrade to a later, rather than earlier, version. Versions of `bison` older than 1.75 may report this error:

```
sql_yacc.yy:#####: fatal error: maximum table size (32767) exceeded
```

The maximum table size is not actually exceeded; the error is caused by bugs in older versions of `bison`.

To build under Windows you must have Microsoft Visual C++ 2005 Express Edition, Visual Studio .Net 2003 (7.1), or Visual Studio 2005 (8.0) compiler system.

Once the necessary tools are installed, you must create a local branch of the MySQL source code on your machine:

1. To obtain a copy of the MySQL source code, you must create a new Bazaar branch. If you do not already have a Bazaar repository directory set up, you need to initialize a new directory:

```
shell> mkdir mysql-server
shell> bzr init-repo --trees mysql-server
```

2. Once you have an initialized directory, you can `branch` from the public MySQL server repositories to create a local source tree. To create a branch of a specific version:

```
shell> cd mysql-server
shell> bzr branch lp:mysql-server/5.1 mysql-5.1
```

3. The initial download will take some time to complete, depending on the speed of your connection. Please be patient. Once you have downloaded the first tree, additional trees should take significantly less time to download.
4. When building from the Bazaar branch, you may want to create a copy of your active branch so that you can make configuration and other changes without affecting the original branch contents. You can achieve this by branching from the original branch:

```
shell> bzr branch mysql-5.1 mysql-5.1-build
```

5. To obtain changes made after you have set up the branch initially, update it using the `pull` option periodically. Use this command in the top-level directory of the local copy:

```
shell> bzr pull
```

You can examine the changeset comments for the tree by using the `log` option to `bzr`:

```
shell> bzr log
```

You can also browse changesets, comments, and source code online. To browse this information for MySQL 5.1, go to the Launchpad [MySQL Server](#) page.

If you see diffs (changes) or code that you have a question about, do not hesitate to send email to the MySQL `internals` mailing list. See [Section 1.6.1, “MySQL Mailing Lists”](#). Also, if you think you have a better idea on how to do something, send an email message to the list with a patch.

After you have the local branch, you can build MySQL server from the source code. On Windows, the build process is different from Unix/Linux: see [Section 2.4.9, “Installing MySQL from Source on Windows”](#).

On Unix/Linux, use the `autoconf` system to create the `configure` script so that you can configure the build environment before building. The following example shows the typical commands required to build MySQL from a source tree.

1. Change location to the top-level directory of the source tree; replace `mysql-5.1` with the appropriate directory name.

```
shell> cd mysql-5.1
```

2. Prepare the source tree for configuration.

Prior to MySQL 5.1.12, you must separately configure the [InnoDB](#) storage engine. Run the following command from the main source directory:

```
shell> (cd storage/innobase; autoreconf --force --install)
```

You can omit the previous command for MySQL 5.1.12 and later, or if you do not require [InnoDB](#) support.

Prepare the remainder of the source tree:

```
shell> autoreconf --force --install
```

As an alternative to the preceding `autoreconf` command, you can use `BUILD/autorun.sh`, which acts as a shortcut for the following sequence of commands:

```
shell> aclocal; autoheader
shell> libtoolize --automake --force
shell> automake --force --add-missing; autoconf
```

If you get some strange errors during this stage, verify that you have the correct version of `libtool` installed.

3. Configure the source tree and compile MySQL:

```
shell> ./configure # Add your favorite options here
shell> make
```

For a description of some `configure` options, see [Section 2.3.3, “Typical configure Options”](#).

A collection of configuration scripts is located in the `BUILD/` subdirectory. For example, you may find it more convenient to use the `BUILD/compile-pentium-debug` script than the preceding set of shell commands. To compile on a different architecture, modify the script by removing flags that are Pentium-specific, or use another script that may be more appropriate. These scripts are provided on an “as-is” basis. They are not supported and their contents may change from release to release.

4. When the build is done, run `make install`. Be careful with this on a production machine; the command may overwrite your live release installation. If you already have MySQL installed and do not want to overwrite it, run `./configure` with values for the `--prefix`, `--with-tcp-port`, and `--with-unix-socket-path` options different from those used for your production server.
5. Play hard with your new installation and try to make the new features crash. Start by running `make test`. See [Section 22.1.2, “MySQL Test Suite”](#).
6. If you have gotten to the `make` stage, but the distribution does not compile, please enter the problem into our bugs database using the instructions given in [Section 1.7, “How to Report Bugs or Problems”](#). If you have installed the latest versions of the required GNU tools, and they crash trying to process our configuration files, please report that also. However, if you get a `command not found` error or a similar problem for `aclocal`, `configure`, or other required tools, do not report it. Instead, make sure that all the required tools are installed and that your `PATH` variable is set correctly so that your shell can find them.

## 2.3.5. Dealing with Problems Compiling MySQL

All MySQL programs compile cleanly for us with no warnings on Solaris or Linux using `gcc`. On other systems, warnings may occur due to differences in system include files. For other problems, check the following list.

The solution to many problems involves reconfiguring. If you do need to reconfigure, take note of the following:

- If `configure` is run after it has previously been run, it may use information that was gathered during its previous invocation. This information is stored in `config.cache`. When `configure` starts up, it looks for that file and reads its contents if it exists, on the assumption that the information is still correct. That assumption is invalid when you reconfigure.
- Each time you run `configure`, you must run `make` again to recompile. However, you may want to remove old object files from previous builds first because they were compiled using different configuration options.

To prevent old configuration information or object files from being used, run these commands before re-running `configure`:

```
shell> rm config.cache
shell> make clean
```

Alternatively, you can run `make distclean`.

The following list describes some of the problems when compiling MySQL that have been found to occur most often:

- If you get errors such as the ones shown here when compiling `sql_yacc.cc`, you probably have run out of memory or swap space:

```
Internal compiler error: program cc1plus got fatal signal 11
Out of virtual memory
Virtual memory exhausted
```

The problem is that `gcc` requires a huge amount of memory to compile `sql_yacc.cc` with inline functions. Try running `configure` with the `--with-low-memory` option:

```
shell> ./configure --with-low-memory
```

This option causes `-fno-inline` to be added to the compile line if you are using `gcc` and `-O0` if you are using something else. You should try the `--with-low-memory` option even if you have so much memory and swap space that you think you can't possibly have run out. This problem has been observed to occur even on systems with generous hardware configurations, and the `--with-low-memory` option usually fixes it.

- By default, `configure` picks `c++` as the compiler name and GNU `c++` links with `-lg++`. If you are using `gcc`, that behavior can cause problems during configuration such as this:

```
configure: error: installation or configuration problem:
C++ compiler cannot create executables.
```

You might also observe problems during compilation related to `g++`, `libg++`, or `libstdc++`.

One cause of these problems is that you may not have `g++`, or you may have `g++` but not `libg++`, or `libstdc++`. Take a look at the `config.log` file. It should contain the exact reason why your C++ compiler didn't work. To work around these problems, you can use `gcc` as your C++ compiler. Try setting the environment variable `CXX` to "`gcc -O3`". For example:

```
shell> CXX="gcc -O3" ./configure
```

This works because `gcc` compiles C++ source files as well as `g++` does, but does not link in `libg++` or `libstdc++` by default.

Another way to fix these problems is to install `g++`, `libg++`, and `libstdc++`. However, do not use `libg++` or `libstdc++` with MySQL because this only increases the binary size of `mysqld` without providing any benefits. Some versions of these libraries have also caused strange problems for MySQL users in the past.

- If your compile fails with errors such as any of the following, you must upgrade your version of `make` to GNU `make`:

```
making all in mit-pthreads
make: Fatal error in reader: Makefile, line 18:
Badly formed macro assignment
```

Or:

```
make: file `Makefile' line 18: Must be a separator (:
```

Or:

```
pthread.h: No such file or directory
```

Solaris and FreeBSD are known to have troublesome `make` programs.

GNU `make` 3.75 is known to work.

- If you want to define flags to be used by your C or C++ compilers, do so by adding the flags to the `CFLAGS` and `CXXFLAGS` environment variables. You can also specify the compiler names this way using `CC` and `CXX`. For example:

```
shell> CC=gcc
```

```
shell> CFLAGS=-O3
shell> CXX=gcc
shell> CXXFLAGS=-O3
shell> export CC CFLAGS CXX CXXFLAGS
```

See [Section 2.2, “Installing MySQL from Generic Binaries on Unix/Linux”](#), for a list of flag definitions that have been found to be useful on various systems.

- If you get errors such as those shown here when compiling `mysqld`, `configure` did not correctly detect the type of the last argument to `accept()`, `getsockname()`, or `getpeername()`:

```
cxx: Error: mysqld.cc, line 645: In this statement, the referenced
 type of the pointer value ''length'' is ''unsigned long'',
 which is not compatible with 'int'.
new_sock = accept(sock, (struct sockaddr *)&cAddr, &length);
```

To fix this, edit the `config.h` file (which is generated by `configure`). Look for these lines:

```
/* Define as the base type of the last arg to accept */
#define SOCKET_SIZE_TYPE XXX
```

Change `XXX` to `size_t` or `int`, depending on your operating system. (You must do this each time you run `configure` because `configure` regenerates `config.h`.)

- The `sql_yacc.cc` file is generated from `sql_yacc.yy`. Normally, the build process does not need to create `sql_yacc.cc` because MySQL comes with a pre-generated copy. However, if you do need to re-create it, you might encounter this error:

```
"sql_yacc.yy", line xxx fatal: default action causes potential...
```

This is a sign that your version of `yacc` is deficient. You probably need to install `bison` (the GNU version of `yacc`) and use that instead.

- On Debian Linux 3.0, you need to install `gawk` instead of the default `mawk`.
- If you need to debug `mysqld` or a MySQL client, run `configure` with the `--with-debug` option, and then recompile and link your clients with the new client library. See [MySQL Internals: Porting](#).
- If you get a compilation error on Linux (for example, SuSE Linux 8.1 or Red Hat Linux 7.3) similar to the following one, you probably do not have `g++` installed:

```
libmysql.c:1329: warning: passing arg 5 of `gethostbyname_r' from
incompatible pointer type
libmysql.c:1329: too few arguments to function `gethostbyname_r'
libmysql.c:1329: warning: assignment makes pointer from integer
without a cast
make[2]: *** [libmysql.lo] Error 1
```

By default, the `configure` script attempts to determine the correct number of arguments by using `g++` (the GNU C++ compiler). This test yields incorrect results if `g++` is not installed. There are two ways to work around this problem:

- Make sure that the GNU C++ `g++` is installed. On some Linux distributions, the required package is called `gpp`; on others, it is named `gcc-c++`.
- Use `gcc` as your C++ compiler by setting the `CXX` environment variable to `gcc`:

```
export CXX=gcc
```

You must run `configure` again after making either of those changes.

## 2.4. Installing MySQL on Microsoft Windows

MySQL for Microsoft Windows is available in a number of different forms. A Microsoft Windows operating system such as Windows 2000, Windows XP, Windows Vista, Windows 7, Windows Server 2003, or Windows Server 2008. Both 32-bit and 64-bit versions are supported.

In addition to running MySQL as a standard application, you can also run the MySQL server as a Windows service. By using a service you can monitor and control the operation of the server through the standard Windows service management tools. For more information, see [Section 2.4.5.7, “Starting MySQL Server as a Microsoft Windows Service”](#).

Generally, you should install MySQL on Windows using an account that has administrator rights. Otherwise, you may encounter problems with certain operations such as editing the `PATH` environment variable or accessing the `Service Control Manager`. Once installed, MySQL does not need to be executed using a user with Administrator privileges.

For a list of limitations within the Windows version of MySQL, see [Section D.7.3, “Windows Platform Limitations”](#).

In addition to the MySQL Server package, you may need or want additional components to use MySQL with your application or development environment. These include, but are not limited to:

- If you plan to connect to the MySQL server using ODBC, you need a Connector/ODBC driver. For more information, including installation and configuration instructions, see [Section 21.1, “MySQL Connector/ODBC”](#).
- If you plan to use MySQL server with .NET applications, you need the Connector/.NET driver. For more information, including installation and configuration instructions, see [Section 21.2, “MySQL Connector/.NET”](#).

MySQL distributions for Windows can be downloaded from <http://dev.mysql.com/downloads/>. See [Section 2.1.3, “How to Get MySQL”](#).

MySQL for Windows is available in several distribution formats, detailed below. Generally speaking, you should use a binary distribution that includes an installer. It is simpler to use than the others, and you need no additional tools to get MySQL up and running. The installer for the Windows version of MySQL, combined with a GUI Config Wizard, automatically installs MySQL, creates an option file, starts the server, and secures the default user accounts.

- Binary installer distribution. The installable distribution comes packaged as a Microsoft Windows Installer (MSI) package that you can install manually or automatically on your systems. Two formats are available, an essentials package that contains all the files you need to install and configure MySQL, but no additional components, and a complete package that includes MySQL, configuration tools, benchmarks and other components. For more information on the specific differences, see [Section 2.4.2, “Choosing the Installation Package for Microsoft Windows”](#)

For instructions on installing MySQL using one of the MSI installation packages, see [Section 2.4.3, “Installing MySQL on Windows Using the MSI Package”](#).

- Standard binary distribution format packaged as a Zip file containing all of the necessary files that you unpack into your chosen location. This package contains all of the files in the full Windows MSI Installer package, but does not include an installation program.

For instructions on installing MySQL using the Zip file, see [Section 2.4.5, “Installing MySQL on Microsoft Windows from a noinstall Zip Archive”](#).

- The source distribution contains all the code and support files for building the executables using the Visual Studio compiler system.

For instructions on building MySQL from source on Windows, see [Section 2.4.9, “Installing MySQL from Source on Windows”](#).

## MySQL on Windows considerations:

- **Large Table Support**

If you need tables with a size larger than 4GB, install MySQL on an NTFS or newer file system. Do not forget to use `MAX_ROWS` and `AVG_ROW_LENGTH` when you create tables. See [Section 12.1.17, “CREATE TABLE Syntax”](#).

- **MySQL and Virus Checking Software**

Using virus scanning software such as Norton/Symantec Anti-Virus on directories containing MySQL data and temporary tables can cause issues, both in terms of the performance of MySQL and the virus-scanning software mis-identifying the contents of the files as containing spam. This is because of the fingerprinting mechanism used by the virus scanning software, and the way in which MySQL rapidly updates different files, which may be identified as a potential security risk.

After installing MySQL Server, it is recommended that you disable virus scanning on the main directory (`datadir`) being used to store your MySQL table data. There is usually a system built into the virus scanning software to permit certain directories to be specifically ignored during virus scanning.

In addition, by default, MySQL creates temporary files in the standard Windows temporary directory. To prevent the temporary files also being scanned, you should configure a separate temporary directory for MySQL temporary files and add this to the virus scanning exclusion list. To do this, add a configuration option for the `tmpdir` parameter to your `my.ini` configuration

file. For more information, see [Section 2.4.5.2, “Creating an Option File”](#).

## 2.4.1. MySQL Installation Layout on Microsoft Windows

For MySQL 5.1 on Windows, the default installation directory is `C:\Program Files\MySQL\MySQL Server 5.1`. Some Windows users prefer to install in `C:\mysql`, the directory that formerly was used as the default. However, the layout of the sub-directories remains the same.

For MySQL 5.1.23 and earlier, all of the files are located within this parent directory, using the following structure:

**Table 2.5. Installation Layout for Windows using MySQL 5.1.23 and earlier**

| Directory             | Contents of Directory                                                                                                                 |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <code>bin</code>      | Client programs and the <code>mysqld</code> server                                                                                    |
| <code>data</code>     | Log files, databases                                                                                                                  |
| <code>Docs</code>     | Manual in CHM format                                                                                                                  |
| <code>examples</code> | Example programs and scripts                                                                                                          |
| <code>include</code>  | Include (header) files                                                                                                                |
| <code>lib</code>      | Libraries                                                                                                                             |
| <code>scripts</code>  | Utility scripts                                                                                                                       |
| <code>share</code>    | Miscellaneous support files, including error messages, character set files, sample configuration files, SQL for database installation |

For MySQL 5.1.24 and later, the default location of data directory was changed. The remainder of the directory structure remains the same:

**Table 2.6. Installation Layout for Windows using MySQL 5.1.24 and later**

| Directory                                                               | Contents of Directory                                                                                                                 |
|-------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <code>bin</code>                                                        | Client programs and the <code>mysqld</code> server                                                                                    |
| <code>C:\Documents and Settings\All Users\Application Data\MySQL</code> | Log files, databases (Windows XP, Windows Server 2003)                                                                                |
| <code>C:\ProgramData\MySQL</code>                                       | Log files, databases (Windows 7, Windows Server 2008)                                                                                 |
| <code>Docs</code>                                                       | Manual in CHM format                                                                                                                  |
| <code>examples</code>                                                   | Example programs and scripts                                                                                                          |
| <code>include</code>                                                    | Include (header) files                                                                                                                |
| <code>lib</code>                                                        | Libraries                                                                                                                             |
| <code>scripts</code>                                                    | Utility scripts                                                                                                                       |
| <code>share</code>                                                      | Miscellaneous support files, including error messages, character set files, sample configuration files, SQL for database installation |

## 2.4.2. Choosing the Installation Package for Microsoft Windows

For MySQL 5.1, there are three installation packages to choose from when installing MySQL on Windows:

**Table 2.7. Microsoft Windows MySQL Installation package comparison**

| Feature                             | Packaging  |          |                  |
|-------------------------------------|------------|----------|------------------|
|                                     | Essentials | Complete | Zip (No-install) |
| Installer                           | Yes        | Yes      | No               |
| Directory-only                      |            |          |                  |
| MySQL Server Instance Config Wizard | Yes        | Yes      | No               |
| Test Suite                          | No         | Yes      | Yes              |
| MySQL Server                        | Yes        | Yes      | Yes              |

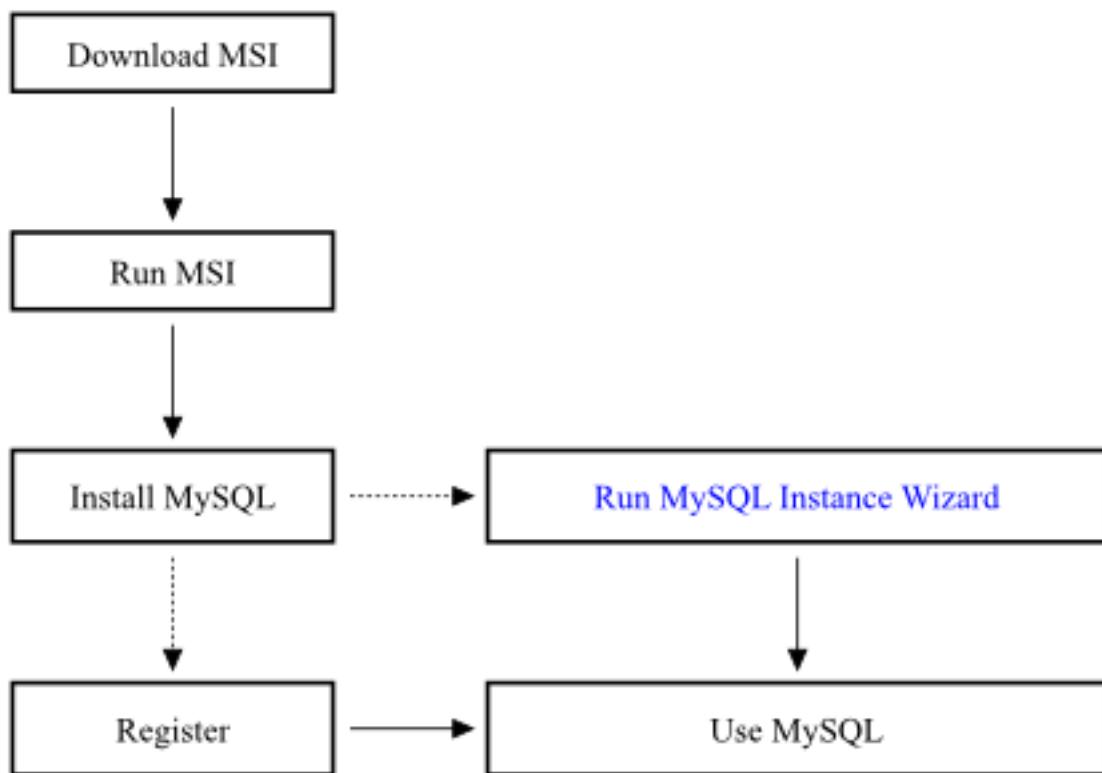

| Feature               | Packaging  |          |                  |
|-----------------------|------------|----------|------------------|
|                       | Essentials | Complete | Zip (No-install) |
| MySQL Client Programs | Yes        | Yes      | Yes              |
| C Headers/Libraries   | Yes        | Yes      | Yes              |
| Embedded Server       | No         | Optional | Yes              |
| Scripts and Examples  | No         | Optional | Yes              |

In the above table:

- *Yes* indicates that the component is installed by default.
- *No* indicates that the component is not installed or included.
- *Optional* indicates that the component is included with the package, but not installed unless explicitly requested using the Custom installation mode.

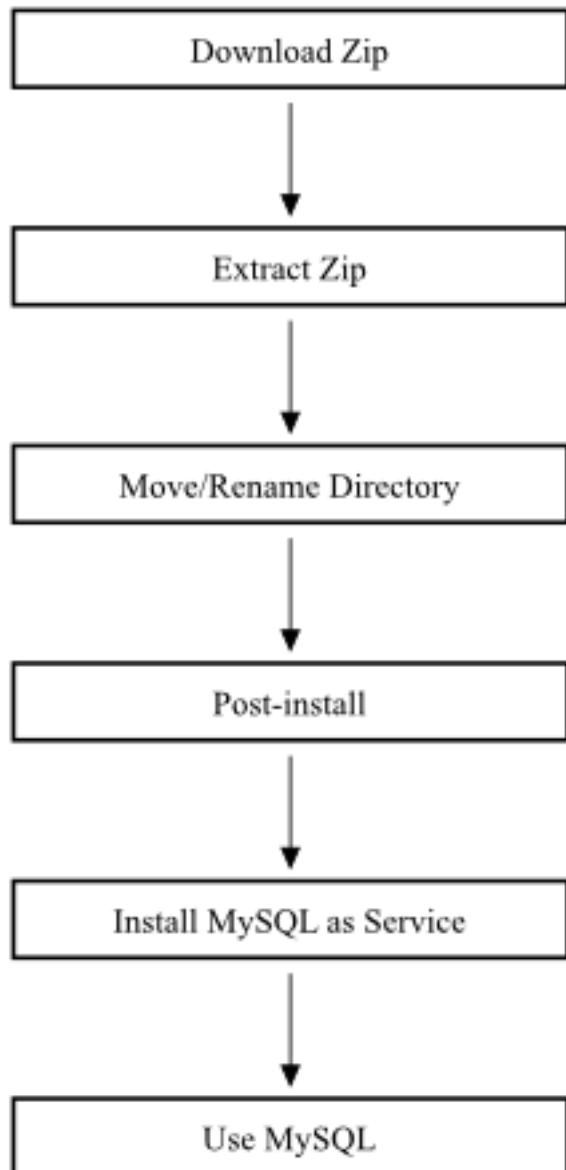

The workflow for installing using the MSI installer is shown below:

**Figure 2.1. Installation Workflow for Windows using MSI**

The workflow for installing using the MSI installer is shown below:

**Figure 2.2. Installation Workflow for Windows using Zip**

**Note**

For the Essentials and Complete packages in the MSI installer, you can select individual components to be installed by using the Custom mode, including disable the components configured for installation by default.

Full details on the components are suggested uses are provided below for reference:

- **Windows Essentials** : This package has a file name similar to `mysql-essential-5.1.52-win32.msi` and is supplied as a Microsoft Installer (MSI) package. The package includes the minimum set of files needed to install MySQL on Windows, including the MySQL Server Instance Config Wizard. This package does not include optional components such as the embedded server, developer headers and libraries or benchmark suite.

To install using this package, see [Section 2.4.3, “Installing MySQL on Windows Using the MSI Package”](#).

- **Windows MSI Installer (Complete)**: This package has a file name similar to `mysql-5.1.52-win32.zip` and contains all files needed for a complete Windows installation, including the MySQL Server Instance Config Wizard. This package includes optional components such as the embedded server and benchmark suite.

To install using this package, see [Section 2.4.3, “Installing MySQL on Windows Using the MSI Package”](#).

- **Without installer:** This package has a file name similar to `mysql-noinstall-5.1.52-win32.zip` and contains all the files found in the Complete install package, with the exception of the MySQL Server Instance Config Wizard. This package does not include an automated installer, and must be manually installed and configured.

The Essentials package is recommended for most users. Both the Essentials and Complete distributions are available as an `.msi` file for use with the Windows Installer. The Noinstall distribution is packaged as Zip archives. To use Zip archives, you must have a tool that can unpack `.zip` files.

When using the MSI installers you can automate the installation process. For more information, see [Section 2.4.3.2, “Automating MySQL Installation on Microsoft Windows using the MSI Package”](#). To automate the creation of a MySQL instance, see [Section 2.4.4.13, “MySQL Server Instance Config Wizard: Creating an Instance from the Command Line”](#).

Your choice of install package affects the installation process you must follow. If you choose to install either the Essentials or Complete install packages, see [Section 2.4.3, “Installing MySQL on Windows Using the MSI Package”](#). If you choose to install MySQL from the Noinstall archive, see [Section 2.4.5, “Installing MySQL on Microsoft Windows from a noinstall Zip Archive”](#).

### 2.4.3. Installing MySQL on Windows Using the MSI Package

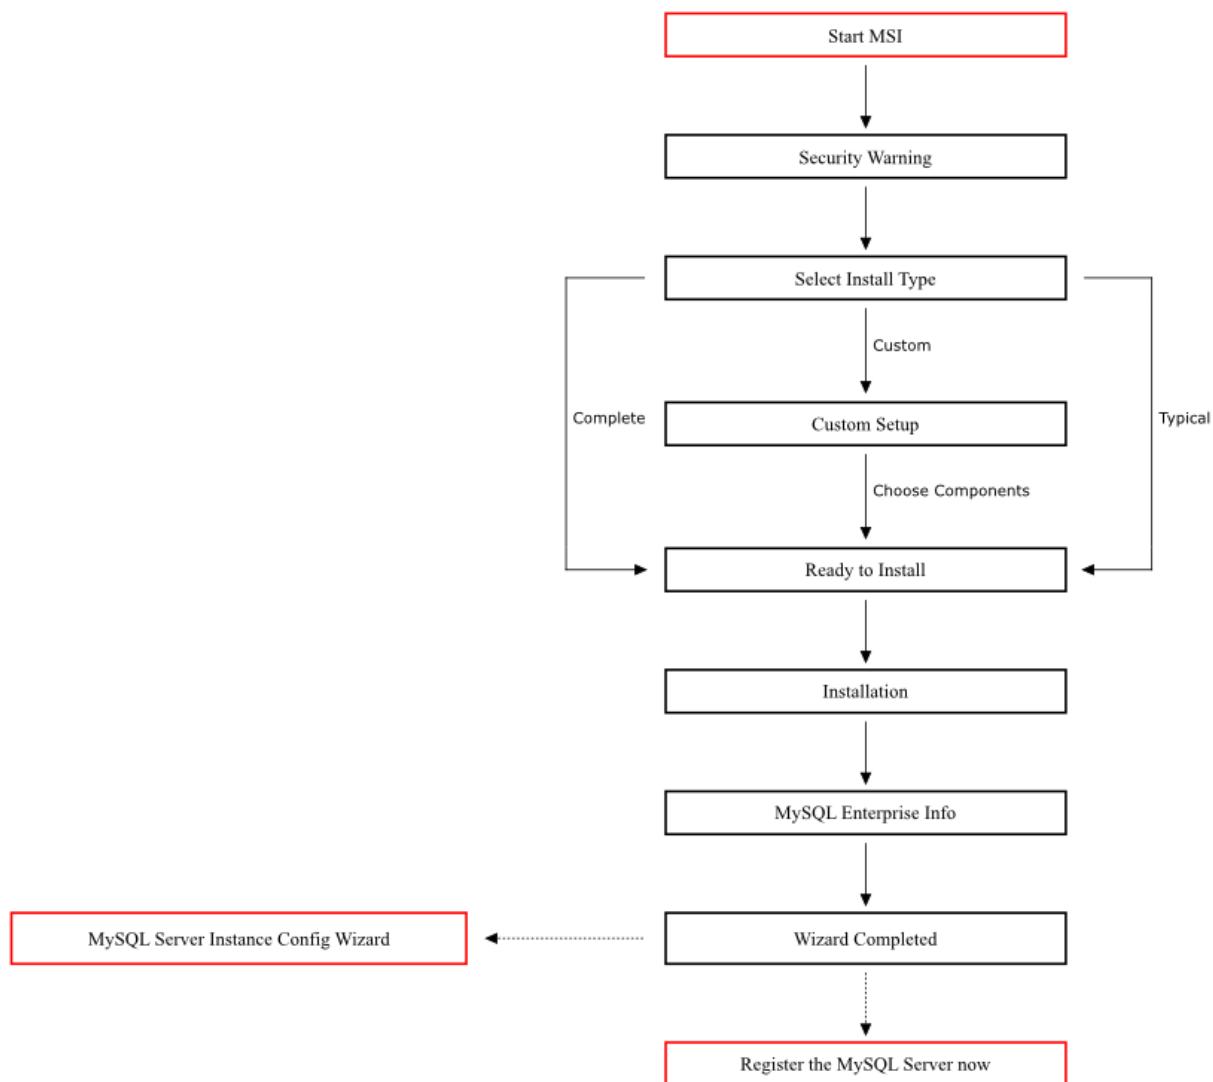

The MSI package is designed to install and configure MySQL in such a way that you can immediately get started using MySQL.

The MySQL Installation Wizard and MySQL Config Wizard are available in the Essentials and Complete install packages. They are recommended for most standard MySQL installations. Exceptions include users who need to install multiple instances of MySQL on a single server host and advanced users who want complete control of server configuration.

- For information on installing using the GUI MSI installer process, see [Section 2.4.3, “Installing MySQL on Windows Using the MSI Package”](#).
- For information on installing using the command line using the MSI package, see [Section 2.4.3.2, “Automating MySQL Installation on Microsoft Windows using the MSI Package”](#).
- If you have previously installed MySQL using the MSI package and want to remove MySQL, see [Section 2.4.3.3, “Removing MySQL When Installed from the MSI Package”](#).

The workflow sequence for using the installer is shown in the figure below:

**Figure 2.3. Installation Workflow for Windows using MSI Installer**

### Note

Microsoft Windows XP and later include a firewall which specifically blocks ports. If you plan on using MySQL through a network port then you should open and create an exception for this port before performing the installation. To check and if necessary add an exception to the firewall settings:

1. First ensure that you are logged in as an Administrator or a user with Administrator privileges.
2. Go to the **CONTROL PANEL**, and double click the **WINDOWS FIREWALL** icon.
3. Choose the **ALLOW A PROGRAM THROUGH WINDOWS FIREWALL** option and click the ADD PORT button.
4. Enter **MySQL** into the **NAME** text box and **3306** (or the port of your choice) into the **PORT NUMBER** text box.
5. Also ensure that the **TCP** protocol radio button is selected.
6. If you wish, you can also limit access to the MySQL server by choosing the **CHANGE SCOPE** button.
7. Confirm your choices by clicking the **OK** button.

Additionally, when running the MySQL Installation Wizard on Windows Vista, ensure that you are logged in as a user with administrative rights.

### Note

When using Windows Vista, you may want to disable User Account Control (UAC) before performing the installation. If you do not do so, then MySQL may be identified as a security risk, which will mean that you need to enable MySQL. You can disable the security checking by following these instructions:

1. Open **CONTROL PANEL**.
2. Under the **USER ACCOUNTS AND FAMILY SAFETY**, select **ADD OR REMOVE USER ACCOUNTS**.
3. Click the **GOT TO THE MAIN USER ACCOUNTS PAGE** link.
4. Click on **TURN USER ACCOUNT CONTROL ON OR OFF**. You may be prompted to provide permission to change this setting. Click **CONTINUE**.
5. Deselect or uncheck the checkbox next to **USE USER ACCOUNT CONTROL (UAC) TO HELP PROTECT YOUR COMPUTER**. Click **OK** to save the setting.

You will need to restart to complete the process. Click **RESTART NOW** to reboot the machine and apply the changes. You can then follow the instructions below for installing Windows.

### 2.4.3.1. Using the MySQL Installation Wizard for Microsoft Windows

MySQL Installation Wizard is an installer for the MySQL server that uses the latest installer technologies for Microsoft Windows. The MySQL Installation Wizard, in combination with the MySQL Config Wizard, enables a user to install and configure a MySQL server that is ready for use immediately after installation.

The MySQL Installation Wizard uses the standard Microsoft Installer Engine (MSI) system is the standard installer for all MySQL server distributions. See [Section 2.4.3.1.6, “MySQL Installation Wizard: Upgrading MySQL”](#), for more information on upgrading from a previous version.

If you are upgrading an installation from MySQL 5.1.31 or earlier to MySQL 5.1.32 or later, read the notes provided in [Section 2.4.3.1.6, “MySQL Installation Wizard: Upgrading MySQL”](#).

The Microsoft Windows Installer Engine was updated with the release of Windows XP; those using a previous version of Windows can reference [this Microsoft Knowledge Base article](#) for information on upgrading to the latest version of the Windows Installer Engine.

In addition, Microsoft has introduced the WiX (Windows Installer XML) toolkit. This is the first highly acknowledged Open Source project from Microsoft. We have switched to WiX because it is an Open Source project and it enables us to handle the complete Windows installation process in a flexible manner using scripts.

Improving the MySQL Installation Wizard depends on the support and feedback of users like you. If you find that the MySQL Installation Wizard is lacking some feature important to you, or if you discover a bug, please report it in our bugs database using the instructions given in [Section 1.7, “How to Report Bugs or Problems”](#).

#### 2.4.3.1.1. MySQL Installation Wizard: Downloading and Starting

The MySQL installation packages can be downloaded from <http://dev.mysql.com/downloads/>. If the package you download is contained within a Zip archive, you need to extract the archive first.

The process for starting the wizard depends on the contents of the installation package you download. If there is a `setup.exe` file present, double-click it to start the installation process. If there is an `.msi` file present, double-click it to start the installation process.

#### 2.4.3.1.2. MySQL Installation Wizard: Choosing an Install Type

There are three installation types available: **Typical**, **Complete**, and **Custom**.

The **Typical** installation type installs the MySQL server, the `mysql` command-line client, and the command-line utilities. The command-line clients and utilities include `mysqldump`, `myisamchk`, and several other tools to help you manage the MySQL server.

The **Complete** installation type installs all components included in the installation package. The full installation package includes components such as the embedded server library, the benchmark suite, support scripts, and documentation.

The **Custom** installation type gives you complete control over which packages you wish to install and the installation path that is used. See [Section 2.4.3.1.3, “MySQL Installation Wizard: The Custom Install Dialog”](#), for more information on performing a custom install.

If you choose the **Typical** or **Complete** installation types and click the NEXT button, you advance to the confirmation screen to verify your choices and begin the installation. If you choose the **Custom** installation type and click the NEXT button, you advance to the custom installation dialog, described in Section 2.4.3.1.3, “MySQL Installation Wizard: The Custom Install Dialog”.

#### 2.4.3.1.3. MySQL Installation Wizard: The Custom Install Dialog

If you wish to change the installation path or the specific components that are installed by the MySQL Installation Wizard, choose the **Custom** installation type.

A tree view on the left side of the custom install dialog lists all available components. Components that are not installed have a red X icon; components that are installed have a gray icon. To change whether a component is installed, click that component's icon and choose a new option from the drop-down list that appears.

You can change the default installation path by clicking the CHANGE... button to the right of the displayed installation path.

After choosing your installation components and installation path, click the NEXT button to advance to the confirmation dialog.

#### 2.4.3.1.4. MySQL Installation Wizard: The Confirmation Dialog

Once you choose an installation type and optionally choose your installation components, you advance to the confirmation dialog. Your installation type and installation path are displayed for you to review.

To install MySQL if you are satisfied with your settings, click the INSTALL button. To change your settings, click the BACK button. To exit the MySQL Installation Wizard without installing MySQL, click the CANCEL button.

In MySQL 5.1.47 and earlier, after installation is complete, you have the option of registering with the MySQL web site. Registration gives you access to post in the MySQL forums at [forums.mysql.com](http://forums.mysql.com), along with the ability to report bugs at [bugs.mysql.com](http://bugs.mysql.com) and to subscribe to our newsletter.

The final screen of the installer provides a summary of the installation and gives you the option to launch the MySQL Config Wizard, which you can use to create a configuration file, install the MySQL service, and configure security settings.

#### 2.4.3.1.5. MySQL Installation Wizard: Changes Made

Once you click the INSTALL button, the MySQL Installation Wizard begins the installation process and makes certain changes to your system which are described in the sections that follow.

##### Changes to the Registry

The MySQL Installation Wizard creates one Windows registry key in a typical install situation, located in `HKEY_LOCAL_MACHINE\SOFTWARE\MySQL AB`. For 64-bit Windows, the registry location is `HKEY_LOCAL_MACHINE\SOFTWARE\Wow6432Node\MySQL AB`. A server version specific entry will be created for each major version of MySQL that you install.

The MySQL Installation Wizard creates a key named after the major version of the server that is being installed, such as `MySQL Server 5.1`. It contains two string values, `Location` and `Version`. The `Location` string contains the path to the installation directory. In a default installation it contains `C:\Program Files\MySQL\MySQL Server 5.1\`. The `Version` string contains the release number. For example, for an installation of MySQL Server 5.1.52, the key contains a value of `5.1.52`.

These registry keys are used to help external tools identify the installed location of the MySQL server, preventing a complete scan of the hard-disk to determine the installation path of the MySQL server. The registry keys are not required to run the server, and if you install MySQL using the `noinstall` Zip archive, the registry keys are not created.

##### Changes to the Start Menu

The MySQL Installation Wizard creates a new entry in the Windows `START` menu under a common MySQL menu heading named after the major version of MySQL that you have installed. For example, if you install MySQL 5.1, the MySQL Installation Wizard creates a MySQL Server 5.1 section in the `START` menu.

The following entries are created within the new `START` menu section:

- MySQL Command Line Client: This is a shortcut to the `mysql` command-line client and is configured to connect as the `root` user. The shortcut prompts for a `root` user password when you connect.
- MySQL Server Instance Config Wizard: This is a shortcut to the MySQL Config Wizard. Use this shortcut to configure a newly installed server, or to reconfigure an existing server.
- MySQL Documentation: This is a link to the MySQL server documentation that is stored locally in the MySQL server installation directory. This option is not available when the MySQL server is installed using the Essentials installation package.

## Changes to the File System

The MySQL Installation Wizard by default installs the MySQL 5.1 server to `C:\Program Files\MySQL\MySQL Server 5.1`, where `Program Files` is the default location for applications in your system, and `5.1` is the major version of your MySQL server. This is the recommended location for the MySQL server, replacing the former default location `C:\mysql`.

By default, all MySQL applications are stored in a common directory at `C:\Program Files\MySQL`, where `Program Files` is the default location for applications in your Windows installation. A typical MySQL installation on a developer machine might look like this:

```
C:\Program Files\MySQL\MySQL Server 5.1
C:\Program Files\MySQL\MySQL Workbench 5.1 OSS
```

This approach makes it easier to manage and maintain all MySQL applications installed on a particular system.

In MySQL 5.1.23 and earlier, the default location for the data files used by MySQL is located within the corresponding MySQL Server installation directory. For MySQL 5.1.24 and later, the default location of the data directory is the `AppData` directory configured for the user that installed the MySQL application.

### 2.4.3.1.6. MySQL Installation Wizard: Upgrading MySQL

The MySQL Installation Wizard can perform server upgrades automatically using the upgrade capabilities of MSI. That means you do not need to remove a previous installation manually before installing a new release. The installer automatically shuts down and removes the previous MySQL service before installing the new version.

Automatic upgrades are available only when upgrading between installations that have the same major and minor version numbers. For example, you can upgrade automatically from MySQL 5.1.5 to MySQL 5.1.6, but not from MySQL 5.0 to MySQL 5.1.

In MySQL 5.1.32 and later, the `EXE` version of the MSI installer packages were removed. When upgrading an existing MySQL installation from the old EXE based installer to the MSI based installer, please keep the following notes in mind:

- The MSI installer will not identify an existing installation that was installed using the old EXE installer. This means that the installer will not stop the existing server, or detect that the existing password is required before installing the new version. To work around this:
  1. Stop the current server manually using `net stop mysqladmin shutdown`.
  2. Remove the existing installation manually by using the **ADD/REMOVE PROGRAMS** control panel. This will keep the existing configuration and data files, as these are not removed automatically.
  3. Install the new version of MySQL using the MSI installer. When running the installation, skip updating the security by deselecting the checkbox on the security screen.
  4. Complete the installation, and then start the server again. You should be able to login with your existing user and password credentials.
- You can only upgrade the version and release using the MSI installer. For example, you can upgrade an open source installation with an open source installer. You cannot upgrade an open source installation using the enterprise installer.

See [Section 2.4.7, “Upgrading MySQL Server on Microsoft Windows”](#).

### 2.4.3.2. Automating MySQL Installation on Microsoft Windows using the MSI Package

The Microsoft Installer (MSI) supports both a *quiet* and a *passive* mode that can be used to install MySQL automatically without requiring intervention. You can use this either in scripts to automatically install MySQL or through a terminal connection such as Telnet where you do not have access to the standard Windows user interface. The MSI packages can also be used in combination with Microsoft's Group Policy system (part of Windows Server 2003 and Windows Server 2008) to install MySQL across multiple machines.

To install MySQL from one of the MSI packages automatically from the command line (or within a script), you need to use the `msiexec.exe` tool. For example, to perform a quiet installation (which shows no dialog boxes or progress):

```
shell> msiexec /i /quiet mysql-5.1.39.msi
```

The `/i` indicates that you want to perform an installation. The `/quiet` option indicates that you want no interactive elements.

To provide a dialog box showing the progress during installation, and the dialog boxes providing information on the installation and registration of MySQL, use `/passive` mode instead of `/quiet`:

```
shell> msieexec /i /passive mysql-5.1.39.msi
```

Regardless of the mode of the installation, installing the package in this manner performs a 'Typical' installation, and installs the default components into the standard location.

You can also use this method to uninstall MySQL by using the `/uninstall` or `/x` options:

```
shell> msieexec /x /quiet mysql-5.1.39.msi
```

To install MySQL and configure a MySQL instance from the command line, see [Section 2.4.4.13, “MySQL Server Instance Config Wizard: Creating an Instance from the Command Line”](#).

For information on using MSI packages to install software automatically using Group Policy, see [How to use Group Policy to remotely install software in Windows Server 2003](#).

### 2.4.3.3. Removing MySQL When Installed from the MSI Package

To uninstall a MySQL where you have used the MSI packages, you must use the **ADD/REMOVE PROGRAMS** tool within **CONTROL PANEL**. To do this:

1. Right-click the **START** menu and choose **CONTROL PANEL**.
2. If the Control Panel is set to category mode (you will see **PICK A CATEGORY** at the top of the **CONTROL PANEL** window), double-click **ADD OR REMOVE PROGRAMS**. If the Control is set to classic mode, double-click the **ADD OR REMOVE PROGRAMS** icon.
3. Find MySQL in the list of installed software. MySQL Server is installed against major version numbers (MySQL 5.0, MySQL 5.1, etc.). Select the version that you want to remove and click **REMOVE**.
4. You will be prompted to confirm the removal. Click **YES** to remove MySQL.

When MySQL is removed using this method, only the installed components are removed. Any database information (including the tables and data), import or export files, log files, and binary logs produced during execution are kept in their configured location.

If you try to install MySQL again the information will be retained and you will be prompted to enter the password configured with the original installation.

If you want to delete MySQL completely:

- Delete the associated data directory. On Windows XP and Windows Server 2003, before MySQL 5.1.24, the default data directory would be located within the MySQL installation directory. On MySQL 5.1.24 and later, the default data directory is the configured AppData directory, which is `C:\Documents and Settings\All Users\Application Data\MySQL` by default.
- On Windows 7 and Windows Server 2008, the default data directory location is `C:\ProgramData\MySQL`.

#### Note

The `C:\ProgramData` directory is hidden by default. You must change your folder options to view the hidden file. Choose ORGANIZE, Folder and search options, **SHOW HIDDEN FOLDERS**.

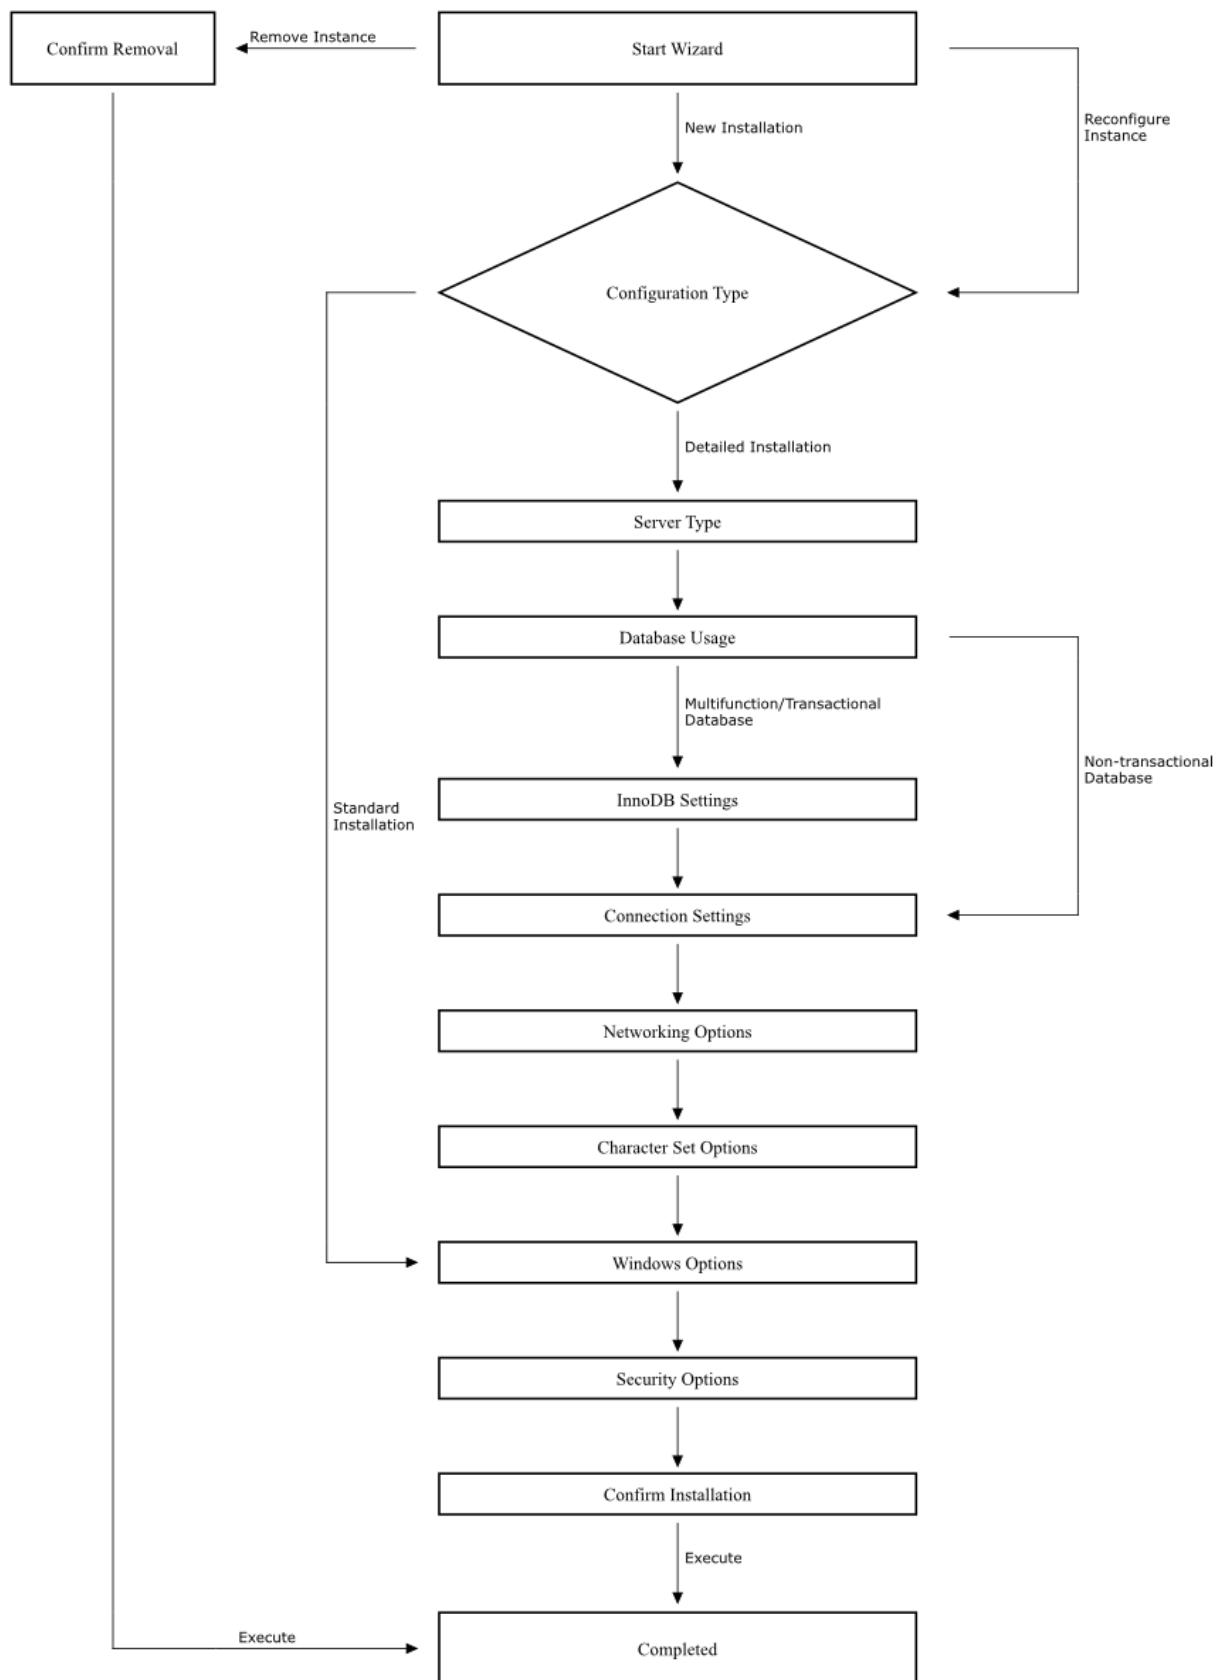

### 2.4.4. Using the MySQL Server Instance Config Wizard

The MySQL Server Instance Config Wizard helps automate the process of configuring your server. It creates a custom MySQL configuration file (`my.ini` or `my.cnf`) by asking you a series of questions and then applying your responses to a template to generate the configuration file that is tuned to your installation.

The complete and essential MSI installation packages include the MySQL Server Instance Config Wizard in the MySQL 5.1 server. The MySQL Server Instance Config Wizard is only available for Windows.

The workflow sequence for using the MySQL Server Instance Config Wizard is shown in the figure below:

**Figure 2.4. MySQL Server Instance Config Wizard Workflow**

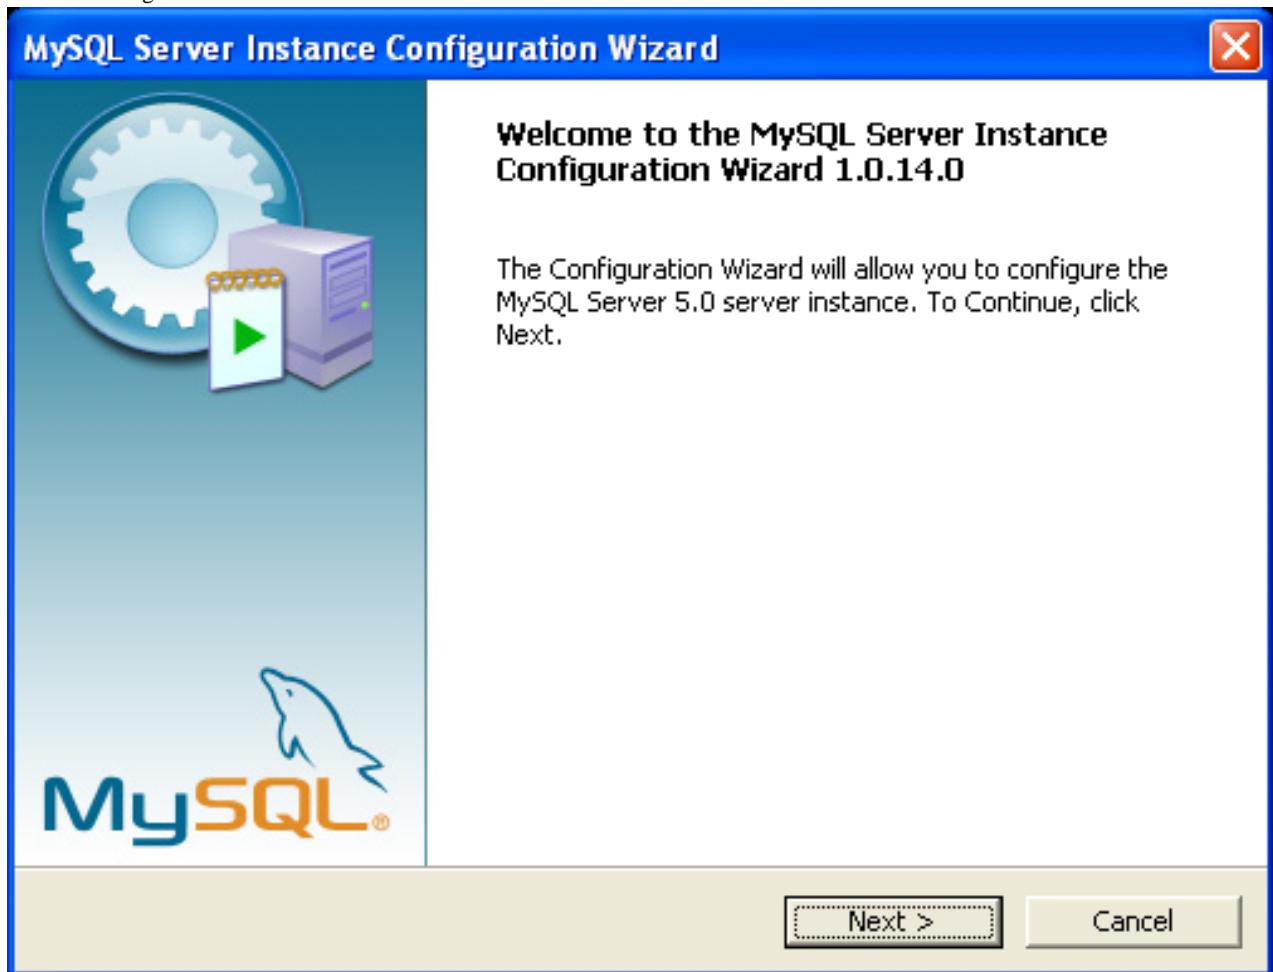

#### 2.4.4.1. Starting the MySQL Server Instance Config Wizard

The MySQL Server Instance Config Wizard is normally started as part of the installation process. You should only need to run the

MySQL Server Instance Config Wizard again when you need to change the configuration parameters of your server.

If you chose not to open a port prior to installing MySQL on Windows Vista, you can choose to use the MySQL Server Instance Config Wizard after installation. However, you must open a port in the Windows Firewall. To do this see the instructions given in [Section 2.4.3.1.1, “MySQL Installation Wizard: Downloading and Starting”](#). Rather than opening a port, you also have the option of adding MySQL as a program that bypasses the Windows Firewall. One or the other option is sufficient—you need not do both. Additionally, when running the MySQL Server Config Wizard on Windows Vista ensure that you are logged in as a user with administrative rights.

You can launch the MySQL Config Wizard by clicking the MySQL Server Instance Config Wizard entry in the MySQL section of the Windows [START](#) menu.

Alternatively, you can navigate to the `bin` directory of your MySQL installation and launch the `MySQLInstanceConfig.exe` file directly.

The MySQL Server Instance Config Wizard places the `my.ini` file in the installation directory for the MySQL server. This helps associate configuration files with particular server instances.

To ensure that the MySQL server knows where to look for the `my.ini` file, an argument similar to this is passed to the MySQL server as part of the service installation:

```
--defaults-file="C:\Program Files\MySQL\MySQL Server 5.1\my.ini"
```

Here, `C:\Program Files\MySQL\MySQL Server 5.1` is replaced with the installation path to the MySQL Server. The `--defaults-file` option instructs the MySQL server to read the specified file for configuration options when it starts.

Apart from making changes to the `my.ini` file by running the MySQL Server Instance Config Wizard again, you can modify it by opening it with a text editor and making any necessary changes. You can also modify the server configuration with the `http://www.mysql.com/products/administrator/` utility. For more information about server configuration, see [Section 5.1.2, “Server Command Options”](#).

MySQL clients and utilities such as the `mysql` and `mysqldump` command-line clients are not able to locate the `my.ini` file loc-

ated in the server installation directory. To configure the client and utility applications, create a new `my.ini` file in the Windows installation directory (for example, `C:\WINDOWS`).

Under Windows Server 2003, Windows Server 2000, Windows XP, and Windows Vista MySQL Server Instance Config Wizard will configure MySQL to work as a Windows service. To start and stop MySQL you use the `Services` application that is supplied as part of the Windows Administrator Tools.

#### 2.4.4.2. MySQL Server Instance Config Wizard: Choosing a Maintenance Option

If the MySQL Server Instance Config Wizard detects an existing configuration file, you have the option of either reconfiguring your existing server, or removing the server instance by deleting the configuration file and stopping and removing the MySQL service.

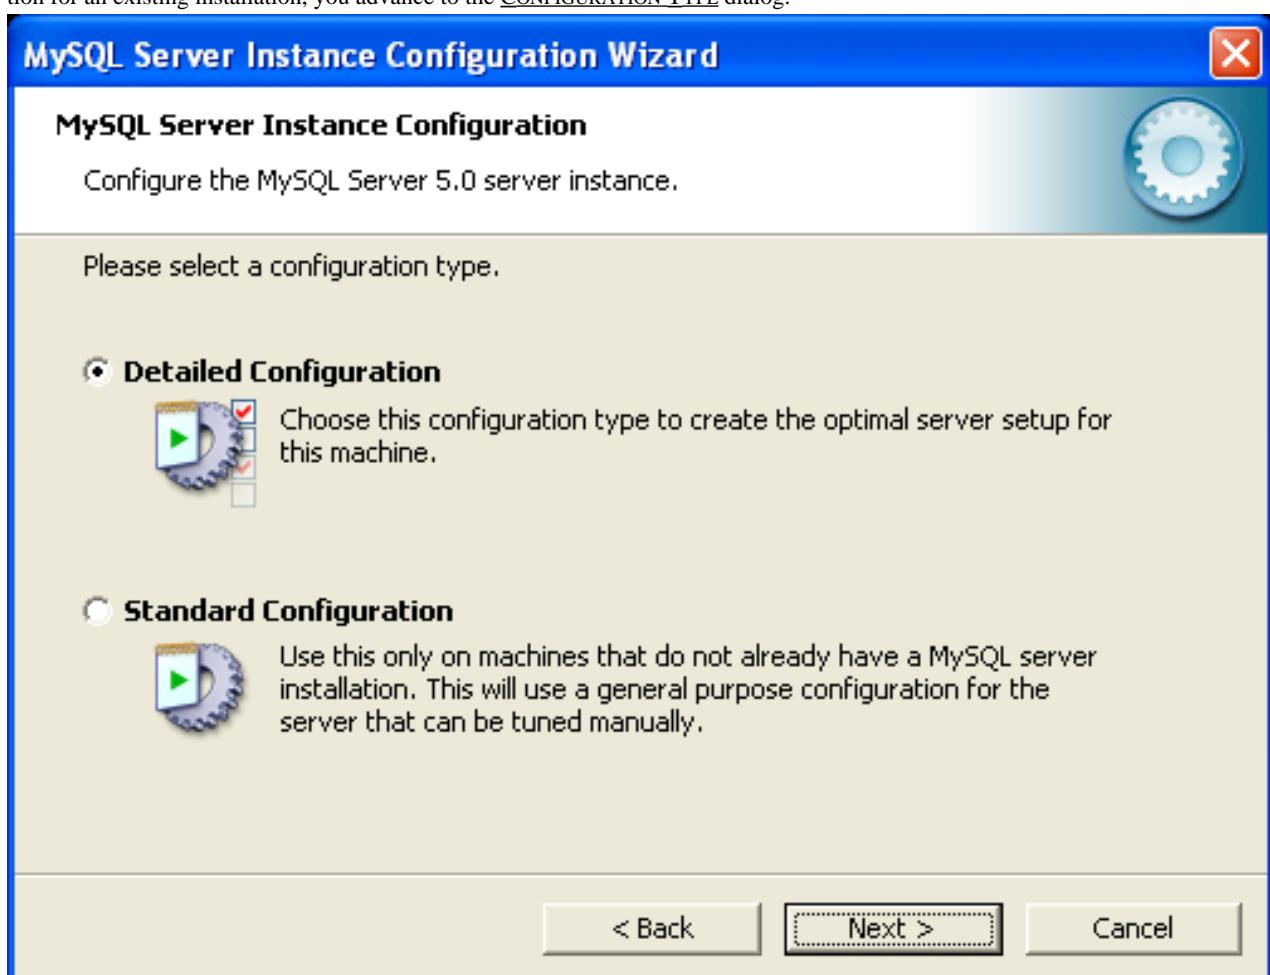

To reconfigure an existing server, choose the Re-configure Instance option and click the NEXT button. Any existing configuration file is not overwritten, but renamed (within the same directory) using a timestamp (Windows) or sequential number (Linux). To remove the existing server instance, choose the Remove Instance option and click the NEXT button.

If you choose the Remove Instance option, you advance to a confirmation window. Click the EXECUTE button. The MySQL Server Config Wizard stops and removes the MySQL service, and then deletes the configuration file. The server installation and its `data` folder are not removed.

If you choose the Re-configure Instance option, you advance to the CONFIGURATION TYPE dialog where you can choose the type of installation that you wish to configure.

#### 2.4.4.3. MySQL Server Instance Config Wizard: Choosing a Configuration Type

When you start the MySQL Server Instance Config Wizard for a new MySQL installation, or choose the Re-configure Instance option for an existing installation, you advance to the CONFIGURATION TYPE dialog.

There are two configuration types available: Detailed Configuration and Standard Configuration. The Standard Configuration option is intended for new users who want to get started with MySQL quickly without having to make many decisions about server configuration. The Detailed Configuration option is intended for advanced users who want more fine-grained control over server configuration.

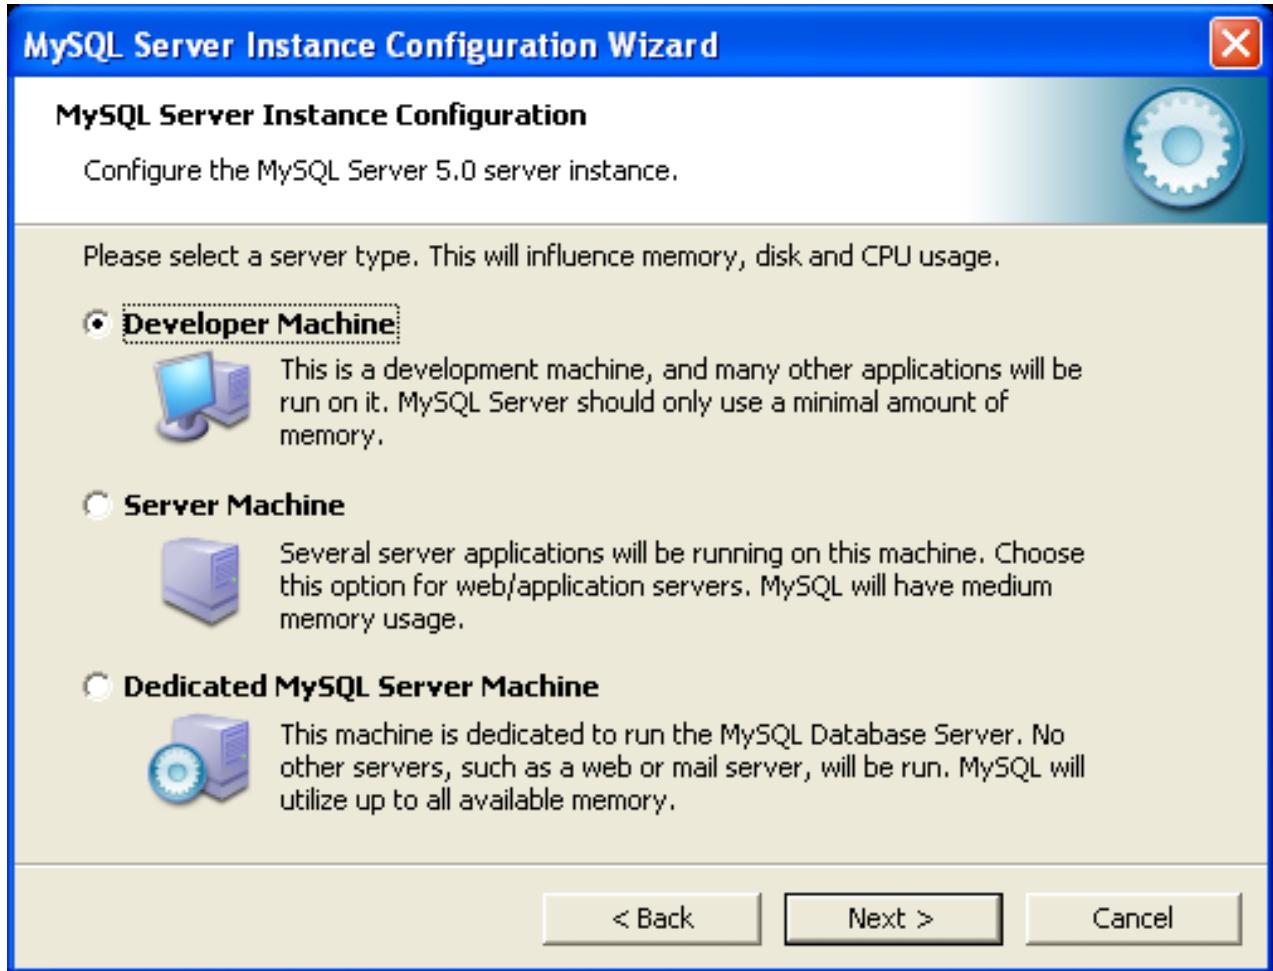

If you are new to MySQL and need a server configured as a single-user developer machine, the Standard Configuration should suit your needs. Choosing the Standard Configuration option causes the MySQL Config Wizard to set all configuration options automatically with the exception of Service Options and Security Options.

The Standard Configuration sets options that may be incompatible with systems where there are existing MySQL installations. If you have an existing MySQL installation on your system in addition to the installation you wish to configure, the Detailed Configuration option is recommended.

To complete the Standard Configuration, please refer to the sections on Service Options and Security Options in [Section 2.4.4.10, “MySQL Server Instance Config Wizard: The Service Options Dialog”](#), and [Section 2.4.4.11, “MySQL Server Instance Config Wizard: The Security Options Dialog”](#), respectively.

#### 2.4.4.4. MySQL Server Instance Config Wizard: The Server Type Dialog

There are three different server types available to choose from. The server type that you choose affects the decisions that the MySQL Server Instance Config Wizard makes with regard to memory, disk, and processor usage.

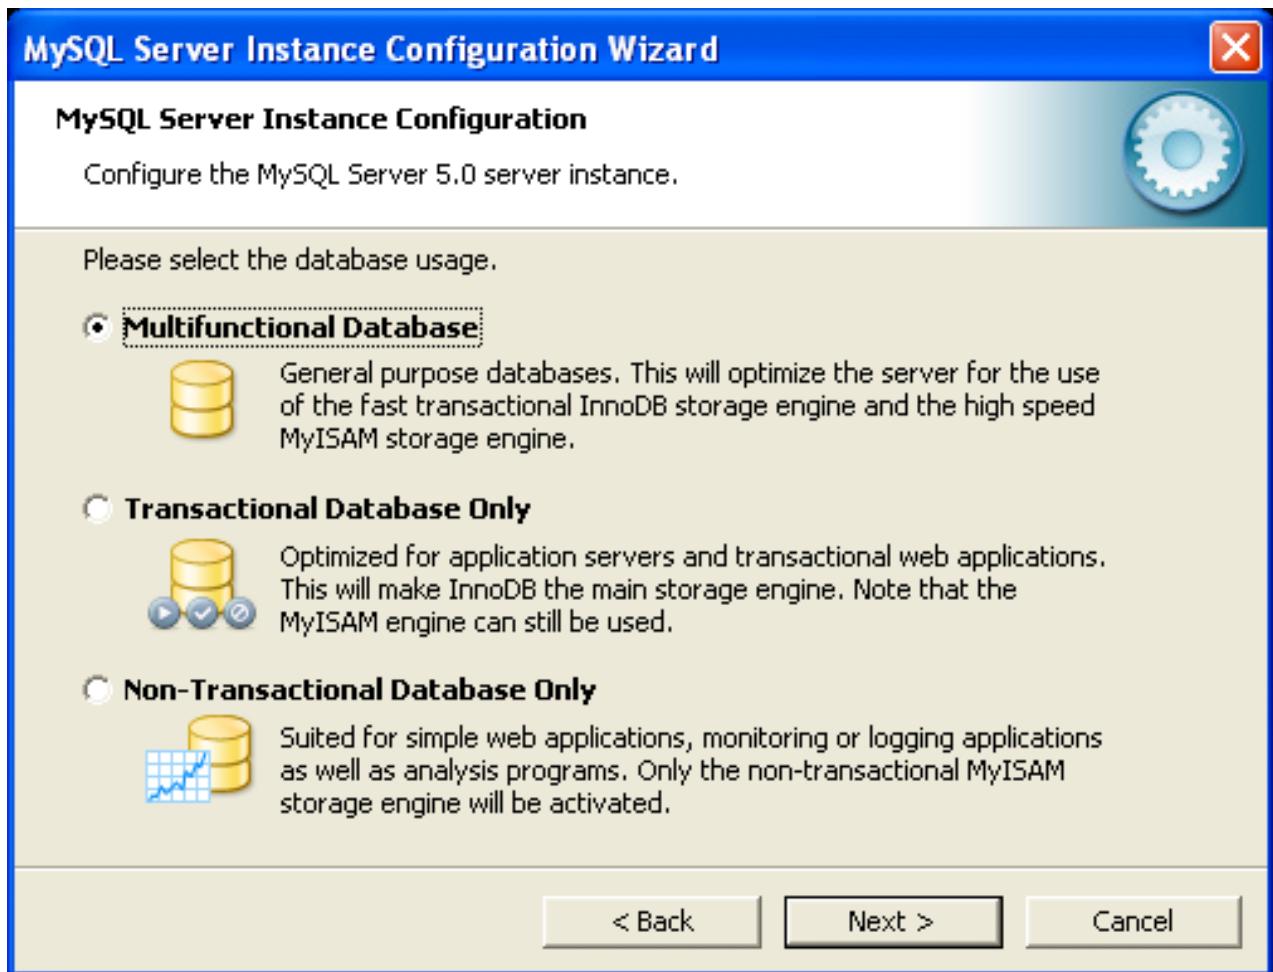

- Developer Machine: Choose this option for a typical desktop workstation where MySQL is intended only for personal use. It is assumed that many other desktop applications are running. The MySQL server is configured to use minimal system resources.
- Server Machine: Choose this option for a server machine where the MySQL server is running alongside other server applications such as FTP, email, and Web servers. The MySQL server is configured to use a moderate portion of the system resources.
- Dedicated MySQL Server Machine: Choose this option for a server machine that is intended to run only the MySQL server. It is assumed that no other applications are running. The MySQL server is configured to use all available system resources.

##### Note

By selecting one of the preconfigured configurations, the values and settings of various options in your `my.cnf` or `my.ini` will be altered accordingly. The default values and options as described in the reference manual may therefore be different to the options and values that were created during the execution of the Config Wizard.

#### 2.4.4.5. MySQL Server Instance Config Wizard: The Database Usage Dialog

The **DATABASE USAGE** dialog enables you to indicate the storage engines that you expect to use when creating MySQL tables. The option you choose determines whether the **InnoDB** storage engine is available and what percentage of the server resources are available to **InnoDB**.

- Multifunctional Database: This option enables both the **InnoDB** and **MyISAM** storage engines and divides resources evenly between the two. This option is recommended for users who use both storage engines on a regular basis.
- Transactional Database Only: This option enables both the **InnoDB** and **MyISAM** storage engines, but dedicates most server resources to the **InnoDB** storage engine. This option is recommended for users who use **InnoDB** almost exclusively and make only minimal use of **MyISAM**.
- Non-Transactional Database Only: This option disables the **InnoDB** storage engine completely and dedicates all server resources to the **MyISAM** storage engine. This option is recommended for users who do not use **InnoDB**.

The Config Wizard uses a template to generate the server configuration file. The **DATABASE USAGE** dialog sets one of the following option strings:

```
Multifunctional Database: MIXED
Transactional Database Only: INNODB
Non-Transactional Database Only: MYISAM
```

When these options are processed through the default template (my-template.ini) the result is:

```
Multifunctional Database:
default-storage-engine=InnoDB
_myisam_pct=50

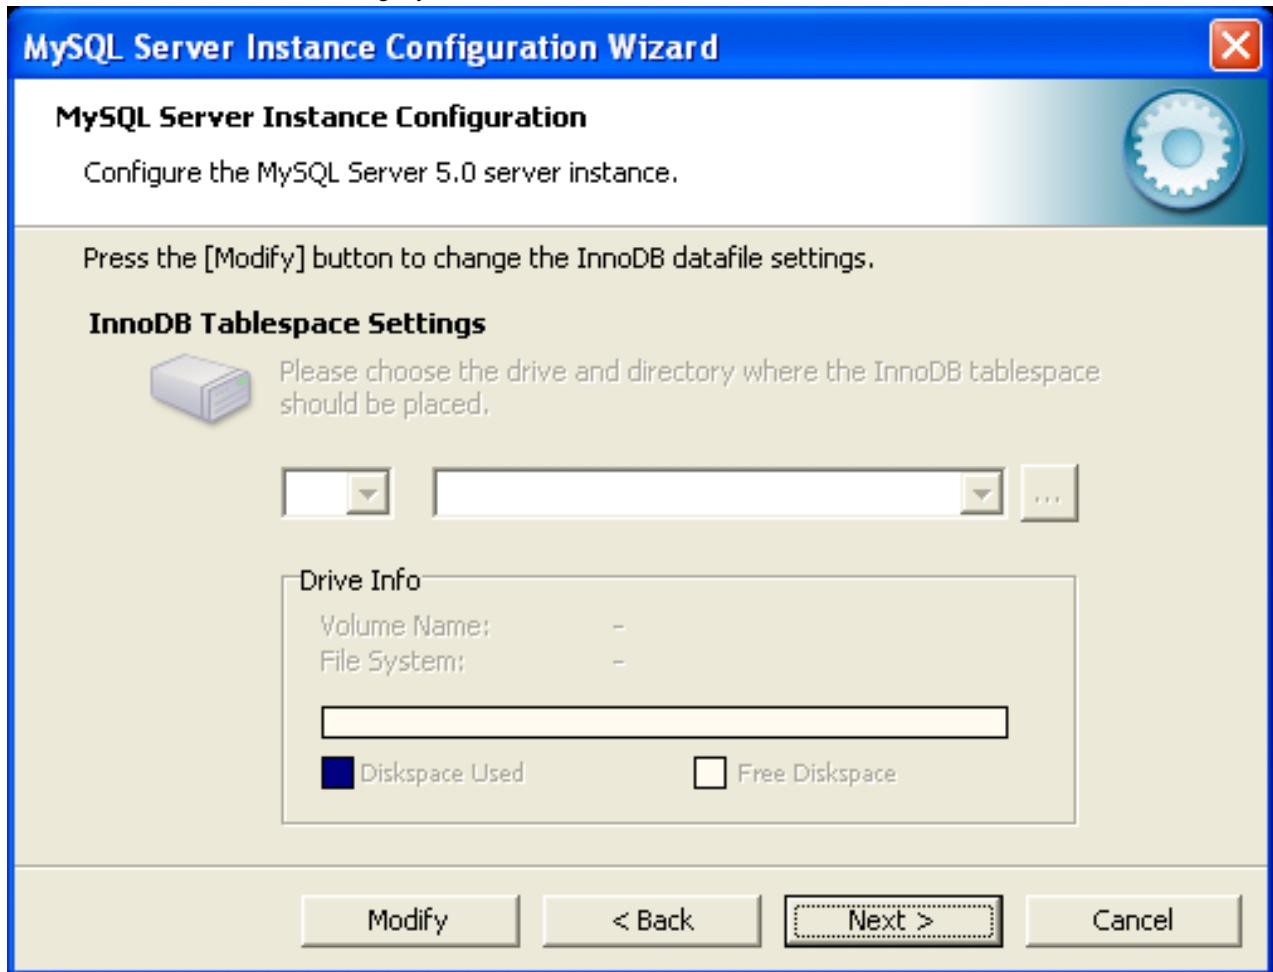

Transactional Database Only:
default-storage-engine=InnoDB
_myisam_pct=5
```

```
Non-Transactional Database Only:
default-storage-engine=MyISAM
_myisam_pct=100
skip-innodb
```

The `_myisam_pct` value is used to calculate the percentage of resources dedicated to [MyISAM](#). The remaining resources are allocated to [InnoDB](#).

#### 2.4.4.6. MySQL Server Instance Config Wizard: The InnoDB Tablespace Dialog

Some users may want to locate the [InnoDB](#) tablespace files in a different location than the MySQL server data directory. Placing the tablespace files in a separate location can be desirable if your system has a higher capacity or higher performance storage device available, such as a RAID storage system.

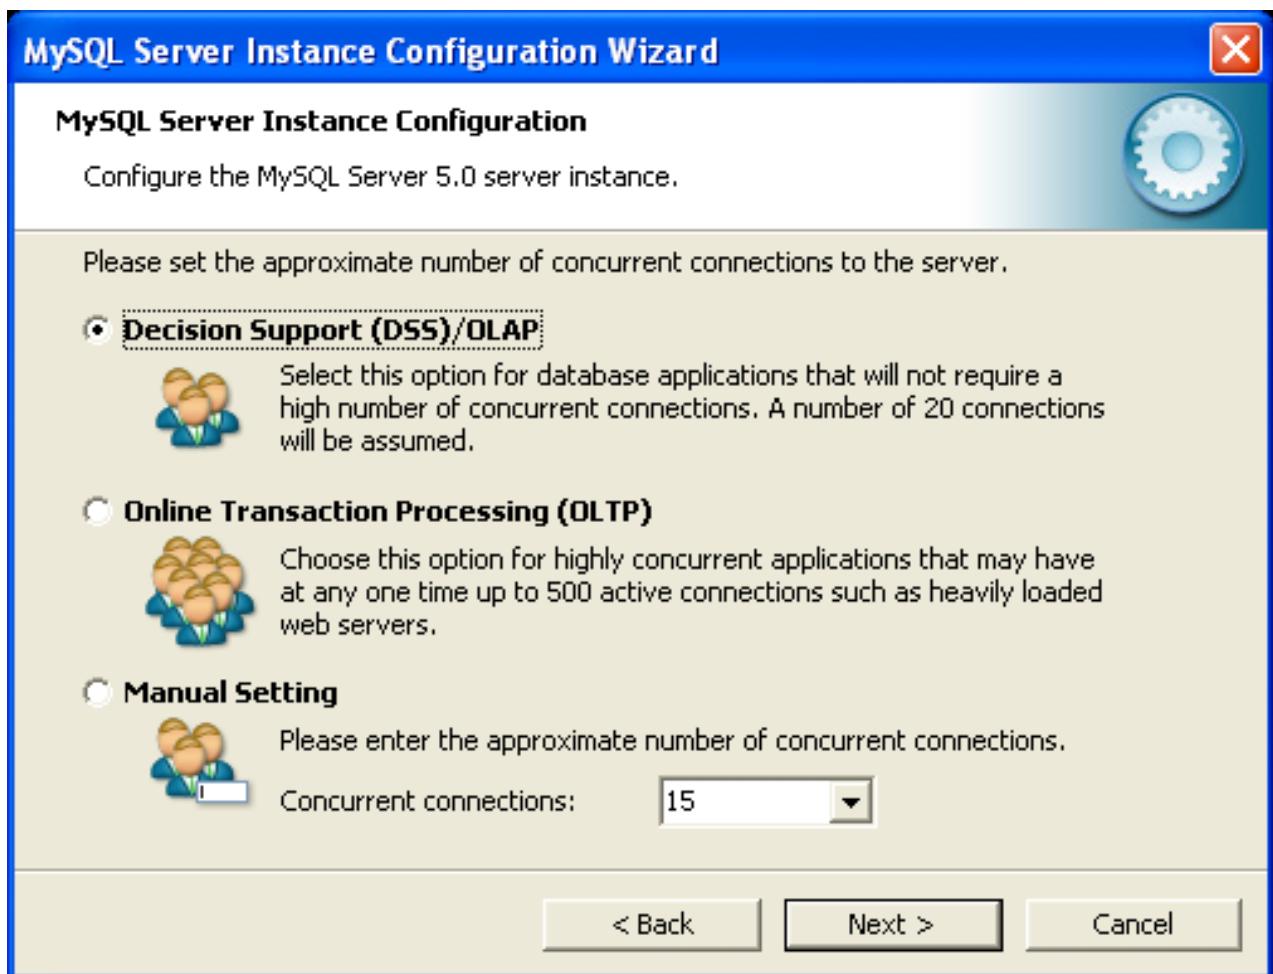

To change the default location for the [InnoDB](#) tablespace files, choose a new drive from the drop-down list of drive letters and choose a new path from the drop-down list of paths. To create a custom path, click the ... button.

If you are modifying the configuration of an existing server, you must click the MODIFY button before you change the path. In this situation you must move the existing tablespace files to the new location manually before starting the server.

#### 2.4.4.7. MySQL Server Instance Config Wizard: The Concurrent Connections Dialog

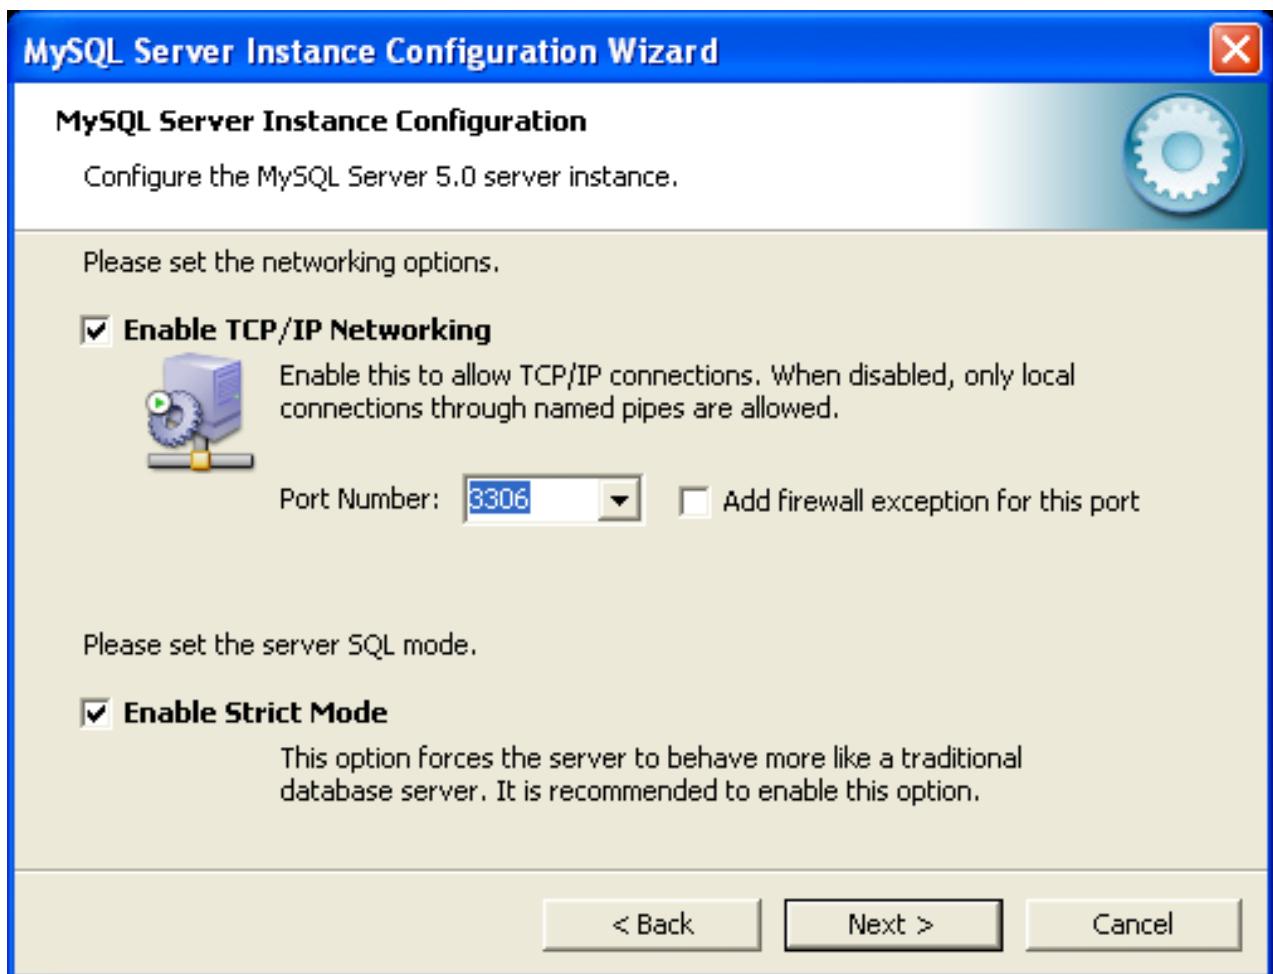

To prevent the server from running out of resources, it is important to limit the number of concurrent connections to the MySQL server that can be established. The [CONCURRENT CONNECTIONS](#) dialog enables you to choose the expected usage of your server, and sets the limit for concurrent connections accordingly. It is also possible to set the concurrent connection limit manually.

- Decision Support (DSS)/OLAP: Choose this option if your server does not require a large number of concurrent connections. The maximum number of connections is set at 100, with an average of 20 concurrent connections assumed.
- Online Transaction Processing (OLTP): Choose this option if your server requires a large number of concurrent connections. The maximum number of connections is set at 500.
- Manual Setting: Choose this option to set the maximum number of concurrent connections to the server manually. Choose the number of concurrent connections from the drop-down box provided, or enter the maximum number of connections into the drop-down box if the number you desire is not listed.

#### 2.4.4.8. MySQL Server Instance Config Wizard: The Networking and Strict Mode Options Dialog

Use the [NETWORKING OPTIONS](#) dialog to enable or disable TCP/IP networking and to configure the port number that is used to connect to the MySQL server.

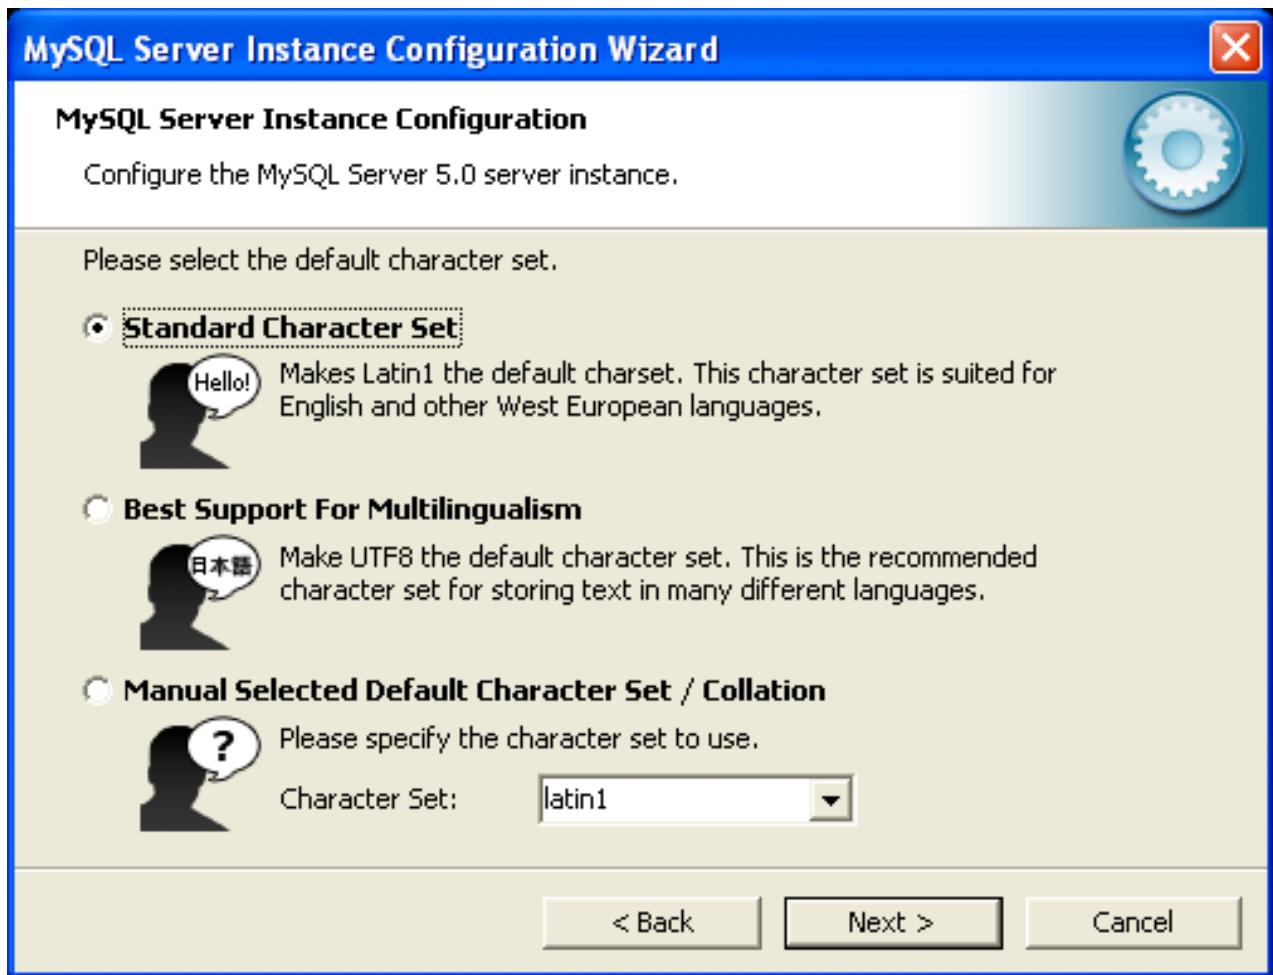

TCP/IP networking is enabled by default. To disable TCP/IP networking, uncheck the box next to the Enable TCP/IP Networking option.

Port 3306 is used by default. To change the port used to access MySQL, choose a new port number from the drop-down box or type a new port number directly into the drop-down box. If the port number you choose is in use, you are prompted to confirm your choice of port number.

Set the [SERVER SQL MODE](#) to either enable or disable strict mode. Enabling strict mode (default) makes MySQL behave more like other database management systems. *If you run applications that rely on MySQL's old "forgiving" behavior, make sure to either adapt those applications or to disable strict mode.* For more information about strict mode, see [Section 5.1.7, “Server SQL Modes”](#).

#### 2.4.4.9. MySQL Server Instance Config Wizard: The Character Set Dialog

The MySQL server supports multiple character sets and it is possible to set a default server character set that is applied to all tables, columns, and databases unless overridden. Use the [CHARACTER SET](#) dialog to change the default character set of the MySQL server.

- Standard Character Set: Choose this option if you want to use `latin1` as the default server character set. `latin1` is used for English and many Western European languages.
- Best Support For Multilingualism: Choose this option if you want to use `utf8` as the default server character set. This is a Unicode character set that can store characters from many different languages.
- Manual Selected Default Character Set / Collation: Choose this option if you want to pick the server's default character set manually. Choose the desired character set from the provided drop-down list.

#### 2.4.4.10. MySQL Server Instance Config Wizard: The Service Options Dialog

On Windows platforms, the MySQL server can be installed as a Windows service. When installed this way, the MySQL server can be started automatically during system startup, and even restarted automatically by Windows in the event of a service failure.

The MySQL Server Instance Config Wizard installs the MySQL server as a service by default, using the service name `MySQL`. If you do not wish to install the service, uncheck the box next to the Install As Windows Service option. You can change the service name by picking a new service name from the drop-down box provided or by entering a new service name into the drop-down box.

##### Note

Service names can include any legal character except forward (/) or backward (\) slashes, and must be less than 256 characters long.

##### Warning

If you are installing multiple versions of MySQL onto the same machine, you *must* choose a different service name for each version that you install. If you do not choose a different service for each installed version then the service manager information will be inconsistent and this will cause problems when you try to uninstall a previous version.

If you have already installed multiple versions using the same service name, you must manually edit the contents of

the `HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services` parameters within the Windows registry to update the association of the service name with the correct server version.

Typically, when installing multiple versions you create a service name based on the version information. For example, you might install MySQL 5.x as `mysql15`, or specific versions such as MySQL 5.1.30 as `mysql150130`.

To install the MySQL server as a service but not have it started automatically at startup, uncheck the box next to the Launch the MySQL Server Automatically option.

#### 2.4.4.11. MySQL Server Instance Config Wizard: The Security Options Dialog

The content of the security options portion of the MySQL Server Instance Configuration Wizard will depend on whether this is a new installation, or modifying an existing installation.

- **Setting the root password for a new installation**

*It is strongly recommended that you set a `root` password for your MySQL server, and the MySQL Server Instance Config Wizard requires by default that you do so. If you do not wish to set a `root` password, uncheck the box next to the Modify Security Settings option.*

##### Note

If you have previously installed MySQL, but not deleted the data directory associated with the previous installation, you may be prompted to provide the current root password. The password will be the one configured with your old data directory. If you do not want to use this data, or do not know the root password, you should cancel the installation, delete the previous installation data, and then restart the installation process. For more information on deleting MySQL data on Microsoft Windows, see [Section 2.4.3.3, “Removing MySQL When Installed from the MSI Package”](#).

- To set the `root` password, enter the desired password into both the New root password and Confirm boxes.

##### Setting the root password for an existing installation

If you are modifying the configuration of an existing configuration, or you are installing an upgrade and the MySQL Server Instance Configuration Wizard has detected an existing MySQL system, then you must enter the existing password for `root` before changing the configuration information.

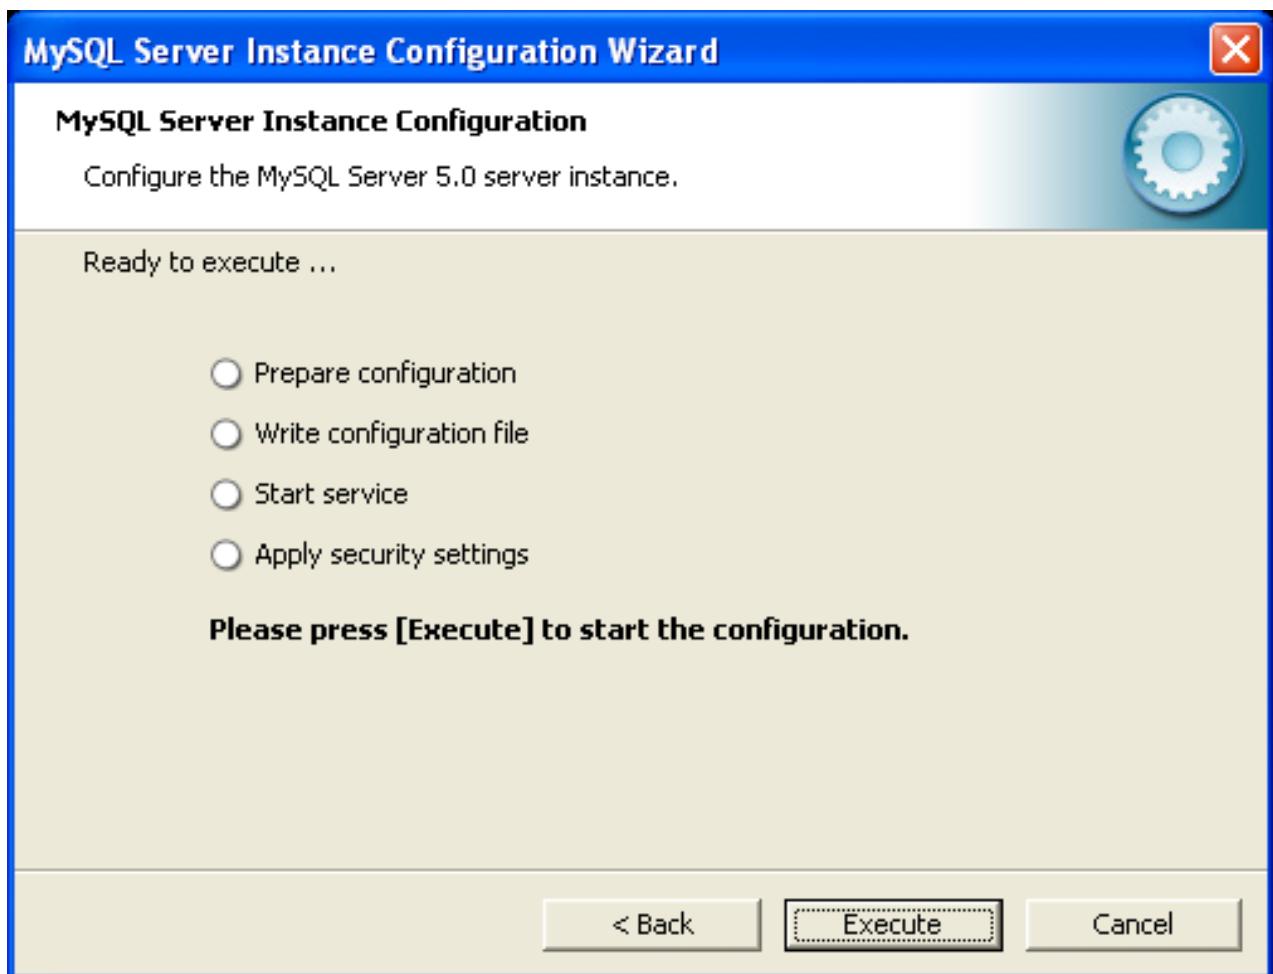

If you want to change the current `root` password, enter the desired new password into both the New root password and Confirm boxes.

To permit `root` logins from across the network, check the box next to the Enable root access from remote machines option. This decreases the security of your `root` account.

To create an anonymous user account, check the box next to the Create An Anonymous Account option. Creating an anonymous account can decrease server security and cause login and permission difficulties. For this reason, it is not recommended.

#### 2.4.4.12. MySQL Server Instance Config Wizard: The Confirmation Dialog

The final dialog in the MySQL Server Instance Config Wizard is the CONFIRMATION DIALOG. To start the configuration process, click the EXECUTE button. To return to a previous dialog, click the BACK button. To exit the MySQL Server Instance Config Wizard without configuring the server, click the CANCEL button.

After you click the EXECUTE button, the MySQL Server Instance Config Wizard performs a series of tasks and displays the progress onscreen as the tasks are performed.

The MySQL Server Instance Config Wizard first determines configuration file options based on your choices using a template prepared by MySQL developers and engineers. This template is named `my-template.ini` and is located in your server installation directory.

The MySQL Config Wizard then writes these options to the corresponding configuration file.

If you chose to create a service for the MySQL server, the MySQL Server Instance Config Wizard creates and starts the service. If you are reconfiguring an existing service, the MySQL Server Instance Config Wizard restarts the service to apply your configuration changes.

If you chose to set a `root` password, the MySQL Config Wizard connects to the server, sets your new `root` password, and applies any other security settings you may have selected.

After the MySQL Server Instance Config Wizard has completed its tasks, it displays a summary. Click the FINISH button to exit the MySQL Server Config Wizard.

#### **2.4.4.13. MySQL Server Instance Config Wizard: Creating an Instance from the Command Line**

In addition to using the GUI interface to the MySQL Server Instance Config Wizard, you can also create instances automatically from the command line.

To use the MySQL Server Instance Config Wizard on the command line, you need to use the `MySQLInstanceConfig.exe` command that is installed with MySQL in the `bin` directory within the installation directory. `MySQLInstanceConfig.exe` takes a number of command-line arguments to set the properties that would normally be selected through the GUI interface, and then creates a new configuration file (`my.ini`) by combining these selections with a template configuration file to produce the working configuration file.

The main command line options are provided in the table below. Some of the options are required, while some options are optional.

**Table 2.8. MySQL Server Instance Config Wizard Command Line Options**

| Option                     | Description                                                                                                                                  |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| Required Parameters        |                                                                                                                                              |
| <code>-nPRODUCTNAME</code> | The name of the instance when installed                                                                                                      |
| <code>-pPATH</code>        | Path of the base directory for installation. This is equivalent to the directory when using the <code>basedir</code> configuration parameter |
| <code>-vVERSION</code>     | The version tag to use for this installation                                                                                                 |
| Action to Perform          |                                                                                                                                              |
| <code>-i</code>            | Install an instance                                                                                                                          |
| <code>-r</code>            | Remove an instance                                                                                                                           |
| <code>-s</code>            | Stop an existing instance                                                                                                                    |
| <code>-q</code>            | Perform the operation quietly                                                                                                                |
| <code>-lFILENAME</code>    | Sae the installation progress in a logfile                                                                                                   |
| Config File to Use         |                                                                                                                                              |
| <code>-tFILENAME</code>    | Path to the template config file that will be used to generate the installed configuration file                                              |
| <code>-cFILENAME</code>    | Path to a config file to be generated                                                                                                        |

The `-t` and `-c` options work together to set the configuration parameters for a new instance. The `-t` option specifies the template configuration file to use as the basic configuration, which are then merged with the configuration parameters generated by the MySQL Server Instance Config Wizard into the configuration file specified by the `-c` option.

A sample template file, `my-template.ini` is provided in the toplevel MySQL installation directory. The file contains elements are replaced automatically by the MySQL Server Instance Config Wizard during configuration.

If you specify a configuration file that already exists, the existing configuration file will be saved in the file with the original, with the date and time added. For example, the `mysql.ini` will be copied to `mysql_2009-10-27_1646.ini.bak`.

The parameters that you can specify on the command line are listed in the table below.

**Table 2.9. MySQL Server Instance Config Wizard Parameters**

| Parameter                                                   | Description                                                                                                                                                                                                                                                                                       |
|-------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>ServiceName=\$</code>                                 | Specify the name of the service to be created                                                                                                                                                                                                                                                     |
| <code>AddBinToPath={yes   no}</code>                        | Specifies whether to add the binary directory of MySQL to the standard <code>PATH</code> environment variable                                                                                                                                                                                     |
| <code>Server-Type={DEVELOPMENT   SERVER   DEDICATED}</code> | Specify the server type. For more information, see <a href="#">Section 2.4.4.4, “MySQL Server Instance Config Wizard: The Server Type Dialog”</a>                                                                                                                                                 |
| <code>DatabaseType={MIXED   INNODB   MYISAM}</code>         | Specify the default database type. For more information, see <a href="#">Section 2.4.4.5, “MySQL Server Instance Config Wizard: The Database Usage Dialog”</a>                                                                                                                                    |
| <code>ConnectionUsage={DSS   OLTP}</code>                   | Specify the type of connection support, this automates the setting for the number of concurrent connections (see the <code>ConnectionCount</code> parameter). For more information, see <a href="#">Section 2.4.4.7, “MySQL Server Instance Config Wizard: The Concurrent Connections Dialog”</a> |
| <code>ConnectionCount=#</code>                              | Specify the number of concurrent connections to support. For more information, see <a href="#">Section 2.4.4.4, “MySQL Server Instance Config Wizard: The Server Type Dialog”</a>                                                                                                                 |
| <code>SkipNetworking={yes   no}</code>                      | Specify whether network support should be supported. Specifying <code>yes</code> disables network access altogether                                                                                                                                                                               |
| <code>Port#=</code>                                         | Specify the network port number to use for network connections. For more information, see <a href="#">Section 2.4.4.8, “MySQL Server Instance Config Wizard: The Networking and Strict Mode Options Dialog”</a>                                                                                   |
| <code>StrictMode={yes   no}</code>                          | Specify whether to use the <code>strict</code> SQL mode. For more information, see <a href="#">Section 2.4.4.8, “MySQL Server Instance Config Wizard: The Networking and Strict Mode Options Dialog”</a>                                                                                          |
| <code>Charset=\$</code>                                     | Specify the default character set. For more information, see <a href="#">Section 2.4.4.9, “MySQL Server Instance Config Wizard: The Character Set Dialog”</a>                                                                                                                                     |
| <code>RootPassword=\$</code>                                | Specify the root password                                                                                                                                                                                                                                                                         |
| <code>RootCurrentPassword=\$</code>                         | Specify the current root password then stopping or reconfiguring an existing service                                                                                                                                                                                                              |

### Note

When specifying options on the command line, you can enclose the entire command-line option and the value you are specifying using double quotation marks. This enables you to use spaces in the options. For example, "`-cC:\mysql.ini`".

The following command installs a MySQL Server 5.1 instance from the directory `C:\Program Files\MySQL\MySQL Server 5.1` using the service name `MySQL51` and setting the root password to 1234.

```
shell> MySQLInstanceConfig.exe -i -q "-lC:\mysql_install_log.txt" >
 "-nMySQL Server 5.1" "-pC:\Program Files\MySQL\MySQL Server 5.1" -v5.1.39 >
 "-tmy-template.ini" "-cC:\mytest.ini" ServerType=DEVELOPMENT DatabaseType=MIXED >
 ConnectionUsage=DSS Port=3311 ServiceName=MySQL51 RootPassword=1234
```

In the above example, a log file will be generated in `mysql_install_log.txt` containing the information about the instance creation process. The log file generated by the above example is shown below:

```
Welcome to the MySQL Server Instance Configuration Wizard 1.0.16.0
Date: 2009-10-27 17:07:21

Installing service ...

Product Name: MySQL Server 5.1
Version: 5.1.39
Installation Path: C:\Program Files\MySQL\MySQL Server 5.1\

Creating configuration file C:\mytest.ini using template my-template.ini.
Options:
DEVELOPMENT
MIXED
DSS
STRICTMODE

Variables:
port: 3311
default-character-set: latin1
basedir: "C:/Program Files/MySQL/MySQL Server 5.1/"
datadir: "C:/Program Files/MySQL/MySQL Server 5.1/Data/"

Creating Windows service entry.
Service name: "MySQL51"
Parameters: "C:\Program Files\MySQL\MySQL Server 5.1\bin\mysqld" --defaults-file="C:\mytest.ini" MySQL51.
Windows service MySQL51 installed.
```

When using the command-line, the return values in the following table indicate an error performing the specified option.

**Table 2.10. Return Value from MySQL Server Instance Config Wizard**

| Value | Description                                      |
|-------|--------------------------------------------------|
| 2     | Configuration template file cannot be found      |
| 3     | The Windows service entry cannot be created      |
| 4     | Could not connect to the Service Control Manager |
| 5     | The MySQL service cannot be started              |
| 6     | The MySQL service cannot be stopped              |
| 7     | The security settings cannot be applied          |
| 8     | The configuration file cannot be written         |
| 9     | The Windows service entry cannot be removed      |

You can perform an installation of MySQL automatically using the MSI package. For more information, see [Section 2.4.3.2, “Automating MySQL Installation on Microsoft Windows using the MSI Package”](#).

## 2.4.5. Installing MySQL on Microsoft Windows from a `noinstall` Zip Archive

Users who are installing from the `noinstall` package can use the instructions in this section to manually install MySQL. The process for installing MySQL from a Zip archive is as follows:

1. Extract the archive to the desired install directory
2. Create an option file

3. Choose a MySQL server type
4. Start the MySQL server
5. Secure the default user accounts

This process is described in the sections that follow.

#### 2.4.5.1. Extracting the Install Archive

To install MySQL manually, do the following:

1. If you are upgrading from a previous version please refer to [Section 2.4.7, “Upgrading MySQL Server on Microsoft Windows”](#), before beginning the upgrade process.
2. Make sure that you are logged in as a user with administrator privileges.
3. Choose an installation location. Traditionally, the MySQL server is installed in `C:\mysql`. The MySQL Installation Wizard installs MySQL under `C:\Program Files\MySQL`. If you do not install MySQL at `C:\mysql`, you must specify the path to the install directory during startup or in an option file. See [Section 2.4.5.2, “Creating an Option File”](#).
4. Extract the install archive to the chosen installation location using your preferred Zip archive tool. Some tools may extract the archive to a folder within your chosen installation location. If this occurs, you can move the contents of the subfolder into the chosen installation location.

#### 2.4.5.2. Creating an Option File

If you need to specify startup options when you run the server, you can indicate them on the command line or place them in an option file. For options that are used every time the server starts, you may find it most convenient to use an option file to specify your MySQL configuration. This is particularly true under the following circumstances:

- The installation or data directory locations are different from the default locations (`C:\Program Files\MySQL\MySQL Server 5.1` and `C:\Program Files\MySQL\MySQL Server 5.1\data`).
- You need to tune the server settings, such as memory, cache, or InnoDB configuration information.

When the MySQL server starts on Windows, it looks for option files in several locations, such as the Windows directory, `C:\`, and the MySQL installation directory (for the full list of locations, see [Section 4.2.3.3, “Using Option Files”](#)). The Windows directory typically is named something like `C:\WINDOWS`. You can determine its exact location from the value of the `WINDIR` environment variable using the following command:

```
C:\> echo %WINDIR%
```

MySQL looks for options in each location first in the `my.ini` file, and then in the `my.cnf` file. However, to avoid confusion, it is best if you use only one file. If your PC uses a boot loader where `C:` is not the boot drive, your only option is to use the `my.ini` file. Whichever option file you use, it must be a plain text file.

You can also make use of the example option files included with your MySQL distribution; see [Section 4.2.3.3.2, “Preconfigured Option Files”](#).

An option file can be created and modified with any text editor, such as Notepad. For example, if MySQL is installed in `E:\mysql` and the data directory is in `E:\mydata\data`, you can create an option file containing a `[mysqld]` section to specify values for the `basedir` and `datadir` options:

```
[mysqld]
set basedir to your installation path
basedir=E:/mysql
set datadir to the location of your data directory
datadir=E:/mydata/data
```

Note that Windows path names are specified in option files using (forward) slashes rather than backslashes. If you do use backslashes, double them:

```
[mysqld]
set basedir to your installation path
basedir=E:\\mysql
set datadir to the location of your data directory
```

```
datadir=E:\\mydata\\data
```

The rules for use of backslash in option file values are given in [Section 4.2.3.3, “Using Option Files”](#).

In MySQL 5.1.23 and earlier, the MySQL installer places the data directory directly under the directory where you install MySQL. On MySQL 5.1.24 and later, the data directory is located within the `AppData` directory for the user running MySQL.

If you would like to use a data directory in a different location, you should copy the entire contents of the `data` directory to the new location. For example, if you want to use `E:\\mydata` as the data directory instead, you must do two things:

1. Move the entire `data` directory and all of its contents from the default location (for example `C:\\Program Files\\MySQL\\MySQL Server 5.1\\data`) to `E:\\mydata`.
2. Use a `--datadir` option to specify the new data directory location each time you start the server.

### 2.4.5.3. Selecting a MySQL Server Type

The following table shows the available servers for Windows in MySQL 5.1.20 and earlier.

**Table 2.11. `mysqld` binary types for Microsoft Windows up to MySQL 5.1.20**

| Binary                    | Description                                                                                             |
|---------------------------|---------------------------------------------------------------------------------------------------------|
| <code>mysqld-nt</code>    | Optimized binary with named-pipe support                                                                |
| <code>mysqld</code>       | Optimized binary without named-pipe support                                                             |
| <code>mysqld-debug</code> | Like <code>mysqld-nt</code> , but compiled with full debugging and automatic memory allocation checking |

The following table shows the available servers for Windows in MySQL 5.1.21 and later.

**Table 2.12. `mysqld` binary types for Microsoft Windows MySQL 5.1.21 and later**

| Binary                    | Description                                                                                          |
|---------------------------|------------------------------------------------------------------------------------------------------|
| <code>mysqld</code>       | Optimized binary with named-pipe support                                                             |
| <code>mysqld-debug</code> | Like <code>mysqld</code> , but compiled with full debugging and automatic memory allocation checking |

All of the preceding binaries are optimized for modern Intel processors, but should work on any Intel i386-class or higher processor.

Each of the servers in a distribution support the same set of storage engines. The `SHOW ENGINES` statement displays which engines a given server supports.

All Windows MySQL 5.1 servers have support for symbolic linking of database directories.

MySQL supports TCP/IP on all Windows platforms. MySQL servers on Windows support named pipes as indicated in the following list. However, the default is to use TCP/IP regardless of platform. (Named pipes are slower than TCP/IP in many Windows configurations.)

Use of named pipes is subject to these conditions:

- Named pipes are enabled only if you start the server with the `--enable-named-pipe` option. It is necessary to use this option explicitly because some users have experienced problems with shutting down the MySQL server when named pipes were used.
- For MySQL 5.1.20 and earlier, named-pipe connections are permitted only by the `mysqld-nt` and `mysqld-debug` servers. For MySQL 5.1.21 and later, the `mysqld` and `mysqld-debug` servers both contain support for named-pipe connections.

#### Note

Most of the examples in this manual use `mysqld` as the server name. If you choose to use a different server, such as `mysqld-nt` or `mysqld-debug`, make the appropriate substitutions in the commands that are shown in the examples.

#### 2.4.5.4. Starting MySQL Server on Microsoft Windows for the First Time

This section gives a general overview of starting the MySQL server. The following sections provide more specific information for starting the MySQL server from the command line or as a Windows service.

The information here applies primarily if you installed MySQL using the `Noinstall` version, or if you wish to configure and test MySQL manually rather than with the GUI tools.

The examples in these sections assume that MySQL is installed under the default location of `C:\Program Files\MySQL\MySQL Server 5.1`. Adjust the path names shown in the examples if you have MySQL installed in a different location.

Clients have two options. They can use TCP/IP, or they can use a named pipe if the server supports named-pipe connections.

MySQL for Windows also supports shared-memory connections if the server is started with the `--shared-memory` option. Clients can connect through shared memory by using the `--protocol=MEMORY` option.

For information about which server binary to run, see [Section 2.4.5.3, “Selecting a MySQL Server Type”](#).

Testing is best done from a command prompt in a console window (or “DOS window”). In this way you can have the server display status messages in the window where they are easy to see. If something is wrong with your configuration, these messages make it easier for you to identify and fix any problems.

To start the server, enter this command:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.1\bin\mysqld" --console
```

For a server that includes `InnoDB` support, you should see the messages similar to those following as it starts (the path names and sizes may differ):

```
InnoDB: The first specified datafile c:\ibdata\ibdata1 did not exist!
InnoDB: a new database to be created!
InnoDB: Setting file c:\ibdata\ibdata1 size to 209715200
InnoDB: Database physically writes the file full: wait...
InnoDB: Log file c:\iblogs\ib_logfile0 did not exist: new to be created
InnoDB: Setting log file c:\iblogs\ib_logfile0 size to 31457280
InnoDB: Log file c:\iblogs\ib_logfile1 did not exist: new to be created
InnoDB: Setting log file c:\iblogs\ib_logfile1 size to 31457280
InnoDB: Log file c:\iblogs\ib_logfile2 did not exist: new to be created
InnoDB: Setting log file c:\iblogs\ib_logfile2 size to 31457280
InnoDB: Doublewrite buffer not found: creating new
InnoDB: Doublewrite buffer created
InnoDB: creating foreign key constraint system tables
InnoDB: foreign key constraint system tables created
011024 10:58:25 InnoDB: Started
```

When the server finishes its startup sequence, you should see something like this, which indicates that the server is ready to service client connections:

```
mysqld: ready for connections
Version: '5.1.52' socket: '' port: 3306
```

The server continues to write to the console any further diagnostic output it produces. You can open a new console window in which to run client programs.

If you omit the `--console` option, the server writes diagnostic output to the error log in the data directory (`C:\Program Files\MySQL\MySQL Server 5.1\data` by default). The error log is the file with the `.err` extension.

##### Note

The accounts that are listed in the MySQL grant tables initially have no passwords. After starting the server, you should set up passwords for them using the instructions in [Section 2.13, “Post-Installation Setup and Testing”](#).

#### 2.4.5.5. Starting MySQL Server from the Windows Command Line

The MySQL server can be started manually from the command line. This can be done on any version of Windows.

To start the `mysqld` server from the command line, you should start a console window (or “DOS window”) and enter this command:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.1\bin\mysqld"
```

The path to `mysqld` may vary depending on the install location of MySQL on your system.

You can stop the MySQL server by executing this command:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.1\bin\mysqladmin" -u root shutdown
```

### Note

If the MySQL `root` user account has a password, you need to invoke `mysqladmin` with the `-p` option and supply the password when prompted.

This command invokes the MySQL administrative utility `mysqladmin` to connect to the server and tell it to shut down. The command connects as the MySQL `root` user, which is the default administrative account in the MySQL grant system. Note that users in the MySQL grant system are wholly independent from any login users under Windows.

If `mysqld` doesn't start, check the error log to see whether the server wrote any messages there to indicate the cause of the problem. The error log is located in the `C:\Program Files\MySQL\MySQL Server 5.1\data` directory. It is the file with a suffix of `.err`. You can also try to start the server as `mysqld --console`; in this case, you may get some useful information on the screen that may help solve the problem.

The last option is to start `mysqld` with the `--standalone` and `--debug` options. In this case, `mysqld` writes a log file `C:\mysqld.trace` that should contain the reason why `mysqld` doesn't start. See [MySQL Internals: Porting](#).

Use `mysqld --verbose --help` to display all the options that `mysqld` supports.

## 2.4.5.6. Customizing the PATH for MySQL Tools

To make it easier to invoke MySQL programs, you can add the path name of the MySQL `bin` directory to your Windows system `PATH` environment variable:

- On the Windows desktop, right-click the My Computer icon, and select Properties.
- Next select the Advanced tab from the SYSTEM PROPERTIES menu that appears, and click the ENVIRONMENT VARIABLES button.
- Under **SYSTEM VARIABLES**, select Path, and then click the EDIT button. The EDIT SYSTEM VARIABLE dialogue should appear.
- Place your cursor at the end of the text appearing in the space marked **VARIABLE VALUE**. (Use the **End** key to ensure that your cursor is positioned at the very end of the text in this space.) Then enter the complete path name of your MySQL `bin` directory (for example, `C:\Program Files\MySQL\MySQL Server 5.1\bin`)

### Note

There must be a semicolon separating this path from any values present in this field.

Dismiss this dialogue, and each dialogue in turn, by clicking OK until all of the dialogues that were opened have been dismissed. You should now be able to invoke any MySQL executable program by typing its name at the DOS prompt from any directory on the system, without having to supply the path. This includes the servers, the `mysql` client, and all MySQL command-line utilities such as `mysqladmin` and `mysqldump`.

You should not add the MySQL `bin` directory to your Windows `PATH` if you are running multiple MySQL servers on the same machine.

### Warning

You must exercise great care when editing your system `PATH` by hand; accidental deletion or modification of any portion of the existing `PATH` value can leave you with a malfunctioning or even unusable system.

## 2.4.5.7. Starting MySQL Server as a Microsoft Windows Service

On Windows, the recommended way to run MySQL is to install it as a Windows service, whereby MySQL starts and stops automatically when Windows starts and stops, and can be managed using the service manager framework. A MySQL server installed as a service can also be controlled from the command line using `NET` commands, or with the graphical `Services` utility. Generally, to install MySQL as a Windows service you should be logged in using an account that has administrator rights.

The `Services` utility (the Windows `Service Control Manager`) can be found in the Windows Control Panel (under Administrative Tools on Windows 2000, XP, Vista and Server 2003). To avoid conflicts, it is advisable to close the `Services` utility while performing server installation or removal operations from the command line.

Before installing MySQL as a Windows service, you should first stop the current server if it is running by using the following command:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.1\bin\mysqladmin"
 -u root shutdown
```

### Note

If the MySQL `root` user account has a password, you need to invoke `mysqladmin` with the `-p` option and supply the password when prompted.

This command invokes the MySQL administrative utility `mysqladmin` to connect to the server and tell it to shut down. The command connects as the MySQL `root` user, which is the default administrative account in the MySQL grant system. Note that users in the MySQL grant system are wholly independent from any login users under Windows.

Install the server as a service using this command:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.1\bin\mysqld" --install
```

### Note

The service-installation command does not start the server.

The following additional arguments can be used in MySQL 5.1 when installing the service:

- You can specify a service name immediately following the `--install` option. The default service name is `MySQL`.
- If a service name is given, it can be followed by a single option. By convention, this should be `--defaults-file=file_name` to specify the name of an option file from which the server should read options when it starts.

The use of a single option other than `--defaults-file` is possible but discouraged. `--defaults-file` is more flexible because it enables you to specify multiple startup options for the server by placing them in the named option file.

- You can also specify a `--local-service` option following the service name. This causes the server to run using the `LocalService` Windows account that has limited system privileges. This account is available only for Windows XP or newer. If both `--defaults-file` and `--local-service` are given following the service name, they can be in any order.

For a MySQL server that is installed as a Windows service, the following rules determine the service name and option files that the server uses:

- If the service-installation command specifies no service name or the default service name (`MySQL`) following the `--install` option, the server uses the a service name of `MySQL` and reads options from the `[mysqld]` group in the standard option files.
- If the service-installation command specifies a service name other than `MySQL` following the `--install` option, the server uses that service name. It reads options from the `[mysqld]` group and the group that has the same name as the service in the standard option files. This enables you to use the `[mysqld]` group for options that should be used by all MySQL services, and an option group with the service name for use by the server installed with that service name.
- If the service-installation command specifies a `--defaults-file` option after the service name, the server reads options only from the `[mysqld]` group of the named file and ignores the standard option files.

As a more complex example, consider the following command:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.1\bin\mysqld"
 --install MySQL --defaults-file=C:\my-opt.cnf
```

Here, the default service name (`MySQL`) is given after the `--install` option. If no `--defaults-file` option had been given, this command would have the effect of causing the server to read the `[mysqld]` group from the standard option files. However, because the `--defaults-file` option is present, the server reads options from the `[mysqld]` option group, and only from the named file.

You can also specify options as Start parameters in the Windows `Services` utility before you start the MySQL service.

Once a MySQL server has been installed as a service, Windows starts the service automatically whenever Windows starts. The service also can be started immediately from the `Services` utility, or by using a `NET START MySQL` command. The `NET` command is not case sensitive.

When run as a service, `mysqld` has no access to a console window, so no messages can be seen there. If `mysqld` does not start,

check the error log to see whether the server wrote any messages there to indicate the cause of the problem. The error log is located in the MySQL data directory (for example, `C:\Program Files\MySQL\MySQL Server 5.1\data`). It is the file with a suffix of `.err`.

When a MySQL server has been installed as a service, and the service is running, Windows stops the service automatically when Windows shuts down. The server also can be stopped manually by using the `Services` utility, the `NET STOP MySQL` command, or the `mysqladmin shutdown` command.

You also have the choice of installing the server as a manual service if you do not wish for the service to be started automatically during the boot process. To do this, use the `--install-manual` option rather than the `--install` option:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.1\bin\mysqld" --install-manual
```

To remove a server that is installed as a service, first stop it if it is running by executing `NET STOP MySQL`. Then use the `--remove` option to remove it:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.1\bin\mysqld" --remove
```

If `mysqld` is not running as a service, you can start it from the command line. For instructions, see [Section 2.4.5.5, “Starting MySQL Server from the Windows Command Line”](#).

Please see [Section 2.4.6, “Troubleshooting a Microsoft Windows MySQL Server Installation”](#), if you encounter difficulties during installation.

## 2.4.5.8. Testing The MySQL Server Installation on Microsoft Windows

You can test whether the MySQL server is working by executing any of the following commands:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.1\bin\mysqlshow"
C:\> "C:\Program Files\MySQL\MySQL Server 5.1\bin\mysqlshow" -u root mysql
C:\> "C:\Program Files\MySQL\MySQL Server 5.1\bin\mysqladmin" version status proc
C:\> "C:\Program Files\MySQL\MySQL Server 5.1\bin\mysql" test
```

### Note

By default, `mysqlshow` will try to connect using the `ODBC` user. This user is not created by default. You should specify a valid user, or `root` with the right password to check the operation of the server.

If `mysqld` is slow to respond to TCP/IP connections from client programs, there is probably a problem with your DNS. In this case, start `mysqld` with the `--skip-name-resolve` option and use only `localhost` and IP numbers in the `Host` column of the MySQL grant tables.

You can force a MySQL client to use a named-pipe connection rather than TCP/IP by specifying the `--pipe` or `--protocol=PIPE` option, or by specifying `.` (period) as the host name. Use the `--socket` option to specify the name of the pipe if you do not want to use the default pipe name.

Note that if you have set a password for the `root` account, deleted the anonymous account, or created a new user account, then you must use the appropriate `-u` and `-p` options with the commands shown above to connect with the MySQL Server. See [Section 4.2.2, “Connecting to the MySQL Server”](#).

For more information about `mysqlshow`, see [Section 4.5.6, “mysqlshow — Display Database, Table, and Column Information”](#).

## 2.4.6. Troubleshooting a Microsoft Windows MySQL Server Installation

When installing and running MySQL for the first time, you may encounter certain errors that prevent the MySQL server from starting. The purpose of this section is to help you diagnose and correct some of these errors.

Your first resource when troubleshooting server issues is the error log. The MySQL server uses the error log to record information relevant to the error that prevents the server from starting. The error log is located in the data directory specified in your `my.ini` file. The default data directory location is `C:\Program Files\MySQL\MySQL Server 5.1\data`, or `C:\ProgramData\MySQL` on Windows 7 and Windows Server 2008. The `C:\ProgramData` directory is hidden by default. You need to change your folder options to see the directory and contents. For more information on the error log and understanding the content, see [Section 5.2.2, “The Error Log”](#).

Another source of information regarding possible errors is the console messages displayed when the MySQL service is starting. Use the `NET START MySQL` command from the command line after installing `mysqld` as a service to see any error messages regarding the starting of the MySQL server as a service. See [Section 2.4.5.7, “Starting MySQL Server as a Microsoft Windows Service”](#).

The following examples show other common error messages you may encounter when installing MySQL and starting the server for the first time:

- If the MySQL server cannot find the `mysql` privileges database or other critical files, you may see these messages:

```
System error 1067 has occurred.
Fatal error: Can't open privilege tables: Table 'mysql.host' doesn't exist
```

These messages often occur when the MySQL base or data directories are installed in different locations than the default locations (`C:\Program Files\MySQL\MySQL Server 5.1` and `C:\Program Files\MySQL\MySQL Server 5.1\data`, respectively).

This situation may occur when MySQL is upgraded and installed to a new location, but the configuration file is not updated to reflect the new location. In addition, there may be old and new configuration files that conflict. Be sure to delete or rename any old configuration files when upgrading MySQL.

If you have installed MySQL to a directory other than `C:\Program Files\MySQL\MySQL Server 5.1`, you need to ensure that the MySQL server is aware of this through the use of a configuration (`my.ini`) file. The `my.ini` file needs to be located in your Windows directory, typically `C:\WINDOWS`. You can determine its exact location from the value of the `WINDIR` environment variable by issuing the following command from the command prompt:

```
C:\> echo %WINDIR%
```

An option file can be created and modified with any text editor, such as Notepad. For example, if MySQL is installed in `E:\mysql` and the data directory is `D:\MySQLdata`, you can create the option file and set up a [`mysqld`] section to specify values for the `basedir` and `datadir` options:

```
[mysqld]
set basedir to your installation path
basedir=E:/mysql
set datadir to the location of your data directory
datadir=D:/MySQLdata
```

Note that Windows path names are specified in option files using (forward) slashes rather than backslashes. If you do use backslashes, double them:

```
[mysqld]
set basedir to your installation path
basedir=C:\\Program Files\\\\MySQL\\\\MySQL Server 5.1
set datadir to the location of your data directory
datadir=D:\\MySQLdata
```

The rules for use of backslash in option file values are given in [Section 4.2.3.3, “Using Option Files”](#).

If you change the `datadir` value in your MySQL configuration file, you must move the contents of the existing MySQL data directory before restarting the MySQL server.

See [Section 2.4.5.2, “Creating an Option File”](#).

- If you reinstall or upgrade MySQL without first stopping and removing the existing MySQL service and install MySQL using the MySQL Config Wizard, you may see this error:

```
Error: Cannot create Windows service for MySql. Error: 0
```

This occurs when the Config Wizard tries to install the service and finds an existing service with the same name.

One solution to this problem is to choose a service name other than `mysql` when using the configuration wizard. This enables the new service to be installed correctly, but leaves the outdated service in place. Although this is harmless, it is best to remove old services that are no longer in use.

To permanently remove the old `mysql` service, execute the following command as a user with administrative privileges, on the command-line:

```
C:\> sc delete mysql
[SC] DeleteService SUCCESS
```

If the `sc` utility is not available for your version of Windows, download the `delsrv` utility from <http://www.microsoft.com/windows2000/techinfo/reskit/tools/existing/delsrv-o.asp> and use the `delsrv mysql` syntax.

## 2.4.7. Upgrading MySQL Server on Microsoft Windows

This section lists some of the steps you should take when upgrading MySQL on Windows.

1. Review [Section 2.12.1, “Upgrading MySQL”](#), for additional information on upgrading MySQL that is not specific to Windows.
2. You should always back up your current MySQL installation before performing an upgrade. See [Section 6.2, “Database Backup Methods”](#).
3. Download the latest Windows distribution of MySQL from <http://dev.mysql.com/downloads/>.
4. Before upgrading MySQL, you must stop the server. If the server is installed as a service, stop the service with the following command from the command prompt:

```
C:\> NET STOP MySQL
```

If you are not running the MySQL server as a service, use the `mysqladmin` command to stop it:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.1\bin\mysqladmin" -u root shutdown
```

### Note

If the MySQL `root` user account has a password, you need to invoke `mysqladmin` with the `-p` option and supply the password when prompted.

5. When upgrading to MySQL 5.1 from a version previous to 4.1.5, or when upgrading from a version of MySQL installed from a Zip archive to a version of MySQL installed with the MySQL Installation Wizard, you must manually remove the previous installation and MySQL service (if the server is installed as a service).

To remove the MySQL service, use the following command:

```
C:\> C:\mysql\bin\mysqld --remove
```

### Important

If you do not remove the existing service, the MySQL Installation Wizard may fail to properly install the new MySQL service.

6. When upgrading from MySQL 5.1.23 to MySQL 5.1.24, the change in the default location of the data directory from a directory within the MySQL installation to the `AppData` folder means that you must manually copy the data files from your old installation to the new location.
7. If you are using the MySQL Installation Wizard, start the wizard as described in [Section 2.4.3.1, “Using the MySQL Installation Wizard for Microsoft Windows”](#).
8. If you are installing MySQL from a Zip archive, extract the archive. You may either overwrite your existing MySQL installation (usually located at `C:\mysql`), or install it into a different directory, such as `C:\mysql5`. Overwriting the existing installation is recommended.
9. If you were running MySQL as a Windows service and you had to remove the service earlier in this procedure, reinstall the service. (See [Section 2.4.5.7, “Starting MySQL Server as a Microsoft Windows Service”](#).)
10. Restart the server. For example, use `NET START MySQL` if you run MySQL as a service, or invoke `mysqld` directly otherwise.
11. If you encounter errors, see [Section 2.4.6, “Troubleshooting a Microsoft Windows MySQL Server Installation”](#).

## 2.4.8. MySQL Server on Microsoft Windows Post-Installation Procedures

On Windows, you need not create the data directory and the grant tables. MySQL Windows distributions include the grant tables with a set of preinitialized accounts in the `mysql` database under the data directory. It is unnecessary to run the `mysql_install_db` script that is used on Unix. Regarding passwords, if you installed MySQL using the Windows Installation Wizard, you may have already assigned passwords to the accounts. (See [Section 2.4.3.1, “Using the MySQL Installation Wizard for Microsoft Windows”](#).) Otherwise, use the password-assignment procedure given in [Section 2.13.2, “Securing the Initial MySQL Accounts”](#).

Before setting up passwords, you might want to try running some client programs to make sure that you can connect to the server and that it is operating properly. Make sure that the server is running (see [Section 2.4.5.4, “Starting MySQL Server on Microsoft Windows for the First Time”](#)), and then issue the following commands to verify that you can retrieve information from the server. You may need to specify directory different from `C:\mysql\bin` on the command line. If you used the Windows Installation Wizard, the default directory is `C:\Program Files\MySQL\MySQL Server 5.1`, and the `mysql` and `mysqlshow` client programs are in `C:\Program Files\MySQL\MySQL Server 5.1\bin`. See [Section 2.4.3.1, “Using the MySQL Installation Wizard for Microsoft Windows”](#), for more information.

Use `mysqlshow` to see what databases exist:

```
C:\> C:\mysql\bin\mysqlshow
+-----+
| Databases |
+-----+
| information_schema |
| mysql |
| test |
+-----+
```

The list of installed databases may vary, but will always include the minimum of `mysql` and `information_schema`. In most cases, the `test` database will also be installed automatically.

The preceding command (and commands for other MySQL programs such as `mysql`) may not work if the correct MySQL account does not exist. For example, the program may fail with an error, or you may not be able to view all databases. If you installed using the MSI packages and used the MySQL Server Instance Config Wizard, then the `root` user will have been created automatically with the password you supplied. In this case, you should use the `-u root` and `-p` options. (You will also need to use the `-u root` and `-p` options if you have already secured the initial MySQL accounts.) With `-p`, you will be prompted for the `root` password. For example:

```
C:\> C:\mysql\bin\mysqlshow -u root -p
Enter password: (enter root password here)
+-----+
| Databases |
+-----+
| information_schema |
| mysql |
| test |
+-----+
```

If you specify a database name, `mysqlshow` displays a list of the tables within the database:

```
C:\> C:\mysql\bin\mysqlshow mysql
Database: mysql
+-----+
| Tables |
+-----+
| columns_priv |
| db |
| event |
| func |
| help_category |
| help_keyword |
| help_relation |
| help_topic |
| host |
| plugin |
| proc |
| procs_priv |
| servers |
| tables_priv |
| time_zone |
| time_zone_leap_second |
| time_zone_name |
| time_zone_transition |
| time_zone_transition_type |
| user |
+-----+
```

Use the `mysql` program to select information from a table in the `mysql` database:

```
C:\> C:\mysql\bin\mysql -e "SELECT Host,Db,User FROM mysql.db"
+-----+-----+-----+
| host | db | user |
+-----+-----+-----+
| % | test |
| % | test_%|
+-----+-----+-----+
```

For more information about `mysqlshow` and `mysql`, see [Section 4.5.6, “mysqlshow — Display Database, Table, and Column Information”](#), and [Section 4.5.1, “mysql — The MySQL Command-Line Tool”](#).

If you are running a version of Windows that supports services, you can set up the MySQL server to run automatically when Windows starts. See [Section 2.4.5.7, “Starting MySQL Server as a Microsoft Windows Service”](#).

## 2.4.9. Installing MySQL from Source on Windows

These instructions describe how to build binaries from source for MySQL 5.1 on Windows. Instructions are provided for building binaries from a standard source distribution or from the Bazaar tree that contains the latest development source.

### Note

The instructions here are strictly for users who want to test MySQL on Microsoft Windows from the latest source distribution or from the Bazaar tree. For production use, we do not advise using a MySQL server built by yourself from source. Normally, it is best to use precompiled binary distributions of MySQL that are built specifically for optimal performance on Windows by Oracle Corporation. Instructions for installing binary distributions are available in [Section 2.4, “Installing MySQL on Microsoft Windows”](#).

To build MySQL on Windows from source, you must satisfy the following system, compiler, and resource requirements:

- Windows 2000, Windows XP, or newer version.

Windows Vista is supported when using Visual Studio 2005 provided you have installed the following updates:

- [Microsoft Visual Studio 2005 Professional Edition - ENU Service Pack 1 \(KB926601\)](#)
- [Security Update for Microsoft Visual Studio 2005 Professional Edition - ENU \(KB937061\)](#)
- [Update for Microsoft Visual Studio 2005 Professional Edition - ENU \(KB932232\)](#)
- CMake, which can be downloaded from <http://www.cmake.org>. After installing, modify your path to include the `cmake` binary.
- Microsoft Visual C++ 2005 Express Edition, Visual Studio .Net 2003 (7.1), or Visual Studio 2005 (8.0) compiler system.
- If you are using Visual C++ 2005 Express Edition, you must also install an appropriate Platform SDK. More information and links to downloads for various Windows platforms is available from [ht-tp://www.microsoft.com/downloads/details.aspx?familyid=0baf2b35-c656-4969-ace8-e4c0c0716adb](http://www.microsoft.com/downloads/details.aspx?familyid=0baf2b35-c656-4969-ace8-e4c0c0716adb).
- If you are compiling from a Bazaar tree or making changes to the parser, you need `bison` for Windows, which can be downloaded from <http://gnuwin32.sourceforge.net/packages/bison.htm>. Download the package labeled “Complete package, excluding sources”. After installing the package, modify your path to include the `bison` binary and ensure that this binary is accessible from Visual Studio.

### Note

The default location for the Windows version of `bison` installs into the `C:\Program Files\GnuWin32`. Some utilities, including `m4`, may fail to find `bison` because of the space in the directory name. You can resolve this by installing into a directory that does not contain a space; for example `C:\GnuWin32`.

- Cygwin might be necessary if you want to run the test script or package the compiled binaries and support files into a Zip archive. (Cygwin is needed only to test or package the distribution, not to build it.) Cygwin is available from <http://cygwin.com>.
- 3GB to 5GB of disk space.

The exact system requirements for Visual Studio can be found here: [ht-tp://msdn.microsoft.com/vstudio/Previous/2003/sysreqs/default.aspx](http://msdn.microsoft.com/vstudio/Previous/2003/sysreqs/default.aspx) and [ht-tp://msdn.microsoft.com/vstudio/products/sysreqs/default.aspx](http://msdn.microsoft.com/vstudio/products/sysreqs/default.aspx)

You also need a MySQL source distribution for Windows, which can be obtained two ways:

- Obtain a source distribution packaged by Oracle Corporation. These are available from <http://dev.mysql.com/downloads/>.
- Package a source distribution yourself from the latest Bazaar developer source tree. For instructions on pulling the latest source files, see [Section 2.3.4, “Installing from the Development Source Tree”](#).

If you find something not working as expected, or you have suggestions about ways to improve the current build process on Windows, please send a message to the `win32` mailing list. See [Section 1.6.1, “MySQL Mailing Lists”](#).

## 2.4.9.1. Building MySQL from Source Using CMake and Visual Studio

You can build MySQL on Windows by using a combination of `cmake` and Microsoft Visual Studio .NET 2003 (7.1), Microsoft Visual Studio 2005 (8.0), Microsoft Visual Studio 2008 (9.0) or Microsoft Visual C++ 2005 Express Edition. You must have the appropriate Microsoft Platform SDK installed.

### Note

To compile from the source code on Windows you must use the standard source distribution (for example, `mysql-5.1.52.tar.gz`). You build from the same distribution as used to build MySQL on Unix, Linux and other platforms. Do *not* use the Windows Source distributions as they do not contain the necessary configuration script and other files.

Follow this procedure to build MySQL:

1. If you are installing from a packaged source distribution, create a work directory (for example, `C:\workdir`), and unpack the source distribution there using `WinZip` or another Windows tool that can read `.zip` files. This directory is the work directory in the following instructions.

### Note

You must run the commands in the `win` directory from the top-level source directory. Do not change into the `win` directory, as the commands will not be executed correctly.

2. Start a command shell. If you have not configured the `PATH` and other environment variables for all command shells, you may be able to start a command shell from the **START MENU** within the Windows Visual Studio menu that contains the necessary environment changes.
3. Within the command shell, navigate to the work directory and run the following command:

```
C:\workdir>win\configure.js options
```

If you have associated the `.js` file extension with an application such as a text editor, then you may need to use the following command to force `configure.js` to be executed as a script:

```
C:\workdir>cscript win\configure.js options
```

These options are available for `configure.js`:

- `WITH_INNODB_STORAGE_ENGINE`: Enable the `InnoDB` storage engine.
- `WITH_PARTITION_STORAGE_ENGINE`: Enable user-defined partitioning.
- `WITH_ARCHIVE_STORAGE_ENGINE`: Enable the `ARCHIVE` storage engine.
- `WITH_BLACKHOLE_STORAGE_ENGINE`: Enable the `BLACKHOLE` storage engine.
- `WITH_EXAMPLE_STORAGE_ENGINE`: Enable the `EXAMPLE` storage engine.
- `WITH_FEDERATED_STORAGE_ENGINE`: Enable the `FEDERATED` storage engine.
- `WITH_NDBCLUSTER_STORAGE_ENGINE`: Enable the `NDBCLUSTER` storage engine in the MySQL server; cause binaries for the MySQL Cluster management and data node, management client, and other programs to be built.

This option is supported only in MySQL Cluster NDB 7.0 (`NDBCLUSTER` storage engine versions 6.4.0 and later) using the MySQL Cluster sources. It cannot be used to enable clustering support in other MySQL source trees or distributions.

- `MYSQL_SERVER_SUFFIX=suffix`: Server suffix, default none.
- `COMPILE_COMMENT=comment`: Server comment, default "Source distribution".
- `MYSQL_TCP_PORT=port`: Server port, default 3306.
- `DISABLE_GRANT_OPTIONS`: Disables the `--bootstrap`, `--skip-grant-tables`, and `--init-file` options for `mysqld`. This option is available as of MySQL 5.1.15.

For example (type the command on one line):

```
C:\workdir>win\configure.js WITH_INNODB_STORAGE_ENGINE
WITH_PARTITION_STORAGE_ENGINE MYSQL_SERVER_SUFFIX=-pro
```

4. From the work directory, execute the `win\build-vs9.bat` (Windows Visual Studio 2008), `win\build-vs8.bat` (Windows Visual Studio 2005), or `win\build-vs71.bat` (Windows Visual Studio 2003) script, depending on the version of Visual Studio you have installed. The script invokes CMake, which generates the `mysql.sln` solution file.

You can also use the corresponding 64-bit file (for example `win\build-vs8_x64.bat` or `win\build-vs9_x64.bat`) to build the 64-bit version of MySQL. However, you cannot build the 64-bit version with Visual Studio Express Edition. You must use Visual Studio 2005 (8.0) or higher.

5. From the work directory, open the generated `mysql.sln` file with Visual Studio and select the proper configuration using the `CONFIGURATION` menu. The menu provides Debug, Release, RelWithDebInfo, MinRelInfo options. Then select `SOLUTION` > Build to build the solution.

Remember the configuration that you use in this step. It is important later when you run the test script because that script needs to know which configuration you used.

6. Test the server. The server built using the preceding instructions expects that the MySQL base directory and data directory are `C:\mysql` and `C:\mysql\data` by default. If you want to test your server using the source tree root directory and its data directory as the base directory and data directory, you need to tell the server their path names. You can either do this on the command line with the `--basedir` and `--datadir` options, or by placing appropriate options in an option file. (See [Section 4.2.3.3, “Using Option Files”](#).) If you have an existing data directory elsewhere that you want to use, you can specify its path name instead.

When the server is running in standalone fashion or as a service based on your configuration, try to connect to it from the `mysql` interactive command-line utility.

You can also run the standard test script, `mysql-test-run.pl`. This script is written in Perl, so you'll need either Cygwin or ActiveState Perl to run it. You may also need to install the modules required by the script. To run the test script, change location into the `mysql-test` directory under the work directory, set the `MTR_VS_CONFIG` environment variable to the configuration you selected earlier (or use the `--vs-config` option), and invoke `mysql-test-run.pl`. For example (using Cygwin and the `bash` shell):

```
shell> cd mysql-test
shell> export MTR_VS_CONFIG=debug
shell> ./mysql-test-run.pl --force --timer
shell> ./mysql-test-run.pl --force --timer --ps-protocol
```

When you are satisfied that the programs you have built are working correctly, stop the server. Now you can install the distribution. One way to do this is to use the `make_win_bin_dist` script in the `scripts` directory of the MySQL source distribution (see [Section 4.4.2, “make\\_win\\_bin\\_dist — Package MySQL Distribution as ZIP Archive”](#)). This is a shell script, so you must have Cygwin installed if you want to use it. It creates a Zip archive of the built executables and support files that you can unpack in the location at which you want to install MySQL.

It is also possible to install MySQL by copying directories and files directly:

1. Create the directories where you want to install MySQL. For example, to install into `C:\mysql`, use these commands:

```
C:\> mkdir C:\mysql
C:\> mkdir C:\mysql\bin
C:\> mkdir C:\mysql\data
C:\> mkdir C:\mysql\share
C:\> mkdir C:\mysql\scripts
```

If you want to compile other clients and link them to MySQL, you should also create several additional directories:

```
C:\> mkdir C:\mysql\include
C:\> mkdir C:\mysql\lib
C:\> mkdir C:\mysql\lib\debug
C:\> mkdir C:\mysql\lib\opt
```

If you want to benchmark MySQL, create this directory:

```
C:\> mkdir C:\mysql\sql-bench
```

Benchmarking requires Perl support. See [Section 2.15, “Perl Installation Notes”](#).

2. From the work directory, copy into the `C:\mysql` directory the following files and directories:

```
C:\> cd \workdir
C:\workdir> mkdir C:\mysql
```

```
C:\workdir> mkdir C:\mysql\bin
C:\workdir> copy client\Release*.exe C:\mysql\bin
C:\workdir> copy sql\Release\mysqld.exe C:\mysql\bin\mysqld.exe
C:\workdir> xcopy scripts*.* C:\mysql\scripts /E
C:\workdir> xcopy share*.* C:\mysql\share /E
```

If you want to compile other clients and link them to MySQL, you should also copy several libraries and header files:

```
C:\workdir> copy lib\Release\mysqlclient.lib C:\mysql\lib\debug
C:\workdir> copy lib\Release\libmysql.* C:\mysql\lib\debug
C:\workdir> copy lib\Release\zlib.* C:\mysql\lib\debug
C:\workdir> copy lib\Release\mysqlclient.lib C:\mysql\lib\opt
C:\workdir> copy lib\Release\libmysql.* C:\mysql\lib\opt
C:\workdir> copy lib\Release\zlib.* C:\mysql\lib\opt
C:\workdir> copy include*.h C:\mysql\include
C:\workdir> copy libmysql\libmysql.def C:\mysql\include
```

### Note

If you have compiled a Debug, rather than Release solution, you can replace `Release` with `Debug` in the source file names shown above.

If you want to benchmark MySQL, you should also do this:

```
C:\workdir> xcopy sql-bench*.* C:\mysql\bench /E
```

After installation, set up and start the server in the same way as for binary Windows distributions. This includes creating the system tables by running `mysql_install_db`. For more information, see [Section 2.4, “Installing MySQL on Microsoft Windows”](#).

## 2.4.10. Compiling MySQL Clients on Microsoft Windows

In your source files, you should include `my_global.h` before `mysql.h`:

```
#include <my_global.h>
#include <mysql.h>
```

`my_global.h` includes any other files needed for Windows compatibility (such as `windows.h`) if you compile your program on Windows.

You can either link your code with the dynamic `libmysql.lib` library, which is just a wrapper to load in `libmysql.dll` on demand, or link with the static `mysqlclient.lib` library.

The MySQL client libraries are compiled as threaded libraries, so you should also compile your code to be multi-threaded.

## 2.5. Installing MySQL on Mac OS X

MySQL for Mac OS X is available in a number of different forms:

- Native Package Installer format, which uses the native Mac OS X installer to walk you through the installation of MySQL. For more information, see [Section 2.5.2, “Installing MySQL on Mac OS X Using Native Packages”](#). You can use the package installer with Mac OS X 10.3 and later, and the package is available for both PowerPC and Intel architectures, and 32-bit and 64-bit architectures. There is no Universal Binary available using the package installation method. The user you use to perform the installation must have administrator privileges.
- Tar package format, which uses a file packaged using the Unix `tar` and `gzip` commands. To use this method, you will need to open a `Terminal` window. You do not need administrator privileges using this method, as you can install the MySQL server anywhere using this method. For more information on using this method, you can use the generic instructions for using a tar-ball, [Section 2.2, “Installing MySQL from Generic Binaries on Unix/Linux”](#). You can use the package installer with Mac OS X 10.3 and later, and available for both PowerPC and Intel architectures, and both 32-bit and 64-bit architectures. A Universal Binary, incorporating both Power PC and Intel architectures and 32-bit and 64-bit binaries is available.

In addition to the core installation, the Package Installer also includes [Section 2.5.3, “Installing the MySQL Startup Item”](#) and [Section 2.5.4, “Installing and Using the MySQL Preference Pane”](#), both of which simplify the management of your installation.

- Mac OS X server includes a version of MySQL as standard. If you want to use a more recent version than that supplied with the Mac OS X server release, you can make use of the package or tar formats. For more information on using the MySQL bundled with Mac OS X, see [Section 2.5.5, “Using the Bundled MySQL on Mac OS X Server”](#).

For additional information on using MySQL on Mac OS X, see [Section 2.5.1, “General Notes on Installing MySQL on Mac OS X”](#).

## 2.5.1. General Notes on Installing MySQL on Mac OS X

You should keep the following issues and notes in mind:

- The default location for the MySQL Unix socket is different on Mac OS X and Mac OS X Server depending on the installation type you chose. The default locations by installation are as follows:

**Table 2.13. MySQL Unix Socket locations on Mac OS X by install type**

|                                    |                       |
|------------------------------------|-----------------------|
| Package Installer from MySQL       | /tmp/mysql.sock       |
| Tarball from MySQL                 | /tmp/mysql.sock       |
| MySQL Bundled with Mac OS X Server | /var/mysql/mysql.sock |

To prevent issues, you should either change the configuration of the socket used within your application (for example, changing `php.ini`), or you should configure the socket location using a MySQL configuration file and the `socket` option. For more information, see [Section 5.1.2, “Server Command Options”](#).

- You may need (or want) to create a specific `mysql` user to own the MySQL directory and data. On Mac OS X 10.4 and lower you can do this by using the `Netinfo Manager` application, located within the `Utilities` folder within the `Applications` folder. On Mac OS X 10.5 and later you can do this through the `Directory Utility`. From Mac OS X 10.5 and later (including Mac OS X Server 10.5) the `mysql` should already exist. For use in single user mode, an entry for `_mysql` (note the underscore prefix) should already exist within the system `/etc/passwd` file.
- Due to a bug in the Mac OS X package installer, you may see this error message in the destination disk selection dialog:

```
You cannot install this software on this disk. (null)
```

If this error occurs, click the `Go Back` button once to return to the previous screen. Then click `Continue` to advance to the destination disk selection again, and you should be able to choose the destination disk correctly. We have reported this bug to Apple and it is investigating this problem.

- Because the MySQL package installer installs the MySQL contents into a version and platform specific directory, you can use this to upgrade and migrate your database between versions. You will need to either copy the `data` directory from the old version to the new version, or alternatively specify an alternative `datadir` value to set location of the data directory.
- You might want to add aliases to your shell's resource file to make it easier to access commonly used programs such as `mysql` and `mysqladmin` from the command line. The syntax for `bash` is:

```
alias mysql=/usr/local/mysql/bin/mysql
alias mysqladmin=/usr/local/mysql/bin/mysqladmin
```

For `tcsh`, use:

```
alias mysql /usr/local/mysql/bin/mysql
alias mysqladmin /usr/local/mysql/bin/mysqladmin
```

Even better, add `/usr/local/mysql/bin` to your `PATH` environment variable. You can do this by modifying the appropriate startup file for your shell. For more information, see [Section 4.2.1, “Invoking MySQL Programs”](#).

- After you have copied over the MySQL database files from the previous installation and have successfully started the new server, you should consider removing the old installation files to save disk space. Additionally, you should also remove older versions of the Package Receipt directories located in `/Library/Receipts/mysql-VERSION.pkg`.

## 2.5.2. Installing MySQL on Mac OS X Using Native Packages

You can install MySQL on Mac OS X 10.3.x (“Panther”) or newer using a Mac OS X binary package in PKG format instead of the binary tarball distribution. Please note that older versions of Mac OS X (for example, 10.1.x or 10.2.x) are **not** supported by this package.

The package is located inside a disk image (`.dmg`) file that you first need to mount by double-clicking its icon in the Finder. It should then mount the image and display its contents.

**Note**

Before proceeding with the installation, be sure to shut down all running MySQL server instances by using either the MySQL Manager Application (on Mac OS X Server) or `mysqladmin shutdown` on the command line.

When installing from the package version, you should also install the MySQL Preference Pane, which will enable you to control the startup and execution of your MySQL server from System Preferences. For more information, see [Section 2.5.4, “Installing and Using the MySQL Preference Pane”](#).

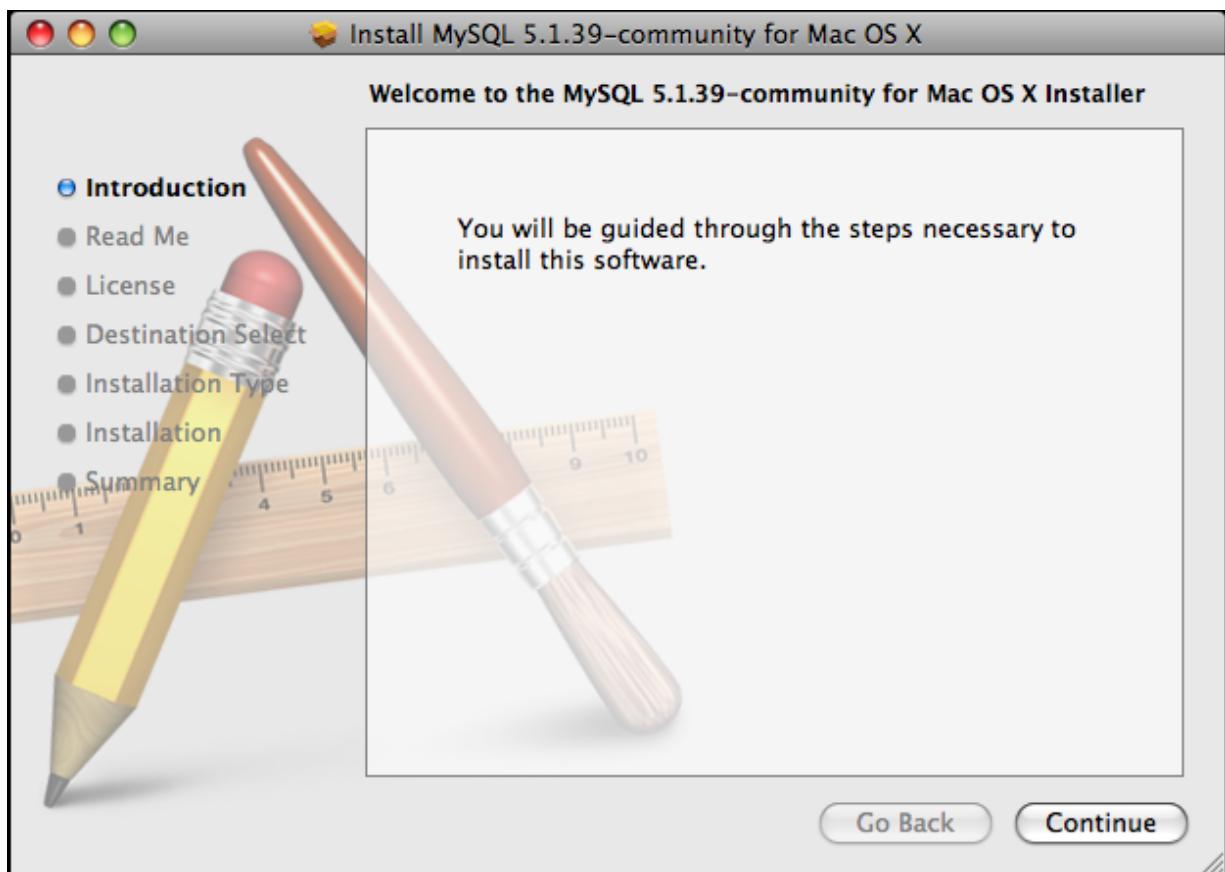

When installing using the package installer, the files are installed into a directory within `/usr/local` matching the name of the installation version and platform. For example, the installer file `mysql-5.1.39-osx10.5-x86_64.pkg` installs MySQL into `/usr/local/mysql-5.1.39-osx10.5-x86_64`. The installation layout of the directory is as shown in the following table:

**Table 2.14. MySQL Directory Layout on Mac OS X**

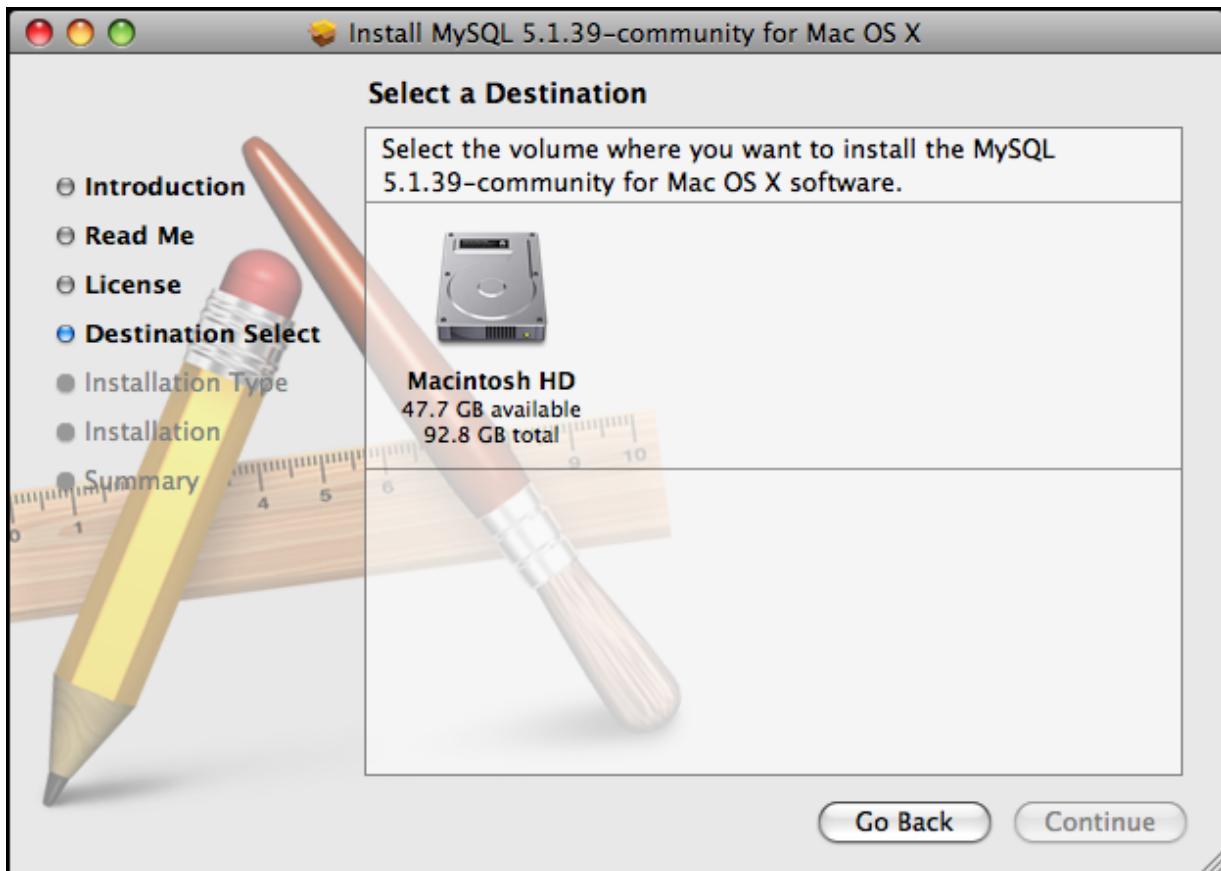

| Directory                    | Contents of Directory                                                                                            |
|------------------------------|------------------------------------------------------------------------------------------------------------------|
| <code>bin</code>             | Client programs and the <code>mysqld</code> server                                                               |
| <code>data</code>            | Log files, databases                                                                                             |
| <code>docs</code>            | Manual in Info format                                                                                            |
| <code>include</code>         | Include (header) files                                                                                           |
| <code>lib</code>             | Libraries                                                                                                        |
| <code>man</code>             | Unix manual pages                                                                                                |
| <code>mysql-test</code>      | MySQL test suite                                                                                                 |
| <code>scripts</code>         | Contains the <code>mysql_install_db</code> script                                                                |
| <code>share/mysql</code>     | Miscellaneous support files, including error messages, sample configuration files, SQL for database installation |
| <code>sql-bench</code>       | Benchmarks                                                                                                       |
| <code>support-files</code>   | Scripts and sample configuration files                                                                           |
| <code>/tmp/mysql.sock</code> | The location of the MySQL Unix socket                                                                            |

During the package installer process, a symbolic link from `/usr/local/mysql` to the version/platform specific directory created during installation will be created automatically.

1. Download and open the MySQL package installer, which is provided on a disk image (`.dmg`). Double-click to open the disk image, which includes the main MySQL installation package, the `MySQLStartupItem.pkg` installation package, and the `MySQL.prefPane`.
2. Double-click the MySQL installer package. It will be named according to the version of MySQL you have downloaded. For example, if you have downloaded MySQL 5.1.39, double-click `mysql-5.1.39-osx10.5-x86.pkg`.
3. You will be presented with the opening installer dialog. Click CONTINUE to begin installation.

4. A copy of the installation instructions and other important information relevant to this installation are displayed. Click CONTINUE .
5. If you have downloaded the community version of MySQL, you will be shown a copy of the relevant GNU General Public License. Click CONTINUE .
6. Select the drive you want to use to install the MySQL Startup Item. The drive must have a valid, bootable, Mac OS X operating system installed. Click CONTINUE .

7. You will be asked to confirm the details of the installation, including the space required for the installation. To change the drive on which the startup item is installed you can click either GO BACK or CHANGE INSTALL LOCATION.... To install the startup item, click INSTALL.
8. Once the installation has been completed successfully, you will be shown an **INSTALL SUCCEEDED** message.

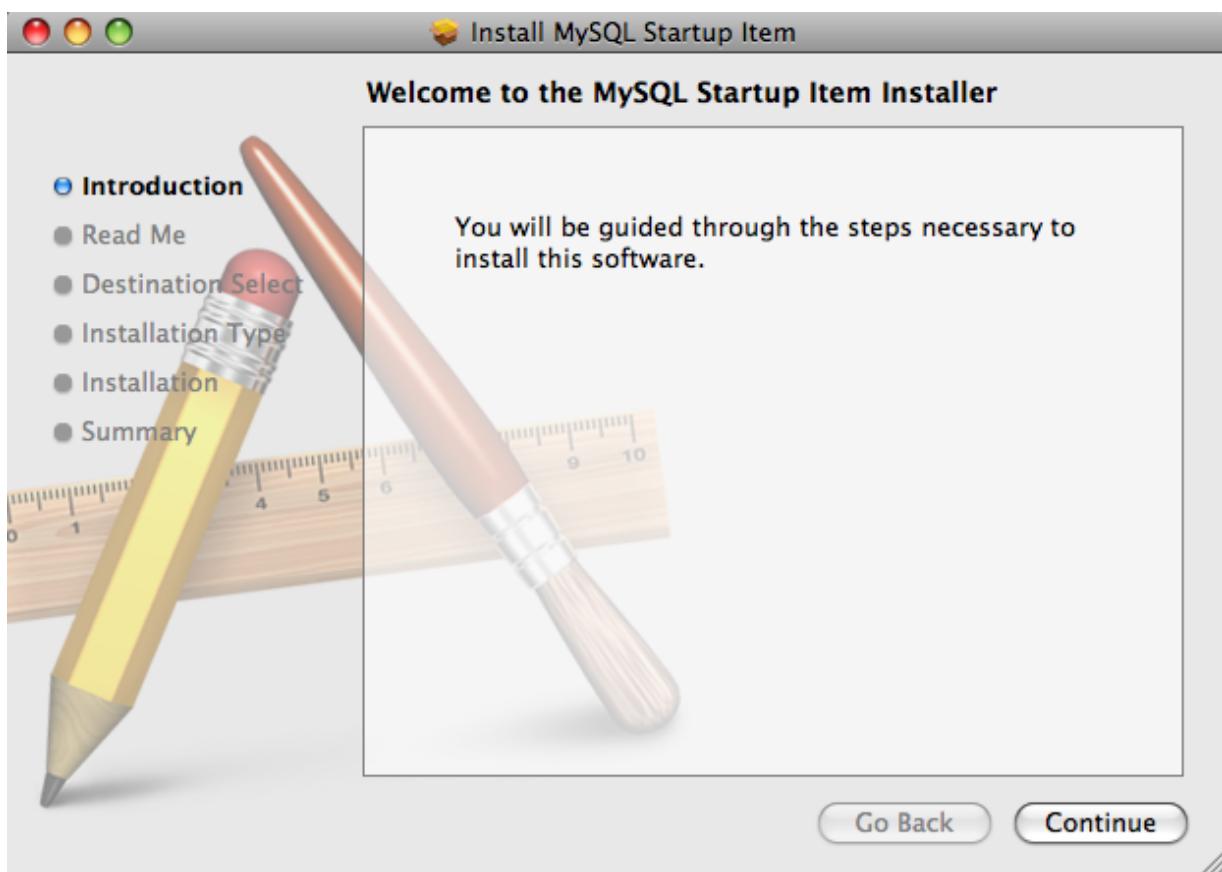

For convenience, you may also want to install the [Section 2.5.3, “Installing the MySQL Startup Item”](#) and [Section 2.5.4, “Installing and Using the MySQL Preference Pane”](#).

### 2.5.3. Installing the MySQL Startup Item

The MySQL Installation Package includes a startup item that can be used to automatically start up and shut down MySQL.

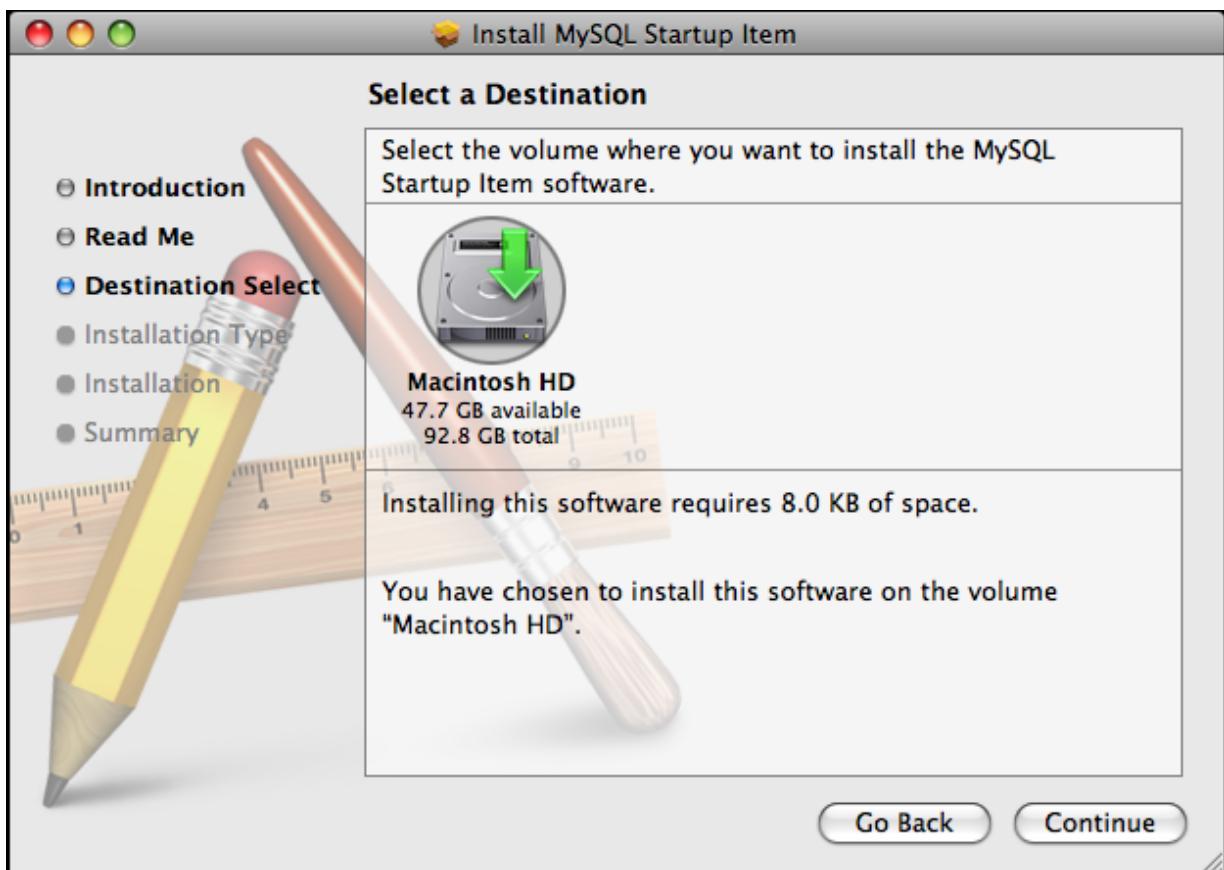

To install the MySQL Startup Item:

1. Download and open the MySQL package installer, which is provided on a disk image (`.dmg`). Double-click to open the disk image, which includes the main MySQL installation package, the `MySQLStartupItem.pkg` installation package, and the `MySQL.prefPane`.
2. Double-click the `MySQLStartupItem.pkg` file to start the installation process.
3. You will be presented with the **INSTALL MySQL STARTUP ITEM** dialog.

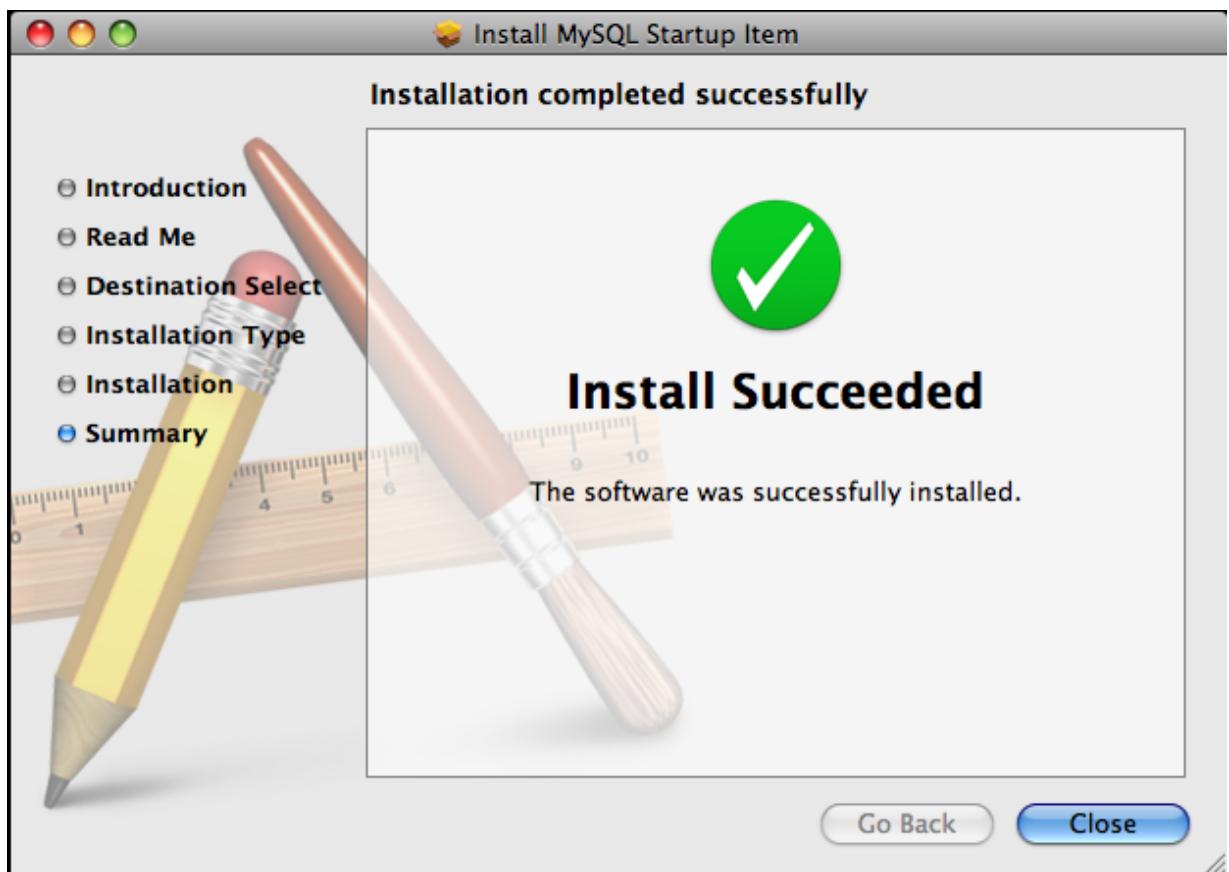

Click CONTINUE to continue the installation process.

4. A copy of the installation instructions and other important information relevant to this installation are displayed. Click CONTINUE .
5. Select the drive you want to use to install the MySQL Startup Item. The drive must have a valid, bootable, Mac OS X operating system installed. Click CONTINUE .

6. You will be asked to confirm the details of the installation. To change the drive on which the startup item is installed you can click either Go BACK or CHANGE INSTALL LOCATION.... To install the startup item, click INSTALL.
7. Once the installation has been completed successfully, you will be shown an **INSTALL SUCCEEDED** message.

The Startup Item for MySQL is installed into `/Library/StartupItems/MySQLCOM`. The Startup Item installation adds a variable `MYSQLCOM=YES` to the system configuration file `/etc/hostconfig`. If you want to disable the automatic startup of MySQL, change this variable to `MYSQLCOM=NO`.

After the installation, you can start up MySQL by running the following commands in a terminal window. You must have administrator privileges to perform this task.

If you have installed the Startup Item, use this command to start the server:

```
shell> sudo /Library/StartupItems/MySQLCOM/MySQLCOM start
```

You may be prompted for your password to complete the startup.

If you have installed the Startup Item, use this command to stop the server:

```
shell> sudo /Library/StartupItems/MySQLCOM/MySQLCOM stop
```

You may be prompted for your password to complete the shutdown.

## 2.5.4. Installing and Using the MySQL Preference Pane

The MySQL Package installer disk image also includes a custom MySQL Preference Pane that enables you to start, stop and control automated startup during boot of your MySQL installation.

To install the MySQL Preference Pane:

1. Download and open the MySQL package installer package, which is provided on a disk image (`.dmg`). Double-click to open the disk image, which includes the main MySQL installation package, the `MySQLStartupItem.pkg` installation package, and the `MySQL.prefPane`.
2. Double-click the `MySQL.prefPane`. The MySQL System Preferences will open.
3. If this is the first time you have installed the preference pane, you will be asked to confirm installation and whether you want

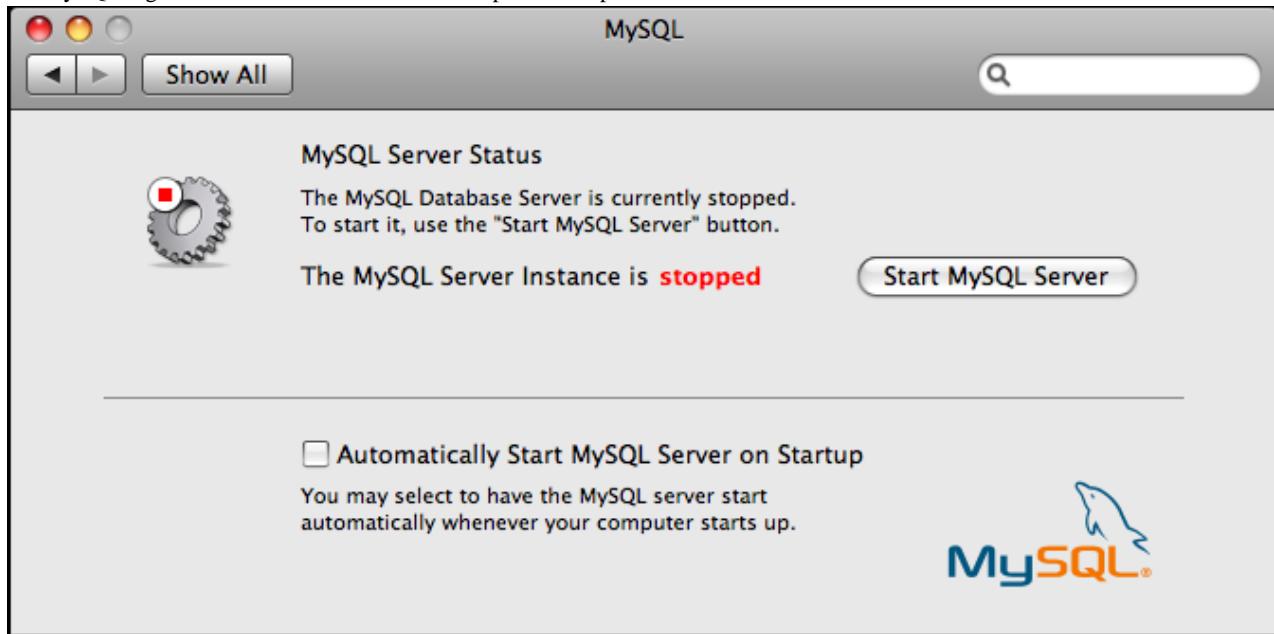

to install the preference pane for all users, or only the current user. To install the preference pane for all users you will need administrator privileges. If necessary, you will be prompted for the username and password for a user with administrator privileges.

4. If you already have the MySQL Preference Pane installed, you will be asked to confirm whether you want to overwrite the existing MySQL Preference Pane.

#### **Note**

The MySQL Preference Pane only starts and stops MySQL installation installed from the MySQL package installation that have been installed in the default location.

Once the MySQL Preference Pane has been installed, you can control your MySQL server instance using the preference pane. To use the preference pane, open the **SYSTEM PREFERENCES...** from the Apple menu. Select the MySQL preference pane by clicking the MySQL logo within the **OTHER** section of the preference panes list.

The MySQL Preference Pane shows the current status of the MySQL server, showing **STOPPED** (in red) if the server is not running and **RUNNING** (in green) if the server has already been started. The preference pane will also show the current setting for whether the MySQL server has been set to start up automatically.

- **To start MySQL using the preference pane:**

Click START MySQL SERVER. You may be prompted for the username and password of a user with administrator privileges to start the MySQL server.

- **To stop MySQL using the preference pane:**

Click STOP MySQL SERVER. You may be prompted for the username and password of a user with administrator privileges to shutdown the MySQL server.

- *To automatically start the MySQL server when the system boots:*

Check the checkbox next to **AUTOMATICALLY START MySQL SERVER ON STARTUP**.

- *To disable the automatic starting of the MySQL server when the system boots:*

Uncheck the checkbox next to **AUTOMATICALLY START MySQL SERVER ON STARTUP**.

You can close the **System Preferences...** once you have completed your settings.

## 2.5.5. Using the Bundled MySQL on Mac OS X Server

If you are running Mac OS X Server, a version of MySQL should already be installed. The following table shows the versions of

MySQL that ship with Mac OS X Server versions.

**Table 2.15. MySQL Versions Pre-installed with Mac OS X Server**

| Mac OS X Server Version | MySQL Version |
|-------------------------|---------------|
| 10.2-10.2.2             | 3.23.51       |
| 10.2.3-10.2.6           | 3.23.53       |
| 10.3                    | 4.0.14        |
| 10.3.2                  | 4.0.16        |
| 10.4.0                  | 4.1.10a       |
| 10.5.0                  | 5.0.45        |
| 10.6.0                  | 5.0.82        |

The installation layout of MySQL on Mac OS X Server is as shown in the table below:

**Table 2.16. MySQL Directory Layout for Pre-installed MySQL installations on Mac OS X Server**

| Directory                   | Contents of Directory                                                                                                                 |
|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| /usr/bin                    | Client programs                                                                                                                       |
| /var/mysql                  | Log files, databases                                                                                                                  |
| /usr/libexec                | The <code>mysqld</code> server                                                                                                        |
| /usr/share/man              | Unix manual pages                                                                                                                     |
| /usr/share/mysql/mysql-test | MySQL test suite                                                                                                                      |
| /usr/share/mysql            | Miscellaneous support files, including error messages, character set files, sample configuration files, SQL for database installation |
| /var/mysql/mysql.sock       | The location of the MySQL Unix socket                                                                                                 |

### Note

The MySQL server bundled with Mac OS X Server does not include the MySQL client libraries and header files required if you want to access and use MySQL from a third-party driver, such as Perl DBI or PHP. For more information on obtaining and installing MySQL libraries, see [Mac OS X Server version 10.5: MySQL libraries available for download](#). Alternatively, you can ignore the bundled MySQL server and install MySQL from the package or tarball installation.

For more information on managing the bundled MySQL instance in Mac OS X Server 10.5, see [Mac OS X Server: Web Technologies Administration For Version 10.5 Leopard](#). For more information on managing the bundled MySQL instance in Mac OS X Server 10.6, see [Mac OS X Server: Web Technologies Administration Version 10.6 Snow Leopard](#).

## 2.6. Installing MySQL on Linux

Linux supports a number of different solutions for installing MySQL. The recommended method is to use one of the distributions from Oracle. If you choose this method, there are three options available:

- Installing from a generic binary package in `.tar.gz` format. See [Section 2.2, “Installing MySQL from Generic Binaries on Unix/Linux”](#) for more information.
- Extracting and compiling MySQL from a source distribution. For detailed instructions, see [Section 2.3, “Installing MySQL Using a Source Distribution”](#).
- Installing using a pre-compiled RPM package. For more information on using the RPM solution, see [Section 2.6.1, “Installing MySQL from RPM Packages on Linux”](#).

As an alternative, you can use the native package manager within your Linux distribution to automatically download and install MySQL for you. Native package installations can take care of the download and dependencies required to run MySQL, but the MySQL version will often be some way behind the currently available release. You will also normally be unable to install developmental releases, as these are not usually made available in the native repository. For more information on using the native package installers, see [Section 2.6.2, “Installing MySQL on Linux using Native Package Manager”](#).

**Note**

For many Linux installations, you will want to set up MySQL to be started automatically when your machine starts. Many of the native package installations perform this operation for you, but for source, binary and RPM solutions you may need to set this up separately. The required script, `mysql.server`, can be found in the `support-files` directory under the MySQL installation directory or in a MySQL source tree. You can install it as `/etc/init.d/mysql` for automatic MySQL startup and shutdown. See [Section 2.13.1.2, “Starting and Stopping MySQL Automatically”](#).

## 2.6.1. Installing MySQL from RPM Packages on Linux

The recommended way to install MySQL on RPM-based Linux distributions is by using the RPM packages. The RPMs that we provide to the community should work on all versions of Linux that support RPM packages and use `glibc` 2.3. To obtain RPM packages, see [Section 2.1.3, “How to Get MySQL”](#).

For non-RPM Linux distributions, you can install MySQL using a `.tar.gz` package. See [Section 2.2, “Installing MySQL from Generic Binaries on Unix/Linux”](#).

Installations created from our Linux RPM distributions result in files under the following system directories.

**Table 2.17. MySQL Installation Layout for Linux RPM**

| Directory                         | Contents of Directory                                                                                                                 |
|-----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <code>/usr/bin</code>             | Client programs and scripts                                                                                                           |
| <code>/usr/sbin</code>            | The <code>mysqld</code> server                                                                                                        |
| <code>/var/lib/mysql</code>       | Log files, databases                                                                                                                  |
| <code>/usr/share/info</code>      | Manual in Info format                                                                                                                 |
| <code>/usr/share/man</code>       | Unix manual pages                                                                                                                     |
| <code>/usr/include/mysql</code>   | Include (header) files                                                                                                                |
| <code>/usr/lib/mysql</code>       | Libraries                                                                                                                             |
| <code>/usr/share/mysql</code>     | Miscellaneous support files, including error messages, character set files, sample configuration files, SQL for database installation |
| <code>/usr/share/sql-bench</code> | Benchmarks                                                                                                                            |

**Note**

RPM distributions of MySQL often are provided by other vendors. Be aware that they may differ in features and capabilities from those built by us, and that the instructions in this manual do not necessarily apply to installing them. The vendor's instructions should be consulted instead.

In most cases, you need to install only the `MySQL-server` and `MySQL-client` packages to get a functional MySQL installation. The other packages are not required for a standard installation.

**RPMs for MySQL Cluster.** Beginning with MySQL 5.1.24, standard MySQL server RPMs built by MySQL no longer provide support for the `NDBCLUSTER` storage engine. MySQL Cluster users wanting to upgrade MySQL 5.1.23 or earlier installations from RPMs built by MySQL should upgrade to MySQL Cluster NDB 6.2 or MySQL Cluster NDB 6.3; RPMs that should work with most Linux distributions are available for both of these release series.

**Important**

When upgrading a MySQL Cluster RPM installation, you must upgrade *all* installed RPMs, including the `Server` and `Client` RPMs.

For more information about installing MySQL Cluster from RPMs, see [Section 17.2.1.1, “MySQL Cluster Multi-Computer Installation”](#).

For upgrades, if your installation was originally produced by installing multiple RPM packages, it is best to upgrade all the packages, not just some. For example, if you previously installed the server and client RPMs, do not upgrade just the server RPM.

The RPM packages shown in the following list are available. The names shown here use a suffix of `.glibc23.i386.rpm`, but particular packages can have different suffixes, described later.

- `MySQL-server-VERSION.glibc23.i386.rpm`

The MySQL server. You need this unless you only want to connect to a MySQL server running on another machine.

- `MySQL-client-VERSION.glibc23.i386.rpm`

The standard MySQL client programs. You probably always want to install this package.

- `MySQL-devel-VERSION.glibc23.i386.rpm`

The libraries and include files that are needed if you want to compile other MySQL clients, such as the Perl modules.

- `MySQL-debuginfo-VERSION.glibc23.i386.rpm`

This package contains debugging information. `debuginfo` RPMs are never needed to use MySQL software; this is true both for the server and for client programs. However, they contain additional information that might be needed by a debugger to analyze a crash.

- `MySQL-shared-VERSION.glibc23.i386.rpm`

This package contains the shared libraries (`libmysqlclient.so*`) that certain languages and applications need to dynamically load and use MySQL. It contains single-threaded and thread-safe libraries. If you install this package, do not install the `MySQL-shared-compat` package.

- `MySQL-shared-compat-VERSION.glibc23.i386.rpm`

This package includes the shared libraries for MySQL 3.23, 4.0, and so on, up to the current release. It contains single-threaded and thread-safe libraries. Install this package instead of `MySQL-shared` if you have applications installed that are dynamically linked against older versions of MySQL but you want to upgrade to the current version without breaking the library dependencies.

- `MySQL-shared-compat-advanced-gpl-VERSION.glibc23.i386.rpm`, `MySQL-shared-compat-advanced-VERSION.glibc23.i386.rpm`

These are like the `MySQL-shared-compat` package, but are for the “MySQL Enterprise Server – Advanced Edition” products. Install these packages rather than the normal `MySQL-shared-compat` package if you want to included shared client libraries for older MySQL versions.

- `MySQL-embedded-VERSION.glibc23.i386.rpm`

The embedded MySQL server library.

- `MySQL-ndb-management-VERSION.glibc23.i386.rpm`,  
`MySQL-ndb-storage-VERSION.glibc23.i386.rpm`, `MySQL-ndb-tools-VERSION.glibc23.i386.rpm`,  
`MySQL-ndb-extra-VERSION.glibc23.i386.rpm`

Packages that contain additional files for MySQL Cluster installations.

## Note

The `MySQL-ndb-tools` RPM requires a working installation of perl. Prior to MySQL 5.1.18, the `DBI` and `HTML::Template` packages were also required. See [Section 2.15, “Perl Installation Notes”](#), and [Section 17.4.21, “ndb\\_size.pl — NDBCLUSTER Size Requirement Estimator”](#), for more information.

- `MySQL-test-VERSION.glibc23.i386.rpm`

This package includes the MySQL test suite.

- `MySQL-VERSION.src.rpm`

This contains the source code for all of the previous packages. It can also be used to rebuild the RPMs on other architectures (for example, Alpha or SPARC).

The suffix of RPM package names (following the `VERSION` value) has the following syntax:

`.PLATFORM.CPU.rpm`

The `PLATFORM` and `CPU` values indicate the type of system for which the package is built. `PLATFORM` indicates the platform and `CPU` indicates the processor type or family.

All packages are dynamically linked against `glibc` 2.3. The `PLATFORM` value indicates whether the package is platform inde-

pendent or intended for a specific platform, as shown in the following table.

**Table 2.18. MySQL Linux Installation Packages**

|                            |                                                                                                 |
|----------------------------|-------------------------------------------------------------------------------------------------|
| <code>glibc23</code>       | Platform independent, should run on any Linux distribution that supports <code>glibc</code> 2.3 |
| <code>rhel3, rhel4</code>  | Red Hat Enterprise Linux 3 or 4                                                                 |
| <code>sles9, sles10</code> | SuSE Linux Enterprise Server 9 or 10                                                            |

In MySQL 5.1, only `glibc23` packages are available currently.

The `CPU` value indicates the processor type or family for which the package is built.

**Table 2.19. MySQL Installation packages for Linux CPU identifier**

|                     |                               |
|---------------------|-------------------------------|
| <code>i386</code>   | x86 processor, 386 and up     |
| <code>i586</code>   | x86 processor, Pentium and up |
| <code>x86_64</code> | 64-bit x86 processor          |
| <code>ia64</code>   | Itanium (IA-64) processor     |

To see all files in an RPM package (for example, a `MySQL-server` RPM), run a command like this:

```
shell> rpm -qpl MySQL-server-VERSION.glibc23.i386.rpm
```

To perform a standard minimal installation, install the server and client RPMs:

```
shell> rpm -i MySQL-server-VERSION.glibc23.i386.rpm
shell> rpm -i MySQL-client-VERSION.glibc23.i386.rpm
```

To install only the client programs, install just the client RPM:

```
shell> rpm -i MySQL-client-VERSION.glibc23.i386.rpm
```

RPM provides a feature to verify the integrity and authenticity of packages before installing them. If you would like to learn more about this feature, see [Section 2.1.4, “Verifying Package Integrity Using MD5 Checksums or GnuPG”](#).

The server RPM places data under the `/var/lib/mysql` directory. The RPM also creates a login account for a user named `mysql` (if one does not exist) to use for running the MySQL server, and creates the appropriate entries in `/etc/init.d/` to start the server automatically at boot time. (This means that if you have performed a previous installation and have made changes to its startup script, you may want to make a copy of the script so that you do not lose it when you install a newer RPM.) See [Section 2.13.1.2, “Starting and Stopping MySQL Automatically”](#), for more information on how MySQL can be started automatically on system startup.

If you want to install the MySQL RPM on older Linux distributions that do not support initialization scripts in `/etc/init.d` (directly or through a symlink), you should create a symbolic link that points to the location where your initialization scripts actually are installed. For example, if that location is `/etc/rc.d/init.d`, use these commands before installing the RPM to create `/etc/init.d` as a symbolic link that points there:

```
shell> cd /etc
shell> ln -s rc.d/init.d .
```

However, all current major Linux distributions should support the new directory layout that uses `/etc/init.d`, because it is required for LSB (Linux Standard Base) compliance.

In MySQL 5.1.49 and later, during an upgrade installation using the RPM packages, if the MySQL server is running when the upgrade occurs, the MySQL server is stopped, the upgrade occurs, and the MySQL server is restarted. If the MySQL server is not already running when the RPM upgrade occurs, the MySQL server is not started at the end of the installation.

If the RPM files that you install include `MySQL-server`, the `mysqld` server should be up and running after installation. You should be able to start using MySQL.

If something goes wrong, you can find more information in the binary installation section. See [Section 2.2, “Installing MySQL from Generic Binaries on Unix/Linux”](#).

### Note

The accounts that are listed in the MySQL grant tables initially have no passwords. After starting the server, you should set up passwords for them using the instructions in [Section 2.13, “Post-Installation Setup and Testing”](#).

During RPM installation, a user named `mysql` and a group named `mysql` are created on the system. This is done using the `useradd`, `groupadd`, and `usermod` commands. Those commands require appropriate administrative privileges, which is required for locally managed users and groups (as listed in the `/etc/passwd` and `/etc/group` files) by the RPM installation process being run by `root`.

If you log in as the `mysql` user, you may find that MySQL displays “Invalid (old?) table or database name” errors that mention `.mysqlgui`, `.lost+found`, `.mysqlgui`, `.bash_history`, `.fonts.cache-1`, `.lessht`, `.mysql_history`, `.profile`, `.viminfo`, and similar files created by MySQL or operating system utilities. You can safely ignore these error messages or remove the files or directories that cause them if you do not need them.

For nonlocal user management (LDAP, NIS, and so forth), the administrative tools may require additional authentication (such as a password), and will fail if the installing user does not provide this authentication. Even if they fail, the RPM installation will not abort but succeed, and this is intentional. If they failed, some of the intended transfer of ownership may be missing, and it is recommended that the system administrator then manually ensures some appropriate user and group exists and manually transfers ownership following the actions in the RPM spec file.

## 2.6.2. Installing MySQL on Linux using Native Package Manager

Many Linux distributions include a version of the MySQL server, client tools, and development components into the standard package management system built into distributions such as Fedora, Debian, Ubuntu, and Gentoo. This section provides basic instructions for installing MySQL using these systems.

### Important

Native package installations can take care of the download and dependencies required to run MySQL, but the MySQL version will often be some way behind the currently available release. You will also normally be unable to install developmental releases, as these are not usually made available in the native repository.

Distribution specific instructions are shown below:

- **RedHat Linux, Fedora, CentOS**

For RedHat and similar distributions, the MySQL distribution is divided into a number of separate packages, `mysql` for the client tools, `mysql-server` for the server and associated tools, and `mysql-libs` for the libraries. The libraries are required if you want to provide connectivity from different languages and environments such as Perl, Python and others.

To install, use the `yum` command to specify the packages that you want to install. For example:

```
root-shell> install mysql mysql-server mysql-libs mysql-server
Loaded plugins: presto, refresh-packagekit
Setting up Install Process

Dependency Installed:
 perl-DBD-MySQL.x86_64 0:4.017-1.fc13

Complete!
```

MySQL and the MySQL server should now be installed. A sample configuration file is installed into `/etc/my.cnf`. An init script, to start and stop the server, will have been installed into `/etc/init.d/mysqld`. To start the MySQL server use `service`:

```
root-shell> service mysqld start
```

To enable the server to be started and stopped automatically during boot, use `chkconfig`:

```
root-shell> chkconfig --levels 235 mysqld on
```

Which enables the MySQL server to be started (and stopped) automatically at the specified the run levels.

The database tables will have been automatically created for you, if they do not already exist. You should, however, run `mysql_secure_installation` to set the root passwords on your server.

- **Debian, Ubuntu, Kubuntu**

On Debian and related distributions, there are two packages, `mysql-client` and `mysql-server`, for the client and server components respectively. You should specify an explicit version, for example `mysql-client-5.1`, to ensure that you install the version of MySQL that you want.

To download and install, including any dependencies, use the `apt-get` command, specifying the packages that you want to install.

### Note

Before installing, make sure that you update your `apt-get` index files to ensure you are downloading the latest available version.

A sample installation of the MySQL packages might look like this (some sections trimmed for clarity):

```
root-shell> apt-get install mysql-client-5.1 mysql-server-5.1
Reading package lists... Done
Building dependency tree
Reading state information... Done
The following packages were automatically installed and are no longer required:
 linux-headers-2.6.28-11 linux-headers-2.6.28-11-generic
Use 'apt-get autoremove' to remove them.
The following extra packages will be installed:
 bsd-mailx libdbd-mysql-perl libdbi-perl libhtml-template-perl
 libmysqlclient15off libmysqlclient16 libnet-daemon-perl libplrpc-perl mailx
 mysql-common postfix
Suggested packages:
 dbi shell libipc-sharedcache-perl tinyca procmail postfix-mysql postfix-pgsql
 postfix-ldap postfix-pcre sasl2-bin resolvconf postfix-cdb
The following NEW packages will be installed
 bsd-mailx libdbd-mysql-perl libdbi-perl libhtml-template-perl
 libmysqlclient15off libmysqlclient16 libnet-daemon-perl libplrpc-perl mailx
 mysql-client-5.1 mysql-common mysql-server-5.1 postfix

```

### Note

The `apt-get` command will install a number of packages, including the MySQL server, in order to provide the typical tools and application environment. This can mean that you install a large number of packages in addition to the main MySQL package.

During installation, the initial database will be created, and you will be prompted for the MySQL root password (and confirmation). A configuration file will have been created in `/etc/mysql/my.cnf`. An init script will have been created in `/etc/init.d/mysql`.

The server will already be started. You can manually start and stop the server using:

```
root-shell> service mysql [start|stop]
```

The service will automatically be added to the 2, 3 and 4 run levels, with stop scripts in the single, shutdown and restart levels.

- **Gentoo Linux**

As a source-based distribution, installing MySQL on Gentoo involves downloading the source, patching the Gentoo specifics, and then compiling the MySQL server and installing it. This process is handled automatically by the `emerge` command. Depending on the version of MySQL that you want to install, you may need to unmask the specific version that you want for your chosen platform.

The MySQL server and client tools are provided within a single package, `dev-db/mysql`. You can obtain a list of the versions available to install by looking at the portage directory for the package:

```
root-shell> ls /usr/portage/dev-db/mysql/mysql-5.1*
mysql-5.1.39-r1.ebuild
mysql-5.1.44-r1.ebuild
mysql-5.1.44-r2.ebuild
mysql-5.1.44-r3.ebuild
mysql-5.1.44.ebuild
mysql-5.1.45-r1.ebuild
mysql-5.1.45.ebuild
mysql-5.1.46.ebuild
```

To install a specific MySQL version, you must specify the entire atom. For example:

```
root-shell> emerge =dev-db/mysql-5.1.46
```

A simpler alternative is to use the `virtual/mysql-5.1` package, which will install the latest version:

```
root-shell> emerge =virtual/mysql-5.1
```

If the package is masked (because it is not tested or certified for the current platform), use the `ACCEPT_KEYWORDS` environment variable. For example:

```
root-shell> ACCEPT_KEYWORDS="~x86" emerge =virtual/mysql-5.1
```

After installation, you should create a new database using `mysql_install_db`, and set the password for the root user on

MySQL. You can use the configuration interface to set the password and create the initial database:

```
root-shell> emerge --config =dev-db/mysql-5.1.46
```

A sample configuration file will have been created for you in `/etc/mysql/my.cnf`, and an init script will have been created in `/etc/init.d/mysql`.

To enable MySQL to start automatically at the normal (default) run levels, you can use:

```
root-shell> rc-update add default mysql
```

## 2.7. Installing MySQL on Solaris and OpenSolaris

MySQL on Solaris and OpenSolaris is available in a number of different formats.

- For information on installing using the native Solaris `PKG` format, see [Section 2.7.1, “Installing MySQL on Solaris using a Solaris PKG”](#).
- On OpenSolaris, the standard package repositories include MySQL packages specially built for OpenSolaris that include entries for the Service Management Framework (SMF) to enable control of the installation using the SMF administration commands. For more information, see [Section 2.7.2, “Installing MySQL on OpenSolaris using IPS”](#).
- To use a standard `tar` binary installation, use the notes provided in [Section 2.2, “Installing MySQL from Generic Binaries on Unix/Linux”](#). Check the notes and hints at the end of this section for Solaris specific notes that you may need before or after installation.
- For information on installing MySQL on Solaris or OpenSolaris using a source distribution, first check the Solaris advice, [Section 2.7.3, “Notes on Installing MySQL on Solaris from Source”](#). For detailed instructions on installing from source, see [Section 2.3, “Installing MySQL Using a Source Distribution”](#).

To obtain a binary MySQL distribution for Solaris in tarball or PKG format, <http://dev.mysql.com/downloads/mysql/5.1.html>.

Additional notes to be aware of when installing and using MySQL on Solaris:

- If you want to use MySQL with the `mysql` user and group, use the `groupadd` and `useradd` commands:

```
groupadd mysql
useradd -g mysql mysql
```

- If you install MySQL using a binary tarball distribution on Solaris, you may run into trouble even before you get the MySQL distribution unpacked, as the Solaris `tar` cannot handle long file names. This means that you may see errors when you try to unpack MySQL.

If this occurs, you must use GNU `tar (gtar)` to unpack the distribution. In Solaris 10 and OpenSolaris `gtar` is normally located in `/usr/sfw/bin/gtar`, but may not be included in the default path definition.

- When using Solaris 10 for `x86_64`, you should mount any file systems on which you intend to store `InnoDB` files with the `forcedirectio` option. (By default mounting is done without this option.) Failing to do so will cause a significant drop in performance when using the `InnoDB` storage engine on this platform.
- If you would like MySQL to start automatically, you can copy `support-files/mysql.server` to `/etc/init.d` and create a symbolic link to it named `/etc/rc3.d/S99mysql.server`.
- If too many processes try to connect very rapidly to `mysqld`, you should see this error in the MySQL log:

```
Error in accept: Protocol error
```

You might try starting the server with the `--back_log=50` option as a workaround for this.

- To configure the generation of core files on Solaris you should use the `coreadm` command. Because of the security implications of generating a core on a `setuid()` application, by default, Solaris does not support core files on `setuid()` programs. However, you can modify this behavior using `coreadm`. If you enable `setuid()` core files for the current user, they will be generated using the mode 600 and owned by the superuser.

## 2.7.1. Installing MySQL on Solaris using a Solaris PKG

You can install MySQL on Solaris and OpenSolaris using a binary package using the native Solaris PKG format instead of the binary tarball distribution.

To use this package, download the corresponding `mysql-VERSION-solaris10-PLATFORM.pkg.gz` file, then decompress it. For example

```
shell> gunzip mysql-5.1.48-solaris10-x86_64.pkg.gz
```

To install a new package, use `pkgadd` and follow the onscreen prompts. You must have root privileges to perform this operation:

```
shell> pkgadd -d mysql-5.1.48-solaris10-x86_64.pkg
The following packages are available:
 1 mysql MySQL Community Server (GPL)
 (i86pc) 5.1.48
Select package(s) you wish to process (or 'all' to process
all packages). (default: all) [?.,q]:
```

The `PKG` installer installs all of the files and tools needed, and then initializes your database if one does not exist. To complete the installation, you should set the root password for MySQL as provided in the instructions at the end of the installation. Alternatively, you can run the `mysql_secure_installation` script that comes with the installation.

The default installation directory is `/opt/mysql`. You can only change the root path of the installation when using `pkgadd`, which can be used to install MySQL in a different Solaris zone. If you need to install in a specific directory, use the binary `tar` file.

The `pkg` installer copies a suitable startup script for MySQL into `/etc/init.d/mysql`. To enable MySQL to startup and shutdown automatically, you should create a link between this file and the init script directories. For example, to ensure safe startup and shutdown of MySQL you could use the following commands to add the right links:

```
shell> ln /etc/init.d/mysql /etc/rc3.d/S91mysql
shell> ln /etc/init.d/mysql /etc/rc0.d/K02mysql
```

To remove MySQL, the installed package name is `mysql`. You can use this in combination with the `pkgrm` command to remove the installation.

To upgrade when using the Solaris package file format, you must remove the existing installation before installing the updated package. Removal of the package does not delete the existing database information, only the server, binaries and support files. The typical upgrade sequence is therefore:

```
shell> mysqladmin shutdown
shell> pkgrm mysql
shell> pkgadd -d mysql-5.1.48-solaris10-x86_64.pkg
shell> mysql_upgrade
shell> mysqld_safe &
```

You should check the notes in [Section 2.12, “Upgrading or Downgrading MySQL”](#) before performing any upgrade.

## 2.7.2. Installing MySQL on OpenSolaris using IPS

OpenSolaris includes standard packages for MySQL in the core repository. The MySQL packages are based on a specific release of MySQL and updated periodically. For the latest release you must either the native Solaris `PKG`, `tar` or source installations. The native OpenSolaris packages include SMF files so that you can easily control your MySQL installation, including automatic startup and recovery, using the native service management tools.

To install MySQL on OpenSolaris, use the `pkg` command. You will need to be logged in as root, or use the `pfexec` tool, as shown in the example below:

```
shell> pfexec pkg install SUNWmysql51
```

The package set installs three individual packages, `SUNWmysql51lib`, which contains the MySQL client libraries; `SUNWmysql51r` which contains the root components, including SMF and configuration files; and `SUNWmysql51u` which contains the scripts, binary tools and other files. You can install these packages individually if you only need the corresponding components.

The MySQL files are installed into `/usr/mysql` which symbolic links for the sub directories (`bin`, `lib`, etc.) to a version specific directory. For MySQL 5.1, the full installation is located in `/usr/mysql/5.1`. The default data directory is `/var/mysql/5.1/data`. The configuration file is installed in `/etc/mysql/5.1/my.cnf`. This layout permits multiple versions of MySQL to be installed, without overwriting the data and binaries from other versions.

Once installed, you must run `mysql_install_db` to initialize the database, and use the `mysql_secure_installation` to secure your installation.

## Using SMF to manage your MySQL installation

Once installed, you can start and stop your MySQL server using the installed SMF configuration. The service name is `mysql`, or if you have multiple versions installed, you should use the full version name, for example `mysql:version_51`. To start and enable MySQL to be started at boot time:

```
shell> svcadm enable mysql
```

To disable MySQL from starting during boot time, and shut the MySQL server down if it is running, use:

```
shell> svcadm disable mysql
```

To restart MySQL, for example after a configuration file changes, use the `restart` option:

```
shell> svcadm restart mysql
```

You can also use SMF to configure the data directory and enable full 64-bit mode. For example, to set the data directory used by MySQL:

```
shell> svccfg
svc:> select mysql:version_51
svc:/application/database/mysql:version_51> setprop mysql/data=/data0/mysql
```

By default, the 32-bit binaries are used. To enable the 64-bit server on 64-bit platforms, set the `enable_64bit` parameter. For example:

```
svc:/application/database/mysql:version_51> setprop mysql/enable_64bit=1
```

You need to refresh the SMF after settings these options:

```
shell> svcadm refresh mysql
```

### 2.7.3. Notes on Installing MySQL on Solaris from Source

When building MySQL on Solaris you can use either the Sun Studio or GNU cc compilers. For more information on specific notes and environments, use the following hints.

- When building you should ensure that your `PATH` variable includes the necessary tools, including `ar` for building libraries. Some tools are located in `/usr/ccs/bin`.
- When running `configure`, you should specify the C and C++ compiler explicitly to ensure that the right C compiler combination is used:

```
$ configure CC=gcc CXX=g++
```

- For detailed information on performance tuning your MySQL installation for Solaris, you can use the information from [Krish Shankar](#) and the [Sun Solaris MySQL Performance Tuning](#) pages.
- If you have an UltraSPARC system, you can get 4% better performance by adding `-mcpu=v8 -Wa,-xarch=v8plusa` to the `CFLAGS` and `CXXFLAGS` environment variables.
- If you have Sun's Forte 5.00 (or newer) or Sun Studio compiler, you can run `configure` like this:

```
CC=cc CFLAGS="-Xa -fast -native -xstrconst -mt" \
CXX=CC CXXFLAGS="-noex -mt" \
./configure --prefix=/usr/local/mysql --enable-assembler
```

- To create a 64-bit SPARC binary with Sun's Forte or Sun Studio compiler, use the following configuration options:

```
CC=cc CFLAGS="-Xa -fast -native -xstrconst -mt -xarch=v9" \
CXX=CC CXXFLAGS="-noex -mt -xarch=v9" ASFLAGS="-xarch=v9" \
./configure --prefix=/usr/local/mysql --enable-assembler
```

To create a 64-bit Solaris binary using `gcc`, add `-m64` to `CFLAGS` and `CXXFLAGS` and remove `--enable-assembler` from the `configure` line.

In the MySQL benchmarks, we obtained a 4% speed increase on UltraSPARC when using Forte 5.0 in 32-bit mode, as compared to using `gcc` 3.2 with the `-mcpu` flag.

If you create a 64-bit `mysqld` binary, it is 4% slower than the 32-bit binary, but can handle more threads and memory.

- If you get a problem with `fdatasync` or `sched_yield`, you can fix this by adding `LIBS=-lrt` to the `configure` line
- Solaris does not provide static versions of all system libraries (`libpthread` and `libdl`), so you cannot compile MySQL with `--static`. If you try to do so, you get one of the following errors:

```
ld: fatal: library -ldl: not found
undefined reference to `dlopen'
cannot find -lrt
```

- If you link your own MySQL client programs, you may see the following error at runtime:

```
ld.so.1: fatal: libmysqlclient.so.#:
open failed: No such file or directory
```

This problem can be avoided by one of the following methods:

- Use the `crle` tool to add the directory containing the `libmysqlclient` library file to the list of standard library directories. You need administrator privileges to do this. Make sure you update the library information, rather than replace it with the new path. For example, the following command adds the directory to the list of standard directories searched for libraries.

```
shell> crle -u -l /usr/local/mysql/lib
```

For 64-bit libraries, add the `-64` option:

```
shell> crle -64 -u -l /usr/local/mysql/lib
```

- Link clients with the `-Wl,r/full/path/to/libmysqlclient.so` flag rather than with `-Lpath`.
- Copy `libmysqlclient.so` to `/usr/lib`.
- Add the path name of the directory where `libmysqlclient.so` is located to the `LD_RUN_PATH` environment variable before running your client.
- If you have problems with `configure` trying to link with `-lz` when you do not have `zlib` installed, you have two options:
  - If you want to be able to use the compressed communication protocol, you need to get and install `zlib` from [ftp.gnu.org](http://ftp.gnu.org).
  - Run `configure` with the `--with-named-z-libs=no` option when building MySQL.
- If you are using `gcc` and have problems with loading user-defined functions (UDFs) into MySQL, try adding `-lgcc` to the link line for the UDF.

## 2.8. Installing MySQL on IBM AIX

MySQL for IBM AIX is available in a number of different forms:

- Using a binary tarball distribution provided at <http://dev.mysql.com/downloads/>. Please read the [general notes on AIX installation](#) before continuing. For more information on binary installations, see [Section 2.2, “Installing MySQL from Generic Binaries on Unix/Linux”](#).
- Using a source tarball and compiling MySQL. Please read the [general notes on AIX installation](#) before continuing. You should also check the instructions on [building on AIX from source](#). For general information on building from source, see [Section 2.3, “Installing MySQL Using a Source Distribution”](#).

### 2.8.1. General Notes on Installing MySQL on AIX

General notes on using MySQL on IBM AIX:

- If you have problems with threads on AIX 5.3, you should upgrade AIX 5.3 to technology level 7 (5300-07).

## 2.8.2. Notes on Installing MySQL on AIX from Source

General notes on building MySQL from source on IBM AIX:

- Automatic detection of `xlc` is missing from Autoconf, so a number of variables need to be set before running `configure`. The following example uses the IBM compiler:

```
export CC="xlc_r -ma -O3 -qstrict -qoptimize=3 -qmaxmem=8192 "
export CXX="xlc_r -ma -O3 -qstrict -qoptimize=3 -qmaxmem=8192"
export CFLAGS="-I /usr/local/include"
export LDFLAGS="-L /usr/local/lib"
export CPPFLAGS=$CFLAGS
export CXXFLAGS=$CFLAGS

./configure --prefix=/usr/local \
 --localstatedir=/var/mysql \
 --sbindir='/usr/local/bin' \
 --libexecdir='/usr/local/bin' \
 --enable-thread-safe-client \
 --enable-large-files
```

The preceding options are used to compile the MySQL distribution that can be found at <http://www-frec.bull.com/>.

- If you change the `-O3` to `-O2` in the preceding `configure` line, you must also remove the `-qstrict` option. This is a limitation in the IBM C compiler.
- If you are using `gcc` to compile MySQL, you *must* use the `-fno-exceptions` flag, because the exception handling in `gcc` is not thread-safe. There are also some known problems with IBM's assembler that may cause it to generate bad code when used with `gcc`.
- If you have problems with signals (MySQL dies unexpectedly under high load), you may have found an OS bug with threads and signals. In this case, you can tell MySQL not to use signals by configuring as follows:

```
CFLAGS=-DDONT_USE_THR_ALARM CXX=gcc \
CXXFLAGS="-felide-constructors -fno-exceptions -fno-rtti \
-DDONT_USE_THR_ALARM" \
./configure --prefix=/usr/local/mysql --with-debug \
 --with-low-memory
```

This doesn't affect the performance of MySQL, but has the side effect that you can't kill clients that are "sleeping" on a connection with `mysqladmin kill` or `mysqladmin shutdown`. Instead, the client dies when it issues its next command.

- On some versions of AIX, linking with `libbind.a` makes `getservbyname()` dump core. This is an AIX bug and should be reported to IBM.

## 2.9. Installing MySQL on HP-UX

MySQL for HP-UX is available in a number of different forms:

- Using a DEPOT distribution provided at <http://dev.mysql.com/downloads/>. Please read the [general notes on HP-UX installation](#) before continuing. For more information on DEPOT installations, see [Section 2.9.3, “Installing MySQL on HP-UX using DEPOT”](#).
- Using a binary tarball distribution provided at <http://dev.mysql.com/downloads/>. Please read the [general notes on HP-UX installation](#) before continuing. For more information on binary installations, see [Section 2.2, “Installing MySQL from Generic Binaries on Unix/Linux”](#).
- Using a source tarball and compiling MySQL. Please read the [general notes on HP-UX installation](#) before continuing. You should also check the instructions on [building on HP-UX from source](#). For general information on building from source, see [Section 2.3, “Installing MySQL Using a Source Distribution”](#).

### 2.9.1. General Notes on Installing MySQL on HP-UX

Some additional notes on installing and using MySQL on HP-UX:

- If you install MySQL using a binary tarball distribution on HP-UX, you may run into trouble even before you get the MySQL distribution unpacked, as the HP-UX `tar` cannot handle long file names. This means that you may see errors when you try to unpack MySQL.

If this occurs, you must use GNU `tar` (`gtar`) to unpack the distribution.

- Because of some critical bugs in the standard HP-UX libraries, you should install the following patches before trying to run MySQL on HP-UX 11.0:

```
PHKL_22840 Streams cumulative
PHNE_22397 ARPA cumulative
```

This solves the problem of getting `EWOULDBLOCK` from `recv()` and `EBADF` from `accept()` in threaded applications.

## 2.9.2. Notes on Installing MySQL on HP-UX from Source

Additional notes on compiling MySQL on HP-UX.

- If you are using HP-UX compiler, you can use the following command (which has been tested with `cc` B.11.11.04):

```
CC=cc CXX=aCC CFLAGS+=DD64 CXXFLAGS+=DD64 ./configure \
--with-extra-character-set=complex
```

You can ignore any errors of the following type:

```
aCC: warning 901: unknown option: `‐3': use +help for online
documentation
```

- If you get the following error from `configure`, verify that you do not have the path to the K&R compiler before the path to the HP-UX C and C++ compiler:

```
checking for cc option to accept ANSI C... no
configure: error: MySQL requires an ANSI C compiler (and a C++ compiler).
Try gcc. See the Installation chapter in the Reference Manual.
```

- Another reason for not being able to compile is that you didn't define the `+DD64` flags as just described.

## 2.9.3. Installing MySQL on HP-UX using DEPOT

The HP-UX DEPOT format packages can be installed using the `swinstall` command. You should install the `ncurses` and `zlib` libraries before installing the MySQL DEPOT package. You can use the free software `depothelper` tool to install these packages and any dependencies for you automatically.

To install using the MySQL DEPOT packages, follow this guide:

1. Download the MySQL DEPOT package from <http://dev.mysql.com/downloads/>. You must decompress the package before installation:

```
root-shell> gunzip mysql-5.1.48-hpux11.31-ia64-64bit.depot.gz
```

2. Install the DEPOT package using `swinstall`:

```
root-shell> swinstall -s mysql-5.1.49-hpux11.31-ia64-64bit.depot
```

MySQL will be installed into a directory matching the depot package name, within `/usr/local`. For convenience, you may want to create a symbolic link to the installed directory, for example:

```
root-shell> ln -s mysql-5.1.49-hpux11.31-ia64-64bit mysql
```

3. Your package is now installed. You should complete the configuration of MySQL by creating a user and group:

```
root-shell> /usr/sbin/groupadd mysql
```

```
root-shell> /usr/sbin/useradd -g mysql -d /var/lib/mysql/ -s /bin/false mysql
```

4. Create the standard database using the new user/group you have created, and set the permissions:

```
root-shell> cd /usr/local/
root-shell> scripts/mysql_install_db --user=mysql
root-shell> chown -R root .
root-shell> chown -R mysql data
```

5. Finally, secure your new installation by setting the root passwords, and then start your MySQL server using the `mysql` user:

```
root-shell> mysql_secure_installation
root-shell> mysqld_safe --user=mysql &
```

## 2.10. Installing MySQL on FreeBSD

This section provides information about installing MySQL on variants of FreeBSD Unix.

You can install MySQL on FreeBSD by using the binary distribution provided by Oracle. For more information, see [Section 2.2, “Installing MySQL from Generic Binaries on Unix/Linux”](#).

The easiest (and preferred) way to install MySQL is to use the `mysql-server` and `mysql-client` ports available at <http://www.freebsd.org/>. Using these ports gives you the following benefits:

- A working MySQL with all optimizations enabled that are known to work on your version of FreeBSD.
- Automatic configuration and build.
- Startup scripts installed in `/usr/local/etc/rc.d`.
- The ability to use `pkg_info -L` to see which files are installed.
- The ability to use `pkg_delete` to remove MySQL if you no longer want it on your machine.

The MySQL build process requires GNU make (`gmake`) to work. If GNU `make` is not available, you must install it first before compiling MySQL.

To install using the ports system:

```
cd /usr/ports/databases/mysql51-server
make
...
cd /usr/ports/databases/mysql51-client
make
...
```

The standard port installation places the server into `/usr/local/libexec/mysqld`, with the startup script for the MySQL server placed in `/usr/local/etc/rc.d/mysql-server`.

Some additional notes on the BSD implementation:

- To remove MySQL after installation using the ports system:

```
cd /usr/ports/databases/mysql51-server
make deinstall
...
cd /usr/ports/databases/mysql51-client
make deinstall
...
```

- If you get problems with the current date in MySQL, setting the `TZ` variable should help. See [Section 2.14, “Environment Variables”](#).

## 2.11. Installing MySQL on i5/OS

The i5/OS POWER MySQL package was created in cooperation with IBM. MySQL works within the Portable Application Solu-

tion Environment (PASE) on the System i series of hardware and will also provide database services for the Zend Core for i5/OS.

MySQL for i5/OS is provided both as a `tar` file and as a save file (`.savf`) package that can be downloaded and installed directly without any additional installation steps required. To install MySQL using the `tar` file, see [Section 2.2, “Installing MySQL from Generic Binaries on Unix/Linux”](#).

MySQL is only supported on i5/OS V5R4 or later releases. The i5/OS PASE must be installed for MySQL to operate. You must be able to login as a user in `*SECOFR` class.

You should the installation notes and tips for i5/OS before starting installation. See [i5/OS Installation Notes](#).

#### Before Installation:

##### Note

The installation package will use an existing configuration if you have previously installed MySQL (which is identified by looking for the file `/etc/my.cnf`). The values for the data directory (`DATADIR`) and owner of the MySQL files (`USRPRF`) specified during the installation will be ignored, and the values determined from the `/etc/my.cnf` will be used instead.

If you want to change these parameters during a new install, you should temporarily rename `/etc/my.cnf`, install MySQL using the new parameters you want to use, and then merge your previous `/etc/my.cnf` configuration settings with the new `/etc/my.cnf` file that is created during installation.

- You must have a user profile with PASE with suitable privileges. The user should be within the `*SECOFR` class, such as the `QSECOFR` user ID. You can use the `WRKUSRPRF` command to check your user profile.
- For network connections to MySQL, you must have TCP/IP enabled. You should also check the following:
  - Ensure that a name has defined for the system. Run the Configure TCP/IP (`CFGTCP`) command and select option 12 (Change TCP/IP domain information) to display this setting. Make sure that a value is listed in the Host name field.
  - Make sure that the system has a loopback entry which represents the `localhost` or `127.0.0.1`.
  - Ensure that the IP address of the IBM i machine is mapped correctly to the host name.

To install MySQL on i5/OS, follow these steps:

1. On the System i machine, create a save file that will be used to receive the downloaded installation save file. The file should be located within the General Purpose Library (`QGPL`):

```
CRTSAVF FILE(QGPL/MYSQLINST) TESXT('MySQL Save file')
```

2. Download the MySQL installation save file in 32-bit (`mysql-5.1.39-i5os-power-32bit.savf`) or 64-bit (`mysql-5.1.39-i5os-power-64bit.savf`) from [MySQL Downloads](#).
3. You need to FTP the downloaded `.savf` file directly into the `QGPL/MYSQLINST` file on the System i server. You can do this through FTP using the following steps after logging in to the System i machine:

```
ftp> bin
ftp> cd qgpl
ftp> put mysql-5.1.39-i5os-power.savf mysqlinst
```

4. Log into the System i server using a user in the `*SECOFR` class, such as the `QSECOFR` user ID.
5. You need to restore the installation library stored in the `.savf` save file:

```
RSTLIB MYSQLINST DEV(*SAVF) SAVF(QGPL/MYSQLINST) MBROPT(*ALL) ALWOBJDIF(*ALL)
```

##### Note

You can ignore the security changes-type message at the bottom of the installation panel.

6. Once you have finished restoring the `MYSQLINST` library, check that all the necessary objects for installation are on the system by using the Display Library (`DSPLIB`) command:

```
DSPLIB LIB(MYSQLINST)
```

7. You need to execute the installation command, `MYSQLINST/INSMYSQL`. You can specify three parameter settings during installation:
  - `DIR( '/QOpenSys/usr/local/mysql' )` sets the installation location for the MySQL files. The directory will be created if it does not already exist.
  - `DATADIR( '/QOpenSys/usr/local/mysql/data' )` sets the location of the directory that will be used to store the database files and binary logs. The default setting is `/QOpenSys/usr/local/mysql/data`. Note that if the installer detects an existing installation (due to the existence of `/etc/my.cnf`), then the existing setting will be used instead of the default.
  - `USRPRF(MYSQL)` sets the user profile that will own the files that are installed. The profile will be created if it does not already exist.

**Note**

You should choose an appropriate user for using the MySQL server installation. The user will be used whenever you need to do any administration on the MySQL server.

Once you have set the appropriate parameters, you can begin the installation.

The installation copies all the necessary files into a directory matching the `DIR` configuration value; sets the ownership on those files, sets up the MySQL environment and creates the MySQL configuration file (in `/etc/my.cnf`) completing all the steps in a typical binary installation process automatically. If this is a new installation of MySQL, or if the installer detects that this is a new version (because the `/etc/my.cnf` file does not exist), then the initial core MySQL databases will also be created during installation.

Once the installation has been completed, you will get a notice advising you to set the password for the root user. For more information, [Section 2.13, “Post-Installation Setup and Testing”](#).

8. Once the installation has completed, you can delete the installation file:

```
DLTLIB LIB(MYSQLINST)
```

## Upgrading an existing MySQL instance

You need to execute the upgrade command, `MYSQLINST/UPGMYSQL`.

**Note**

You cannot use `MYSQLINST/UPGMYSQL` to upgrade between major versions of MySQL (for example from 5.0 to 5.1). For information and advice on migrating between major versions you can use the advice provided in [Section 2.12.1.1, “Upgrading from MySQL 5.0 to 5.1”](#).

You must specify 6 parameters to perform an upgrade:

- `DIR( '/QOpenSys/usr/local/' )`: Sets the installation location for the MySQL files. The directory will be created if it does not already exist. This is the directory that the MySQL server will be installed into, inside a directory with a name matching the version and release. For example, if installing MySQL 5.1.39 with the `DIR` set to `/QOpenSys/usr/local/` would result in `/QOpenSys/usr/local/mysql-5.1.39-i5os-power64` and a symbolic link to this directory will be created in `/QOpenSys/usr/local/mysql`.
- `DATADIR( '/QOpenSys/mysql/data' )`: Sets the location of the directory that will be upgraded.
- `USRPRF( 'MYSQL' )`: Sets the user profile that will own the files that are installed. The profile will be created if it does not already exist; if it is created as part of the upgrade process, it will be disabled initially. You may wish to enable this user profile so that it can be used to start the MySQL server later. It is best practice to use the one previously created during the first installation.
- `MYSQLUSR( 'root user' )`: Any user account in the current MySQL server with `SUPER` privileges.
- `PASSWORD( 'root user password' )`: The password for the above account. This is necessary as the upgrade starts the MySQL server to upgrade the tables and the password is needed to be able to shutdown the MySQL server.
- `CURINST( 'path to previous install' )`: The full path to the installation that is being upgraded. For example an installation in `/QOpenSys/usr/local/` will be `/QOpenSys/usr/local/mysql-5.1.30-i5os-power64`. Failure to specify this option may result in corruption of your existing data files.

For example:

```
MYSQLINST/UPGMYSQL DIR('/QOpenSys/usr/local/') DATADIR('/QOpenSys/mysql/data') »
 USERPRF(MYSQL) MYSQLUSR('root') PASSWORD('root') CURINST('/QOpenSys/usr/local/mysql-5.1.30-i5os-power64')
```

You should receive a Program Message indicating **UPGRADE SUCCESSFUL!** upon completion or an error message if there is a problem. You can view the upgrade programs progression and the error in the text file `upgrade.log` in the installation directory.

#### To start MySQL:

1. Log into the System i server using the user profile create or specified during installation. By default, this is **MYSQL**.

##### Note

You should start `mysqld_safe` using a user that in the PASE environment has the id=0 (the equivalent of the standard Unix `root` user). If you do not use a user with this ID then the system will be unable to change the user when executing `mysqld` as set using `--user` option. If this happens, `mysqld` may be unable to read the files located within the MySQL data directory and the execution will fail.

2. Enter the PASE environment using `call qp2term`.
3. Start the MySQL server by changing to the installation directory and running `mysqld_safe`, specifying the user name used to install the server. The installer conveniently installs a symbolic link to the installation directory (`mysql-5.0.42-i5os-power-32bit`) as `/opt/mysql/mysql`:

```
> cd /opt/mysql/mysql
> bin/mysqld_safe --user=mysql &
```

You should see a message similar to the following:

```
Starting mysqld daemon with databases »
 from /opt/mysql/mysql-enterprise-5.0.42-i5os-power-32bit/data
```

If you are having problems starting MySQL server, see [Section 2.13.1.3, “Starting and Troubleshooting the MySQL Server”](#).

#### To stop MySQL:

1. Log into the System i server using the user profile create or specified during installation. By default, this is **MYSQL**.
2. Enter the PASE environment using `call qp2term`.
3. Stop the MySQL server by changing into the installation directory and running `mysqladmin`, specifying the user name used to install the server:

```
> cd /opt/mysql/mysql
> bin/mysqladmin -u root shutdown
```

If the session that you started and stopped MySQL are the same, you may get the log output from `mysqld`:

```
STOPPING server from pid file »
 /opt/mysql/mysql-enterprise-5.0.42-i5os-power-32bit/data/I5DBX.RCHLAND.IBM.COM.pid
070718 10:34:20 mysqld ended
```

If the sessions used to start and stop MySQL are different, you will not receive any confirmation of the shutdown.

#### Note and tips

- A problem has been identified with the installation process on DBCS systems. If you are having problems install MySQL on a DBCS system, you need to change your job's coded character set identifier (`CSSID`) to 37 (`EBCDIC`) before executing the install command, `INSMYSQL`. To do this, determine your existing `CSSID` (using `DSPJOB` and selecting option 2), execute `CHGJOB CSSID(37)`, run `INSMYSQL` to install MySQL and then execute `CHGJOB` again with your original `CSSID`.
- If you want to use the Perl scripts that are included with MySQL, you need to download the iSeries Tools for Developers (5799-PTL). See <http://www-03.ibm.com/servers/enable/site/porting/tools/>.

## 2.12. Upgrading or Downgrading MySQL

### 2.12.1. Upgrading MySQL

As a general rule, to upgrade from one release series to another, you should go to the next series rather than skipping a series. To upgrade from a release series previous to MySQL 5.0, upgrade to each successive release series in turn until you have reached MySQL 5.0, and then proceed with the upgrade to MySQL 5.1. For example, if you currently are running MySQL 4.1 and wish to upgrade to a newer series, upgrade to MySQL 5.0 first before upgrading to 5.1, and so forth. For information on upgrading to MySQL 5.0, see the *MySQL 5.0 Reference Manual*; for earlier releases, see the *MySQL 3.23, 4.0, 4.1 Reference Manual*.

If you perform a binary (in-place) upgrade without dumping and reloading tables, you cannot upgrade directly from MySQL 4.1 to 5.1. This occurs due to an incompatible change in the `MyISAM` table index format in MySQL 5.0. Upgrade from MySQL 4.1 to 5.0 and repair all `MyISAM` tables (see [Section 2.12.4, “Rebuilding or Repairing Tables or Indexes”](#)). Then upgrade from MySQL 5.0 to 5.1 and check and repair your tables.

To upgrade from MySQL 5.0 to 5.1, use the items in the following checklist as a guide:

- Before any upgrade, back up your databases, including the `mysql` database that contains the grant tables. See [Section 6.2, “Database Backup Methods”](#).
- Read *all* the notes in [Section 2.12.1.1, “Upgrading from MySQL 5.0 to 5.1”](#). These notes enable you to identify upgrade issues that apply to your current MySQL installation. Some incompatibilities discussed in that section require your attention *before* upgrading. Others should be dealt with *after* upgrading.
- Read [Appendix C, MySQL Change History](#) as well, which provides information about features that are new in MySQL 5.1 or differ from those found in MySQL 5.0.
- After upgrading to a new version of MySQL, run `mysql_upgrade` (see [Section 4.4.8, “mysql\\_upgrade — Check Tables for MySQL Upgrade”](#)). This program checks your tables, and attempts to repair them if necessary. It also updates your grant tables to make sure that they have the current structure so that you can take advantage of any new capabilities. (Some releases of MySQL introduce changes to the structure of the grant tables to add new privileges or features.)

`mysql_upgrade` does not upgrade the contents of the help tables. For upgrade instructions, see [Section 5.1.8, “Server-Side Help”](#).

- If you run MySQL Server on Windows, see [Section 2.4.7, “Upgrading MySQL Server on Microsoft Windows”](#).
- If you use replication, see [Section 16.4.3, “Upgrading a Replication Setup”](#), for information on upgrading your replication setup.
- If you upgrade an installation originally produced by installing multiple RPM packages, it is best to upgrade all the packages, not just some. For example, if you previously installed the server and client RPMs, do not upgrade just the server RPM.
- As of MySQL 5.1.9, the `mysqld-max` server is included in binary distributions. There is no separate MySQL-Max distribution. As of MySQL 5.1.12, there is no `mysqld-max` server at all in binary distributions. They contain a server that includes the features previously included in `mysqld-max`.
- If you have created a user-defined function (UDF) with a given name and upgrade MySQL to a version that implements a new built-in function with the same name, the UDF becomes inaccessible. To correct this, use `DROP FUNCTION` to drop the UDF, and then use `CREATE FUNCTION` to re-create the UDF with a different nonconflicting name. The same is true if the new version of MySQL implements a built-in function with the same name as an existing stored function. See [Section 8.2.4, “Function Name Parsing and Resolution”](#), for the rules describing how the server interprets references to different kinds of functions.

You can always move the MySQL format files and data files between different versions on systems with the same architecture as long as you stay within versions for the same release series of MySQL.

If you are cautious about using new versions, you can always rename your old `mysqld` before installing a newer one. For example, if you are using MySQL 5.0.13 and want to upgrade to 5.1.10, rename your current server from `mysqld` to `mysqld-5.0.13`. If your new `mysqld` then does something unexpected, you can simply shut it down and restart with your old `mysqld`.

If, after an upgrade, you experience problems with compiled client programs, such as `Commands out of sync` or unexpected core dumps, you probably have used old header or library files when compiling your programs. In this case, you should check the date for your `mysql.h` file and `libmysqlclient.a` library to verify that they are from the new MySQL distribution. If not, recompile your programs with the new headers and libraries. Recompilation might also be necessary for programs compiled against the shared client library if the library major version number has changed (for example from `libmysqlclient.so.15` to `libmysqlclient.so.16`).

If problems occur, such as that the new `mysqld` server does not start or that you cannot connect without a password, verify that

you do not have an old `my.cnf` file from your previous installation. You can check this with the `--print-defaults` option (for example, `mysqld --print-defaults`). If this command displays anything other than the program name, you have an active `my.cnf` file that affects server or client operation.

If your MySQL installation contains a large amount of data that might take a long time to convert after an in-place upgrade, you might find it useful to create a “dummy” database instance for assessing what conversions might be needed and the work involved to perform them. Make a copy of your MySQL instance that contains a full copy of the `mysql` database, plus all other databases without data. Run your upgrade procedure on this dummy instance to see what actions might be needed so that you can better evaluate the work involved when performing actual data conversion on your original database instance.

It is a good idea to rebuild and reinstall the Perl `DBD::mysql` module whenever you install a new release of MySQL. The same applies to other MySQL interfaces as well, such as PHP `mysql` extensions and the Python `MySQLdb` module.

### 2.12.1.1. Upgrading from MySQL 5.0 to 5.1

After upgrading a 5.0 installation to 5.0.10 or above, it is *necessary* to upgrade your grant tables. Otherwise, creating stored procedures and functions might not work. To perform this upgrade, run `mysql_upgrade`.

#### Note

It is good practice to back up your data before installing any new version of software. Although MySQL works very hard to ensure a high level of quality, you should protect your data by making a backup.

To upgrade to 5.1 from any previous version, MySQL recommends that you dump your tables with `mysqldump` before upgrading and reload the dump file after upgrading.

If you perform a binary (in-place) upgrade without dumping and reloading tables, you cannot upgrade directly from MySQL 4.1 to 5.1. This occurs due to an incompatible change in the `MyISAM` table index format in MySQL 5.0. Upgrade from MySQL 4.1 to 5.0 and repair all `MyISAM` tables (see [Section 2.12.4, “Rebuilding or Repairing Tables or Indexes”](#)). Then upgrade from MySQL 5.0 to 5.1 and check and repair your tables.

In general, you should do the following when upgrading from MySQL 5.0 to 5.1:

- Read *all* the items in the following sections to see whether any of them might affect your applications:
  - [Section 2.12.1, “Upgrading MySQL”](#), has general update information.
  - The items in the change lists found later in this section enable you to identify upgrade issues that apply to your current MySQL installation.
  - The MySQL 5.1 change history describes significant new features you can use in 5.1 or that differ from those found in MySQL 5.0. Some of these changes may result in incompatibilities. See [Section C.1, “Changes in Release 5.1.x \(Production\)”](#).

Note particularly any changes that are marked **Known issue** or **Incompatible change**. These incompatibilities with earlier versions of MySQL may require your attention *before you upgrade*. Our aim is to avoid these changes, but occasionally they are necessary to correct problems that would be worse than an incompatibility between releases. If any upgrade issue applicable to your installation involves an incompatibility that requires special handling, follow the instructions given in the incompatibility description. Often this will involve dumping and reloading tables, or use of a statement such as `CHECK TABLE` or `REPAIR TABLE`.

For dump and reload instructions, see [Section 2.12.4, “Rebuilding or Repairing Tables or Indexes”](#). Any procedure that involves `REPAIR TABLE` with the `USE_FRM` option *must* be done before upgrading. Use of this statement with a version of MySQL different from the one used to create the table (that is, using it after upgrading) may damage the table. See [Section 12.4.2.6, “REPAIR TABLE Syntax”](#).

- Before upgrading to a new version of MySQL, [Section 2.12.3, “Checking Whether Tables or Indexes Must Be Rebuilt”](#), to see whether changes to table formats or to character sets or collations were made between your current version of MySQL and the version to which you are upgrading. If so and these changes result in an incompatibility between MySQL versions, you will need to upgrade the affected tables using the instructions in [Section 2.12.4, “Rebuilding or Repairing Tables or Indexes”](#).
- After upgrading to a new version of MySQL, run `mysql_upgrade` (see [Section 4.4.8, “mysql\\_upgrade — Check Tables for MySQL Upgrade”](#)). This program checks your tables, and attempts to repair them if necessary. It also updates your grant tables to make sure that they have the current structure so that you can take advantage of any new capabilities. (Some releases of MySQL introduce changes to the structure of the grant tables to add new privileges or features.)

`mysql_upgrade` does not upgrade the contents of the help tables. For upgrade instructions, see [Section 5.1.8, “Server-Side Help”](#).

- If you run MySQL Server on Windows, see [Section 2.4.7, “Upgrading MySQL Server on Microsoft Windows”](#).

- If you use replication, see [Section 16.4.3, “Upgrading a Replication Setup”](#), for information on upgrading your replication setup.

If your MySQL installation contains a large amount of data that might take a long time to convert after an in-place upgrade, you might find it useful to create a “dummy” database instance for assessing what conversions might be needed and the work involved to perform them. Make a copy of your MySQL instance that contains a full copy of the `mysql` database, plus all other databases without data. Run your upgrade procedure on this dummy instance to see what actions might be needed so that you can better evaluate the work involved when performing actual data conversion on your original database instance.

The following lists describe changes that may affect applications and that you should watch out for when upgrading from MySQL 5.0 to 5.1.

#### Configuration Changes:

- Before MySQL 5.1.11, to build MySQL from source with SSL support enabled, you would invoke `configure` with either the `--with-openssl` or `--with-yassl` option. In MySQL 5.1.11, those options both have been replaced by the `--with-ssl` option. By default, `--with-ssl` causes the bundled yaSSL library to be used. To select OpenSSL instead, give the option as `--with-ssl=path`, where `path` is the directory where the OpenSSL header files and libraries are located.

#### Server Changes:

- **Known issue:** After a binary upgrade to MySQL 5.1 from a MySQL 5.0 installation that contains `ARCHIVE` tables, accessing those tables will cause the server to crash, even if you have run `mysql_upgrade` or `CHECK TABLE ... FOR UPGRADE`. To work around this problem, use `mysqldump` to dump all `ARCHIVE` tables before upgrading, and reload them into MySQL 5.1 after upgrading.
- **Known issue:** The fix for [Bug#23491](#) introduced a problem with `SHOW CREATE VIEW`, which is used by `mysqldump`. This causes an incompatibility when upgrading from versions affected by that bug fix (MySQL 5.0.40 through 5.0.43, MySQL 5.1.18 through 5.1.19): If you use `mysqldump` before upgrading from an affected version and reload the data after upgrading to a higher version, you must drop and recreate your views.
- **Known issue:** Dumps performed by using `mysqldump` to generate a dump file before the upgrade and reloading the file after upgrading are subject to the following problem:

Before MySQL 5.0.40, `mysqldump` displays `SPATIAL` index definitions using prefix lengths for the indexed columns. These prefix lengths are accepted in MySQL 5.0, but not as of MySQL 5.1. If you use `mysqldump` from versions of MySQL older than 5.0.40, any table containing `SPATIAL` indexes will cause an error when the dump file is reloaded into MySQL 5.1 or higher.

For example, a table definition might look like this when dumped in MySQL 5.0:

```
CREATE TABLE `t` (
 `g` geometry NOT NULL,
 SPATIAL KEY `g` (`g`(32))
) ENGINE=MyISAM DEFAULT CHARSET=latin1
```

The `SPATIAL` index definition will not be accepted in MySQL 5.1. To work around this, edit the dump file to remove the prefix:

```
CREATE TABLE `t` (
 `g` geometry NOT NULL,
 SPATIAL KEY `g` (`g`)
) ENGINE=MyISAM DEFAULT CHARSET=latin1
```

Dump files can be large, so it may be preferable to dump table definitions and data separately to make it easier to edit the definitions:

```
shell> mysqldump --no-data other_args > definitions.sql
shell> mysqldump --no-create-info other_args > data.sql
```

Then edit `definitions.sql` before reloading `definitions.sql` and `data.sql`, in that order.

If you upgrade to a version of MySQL 5.0 higher than 5.0.40 before upgrading to MySQL 5.1, this problem does not occur.

- **Known issue:** Before MySQL 5.1.30, the `CHECK TABLE ... FOR UPGRADE` statement did not check for incompatible collation changes made in MySQL 5.1.24. (This also affects `mysqlcheck` and `mysql_upgrade`, which cause that statement to be executed.)

Prior to the fix made in 5.1.30, a binary upgrade (performed without dumping tables with `mysqldump` before the upgrade and reloading the dump file after the upgrade) would corrupt tables. After the fix, `CHECK TABLE ... FOR UPGRADE` properly detects the problem and warns about tables that need repair.

However, the fix is not backward compatible and can result in a downgrading problem under these circumstances:

1. Perform a binary upgrade to a version of MySQL that includes the fix.
2. Run `CHECK TABLE ... FOR UPGRADE` (or `mysqlcheck` or `mysql_upgrade`) to upgrade tables.
3. Perform a binary downgrade to a version of MySQL that does not include the fix.

The solution is to dump tables with `mysqldump` before the downgrade and reload the dump file after the downgrade. Alternatively, drop and recreate affected indexes.

- **Known issue:** MySQL introduces encoding for table names that have non-ASCII characters (see [Section 8.2.3, “Mapping of Identifiers to File Names”](#)). After a binary upgrade from MySQL 5.0 to 5.1 or higher, the server recognizes names that have non-ASCII characters and adds a `#mysql50#` prefix to them.

As of MySQL 5.1.31, `mysql_upgrade` encodes these names by executing the following command:

```
mysqlcheck --all-databases --check-upgrade --fix-db-names --fix-table-names
```

Prior to MySQL 5.1.31, `mysql_upgrade` does not execute this command, so you should execute it manually if you have database or table names that contain nonalphanumeric characters.

Prior to MySQL 5.1.23, the `mysqlcheck` command does not perform the name encoding for views. To work around this problem, drop each affected view and recreate it.

`mysqlcheck` cannot fix names that contain literal instances of the @ character that is used for encoding special characters. If you have databases or tables that contain this character, use `mysqldump` to dump them before upgrading to MySQL 5.1, and then reload the dump file after upgrading.

- **Known issue:** When upgrading from MySQL 5.0 to versions of 5.1 prior to 5.1.23, running `mysqlcheck` (or `mysql_upgrade`, which runs `mysqlcheck`) to upgrade tables fails for names that must be written as quoted identifiers. To work around this problem, rename each affected table to a name that does not require quoting:

```
RENAME TABLE `tab` `le_a` TO table_a;
RENAME TABLE `table b` TO table_b;
```

After renaming the tables, run the `mysql_upgrade` program. Then rename the tables back to their original names:

```
RENAME TABLE table_a TO `tab` `le_a`;
RENAME TABLE table_b TO `table b`;
```

- **Known issue:** In connection with view creation, the server created `arc` directories inside database directories and maintained useless copies of `.frm` files there. Creation and renaming procedures of those copies as well as creation of `arc` directories has been discontinued in MySQL 5.1.29.

This change does cause a problem when downgrading to older server versions which manifests itself under these circumstances:

1. Create a view `v_orig` in MySQL 5.1.29 or higher.
2. Rename the view to `v_new` and then back to `v_orig`.
3. Downgrade to an older 5.1.x server and run `mysql_upgrade`.
4. Try to rename `v_orig` to `v_new` again. This operation fails.

As a workaround to avoid this problem, use either of these approaches:

- Dump your data using `mysqldump` before downgrading and reload the dump file after downgrading.
  - Instead of renaming a view after the downgrade, drop it and recreate it.
- **Incompatible change:** As of MySQL 5.5.6, handling of `CREATE TABLE IF NOT EXISTS ... SELECT` statements has been changed for the case that the destination table already exists:
    - Previously, for `CREATE TABLE IF NOT EXISTS ... SELECT`, MySQL produced a warning that the table exists, but inserted the rows and wrote the statement to the binary log anyway. By contrast, `CREATE TABLE ... SELECT`

(without `IF NOT EXISTS`) failed with an error, but MySQL inserted no rows and did not write the statement to the binary log.

- MySQL now handles both statements the same way when the destination table exists, in that neither statement inserts rows or is written to the binary log. The difference between them is that MySQL produces a warning when `IF NOT EXISTS` is present and an error when it is not.

This change in handling of `IF NOT EXISTS` results in an incompatibility for statement-based replication from a MySQL 5.1 master with the original behavior and a MySQL 5.5 slave with the new behavior. Suppose that `CREATE TABLE IF NOT EXISTS ... SELECT` is executed on the master and the destination table exists. The result is that rows are inserted on the master but not on the slave. (Row-based replication does not have this problem.)

To address this issue, statement-based binary logging for `CREATE TABLE IF NOT EXISTS ... SELECT` is changed in MySQL 5.1 as of 5.1.51:

- If the destination table does not exist, there is no change: The statement is logged as is.
- If the destination table does exist, the statement is logged as the equivalent pair of `CREATE TABLE IF NOT EXISTS` and `INSERT ... SELECT` statements. (If the `SELECT` in the original statement is preceded by `IGNORE` or `REPLACE`, the `INSERT` becomes `INSERT IGNORE` or `REPLACE`, respectively.)

This change provides forward compatibility for statement-based replication from MySQL 5.1 to 5.5 because when the destination table exists, the rows will be inserted on both the master and slave. To take advantage of this compatibility measure, the 5.1 server must be at least 5.1.51 and the 5.5 server must be at least 5.5.6.

To upgrade an existing 5.1-to-5.5 replication scenario, upgrade the master first to 5.1.51 or higher. Note that this differs from the usual replication upgrade advice of upgrading the slave first.

A workaround for applications that wish to achieve the original effect (rows inserted regardless of whether the destination table exists) is to use `CREATE TABLE IF NOT EXISTS` and `INSERT ... SELECT` statements rather than `CREATE TABLE IF NOT EXISTS ... SELECT` statements.

Along with the change just described, the following related change was made: Previously, if an existing view was named as the destination table for `CREATE TABLE IF NOT EXISTS ... SELECT`, rows were inserted into the underlying base table and the statement was written to the binary log. As of MySQL 5.1.51 and 5.5.6, nothing is inserted or logged.

- **Incompatible change:** Prior to MySQL 5.1.51, if you flushed the logs using `FLUSH LOGS` or `mysqladmin flush-logs` and `mysqld` was writing the error log to a file (for example, if it was started with the `--log-error` option), it renames the current log file with the suffix `-old`, then created a new empty log file. This had the problem that a second log-flushing operation thus caused the original error log file to be lost unless you saved it under a different name. For example, you could use the following commands to save the file:

```
shell> mysqladmin flush-logs
shell> mv host_name.err-old backup-directory
```

To avoid the preceding file-loss problem, no renaming occurs as of MySQL 5.1.51; the server merely closes and reopens the log file. To rename the file, you can do so manually before flushing. Then flushing the logs reopens a new file with the original file name. For example, you can rename the file and create a new one using the following commands:

```
shell> mv host_name.err host_name.err-old
shell> mysqladmin flush-logs
shell> mv host_name.err-old backup-directory
```

- **Incompatible change:** Character set or collation changes were made in MySQL 5.1.21, 5.1.23, and 5.1.24 that may require table indexes to be rebuilt. For details, see [Section 2.12.3, “Checking Whether Tables or Indexes Must Be Rebuilt”](#).
- **Incompatible change:** MySQL 5.1 implements support for a plugin API that enables the loading and unloading of components at runtime, without restarting the server. [Section 22.2, “The MySQL Plugin API”](#). The plugin API requires the `mysql.plugin` table. After upgrading from an older version of MySQL, you should run the `mysql_upgrade` command to create this table. See [Section 4.4.8, “mysql\\_upgrade — Check Tables for MySQL Upgrade”](#).

Plugins are installed in the directory named by the `plugin_dir` system variable. This variable also controls the location from which the server loads user-defined functions (UDFs), which is a change from earlier versions of MySQL. That is, all UDF library files now must be installed in the plugin directory. When upgrading from an older version of MySQL, you must migrate your UDF files to the plugin directory.

- **Incompatible change:** The `table_cache` system variable has been renamed to `table_open_cache`. Any scripts that refer to `table_cache` must be updated to use the new name.
- **Incompatible change:** In MySQL 5.1.36, options for loading plugins such as pluggable storage engines were changed from

boolean to tristate format. The implementations overlap, but if you previously used options of the form `--plugin_name=0` or `--plugin_name=1`, you should instead use `--plugin_name=OFF` or `--plugin_name=ON`, respectively. For details, see [Section 5.1.3, “Server Options for Loading Plugins”](#).

- **Incompatible change:** From MySQL 5.1.24 to 5.1.31, the `UPDATE` statement was changed such that assigning `NULL` to a `NOT NULL` column caused an error even when strict SQL mode was not enabled. The original behavior before MySQL 5.1.24 was that such assignments caused an error only in strict SQL mode, and otherwise set the column to the implicit default value for the column data type and generated a warning. (For information about implicit default values, see [Section 10.1.4, “Data Type Default Values”](#).)

The change caused compatibility problems for applications that relied on the original behavior. It also caused replication problems between servers that had the original behavior and those that did not, for applications that assigned `NULL` to `NOT NULL` columns in `UPDATE` statements without strict SQL mode enabled. The change was reverted in MySQL 5.1.32 so that `UPDATE` again had the original behavior. Problems can still occur if you replicate between servers that have the modified `UPDATE` behavior and those that do not.

- **Incompatible change:** As of MySQL 5.1.29, the default binary logging mode has been changed from `MIXED` to `STATEMENT` for compatibility with MySQL 5.0.
- **Incompatible change:** In MySQL 5.1.25, a change was made to the way that the server handles prepared statements. This affects prepared statements processed at the SQL level (using the `PREPARE` statement) and those processed using the binary client-server protocol (using the `mysql_stmt_prepare()` C API function).

Previously, changes to metadata of tables or views referred to in a prepared statement could cause a server crash when the statement was next executed, or perhaps an error at execute time with a crash occurring later. For example, this could happen after dropping a table and recreating it with a different definition.

Now metadata changes to tables or views referred to by prepared statements are detected and cause automatic repreparation of the statement when it is next executed. Metadata changes occur for DDL statements such as those that create, drop, alter, rename, or truncate tables, or that analyze, optimize, or repair tables. Repreparation also occurs after referenced tables or views are flushed from the table definition cache, either implicitly to make room for new entries in the cache, or explicitly due to `FLUSH TABLES`.

Repreparation is automatic, but to the extent that it occurs, performance of prepared statements is diminished.

Table content changes (for example, with `INSERT` or `UPDATE`) do not cause repreparation, nor do `SELECT` statements.

An incompatibility with previous versions of MySQL is that a prepared statement may now return a different set of columns or different column types from one execution to the next. For example, if the prepared statement is `SELECT * FROM t1`, altering `t1` to contain a different number of columns causes the next execution to return a number of columns different from the previous execution.

Older versions of the client library cannot handle this change in behavior. For applications that use prepared statements with the new server, an upgrade to the new client library is strongly recommended.

Along with this change to statement repreparation, the default value of the `table_definition_cache` system variable has been increased from 128 to 256. The purpose of this increase is to lessen the chance that prepared statements will need repreparation due to referred-to tables/views having been flushed from the cache to make room for new entries.

A new status variable, `Com_stmt_reprepare`, has been introduced to track the number of repreparations.

- **Incompatible change:** As of MySQL 5.1.23, within a stored routine, it is no longer permissible to declare a cursor for a `SHOW` or `DESCRIBE` statement. This happened to work in some instances, but is no longer supported. In many cases, a workaround for this change is to use the cursor with a `SELECT` query to read from an `INFORMATION_SCHEMA` table that produces the same information as the `SHOW` statement.
- **Incompatible change:** `SHOW CREATE VIEW` displays view definitions using an `AS alias_name` clause for each column. If a column is created from an expression, the default alias is the expression text, which can be quite long. As of MySQL 5.1.23, aliases for column names in `CREATE VIEW` statements are checked against the maximum column length of 64 characters (not the maximum alias length of 256 characters). As a result, views created from the output of `SHOW CREATE VIEW` fail if any column alias exceeds 64 characters. This can cause problems for replication or loading dump files. For additional information and workarounds, see [Section D.4, “Restrictions on Views”](#).
- **Incompatible change:** Several issues were identified for stored programs (stored procedures and functions, triggers, and events) and views containing non-ASCII symbols. These issues involved conversion errors due to incomplete character set information when translating these objects to and from stored format.

To address these problems, the representation for these objects was changed in MySQL 5.1.21. However, the fixes affect *all* stored programs and views. (For example, you will see warnings about “no creation context.”) To avoid warnings from the server about the use of old definitions from any release prior to 5.1.21, you should dump stored programs and views with

`mysqldump` after upgrading to 5.1.21 or higher, and then reload them to recreate them with new definitions. Invoke `mysqldump` with a `--default-character-set` option that names the non-ASCII character set that was used for the definitions when the objects were originally defined.

- **Incompatible change:** As of MySQL 5.1.20, `mysqld_safe` supports error logging to `syslog` on systems that support the `logger` command. The new `--syslog` and `--skip-syslog` options can be used instead of the `--log-error` option to control logging behavior, as described in [Section 4.3.2, “mysqld\\_safe — MySQL Server Startup Script”](#).

In 5.1.21 and up, the default is `--skip-syslog`, which is compatible with the default behavior of writing an error log file for releases prior to 5.1.20.

**In 5.1.20 only, the following conditions apply:** 1) The default is to use `syslog`, which is not compatible with releases prior to 5.1.20. 2) Logging to `syslog` may fail to operate correctly in some cases. For these reasons, avoid using MySQL 5.1.20.

- **Incompatible change:** As of MySQL 5.1.18, the plugin interface and its handling of system variables was changed. Command-line options such as `--skip-innodb` now cause an error if `InnoDB` is not built-in or plugin-loaded. You should use `--loose-skip-innodb` if you do not want any error even if `InnoDB` is not available. The `--loose` prefix modifier should be used for all command-line options where you are uncertain whether the plugin exists and when you want the operation to proceed even if the option is necessarily ignored due to the absence of the plugin. (For a description of how `--loose` works, see [Section 4.2.3.1, “Using Options on the Command Line”](#).)
- **Incompatible change:** As of MySQL 5.1.15, `InnoDB` rolls back only the last statement on a transaction timeout. A new option, `--innodb_rollback_on_timeout`, causes `InnoDB` to abort and roll back the entire transaction if a transaction timeout occurs (the same behavior as in MySQL 4.1).
- **Incompatible change:** As of MySQL 5.1.15, the following conditions apply to enabling the `read_only` system variable:
  - If you attempt to enable `read_only` while you have any explicit locks (acquired with `LOCK TABLES` or have a pending transaction, an error will occur.
  - If other clients hold explicit table locks or have pending transactions, the attempt to enable `read_only` blocks until the locks are released and the transactions end. While the attempt to enable `read_only` is pending, requests by other clients for table locks or to begin transactions also block until `read_only` has been set.
  - `read_only` can be enabled while you hold a global read lock (acquired with `FLUSH TABLES WITH READ LOCK`) because that does not involve table locks.

Previously, the attempt to enable `read_only` would return immediately even if explicit locks or transactions were pending, so some data changes could occur for statements executing in the server at the same time.

- **Incompatible change:** The number of function names affected by `IGNORE_SPACE` was reduced significantly in MySQL 5.1.13, from about 200 to about 30. (For details about `IGNORE_SPACE`, see [Section 8.2.4, “Function Name Parsing and Resolution”](#).) This change improves the consistency of parser operation. However, it also introduces the possibility of incompatibility for old SQL code that relies on the following conditions:
  - `IGNORE_SPACE` is disabled.
  - The presence or absence of whitespace following a function name is used to distinguish between a built-in function and stored function that have the same name (for example, `PI()` versus `PI ()`).

For functions that are no longer affected by `IGNORE_SPACE` as of MySQL 5.1.13, that strategy no longer works. Either of the following approaches can be used if you have code that is subject to the preceding incompatibility:

- If a stored function has a name that conflicts with a built-in function, refer to the stored function with a schema name qualifier, regardless of whether whitespace is present. For example, write `schema_name.PI()` or `schema_name.PI ()`.
- Alternatively, rename the stored function to use a nonconflicting name and change invocations of the function to use the new name.
- **Incompatible change:** For `utf8` columns, the full-text parser incorrectly considered several nonword punctuation and whitespace characters as word characters, causing some searches to return incorrect results. The fix involves a change to the full-text parser in MySQL 5.1.12, so as of 5.1.12, any tables that have `FULLTEXT` indexes on `utf8` columns must be repaired with `REPAIR TABLE`:

```
REPAIR TABLE tbl_name QUICK;
```

- **Incompatible change:** Storage engines can be pluggable at runtime, so the distinction between disabled and invalid storage engines no longer applies. As of MySQL 5.1.12, this affects the `NO_ENGINE_SUBSTITUTION` SQL mode, as described in [Section 5.1.7, “Server SQL Modes”](#).

- **Incompatible change:** The structure of `FULLTEXT` indexes has been changed in MySQL 5.1.6. After upgrading to MySQL 5.1.6 or greater, any tables that have `FULLTEXT` indexes must be repaired with `REPAIR TABLE`:

```
REPAIR TABLE tbl_name QUICK;
```

- **Incompatible change:** In MySQL 5.1.6, when log tables were implemented, the default log destination for the general query and slow query log was `TABLE`. As of MySQL 5.1.21, this default has been changed to `FILE`, which is compatible with MySQL 5.0, but incompatible with earlier releases of MySQL 5.1. If you are upgrading from MySQL 5.0 to 5.1.21 or higher, no logging option changes should be necessary. However, if you are upgrading from 5.1.6 through 5.1.20 to 5.1.21 or higher and were using `TABLE` logging, use the `--log-output=TABLE` option explicitly to preserve your server's table-logging behavior.
- **Incompatible change:** For `ENUM` columns that had enumeration values containing commas, the commas were mapped to `0xff` internally. However, this rendered the commas indistinguishable from true `0xff` characters in the values. This no longer occurs. However, the fix requires that you dump and reload any tables that have `ENUM` columns containing true `0xff` in their values: Dump the tables using `mysqldump` with the current server before upgrading from a version of MySQL 5.1 older than 5.1.15 to version 5.1.15 or newer.
- As of MySQL 5.1.12, the `lc_time_names` system variable specifies the locale that controls the language used to display day and month names and abbreviations. This variable affects the output from the `DATE_FORMAT()`, `DAYNAME()` and `MONTHNAME()` functions. See [Section 9.7, “MySQL Server Locale Support”](#).
- As of MySQL 5.1.9, `mysqld_safe` no longer implicitly invokes `mysqld-max` if it exists. Instead, it invokes `mysqld` unless a `--mysqld` or `--mysqld-version` option is given to specify another server explicitly. If you previously relied on the implicit invocation of `mysqld-max`, you should use an appropriate option now. As of MySQL 5.1.12, there is no longer any separate `mysqld-max` server, so no change should be necessary.

### SQL Changes:

- **Known issue:** Prior to MySQL 5.1.17, the parser accepted invalid code in SQL condition handlers, leading to server crashes or unexpected execution behavior in stored programs. Specifically, the parser permitted a condition handler to refer to labels for blocks that enclose the handler declaration. This was incorrect because block label scope does not include the code for handlers declared within the labeled block.

As of 5.1.17, the parser rejects this invalid construct, but if you perform a binary upgrade (without dumping and reloading your databases), existing handlers that contain the construct still are invalid and should be rewritten *even if they appear to function as you expect*.

To find affected handlers, use `mysqldump` to dump all stored procedures and functions, triggers, and events. Then attempt to reload them into an upgraded server. Handlers that contain illegal label references will be rejected.

For more information about condition handlers and writing them to avoid invalid jumps, see [Section 12.7.4.2, “DECLARE for Handlers”](#).

- **Incompatible change:** The parser accepted statements that contained `/* ... */` that were not properly closed with `*/`, such as `SELECT 1 /* + 2`. As of MySQL 5.1.23, statements that contain unclosed `/*`-comments now are rejected with a syntax error.

This fix has the potential to cause incompatibilities. Because of [Bug#26302](#), which caused the trailing `*/` to be truncated from comments in views, stored routines, triggers, and events, it is possible that objects of those types may have been stored with definitions that now will be rejected as syntactically invalid. Such objects should be dropped and re-created so that their definitions do not contain truncated comments.

- **Incompatible change:** Multiple-table `DELETE` statements containing ambiguous aliases could have unintended side effects such as deleting rows from the wrong table. Examples:

```
DELETE FROM t1 AS a2 USING t1 AS a1 INNER JOIN t2 AS a2;
DELETE t1 AS a2 FROM t1 AS a1 INNER JOIN t2 AS a2;
```

To avoid ambiguity, declaration of aliases other than in the `table_references` part of the statement should be avoided:

```
DELETE FROM t1 USING t1 AS a1 INNER JOIN t2 AS a2;
DELETE t1 FROM t1 AS a1 INNER JOIN t2 AS a2;
```

As of MySQL 5.1.23, alias declarations outside the `table_references` part of the statement are disallowed for the `USING` variant of multiple-table `DELETE` syntax. (In MySQL 5.5, alias declarations outside `table_references` are disallowed for all multiple-table `DELETE` statements.) Statements containing aliases that are no longer permitted must be rewritten.

- **Incompatible change:** As of MySQL 5.1.8, `TYPE = engine_name` is still accepted as a synonym for the `ENGINE = engine_name` table option but generates a warning. You should note that this option is not available in MySQL 5.1.7, and is removed altogether in MySQL 5.5 and produces a syntax error.

`TYPE` has been deprecated since MySQL 4.0.

- **Incompatible change:** The namespace for triggers changed in MySQL 5.0.10. Previously, trigger names had to be unique per table. Now they must be unique within the schema (database). An implication of this change is that `DROP TRIGGER` syntax now uses a schema name instead of a table name (schema name is optional and, if omitted, the current schema will be used).

When upgrading from a version of MySQL 5 older than 5.0.10 to MySQL 5.0.10 or newer, you must drop all triggers and re-create them or `DROP TRIGGER` will not work after the upgrade. Here is a suggested procedure for doing this:

1. Upgrade to MySQL 5.0.10 or later to be able to access trigger information in the `INFORMATION_SCHEMA.TRIGGERS` table. (This should work even for pre-5.0.10 triggers.)
2. Dump all trigger definitions using the following `SELECT` statement:

```
SELECT CONCAT('CREATE TRIGGER ', t.TRIGGER_SCHEMA, '.', t.TRIGGER_NAME,
 ', ', t.ACTION_TIMING, ', ', t.EVENT_MANIPULATION, ' ON ',
 t.EVENT_OBJECT_SCHEMA, '.', t.EVENT_OBJECT_TABLE,
 ' FOR EACH ROW ', t.ACTION_STATEMENT, '///')
INTO OUTFILE '/tmp/triggers.sql'
FROM INFORMATION_SCHEMA.TRIGGERS AS t;
```

The statement uses `INTO OUTFILE`, so you must have the `FILE` privilege. The file will be created on the server host. Use a different file name if you like. To be 100% safe, inspect the trigger definitions in the `triggers.sql` file, and perhaps make a backup of the file.

3. Stop the server and drop all triggers by removing all `.TRG` files in your database directories. Change location to your data directory and issue this command:

```
shell> rm *.TRG
```

4. Start the server and re-create all triggers using the `triggers.sql` file:

```
mysql> delimiter // ;
mysql> source /tmp/triggers.sql //
```

5. Check that all triggers were successfully created using the `SHOW TRIGGERS` statement.

- **Incompatible change:** MySQL 5.1.6 introduces the `TRIGGER` privilege. Previously, the `SUPER` privilege was needed to create or drop triggers. Now those operations require the `TRIGGER` privilege. This is a security improvement because you no longer need to grant users the `SUPER` privilege to enable them to create triggers. However, the requirement that the account named in a trigger's `DEFINER` clause must have the `SUPER` privilege has changed to a requirement for the `TRIGGER` privilege. When upgrading from a previous version of MySQL 5.0 or 5.1 to MySQL 5.1.6 or newer, be sure to update your grant tables by running `mysql_upgrade`. This will assign the `TRIGGER` privilege to all accounts that had the `SUPER` privilege. If you fail to update the grant tables, triggers may fail when activated. After updating the grant tables, you can revoke the `SUPER` privilege from those accounts that no longer otherwise require it.
- Some keywords may be reserved in MySQL 5.1 that were not reserved in MySQL 5.0. See [Section 8.3, “Reserved Words”](#).
- The `BACKUP TABLE`, and `RESTORE TABLE` statements are deprecated. `mysqldump` or `mysqlhotcopy` can be used as alternatives.
- The `LOAD DATA FROM MASTER` and `LOAD TABLE FROM MASTER` statements are deprecated. See [Section 12.5.2.2, “LOAD DATA FROM MASTER Syntax”](#), for recommended alternatives.
- The `INSTALL PLUGIN` and `UNINSTALL PLUGIN` statements that are used for the plugin API are new. So is the `WITH PARSER` clause for `FULLTEXT` index creation that associates a parser plugin with a full-text index. [Section 22.2, “The MySQL Plugin API”](#).

#### C API Changes:

- **Incompatible change:** As of MySQL 5.1.7, the `mysql_stmt_attr_get()` C API function returns a boolean rather than an unsigned int for `STMT_ATTR_UPDATE_MAX_LENGTH`. ([Bug#16144](#))

## 2.12.2. Downgrading MySQL

This section describes what you should do to downgrade to an older MySQL version in the unlikely case that the previous version worked better than the new one.

If you are downgrading within the same release series (for example, from 5.0.13 to 5.0.12) the general rule is that you just have to install the new binaries on top of the old ones. There is no need to do anything with the databases. As always, however, it is always a good idea to make a backup.

The following items form a checklist of things you should do whenever you perform a downgrade:

- Read the upgrading section for the release series from which you are downgrading to be sure that it does not have any features you really need. See [Section 2.12.1, “Upgrading MySQL”](#).
- If there is a downgrading section for that version, you should read that as well.
- To see which new features were added between the version to which you are downgrading and your current version, see the change logs ([Appendix C, MySQL Change History](#)).
- Check [Section 2.12.3, “Checking Whether Tables or Indexes Must Be Rebuilt”](#), to see whether changes to table formats or to character sets or collations were made between your current version of MySQL and the version to which you are downgrading. If so and these changes result in an incompatibility between MySQL versions, you will need to downgrade the affected tables using the instructions in [Section 2.12.4, “Rebuilding or Repairing Tables or Indexes”](#).

In most cases, you can move the MySQL format files and data files between different versions on the same architecture as long as you stay within versions for the same release series of MySQL.

If you downgrade from one release series to another, there may be incompatibilities in table storage formats. In this case, use `mysqldump` to dump your tables before downgrading. After downgrading, reload the dump file using `mysql` or `mysqlimport` to re-create your tables. For examples, see [Section 2.12.5, “Copying MySQL Databases to Another Machine”](#).

A typical symptom of a downward-incompatible table format change when you downgrade is that you cannot open tables. In that case, use the following procedure:

1. Stop the older MySQL server that you are downgrading to.
2. Restart the newer MySQL server you are downgrading from.
3. Dump any tables that were inaccessible to the older server by using `mysqldump` to create a dump file.
4. Stop the newer MySQL server and restart the older one.
5. Reload the dump file into the older server. Your tables should be accessible.

It might also be the case that system tables in the `mysql` database have changed and that downgrading introduces some loss of functionality or requires some adjustments. Here are some examples:

- Trigger creation requires the `TRIGGER` privilege as of MySQL 5.1. In MySQL 5.0, there is no `TRIGGER` privilege and `SUPER` is required instead. If you downgrade from MySQL 5.1 to 5.0, you will need to give the `SUPER` privilege to those accounts that had the `TRIGGER` privilege in 5.1.
- Triggers were added in MySQL 5.0, so if you downgrade from 5.0 to 4.1, you cannot use triggers at all.
- The `mysql.proc.comment` column definition changed between MySQL 5.1 and 5.5. After a downgrade from 5.5 to 5.1, this table is seen as corrupt and in need of repair. To workaround this problem, execute `mysql_upgrade` from the version of MySQL to which you downgraded.

### 2.12.2.1. Downgrading to MySQL 5.0

When downgrading to MySQL 5.0 from MySQL 5.1, you should keep in mind the following issues relating to features found in MySQL 5.1, but not in MySQL 5.0:

- **Partitioning.** MySQL 5.0 does not support user-defined partitioning. If a table was created as a partitioned table in 5.1 (or if an table created in a previous version of MySQL was altered to include partitions after an upgrade to 5.1), the table is accessible after downgrade only if you do one of the following:

- Export the table using `mysqldump` and then drop it in MySQL 5.1; import the table again following the downgrade to MySQL 5.0.
- Prior to the downgrade, remove the table's partitioning using `ALTER TABLE table_name REMOVE PARTITIONING`.
- **Event Scheduler.** MySQL 5.0 does not support scheduled events. If your databases contain scheduled event definitions, you should prevent them from being dumped when you use `mysqldump` by using the `--skip-events` option. (See [Section 4.5.4, “mysqldump — A Database Backup Program”](#).)
- **Stored routines.** MySQL 5.1.21 added a number of new columns to the `mysql.proc` table in which stored routine definitions are stored. If you are downgrading from MySQL 5.1.21 or later to MySQL 5.0, you cannot import the MySQL 5.1 routine definitions into MySQL 5.0.46 or earlier using the dump of `mysql.proc` created by `mysqldump` (such as when using the `--all-databases` option). Instead, you should run `mysqldump --routines` prior to performing the downgrade and run the stored routines DDL statements following the downgrade.

See [Bug#11986](#), [Bug#30029](#), and [Bug#30660](#), for more information.

- **Triggers.** Trigger creation requires the `TRIGGER` privilege as of MySQL 5.1. In MySQL 5.0, there is no `TRIGGER` privilege and `SUPER` is required instead. If you downgrade from MySQL 5.1 to 5.0, you will need to give the `SUPER` privilege to those accounts that had the `TRIGGER` privilege in 5.1.

### 2.12.3. Checking Whether Tables or Indexes Must Be Rebuilt

A binary upgrade or downgrade is one that installs one version of MySQL “in place” over an existing version, without dumping and reloading tables:

1. Stop the server for the existing version if it is running.
2. Install a different version of MySQL. This is an upgrade if the new version is higher than the original version, a downgrade if the version is lower.
3. Start the server for the new version.

In many cases, the tables from the previous version of MySQL can be used without problem by the new version. However, sometimes changes occur that require tables or table indexes to be rebuilt, as described in this section. If you have tables that are affected by any of the issues described here, rebuild the tables or indexes as necessary using the instructions given in [Section 2.12.4, “Rebuilding or Repairing Tables or Indexes”](#).

#### Table Incompatibilities

After a binary upgrade to MySQL 5.1 from a MySQL 5.0 installation that contains `ARCHIVE` tables, accessing those tables causes the server to crash, even if you have run `mysql_upgrade` or `CHECK TABLE ... FOR UPGRADE`. To work around this problem, use `mysqldump` to dump all `ARCHIVE` tables before upgrading, and reload them into MySQL 5.1 after upgrading. The same problem occurs for binary downgrades from MySQL 5.1 to 5.0.

#### Index Incompatibilities

If you perform a binary upgrade without dumping and reloading tables, you cannot upgrade directly from MySQL 4.1 to 5.1 or higher. This occurs due to an incompatible change in the `MyISAM` table index format in MySQL 5.0. Upgrade from MySQL 4.1 to 5.0 and repair all `MyISAM` tables. Then upgrade from MySQL 5.0 to 5.1 and check and repair your tables.

Modifications to the handling of character sets or collations might change the character sort order, which causes the ordering of entries in any index that uses an affected character set or collation to be incorrect. Such changes result in several possible problems:

- Comparison results that differ from previous results
- Inability to find some index values due to misordered index entries
- Misordered `ORDER BY` results
- Tables that `CHECK TABLE` reports as being in need of repair

The solution to these problems is to rebuild any indexes that use an affected character set or collation, either by dropping and recreating the indexes, or by dumping and reloading the entire table. For information about rebuilding indexes, see [Section 2.12.4,](#)

#### “Rebuilding or Repairing Tables or Indexes”

To check whether a table has indexes that must be rebuilt, consult the following list. It indicates which versions of MySQL introduced character set or collation changes that require indexes to be rebuilt. Each entry indicates the version in which the change occurred and the character sets or collations that the change affects. If the change is associated with a particular bug report, the bug number is given.

The list applies both for binary upgrades and downgrades. For example, [Bug#27877](#) was fixed in MySQL 5.1.24 and 5.4.0, so it applies to upgrades from versions older than 5.1.24 to 5.1.24 or newer, and to downgrades from 5.1.24 or newer to versions older than 5.1.24.

In many cases, you can use `CHECK TABLE ... FOR UPGRADE` to identify tables for which index rebuilding is required. (It will report: `Table upgrade required. Please do "REPAIR TABLE `tbl_name`" or dump/reload to fix it!`) In these cases, you can also use `mysqlcheck --check-upgrade` or `mysql_upgrade`, which execute `CHECK TABLE`. However, the use of `CHECK TABLE` applies only after upgrades, not downgrades. Also, `CHECK TABLE` is not applicable to all storage engines. For details about which storage engines `CHECK TABLE` supports, see [Section 12.4.2.3, “CHECK TABLE Syntax”](#).

Changes that cause index rebuilding to be necessary:

- MySQL 5.0.48, 5.1.21 ([Bug#29461](#))

Affects indexes for columns that use any of these character sets: `euc_jpms`, `euc_kr`, `gb2312`, `latin7`, `macce`, `ujis`

Affected tables can be detected by `CHECK TABLE ... FOR UPGRADE` as of MySQL 5.1.29, 5.4.0 (see [Bug#39585](#)).

- MySQL 5.0.48, 5.1.23 ([Bug#27562](#))

Affects indexes that use the `ascii_general_ci` collation for columns that contain any of these characters: '`' GRAVE ACCENT, '[' LEFT SQUARE BRACKET, '\' REVERSE SOLIDUS, ']' RIGHT SQUARE BRACKET, '˜' TILDE

Affected tables can be detected by `CHECK TABLE ... FOR UPGRADE` as of MySQL 5.1.29, 5.4.0 (see [Bug#39585](#)).

- MySQL 5.1.24, 5.4.0 ([Bug#27877](#))

Affects indexes that use the `utf8_general_ci` or `ucs2_general_ci` collation for columns that contain 'ß' LATIN SMALL LETTER SHARP S (German).

Affected tables can be detected by `CHECK TABLE ... FOR UPGRADE` as of MySQL 5.1.30, 5.4.0 (see [Bug#40053](#)).

## 2.12.4. Rebuilding or Repairing Tables or Indexes

This section describes how to rebuild a table. This can be necessitated by changes to MySQL such as how data types are handled or changes to character set handling. For example, an error in a collation might have been corrected, necessitating a table rebuild to update the indexes for character columns that use the collation. (For examples, see [Section 2.12.3, “Checking Whether Tables or Indexes Must Be Rebuilt”](#).) It might also be that a table repair or upgrade should be done as indicated by a table check operation such as that performed by `CHECK TABLE`, `mysqlcheck`, or `mysql_upgrade`.

Methods for rebuilding a table include dumping and reloading it, or using `ALTER TABLE` or `REPAIR TABLE`.

### Note

If you are rebuilding tables because a different version of MySQL will not handle them after a binary (in-place) upgrade or downgrade, you must use the dump-and-reload method. Dump the tables *before* upgrading or downgrading using your original version of MySQL. Then reload the tables *after* upgrading or downgrading.

If you use the dump-and-reload method of rebuilding tables only for the purpose of rebuilding indexes, you can perform the dump either before or after upgrading or downgrading. Reloading still must be done afterward.

To rebuild a table by dumping and reloading it, use `mysqldump` to create a dump file and `mysql` to reload the file:

```
shell> mysqldump db_name t1 > dump.sql
shell> mysql db_name < dump.sql
```

To rebuild all the tables in a single database, specify the database name without any following table name:

```
shell> mysqldump db_name > dump.sql
shell> mysql db_name < dump.sql
```

To rebuild all tables in all databases, use the `--all-databases` option:

```
shell> mysqldump --all-databases > dump.sql
shell> mysql < dump.sql
```

To rebuild a table with `ALTER TABLE`, use a “null” alteration; that is, an `ALTER TABLE` statement that “changes” the table to use the storage engine that it already has. For example, if `t1` is a `MyISAM` table, use this statement:

```
mysql> ALTER TABLE t1 ENGINE = MyISAM;
```

If you are not sure which storage engine to specify in the `ALTER TABLE` statement, use `SHOW CREATE TABLE` to display the table definition.

If you must rebuild a table because a table checking operation indicates that the table is corrupt or needs an upgrade, you can use `REPAIR TABLE` if that statement supports the table's storage engine. For example, to repair a `MyISAM` table, use this statement:

```
mysql> REPAIR TABLE t1;
```

For storage engines such as `InnoDB` that `REPAIR TABLE` does not support, use `mysqldump` to create a dump file and `mysql` to reload the file, as described earlier.

For specifics about which storage engines `REPAIR TABLE` supports, see [Section 12.4.2.6, “REPAIR TABLE Syntax”](#).

`mysqlcheck --repair` provides command-line access to the `REPAIR TABLE` statement. This can be a more convenient means of repairing tables because you can use the `--databases` or `--all-databases` option to repair all tables in specific databases or all databases, respectively:

```
shell> mysqlcheck --repair --databases db_name ...
shell> mysqlcheck --repair --all-databases
```

## 2.12.5. Copying MySQL Databases to Another Machine

You can copy the `.frm`, `.MYI`, and `.MYD` files for `MyISAM` tables between different architectures that support the same floating-point format. (MySQL takes care of any byte-swapping issues.) See [Section 13.5, “The MyISAM Storage Engine”](#).

In cases where you need to transfer databases between different architectures, you can use `mysqldump` to create a file containing SQL statements. You can then transfer the file to the other machine and feed it as input to the `mysql` client.

Use `mysqldump --help` to see what options are available.

The easiest (although not the fastest) way to move a database between two machines is to run the following commands on the machine on which the database is located:

```
shell> mysqladmin -h 'other_hostname' create db_name
shell> mysqldump db_name | mysql -h 'other_hostname' db_name
```

If you want to copy a database from a remote machine over a slow network, you can use these commands:

```
shell> mysqladmin create db_name
shell> mysqldump -h 'other_hostname' --compress db_name | mysql db_name
```

You can also store the dump in a file, transfer the file to the target machine, and then load the file into the database there. For example, you can dump a database to a compressed file on the source machine like this:

```
shell> mysqldump --quick db_name | gzip > db_name.gz
```

Transfer the file containing the database contents to the target machine and run these commands there:

```
shell> mysqladmin create db_name
shell> gunzip < db_name.gz | mysql db_name
```

You can also use `mysqldump` and `mysqlimport` to transfer the database. For large tables, this is much faster than simply using `mysqldump`. In the following commands, `DUMPDIR` represents the full path name of the directory you use to store the output from `mysqldump`.

First, create the directory for the output files and dump the database:

```
shell> mkdir DUMPDIR
shell> mysqldump --tab=DUMPDIR db_name
```

Then transfer the files in the `DUMPDIR` directory to some corresponding directory on the target machine and load the files into MySQL there:

```
shell> mysqladmin create db_name # create database
shell> cat DUMPDIR/*.sql | mysql db_name # create tables in database
shell> mysqlimport db_name DUMPDIR/*.txt # load data into tables
```

Do not forget to copy the `mysql` database because that is where the grant tables are stored. You might have to run commands as the MySQL `root` user on the new machine until you have the `mysql` database in place.

After you import the `mysql` database on the new machine, execute `mysqladmin flush-privileges` so that the server re-loads the grant table information.

## 2.13. Post-Installation Setup and Testing

After installing MySQL, there are some issues that you should address. For example, on Unix, you should initialize the data directory and create the MySQL grant tables. On all platforms, an important security concern is that the initial accounts in the grant tables have no passwords. You should assign passwords to prevent unauthorized access to the MySQL server. Optionally, you can create time zone tables to enable recognition of named time zones.

The following sections include post-installation procedures that are specific to Windows systems and to Unix systems. Another section, [Section 2.13.1.3, “Starting and Troubleshooting the MySQL Server”](#), applies to all platforms; it describes what to do if you have trouble getting the server to start. [Section 2.13.2, “Securing the Initial MySQL Accounts”](#), also applies to all platforms. You should follow its instructions to make sure that you have properly protected your MySQL accounts by assigning passwords to them.

When you are ready to create additional user accounts, you can find information on the MySQL access control system and account management in [Section 5.4, “The MySQL Access Privilege System”](#), and [Section 5.5, “MySQL User Account Management”](#).

### 2.13.1. Unix Post-Installation Procedures

After installing MySQL on Unix, you must initialize the grant tables, start the server, and make sure that the server works satisfactorily. You may also wish to arrange for the server to be started and stopped automatically when your system starts and stops. You should also assign passwords to the accounts in the grant tables.

On Unix, the grant tables are set up by the `mysql_install_db` program. For some installation methods, this program is run for you automatically if an existing database cannot be found.

- If you install MySQL on Linux using RPM distributions, the server RPM runs `mysql_install_db`.
- Using the native packaging system on many platforms, including Windows (MSI), Debian Linux, Ubuntu Linux, Gentoo Linux and others, the `mysql_install_db` command is run for you.
- If you install MySQL on Mac OS X using a PKG distribution, the installer runs `mysql_install_db`.

For other platforms and installation types, including generic binary and source installs, you'll need to run `mysql_install_db` yourself.

The following procedure describes how to initialize the grant tables (if that has not previously been done) and start the server. It also suggests some commands that you can use to test whether the server is accessible and working properly. For information about starting and stopping the server automatically, see [Section 2.13.1.2, “Starting and Stopping MySQL Automatically”](#).

After you complete the procedure and have the server running, you should assign passwords to the accounts created by `mysql_install_db` and perhaps tighten access to test databases. For instructions, see [Section 2.13.2, “Securing the Initial MySQL Accounts”](#).

In the examples shown here, the server runs under the user ID of the `mysql` login account. This assumes that such an account exists. Either create the account if it does not exist, or substitute the name of a different existing login account that you plan to use for running the server.

1. Change location into the top-level directory of your MySQL installation, represented here by `BASEDIR`:

```
shell> cd BASEDIR
```

`BASEDIR` is the installation directory for your MySQL instance. It is likely to be something like `/usr/local/mysql` or `/`

`usr/local`. The following steps assume that you have changed location to this directory.

2. If necessary, run the `mysql_install_db` program to set up the initial MySQL grant tables containing the privileges that determine how users are permitted to connect to the server. You'll need to do this if you used a distribution type for which the installation procedure doesn't run the program for you.

Typically, `mysql_install_db` needs to be run only the first time you install MySQL, so you can skip this step if you are upgrading an existing installation. However, `mysql_install_db` does not overwrite any existing privilege tables, so it should be safe to run in any circumstances.

The exact location of `mysql_install_db` will depend on the layout for your given installation. To initialize the grant tables, use one of the following commands, depending on whether `mysql_install_db` is located in the `bin` or `scripts` directory:

```
shell> bin/mysql_install_db --user=mysql
shell> scripts/mysql_install_db --user=mysql
```

It might be necessary to specify other options such as `--basedir` or `--datadir` if `mysql_install_db` does not identify the correct locations for the installation directory or data directory. For example:

```
shell> bin/mysql_install_db --user=mysql \
 --basedir=/opt/mysql/mysql \
 --datadir=/opt/mysql/mysql/data
```

The `mysql_install_db` script creates the server's data directory. Under the data directory, it creates directories for the `mysql` database that holds the grant tables and the `test` database that you can use to test MySQL. The script also creates privilege table entries for `root` and anonymous-user accounts. The accounts have no passwords initially. [Section 2.13.2, “Securing the Initial MySQL Accounts”](#), describes the initial privileges. Briefly, these privileges permit the MySQL `root` user to do anything, and permit anybody to create or use databases with a name of `test` or starting with `test_`.

It is important to make sure that the database directories and files are owned by the `mysql` login account so that the server has read and write access to them when you run it later. To ensure this, the `--user` option should be used as shown if you run `mysql_install_db` as `root`. Otherwise, you should execute the script while logged in as `mysql`, in which case you can omit the `--user` option from the command.

`mysql_install_db` creates several tables in the `mysql` database, including `user`, `db`, `host`, `tables_priv`, `columns_priv`, `func`, and others. See [Section 5.4, “The MySQL Access Privilege System”](#), for a complete listing and description of these tables.

If you do not want to have the `test` database, you can remove it after starting the server, using the instructions in [Section 2.13.2, “Securing the Initial MySQL Accounts”](#).

If you have trouble with `mysql_install_db` at this point, see [Section 2.13.1.1, “Problems Running mysql\\_install\\_db”](#).

3. Start the MySQL server:

```
shell> bin/mysqld_safe --user=mysql &
```

It is important that the MySQL server be run using an unprivileged (non-`root`) login account. To ensure this, the `--user` option should be used as shown if you run `mysqld_safe` as system `root`. Otherwise, you should execute the script while logged in to the system as `mysql`, in which case you can omit the `--user` option from the command.

Further instructions for running MySQL as an unprivileged user are given in [Section 5.3.6, “How to Run MySQL as a Normal User”](#).

If you neglected to create the grant tables by running `mysql_install_db` before proceeding to this step, the following message appears in the error log file when you start the server:

```
mysqld: Can't find file: 'host.frm'
```

This error also occurs if you run `mysql_install_db` as `root` without the `--user` option. Remove the `data` directory and run `mysql_install_db` with the `--user` option as described previously.

If you have other problems starting the server, see [Section 2.13.1.3, “Starting and Troubleshooting the MySQL Server”](#).

4. Use `mysqladmin` to verify that the server is running. The following commands provide simple tests to check whether the server is up and responding to connections:

```
shell> bin/mysqladmin version
shell> bin/mysqladmin variables
```

The output from `mysqladmin version` varies slightly depending on your platform and version of MySQL, but should be similar to that shown here:

```
shell> bin/mysqladmin version
mysqladmin Ver 14.12 Distrib 5.1.52, for pc-linux-gnu on i686
...
Server version 5.1.52
Protocol version 10
Connection Localhost via UNIX socket
UNIX socket /var/lib/mysql/mysql.sock
Uptime: 14 days 5 hours 5 min 21 sec

Threads: 1 Questions: 366 Slow queries: 0
Opens: 0 Flush tables: 1 Open tables: 19
Queries per second avg: 0.000
```

To see what else you can do with `mysqladmin`, invoke it with the `--help` option.

- Verify that you can shut down the server:

```
shell> bin/mysqladmin -u root shutdown
```

- Verify that you can start the server again. Do this by using `mysqld_safe` or by invoking `mysqld` directly. For example:

```
shell> bin/mysqld_safe --user=mysql --log &
```

If `mysqld_safe` fails, see [Section 2.13.1.3, “Starting and Troubleshooting the MySQL Server”](#).

- Run some simple tests to verify that you can retrieve information from the server. The output should be similar to what is shown here:

```
shell> bin/mysqlshow
+-----+
| Databases |
+-----+
| information_schema |
| mysql |
| test |
+-----+

shell> bin/mysqlshow mysql
Database: mysql
+-----+
| Tables |
+-----+
| columns_priv |
| db |
| event |
| func |
| help_category |
| help_keyword |
| help_relation |
| help_topic |
| host |
| plugin |
| proc |
| procs_priv |
| servers |
| tables_priv |
| time_zone |
| time_zone_leap_second |
| time_zone_name |
| time_zone_transition |
| time_zone_transition_type |
| user |
+-----+

shell> bin/mysql -e "SELECT Host,Db,User FROM db" mysql
+---+---+---+
| host | db | user |
+---+---+---+
| % | test |
| % | test_%|
+---+---+---+
```

- There is a benchmark suite in the `sql-bench` directory (under the MySQL installation directory) that you can use to compare how MySQL performs on different platforms. The benchmark suite is written in Perl. It requires the Perl DBI module that provides a database-independent interface to the various databases, and some other additional Perl modules:

```
DBI
DBD::mysql
Data::Dumper
```

```
Data::ShowTable
```

These modules can be obtained from CPAN (<http://www.cpan.org/>). See also [Section 2.15.1, “Installing Perl on Unix”](#).

The `sql-bench/Results` directory contains the results from many runs against different databases and platforms. To run all tests, execute these commands:

```
shell> cd sql-bench
shell> perl run-all-tests
```

If you do not have the `sql-bench` directory, you probably installed MySQL using RPM files other than the source RPM. (The source RPM includes the `sql-bench` benchmark directory.) In this case, you must first install the benchmark suite before you can use it. There are separate benchmark RPM files named `mysql-bench-VERSION.i386.rpm` that contain benchmark code and data.

If you have a source distribution, there are also tests in its `tests` subdirectory that you can run. For example, to run `auto_increment.tst`, execute this command from the top-level directory of your source distribution:

```
shell> mysql -vvf test < ./tests/auto_increment.tst
```

The expected result of the test can be found in the `./tests/auto_increment.res` file.

9. At this point, you should have the server running. However, none of the initial MySQL accounts have a password, and the server permits permissive access to test databases. To tighten security, follow the instructions in [Section 2.13.2, “Securing the Initial MySQL Accounts”](#).

The MySQL 5.1 installation procedure creates time zone tables in the `mysql` database. However, you must populate the tables manually using the instructions in [Section 9.6, “MySQL Server Time Zone Support”](#).

### 2.13.1.1. Problems Running `mysql_install_db`

The purpose of the `mysql_install_db` script is to generate new MySQL privilege tables. It does not overwrite existing MySQL privilege tables, and it does not affect any other data.

If you want to re-create your privilege tables, first stop the `mysqld` server if it is running. Then rename the `mysql` directory under the data directory to save it, and then run `mysql_install_db`. Suppose that your current directory is the MySQL installation directory and that `mysql_install_db` is located in the `bin` directory and the data directory is named `data`. To rename the `mysql` database and re-run `mysql_install_db`, use these commands.

```
shell> mv data/mysql data/mysql.old
shell> bin/mysql_install_db --user=mysql
```

When you run `mysql_install_db`, you might encounter the following problems:

- **`mysql_install_db` fails to install the grant tables**

You may find that `mysql_install_db` fails to install the grant tables and terminates after displaying the following messages:

```
Starting mysqld daemon with databases from XXXXXX
mysqld ended
```

In this case, you should examine the error log file very carefully. The log should be located in the directory `XXXXXX` named by the error message and should indicate why `mysqld` didn't start. If you do not understand what happened, include the log when you post a bug report. See [Section 1.7, “How to Report Bugs or Problems”](#).

- **There is a `mysqld` process running**

This indicates that the server is running, in which case the grant tables have probably been created already. If so, there is no need to run `mysql_install_db` at all because it needs to be run only once (when you install MySQL the first time).

- **Installing a second `mysqld` server does not work when one server is running**

This can happen when you have an existing MySQL installation, but want to put a new installation in a different location. For example, you might have a production installation, but you want to create a second installation for testing purposes. Generally the problem that occurs when you try to run a second server is that it tries to use a network interface that is in use by the first

server. In this case, you should see one of the following error messages:

```
Can't start server: Bind on TCP/IP port:
Address already in use
Can't start server: Bind on unix socket...
```

For instructions on setting up multiple servers, see [Section 5.6, “Running Multiple MySQL Servers on the Same Machine”](#).

- **You do not have write access to the `/tmp` directory**

If you do not have write access to create temporary files or a Unix socket file in the default location (the `/tmp` directory) or the `TMPDIR` environment variable, if it has been set, an error occurs when you run `mysql_install_db` or the `mysqld` server.

You can specify different locations for the temporary directory and Unix socket file by executing these commands prior to starting `mysql_install_db` or `mysqld`, where `some_tmp_dir` is the full path name to some directory for which you have write permission:

```
shell> TMPDIR=/some_tmp_dir/
shell> MYSQL_UNIX_PORT=/some_tmp_dir/mysql.sock
shell> export TMPDIR MYSQL_UNIX_PORT
```

Then you should be able to run `mysql_install_db` and start the server with these commands:

```
shell> bin/mysql_install_db --user=mysql
shell> bin/mysqld_safe --user=mysql &
```

If `mysql_install_db` is located in the `scripts` directory, modify the first command to `scripts/mysql_install_db`.

See [Section B.5.4.5, “How to Protect or Change the MySQL Unix Socket File”](#), and [Section 2.14, “Environment Variables”](#).

There are some alternatives to running the `mysql_install_db` script provided in the MySQL distribution:

- If you want the initial privileges to be different from the standard defaults, you can modify `mysql_install_db` before you run it. However, it is preferable to use `GRANT` and `REVOKE` to change the privileges *after* the grant tables have been set up. In other words, you can run `mysql_install_db`, and then use `mysql -u root mysql` to connect to the server as the MySQL `root` user so that you can issue the necessary `GRANT` and `REVOKE` statements.

If you want to install MySQL on several machines with the same privileges, you can put the `GRANT` and `REVOKE` statements in a file and execute the file as a script using `mysql` after running `mysql_install_db`. For example:

```
shell> bin/mysql_install_db --user=mysql
shell> bin/mysql -u root < your_script_file
```

By doing this, you can avoid having to issue the statements manually on each machine.

- It is possible to re-create the grant tables completely after they have previously been created. You might want to do this if you're just learning how to use `GRANT` and `REVOKE` and have made so many modifications after running `mysql_install_db` that you want to wipe out the tables and start over.

To re-create the grant tables, remove all the `.frm`, `.MYI`, and `.MYD` files in the `mysql` database directory. Then run the `mysql_install_db` script again.

- You can start `mysqld` manually using the `--skip-grant-tables` option and add the privilege information yourself using `mysql`:

```
shell> bin/mysqld_safe --user=mysql --skip-grant-tables &
shell> bin/mysql mysql
```

From `mysql`, manually execute the SQL commands contained in `mysql_install_db`. Make sure that you run `mysqladmin flush-privileges` or `mysqladmin reload` afterward to tell the server to reload the grant tables.

Note that by not using `mysql_install_db`, you not only have to populate the grant tables manually, you also have to create them first.

## 2.13.1.2. Starting and Stopping MySQL Automatically

---

Generally, you start the `mysqld` server in one of these ways:

- Invoke `mysqld` directly. This works on any platform.
- Run the MySQL server as a Windows service. The service can be set to start the server automatically when Windows starts, or as a manual service that you start on request. For instructions, see [Section 2.4.5.7, “Starting MySQL Server as a Microsoft Windows Service”](#).
- Invoke `mysqld_safe`, which tries to determine the proper options for `mysqld` and then runs it with those options. This script is used on Unix and Unix-like systems. See [Section 4.3.2, “`mysqld\_safe` — MySQL Server Startup Script”](#).
- Invoke `mysql.server`. This script is used primarily at system startup and shutdown on systems that use System V-style run directories (i.e. `/etc/init.d` and run-level specific directories), where it usually is installed under the name `mysql`. The `mysql.server` script starts the server by invoking `mysqld_safe`. See [Section 4.3.3, “`mysql.server` — MySQL Server Startup Script”](#).
- On Mac OS X, install a separate MySQL Startup Item package to enable the automatic startup of MySQL on system startup. The Startup Item starts the server by invoking `mysql.server`. See [Section 2.5.3, “Installing the MySQL Startup Item”](#), for details. A MySQL Preference Pane also provides control for starting and stopping MySQL through the System Preferences, see [Section 2.5.4, “Installing and Using the MySQL Preference Pane”](#).
- Use the Solaris/OpenSolaris service management framework (SMF) system to initiate and control MySQL startup. For more information, see [Section 2.7.2, “Installing MySQL on OpenSolaris using IPS”](#).

The `mysqld_safe` and `mysql.server` scripts, Windows server, Solaris/OpenSolaris SMF, and the Mac OS X Startup Item (or MySQL Preference Pane) can be used to start the server manually, or automatically at system startup time. `mysql.server` and the Startup Item also can be used to stop the server.

To start or stop the server manually using the `mysql.server` script, invoke it with `start` or `stop` arguments:

```
shell> mysql.server start
shell> mysql.server stop
```

Before `mysql.server` starts the server, it changes location to the MySQL installation directory, and then invokes `mysqld_safe`. If you want the server to run as some specific user, add an appropriate `user` option to the `[mysqld]` group of the `/etc/my.cnf` option file, as shown later in this section. (It is possible that you will need to edit `mysql.server` if you've installed a binary distribution of MySQL in a nonstandard location. Modify it to change location into the proper directory before it runs `mysqld_safe`. If you do this, your modified version of `mysql.server` may be overwritten if you upgrade MySQL in the future, so you should make a copy of your edited version that you can reinstall.)

`mysql.server stop` stops the server by sending a signal to it. You can also stop the server manually by executing `mysqladmin shutdown`.

To start and stop MySQL automatically on your server, you need to add start and stop commands to the appropriate places in your `/etc/rc*` files.

If you use the Linux server RPM package, (`MySQL-server-VERSION.rpm`), or a native Linux package installation, the `mysql.server` script may be installed in the `/etc/init.d` directory with the name `mysql`. See [Section 2.6.1, “Installing MySQL from RPM Packages on Linux”](#), for more information on the Linux RPM packages.

Some vendors provide RPM packages that install a startup script under a different name such as `mysqld`.

If you install MySQL from a source distribution or using a binary distribution format that does not install `mysql.server` automatically, you can install it manually. The script can be found in the `support-files` directory under the MySQL installation directory or in a MySQL source tree.

To install `mysql.server` manually, copy it to the `/etc/init.d` directory with the name `mysql`, and then make it executable. Do this by changing location into the appropriate directory where `mysql.server` is located and executing these commands:

```
shell> cp mysql.server /etc/init.d/mysql
shell> chmod +x /etc/init.d/mysql
```

## Note

Older Red Hat systems use the `/etc/rc.d/init.d` directory rather than `/etc/init.d`. Adjust the preceding commands accordingly. Alternatively, first create `/etc/init.d` as a symbolic link that points to `/etc/rc.d/init.d`:

```
shell> cd /etc
```

```
shell> ln -s rc.d/init.d .
```

After installing the script, the commands needed to activate it to run at system startup depend on your operating system. On Linux, you can use `chkconfig`:

```
shell> chkconfig --add mysql
```

On some Linux systems, the following command also seems to be necessary to fully enable the `mysql` script:

```
shell> chkconfig --level 345 mysql on
```

On FreeBSD, startup scripts generally should go in `/usr/local/etc/rc.d/`. The `rc(8)` manual page states that scripts in this directory are executed only if their basename matches the `*.sh` shell file name pattern. Any other files or directories present within the directory are silently ignored. In other words, on FreeBSD, you should install the `mysql.server` script as `/usr/local/etc/rc.d/mysql.server.sh` to enable automatic startup.

As an alternative to the preceding setup, some operating systems also use `/etc/rc.local` or `/etc/init.d/boot.local` to start additional services on startup. To start up MySQL using this method, you could append a command like the one following to the appropriate startup file:

```
/bin/sh -c 'cd /usr/local/mysql; ./bin/mysqld_safe --user=mysql &'
```

For other systems, consult your operating system documentation to see how to install startup scripts.

You can add options for `mysql.server` in a global `/etc/my.cnf` file. A typical `/etc/my.cnf` file might look like this:

```
[mysqld]
datadir=/usr/local/mysql/var
socket=/var/tmp/mysql.sock
port=3306
user=mysql

[mysql.server]
basedir=/usr/local/mysql
```

The `mysql.server` script supports the following options: `basedir`, `datadir`, and `pid-file`. If specified, they *must* be placed in an option file, not on the command line. `mysql.server` supports only `start` and `stop` as command-line arguments.

The following table shows which option groups the server and each startup script read from option files.

**Table 2.20. MySQL Startup scripts and supported server option groups**

| Script                    | Option Groups                                                                       |
|---------------------------|-------------------------------------------------------------------------------------|
| <code>mysqld</code>       | <code>[mysqld]</code> , <code>[server]</code> , <code>[mysqld-major_version]</code> |
| <code>mysqld_safe</code>  | <code>[mysqld]</code> , <code>[server]</code> , <code>[mysqld_safe]</code>          |
| <code>mysql.server</code> | <code>[mysqld]</code> , <code>[mysql.server]</code> , <code>[server]</code>         |

`[mysqld-major_version]` means that groups with names like `[mysqld-5.0]` and `[mysqld-5.1]` are read by servers having versions 5.0.x, 5.1.x, and so forth. This feature can be used to specify options that can be read only by servers within a given release series.

For backward compatibility, `mysql.server` also reads the `[mysql_server]` group and `mysqld_safe` also reads the `[safe_mysqld]` group. However, you should update your option files to use the `[mysql.server]` and `[mysqld_safe]` groups instead when using MySQL 5.1.

For more information on MySQL configuration files and their structure and contents, see [Section 4.2.3.3, “Using Option Files”](#).

### 2.13.1.3. Starting and Troubleshooting the MySQL Server

This section provides troubleshooting suggestions for problems starting the server on Unix. If you are using Windows, see [Section 2.4.6, “Troubleshooting a Microsoft Windows MySQL Server Installation”](#).

If you have problems starting the server, here are some things to try:

- Check the error log to see why the server does not start.
- Specify any special options needed by the storage engines you are using.

- Make sure that the server knows where to find the data directory.
- Make sure that the server can access the data directory. The ownership and permissions of the data directory and its contents must be set such that the server can read and modify them.
- Verify that the network interfaces the server wants to use are available.

Some storage engines have options that control their behavior. You can create a `my.cnf` file and specify startup options for the engines that you plan to use. If you are going to use storage engines that support transactional tables (`InnoDB`, `NDB`), be sure that you have them configured the way you want before starting the server:

- If you are using `InnoDB` tables, see [Section 13.6.2, “InnoDB Configuration”](#).
- If you are using MySQL Cluster, see [Section 17.3, “MySQL Cluster Configuration”](#).

Storage engines will use default option values if you specify none, but it is recommended that you review the available options and specify explicit values for those for which the defaults are not appropriate for your installation.

When the `mysqld` server starts, it changes location to the data directory. This is where it expects to find databases and where it expects to write log files. The server also writes the pid (process ID) file in the data directory.

The data directory location is hardwired in when the server is compiled. This is where the server looks for the data directory by default. If the data directory is located somewhere else on your system, the server will not work properly. You can determine what the default path settings are by invoking `mysqld` with the `--verbose` and `--help` options.

If the default locations do not match the MySQL installation layout on your system, you can override them by specifying options to `mysqld` or `mysqld_safe` on the command line or in an option file.

To specify the location of the data directory explicitly, use the `--datadir` option. However, normally you can tell `mysqld` the location of the base directory under which MySQL is installed and it looks for the data directory there. You can do this with the `--basedir` option.

To check the effect of specifying path options, invoke `mysqld` with those options followed by the `--verbose` and `--help` options. For example, if you change location into the directory where `mysqld` is installed and then run the following command, it shows the effect of starting the server with a base directory of `/usr/local`:

```
shell> ./mysqld --basedir=/usr/local --verbose --help
```

You can specify other options such as `--datadir` as well, but `--verbose` and `--help` must be the last options.

Once you determine the path settings you want, start the server without `--verbose` and `--help`.

If `mysqld` is currently running, you can find out what path settings it is using by executing this command:

```
shell> mysqladmin variables
```

Or:

```
shell> mysqladmin -h host_name variables
```

`host_name` is the name of the MySQL server host.

If you get `Errcode 13` (which means `Permission denied`) when starting `mysqld`, this means that the privileges of the data directory or its contents do not permit server access. In this case, you change the permissions for the involved files and directories so that the server has the right to use them. You can also start the server as `root`, but this raises security issues and should be avoided.

On Unix, change location into the data directory and check the ownership of the data directory and its contents to make sure the server has access. For example, if the data directory is `/usr/local/mysql/var`, use this command:

```
shell> ls -la /usr/local/mysql/var
```

If the data directory or its files or subdirectories are not owned by the login account that you use for running the server, change their ownership to that account. If the account is named `mysql`, use these commands:

```
shell> chown -R mysql /usr/local/mysql/var
shell> chgrp -R mysql /usr/local/mysql/var
```

If it is possible that even with correct ownership, MySQL may fail to start up if there is other security software running on your system that manages application access to various parts of the file system. In this case, you may need to reconfigure that software to enable `mysqld` to access the directories it uses during normal operation.

If the server fails to start up correctly, check the error log. Log files are located in the data directory (typically `C:\Program Files\MySQL\MySQL Server 5.1\data` on Windows, `/usr/local/mysql/data` for a Unix binary distribution, and `/usr/local/var` for a Unix source distribution). Look in the data directory for files with names of the form `host_name.err` and `host_name.log`, where `host_name` is the name of your server host. Then examine the last few lines of these files. On Unix, you can use `tail` to display them:

```
shell> tail host_name.err
shell> tail host_name.log
```

The error log should contain information that indicates why the server couldn't start.

If either of the following errors occur, it means that some other program (perhaps another `mysqld` server) is using the TCP/IP port or Unix socket file that `mysqld` is trying to use:

```
Can't start server: Bind on TCP/IP port: Address already in use
Can't start server: Bind on unix socket...
```

Use `ps` to determine whether you have another `mysqld` server running. If so, shut down the server before starting `mysqld` again. (If another server is running, and you really want to run multiple servers, you can find information about how to do so in [Section 5.6, “Running Multiple MySQL Servers on the Same Machine”](#).)

If no other server is running, try to execute the command `telnet your_host_name tcp_ip_port_number`. (The default MySQL port number is 3306.) Then press Enter a couple of times. If you do not get an error message like `telnet: Unable to connect to remote host: Connection refused`, some other program is using the TCP/IP port that `mysqld` is trying to use. You'll need to track down what program this is and disable it, or else tell `mysqld` to listen to a different port with the `-port` option. In this case, you'll also need to specify the port number for client programs when connecting to the server using TCP/IP.

Another reason the port might be inaccessible is that you have a firewall running that blocks connections to it. If so, modify the firewall settings to permit access to the port.

If the server starts but you can't connect to it, you should make sure that you have an entry in `/etc/hosts` that looks like this:

```
127.0.0.1 localhost
```

This problem occurs only on systems that do not have a working thread library and for which MySQL must be configured to use MIT-pthreads.

If you cannot get `mysqld` to start, you can try to make a trace file to find the problem by using the `--debug` option. See [MySQL Internals: Porting](#).

## 2.13.2. Securing the Initial MySQL Accounts

Part of the MySQL installation process is to set up the `mysql` database that contains the grant tables:

- Windows distributions contain preinitialized grant tables.
- On Unix, the `mysql_install_db` program populates the grant tables. Some installation methods run this program for you. Others require that you execute it manually. For details, see [Section 2.13.1, “Unix Post-Installation Procedures”](#).

The `mysql.user` grant table defines the initial MySQL user accounts and their access privileges:

- Some accounts have the user name `root`. These are superuser accounts that have all privileges and can do anything. The initial `root` account passwords are empty, so anyone can connect to the MySQL server as `root` without a password and be granted all privileges.
  - On Windows, `root` accounts are created that permit connections from the local host only. Connections can be made by specifying a host name of `localhost` or `127.0.0.1`. If the user selects the **ENABLE ROOT ACCESS FROM REMOTE MACHINES** option during installation, the Windows installer creates another `root` account that permits connections from any host.
  - On Unix, each `root` account permits connections from the local host. Connections can be made by specifying a host name of `localhost`, `127.0.0.1`, or the actual host name or IP number.

An attempt to connect to the host `127.0.0.1` normally resolves to the `localhost` account. However, this fails if the server is run with the `--skip-name-resolve` option, so the `127.0.0.1` account is useful in that case.

- Some accounts are for anonymous users. These have an empty user name. The anonymous accounts have no password, so anyone can use them to connect to the MySQL server.
  - On Windows, there is one anonymous account that permits connections from the local host. Connections can be made by specifying a host name of `localhost`. The account has no global privileges. (Before MySQL 5.1.16, it has all global privileges, just like the `root` accounts.)
  - On Unix, each anonymous account permits connections from the local host. Connections can be made by specifying a host name of `localhost` for one of the accounts, or the actual host name or IP number for the other.

To display which accounts exist in the `mysql.user` table and check whether their passwords are empty, use the following statement:

```
mysql> SELECT User, Host, Password FROM mysql.user;
+-----+-----+-----+
| User | Host | Password |
+-----+-----+-----+
root	localhost	
root	myhost.example.com	
root	127.0.0.1	
	localhost	
	myhost.example.com	
+-----+-----+-----+
```

This output indicates that there are several `root` and anonymous-user accounts, none of which have passwords. The output might differ on your system, but the presence of accounts with empty passwords means that your MySQL installation is unprotected until you do something about it:

- You should assign a password to each MySQL `root` account.
- If you want to prevent clients from connecting as anonymous users without a password, you should either assign a password to each anonymous account or else remove the accounts.

In addition, the `mysql.db` table contains rows that permits all accounts to access the `test` database and other databases with names that start with `test_`. This is true even for accounts that otherwise have no special privileges such as the default anonymous accounts. This is convenient for testing but inadvisable on production servers. Administrators who want database access restricted only to accounts that have permissions granted explicitly for that purpose should remove these `mysql.db` table rows.

The following instructions describe how to set up passwords for the initial MySQL accounts, first for the `root` accounts, then for the anonymous accounts. The instructions also cover how to remove the anonymous accounts, should you prefer not to permit anonymous access at all, and describe how to remove permissive access to test databases. Replace `newpwd` in the examples with the password that you want to use. Replace `host_name` with the name of the server host. You can determine this name from the output of the preceding `SELECT` statement. For the output shown, `host_name` is `myhost.example.com`.

### Note

If you forget your `root` password after setting it, see [Section B.5.4.1, “How to Reset the Root Password”](#).

You might want to defer setting the passwords until later, to avoid the need to specify them while you perform additional setup or testing. However, be sure to set them before using your installation for production purposes.

To set up additional accounts, see [Section 5.5.2, “Adding User Accounts”](#).

## Assigning `root` Account Passwords

The `root` account passwords can be set several ways. The following discussion demonstrates three methods:

- Use the `SET PASSWORD` statement
- Use the `UPDATE` statement
- Use the `mysqladmin` command-line client program

To assign passwords using `SET PASSWORD`, connect to the server as `root` and issue a `SET PASSWORD` statement for each

`root` account listed in the `mysql.user` table. Be sure to encrypt the password using the `PASSWORD()` function.

For Windows, do this:

```
shell> mysql -u root
mysql> SET PASSWORD FOR 'root'@'localhost' = PASSWORD('newpwd');
mysql> SET PASSWORD FOR 'root'@'127.0.0.1' = PASSWORD('newpwd');
mysql> SET PASSWORD FOR 'root'@'%' = PASSWORD('newpwd');
```

The last statement is unnecessary if the `mysql.user` table has no `root` account with a host value of `%`.

For Unix, do this:

```
shell> mysql -u root
mysql> SET PASSWORD FOR 'root'@'localhost' = PASSWORD('newpwd');
mysql> SET PASSWORD FOR 'root'@'127.0.0.1' = PASSWORD('newpwd');
mysql> SET PASSWORD FOR 'root'@'host_name' = PASSWORD('newpwd');
```

You can also use a single statement that assigns a password to all `root` accounts by using `UPDATE` to modify the `mysql.user` table directly. This method works on any platform:

```
shell> mysql -u root
mysql> UPDATE mysql.user SET Password = PASSWORD('newpwd')
 -> WHERE User = 'root';
mysql> FLUSH PRIVILEGES;
```

The `FLUSH` statement causes the server to reread the grant tables. Without it, the password change remains unnoticed by the server until you restart it.

To assign passwords to the `root` accounts using `mysqladmin`, execute the following commands:

```
shell> mysqladmin -u root password "newpwd"
shell> mysqladmin -u root -h host_name password "newpwd"
```

Those commands apply both to Windows and to Unix. The double quotation marks around the password are not always necessary, but you should use them if the password contains spaces or other characters that are special to your command interpreter.

The `mysqladmin` method of setting the `root` account passwords does not work for the `'root'@'127.0.0.1'` account. Use the `SET PASSWORD` method shown earlier.

After the `root` passwords have been set, you must supply the appropriate password whenever you connect as `root` to the server. For example, to shut down the server with `mysqladmin`, use this command:

```
shell> mysqladmin -u root -p shutdown
Enter password: (enter root password here)
```

## Assigning Anonymous Account Passwords

The `mysql` commands in the following instructions include a `-p` option based on the assumption that you have set the `root` account passwords using the preceding instructions and must specify that password when connecting to the server.

To assign passwords to the anonymous accounts, connect to the server as `root`, then use either `SET PASSWORD` or `UPDATE`. Be sure to encrypt the password using the `PASSWORD()` function.

To use `SET PASSWORD` on Windows, do this:

```
shell> mysql -u root -p
Enter password: (enter root password here)
mysql> SET PASSWORD FOR ''@'localhost' = PASSWORD('newpwd');
```

To use `SET PASSWORD` on Unix, do this:

```
shell> mysql -u root -p
Enter password: (enter root password here)
mysql> SET PASSWORD FOR ''@'localhost' = PASSWORD('newpwd');
mysql> SET PASSWORD FOR ''@'host_name' = PASSWORD('newpwd');
```

To set the anonymous-user account passwords with a single `UPDATE` statement, do this (on any platform):

```
shell> mysql -u root -p
Enter password: (enter root password here)
mysql> UPDATE mysql.user SET Password = PASSWORD('newpwd')
 -> WHERE User = '';
mysql> FLUSH PRIVILEGES;
```

The `FLUSH` statement causes the server to reread the grant tables. Without it, the password change remains unnoticed by the server until you restart it.

## Removing Anonymous Accounts

If you prefer to remove any anonymous accounts rather than assigning them passwords, do so as follows on Windows:

```
shell> mysql -u root -p
Enter password: (enter root password here)
mysql> DROP USER ''@'localhost';
```

On Unix, remove the anonymous accounts like this:

```
shell> mysql -u root -p
Enter password: (enter root password here)
mysql> DROP USER ''@'localhost';
mysql> DROP USER ''@'host_name';
```

## Securing Test Databases

By default, the `mysql.db` table contains rows that permit access by any user to the `test` database and other databases with names that start with `test_`. (These rows have an empty `User` column value, which for access-checking purposes matches any user name.) This means that such databases can be used even by accounts that otherwise possess no privileges. If you want to remove any-user access to test databases, do so as follows:

```
shell> mysql -u root -p
Enter password: (enter root password here)
mysql> DELETE FROM mysql.db WHERE Db LIKE 'test%';
mysql> FLUSH PRIVILEGES;
```

The `FLUSH` statement causes the server to reread the grant tables. Without it, the privilege change remains unnoticed by the server until you restart it.

With the preceding change, only users who have global database privileges or privileges granted explicitly for the `test` database can use it. However, if you do not want the database to exist at all, drop it:

```
mysql> DROP DATABASE test;
```

## 2.14. Environment Variables

This section lists all the environment variables that are used directly or indirectly by MySQL. Most of these can also be found in other places in this manual.

Note that any options on the command line take precedence over values specified in option files and environment variables, and values in option files take precedence over values in environment variables.

In many cases, it is preferable to use an option file instead of environment variables to modify the behavior of MySQL. See [Section 4.2.3.3, “Using Option Files”](#).

To set an environment variable within `sh`, `ksh`, `bash`, or `zsh` shells you can use the following commands:

```
shell> ENVVAR=value
shell> export ENVVAR
```

The `export` is required if you want other sub-commands to inherit that value during execution. On more recent shells you can combine the export and setting processes, like this:

```
shell> export set ENVVAR=value
```

For the `csh`, or `tcsh` shells, use the `setenv` command:

```
shell> setenv ENVVAR value
```

Within the Windows Command Prompt use the `set` command to specify the value of a variable:

```
shell> set ENVVAR=value
```

On Unix, Linux, Mac OS X, and Windows, the `set` command without parameters will display the list of currently set variables.

**Table 2.21. MySQL Related Environment Variables**

| Variable           | Description                                                                                                                                                                        |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CXX                | The name of your C++ compiler (for running <code>configure</code> ).                                                                                                               |
| CC                 | The name of your C compiler (for running <code>configure</code> ).                                                                                                                 |
| CFLAGS             | Flags for your C compiler (for running <code>configure</code> ).                                                                                                                   |
| CXXFLAGS           | Flags for your C++ compiler (for running <code>configure</code> ).                                                                                                                 |
| DBI_USER           | The default user name for Perl DBI.                                                                                                                                                |
| DBI_TRACE          | Trace options for Perl DBI.                                                                                                                                                        |
| HOME               | The default path for the <code>mysql</code> history file is <code>\$HOME/.mysql_history</code> .                                                                                   |
| LD_RUN_PATH        | Used to specify the location of <code>libmysqlclient.so</code> .                                                                                                                   |
| MYSQL_DEBUG        | Debug trace options when debugging.                                                                                                                                                |
| MYSQL_GROUP_SUFFIX | Option group suffix value (like specifying <code>--defaults-group-suffix</code> ).                                                                                                 |
| MYSQL_HISTFILE     | The path to the <code>mysql</code> history file. If this variable is set, its value overrides the default for <code>\$HOME/.mysql_history</code> .                                 |
| MYSQL_HOME         | The path to the directory in which the server-specific <code>my.cnf</code> file resides (as of MySQL 5.0.3).                                                                       |
| MYSQL_HOST         | The default host name used by the <code>mysql</code> command-line client.                                                                                                          |
| MYSQL_PS1          | The command prompt to use in the <code>mysql</code> command-line client.                                                                                                           |
| MYSQL_PWD          | The default password when connecting to <code>mysqld</code> . Note that using this is insecure. See <a href="#">Section 5.3.2.2, “End-User Guidelines for Password Security”</a> . |
| MYSQL_TCP_PORT     | The default TCP/IP port number.                                                                                                                                                    |
| MYSQL_UNIX_PORT    | The default Unix socket file name; used for connections to <code>localhost</code> .                                                                                                |
| PATH               | Used by the shell to find MySQL programs.                                                                                                                                          |
| TMPDIR             | The directory where temporary files are created.                                                                                                                                   |
| TZ                 | This should be set to your local time zone. See <a href="#">Section B.5.4.6, “Time Zone Problems”</a> .                                                                            |
| UMASK              | The user-file creation mode when creating files. See note following table.                                                                                                         |
| UMASK_DIR          | The user-directory creation mode when creating directories. See note following table.                                                                                              |
| USER               | The default user name on Windows and NetWare used when connecting to <code>mysqld</code> .                                                                                         |

For information about the `mysql` history file, see [Section 4.5.1.3, “mysql History File”](#).

The `UMASK` and `UMASK_DIR` variables, despite their names, are used as modes, not masks:

- If `UMASK` is set, `mysqld` uses `($UMASK | 0600)` as the mode for file creation, so that newly created files have a mode in the range from 0600 to 0666 (all values octal).
- If `UMASK_DIR` is set, `mysqld` uses `($UMASK_DIR | 0700)` as the base mode for directory creation, which then is ANDed with `~($UMASK & 0666)`, so that newly created directories have a mode in the range from 0700 to 0777 (all values octal). The AND operation may remove read and write permissions from the directory mode, but not execute permissions.

MySQL assumes that the value for `UMASK` or `UMASK_DIR` is in octal if it starts with a zero.

## 2.15. Perl Installation Notes

Perl, and the `DBD::MySQL` module for `DBI`, provide an interface to MySQL databases. These modules must be installed if you want to run the MySQL benchmark scripts; see [Section 7.1.3, “The MySQL Benchmark Suite”](#). It is also required for the MySQL Cluster `ndb_size.pl` utility; see [Section 17.4.21, “ndb\\_size.pl — NDBCLUSTER Size Requirement Estimator”](#).

### Note

Perl support is not included with MySQL distributions. You can obtain the necessary modules from <http://search.cpan.org> for Unix, or by using the ActiveState `ppm` program on Windows. The following sections describe how to do this.

The `DBI/DBD` interface requires Perl 5.6.0, and 5.6.1 or later is preferred. `DBI` *does not work* if you have an older version of Perl.

You should use `DBD::mysql` 4.009 or higher. Although earlier versions are available, they do not support the full functionality of MySQL 5.1.

## 2.15.1. Installing Perl on Unix

MySQL Perl support requires that you have installed MySQL client programming support (libraries and header files). Most installation methods install the necessary files. However, if you installed MySQL from RPM files on Linux, be sure that you've installed the developer RPM. The client programs are in the client RPM, but client programming support is in the developer RPM.

If you want to install Perl support, the files you need can be obtained from the CPAN (Comprehensive Perl Archive Network) at <http://search.cpan.org>.

The easiest way to install Perl modules on Unix is to use the `CPAN` module. For example:

```
shell> perl -MCPAN -e shell
cpan> install DBI
cpan> install DBD::mysql
```

The `DBD::mysql` installation runs a number of tests. These tests attempt to connect to the local MySQL server using the default user name and password. (The default user name is your login name on Unix, and `ODBC` on Windows. The default password is “no password.”) If you cannot connect to the server with those values (for example, if your account has a password), the tests fail. You can use `force install DBD::mysql` to ignore the failed tests.

`DBI` requires the `Data::Dumper` module. It may be installed; if not, you should install it before installing `DBI`.

It is also possible to download the module distributions in the form of compressed `tar` archives and build the modules manually. For example, to unpack and build a `DBI` distribution, use a procedure such as this:

1. Unpack the distribution into the current directory:

```
shell> gunzip < DBI-VERSION.tar.gz | tar xvf -
```

This command creates a directory named `DBI-VERSION`.

2. Change location into the top-level directory of the unpacked distribution:

```
shell> cd DBI-VERSION
```

3. Build the distribution and compile everything:

```
shell> perl Makefile.PL
shell> make
shell> make test
shell> make install
```

The `make test` command is important because it verifies that the module is working. Note that when you run that command during the `DBD::mysql` installation to exercise the interface code, the MySQL server must be running or the test fails.

It is a good idea to rebuild and reinstall the `DBD::mysql` distribution whenever you install a new release of MySQL. This ensures that the latest versions of the MySQL client libraries are installed correctly.

If you do not have access rights to install Perl modules in the system directory or if you want to install local Perl modules, the following reference may be useful: <http://servers.digitaldaze.com/extensions/perl/modules.html#modules>

Look under the heading “Installing New Modules that Require Locally Installed Modules.”

## 2.15.2. Installing ActiveState Perl on Windows

On Windows, you should do the following to install the MySQL `DBD` module with ActiveState Perl:

1. Get ActiveState Perl from <http://www.activestate.com/Products/ActivePerl/> and install it.
2. Open a console window (a “DOS window”).
3. If necessary, set the `HTTP_proxy` variable. For example, you might try a setting like this:

```
set HTTP_proxy=my.proxy.com:3128
```

4. Start the PPM program:

```
C:\> C:\perl\bin\ppm.pl
```

5. If you have not previously done so, install DBI:

```
ppm> install DBI
```

6. If this succeeds, run the following command:

```
ppm> install DBD-mysql
```

This procedure should work with ActiveState Perl 5.6 or newer.

If you cannot get the procedure to work, you should install the MyODBC driver instead and connect to the MySQL server through ODBC:

```
use DBI;
$dbh= DBI->connect("DBI:ODBC:$dsn",$user,$password) ||
 die "Got error $DBI::errstr when connecting to $dsn\n";
```

### 2.15.3. Problems Using the Perl DBI/DBD Interface

If Perl reports that it cannot find the `../mysql/mysql.so` module, the problem is probably that Perl cannot locate the `libmysqlclient.so` shared library. You should be able to fix this problem by one of the following methods:

- Compile the `DBD::mysql` distribution with `perl Makefile.PL -static -config` rather than `perl Makefile.PL`.
- Copy `libmysqlclient.so` to the directory where your other shared libraries are located (probably `/usr/lib` or `/lib`).
- Modify the `-L` options used to compile `DBD::mysql` to reflect the actual location of `libmysqlclient.so`.
- On Linux, you can add the path name of the directory where `libmysqlclient.so` is located to the `/etc/ld.so.conf` file.
- Add the path name of the directory where `libmysqlclient.so` is located to the `LD_RUN_PATH` environment variable. Some systems use `LD_LIBRARY_PATH` instead.

Note that you may also need to modify the `-L` options if there are other libraries that the linker fails to find. For example, if the linker cannot find `libc` because it is in `/lib` and the link command specifies `-L/usr/lib`, change the `-L` option to `-L/lib` or add `-L/lib` to the existing link command.

If you get the following errors from `DBD::mysql`, you are probably using `gcc` (or using an old binary compiled with `gcc`):

```
/usr/bin/perl: can't resolve symbol '__moddi3'
/usr/bin/perl: can't resolve symbol '__divdi3'
```

Add `-L/usr/lib/gcc-lib/... -lgcc` to the link command when the `mysql.so` library gets built (check the output from `make` for `mysql.so` when you compile the Perl client). The `-L` option should specify the path name of the directory where `libgcc.a` is located on your system.

Another cause of this problem may be that Perl and MySQL are not both compiled with `gcc`. In this case, you can solve the mismatch by compiling both with `gcc`.

You may see the following error from `DBD::mysql` when you run the tests:

```
t/00base.....install_driver(mysql) failed:
Can't load '../blib/arch/auto/DBD/mysql/mysql.so' for module DBD::mysql:
../blib/arch/auto/DBD/mysql/mysql.so: undefined symbol:
uncompress at /usr/lib/perl5/5.00503/i586-linux/DynaLoader.pm line 169.
```

This means that you need to include the `-lz` compression library on the link line. That can be done by changing the following line in the file `lib/DBD/mysql/Install.pm`:

```
$sysliblist .= " -lm";
```

Change that line to:

```
$sysliblist .= " -lm -lz";
```

If you want to use the Perl module on a system that does not support dynamic linking (such as SCO), you can generate a static version of Perl that includes `DBI` and `DBD::mysql`. The way this works is that you generate a version of Perl with the `DBI` code linked in and install it on top of your current Perl. Then you use that to build a version of Perl that additionally has the `DBD` code linked in, and install that.

First, create a Perl that includes a statically linked `DBI` module by running these commands in the directory where your `DBI` distribution is located:

```
shell> perl Makefile.PL -static -config
shell> make
shell> make install
shell> make perl
```

Then, you must install the new Perl. The output of `make perl` indicates the exact `make` command you need to execute to perform the installation. On SCO, this is `make -f Makefile.aperl inst_perl MAP_TARGET=perl`.

Next, use the just-created Perl to create another Perl that also includes a statically linked `DBD::mysql` by running these commands in the directory where your `DBD::mysql` distribution is located:

```
shell> perl Makefile.PL -static -config
shell> make
shell> make install
shell> make perl
```

Finally, you should install this new Perl. Again, the output of `make perl` indicates the command to use.

---

# Chapter 3. Tutorial

This chapter provides a tutorial introduction to MySQL by showing how to use the `mysql` client program to create and use a simple database. `mysql` (sometimes referred to as the “terminal monitor” or just “monitor”) is an interactive program that enables you to connect to a MySQL server, run queries, and view the results. `mysql` may also be used in batch mode: you place your queries in a file beforehand, then tell `mysql` to execute the contents of the file. Both ways of using `mysql` are covered here.

To see a list of options provided by `mysql`, invoke it with the `--help` option:

```
shell> mysql --help
```

This chapter assumes that `mysql` is installed on your machine and that a MySQL server is available to which you can connect. If this is not true, contact your MySQL administrator. (If you are the administrator, you need to consult the relevant portions of this manual, such as [Chapter 5, MySQL Server Administration](#).)

This chapter describes the entire process of setting up and using a database. If you are interested only in accessing an existing database, you may want to skip over the sections that describe how to create the database and the tables it contains.

Because this chapter is tutorial in nature, many details are necessarily omitted. Consult the relevant sections of the manual for more information on the topics covered here.

## 3.1. Connecting to and Disconnecting from the Server

To connect to the server, you will usually need to provide a MySQL user name when you invoke `mysql` and, most likely, a password. If the server runs on a machine other than the one where you log in, you will also need to specify a host name. Contact your administrator to find out what connection parameters you should use to connect (that is, what host, user name, and password to use). Once you know the proper parameters, you should be able to connect like this:

```
shell> mysql -h host -u user -p
Enter password: *****
```

`host` and `user` represent the host name where your MySQL server is running and the user name of your MySQL account. Substitute appropriate values for your setup. The `*****` represents your password; enter it when `mysql` displays the `Enter password:` prompt.

If that works, you should see some introductory information followed by a `mysql>` prompt:

```
shell> mysql -h host -u user -p
Enter password: *****
Welcome to the MySQL monitor. Commands end with ; or \g.
Your MySQL connection id is 25338 to server version: 5.1.52-standard
Type 'help;' or '\h' for help. Type '\c' to clear the buffer.
mysql>
```

The `mysql>` prompt tells you that `mysql` is ready for you to enter commands.

If you are logging in on the same machine that MySQL is running on, you can omit the host, and simply use the following:

```
shell> mysql -u user -p
```

If, when you attempt to log in, you get an error message such as `ERROR 2002 (HY000): CAN'T CONNECT TO LOCAL MySQL SERVER THROUGH SOCKET '/TMP/MYSQL.SOCK' (2)`, it means that the MySQL server daemon (Unix) or service (Windows) is not running. Consult the administrator or see the section of [Chapter 2, Installing and Upgrading MySQL](#) that is appropriate to your operating system.

For help with other problems often encountered when trying to log in, see [Section B.5.2, “Common Errors When Using MySQL Programs”](#).

Some MySQL installations permit users to connect as the anonymous (unnamed) user to the server running on the local host. If this is the case on your machine, you should be able to connect to that server by invoking `mysql` without any options:

```
shell> mysql
```

After you have connected successfully, you can disconnect any time by typing `QUIT` (or `\q`) at the `mysql>` prompt:

```
mysql> QUIT
Bye
```

On Unix, you can also disconnect by pressing Control-D.

Most examples in the following sections assume that you are connected to the server. They indicate this by the `mysql>` prompt.

## 3.2. Entering Queries

Make sure that you are connected to the server, as discussed in the previous section. Doing so does not in itself select any database to work with, but that is okay. At this point, it is more important to find out a little about how to issue queries than to jump right in creating tables, loading data into them, and retrieving data from them. This section describes the basic principles of entering commands, using several queries you can try out to familiarize yourself with how `mysql` works.

Here is a simple command that asks the server to tell you its version number and the current date. Type it in as shown here following the `mysql>` prompt and press Enter:

```
mysql> SELECT VERSION(), CURRENT_DATE;
+-----+-----+
| VERSION() | CURRENT_DATE |
+-----+-----+
| 5.1.2-alpha-log | 2005-10-11 |
+-----+-----+
1 row in set (0.01 sec)
mysql>
```

This query illustrates several things about `mysql`:

- A command normally consists of an SQL statement followed by a semicolon. (There are some exceptions where a semicolon may be omitted. `QUIT`, mentioned earlier, is one of them. We'll get to others later.)
- When you issue a command, `mysql` sends it to the server for execution and displays the results, then prints another `mysql>` prompt to indicate that it is ready for another command.
- `mysql` displays query output in tabular form (rows and columns). The first row contains labels for the columns. The rows following are the query results. Normally, column labels are the names of the columns you fetch from database tables. If you're retrieving the value of an expression rather than a table column (as in the example just shown), `mysql` labels the column using the expression itself.
- `mysql` shows how many rows were returned and how long the query took to execute, which gives you a rough idea of server performance. These values are imprecise because they represent wall clock time (not CPU or machine time), and because they are affected by factors such as server load and network latency. (For brevity, the "rows in set" line is sometimes not shown in the remaining examples in this chapter.)

Keywords may be entered in any lettercase. The following queries are equivalent:

```
mysql> SELECT VERSION(), CURRENT_DATE;
mysql> select version(), current_date;
mysql> SeLeCt vErSiOn(), current_DATE;
```

Here is another query. It demonstrates that you can use `mysql` as a simple calculator:

```
mysql> SELECT SIN(PI()/4), (4+1)*5;
+-----+-----+
| SIN(PI()/4) | (4+1)*5 |
+-----+-----+
| 0.70710678118655 | 25 |
+-----+-----+
1 row in set (0.02 sec)
```

The queries shown thus far have been relatively short, single-line statements. You can even enter multiple statements on a single line. Just end each one with a semicolon:

```
mysql> SELECT VERSION(); SELECT NOW();
+-----+
| VERSION() |
+-----+
| 5.1.2-alpha-log |
+-----+
1 row in set (0.00 sec)

+-----+
| NOW() |
+-----+
| 2005-10-11 15:15:00 |
+-----+
1 row in set (0.00 sec)
```

A command need not be given all on a single line, so lengthy commands that require several lines are not a problem. `mysql` determines where your statement ends by looking for the terminating semicolon, not by looking for the end of the input line. (In other words, `mysql` accepts free-format input: it collects input lines but does not execute them until it sees the semicolon.)

Here is a simple multiple-line statement:

```
mysql> SELECT
-> USER()
-> ,
-> CURRENT_DATE;
+-----+-----+
| USER() | CURRENT_DATE |
+-----+-----+
| jon@localhost | 2005-10-11 |
+-----+-----+
```

In this example, notice how the prompt changes from `mysql>` to `->` after you enter the first line of a multiple-line query. This is how `mysql` indicates that it has not yet seen a complete statement and is waiting for the rest. The prompt is your friend, because it provides valuable feedback. If you use that feedback, you can always be aware of what `mysql` is waiting for.

If you decide you do not want to execute a command that you are in the process of entering, cancel it by typing `\c`:

```
mysql> SELECT
-> USER()
-> \c
mysql>
```

Here, too, notice the prompt. It switches back to `mysql>` after you type `\c`, providing feedback to indicate that `mysql` is ready for a new command.

The following table shows each of the prompts you may see and summarizes what they mean about the state that `mysql` is in.

| Prompt                 | Meaning                                                                                          |
|------------------------|--------------------------------------------------------------------------------------------------|
| <code>mysql&gt;</code> | Ready for new command.                                                                           |
| <code>-&gt;</code>     | Waiting for next line of multiple-line command.                                                  |
| <code>'&gt;</code>     | Waiting for next line, waiting for completion of a string that began with a single quote ("').   |
| <code>"&gt;</code>     | Waiting for next line, waiting for completion of a string that began with a double quote ("").   |
| <code>`&gt;</code>     | Waiting for next line, waiting for completion of an identifier that began with a backtick ("`"). |
| <code>/*&gt;</code>    | Waiting for next line, waiting for completion of a comment that began with /*.                   |

Multiple-line statements commonly occur by accident when you intend to issue a command on a single line, but forget the terminating semicolon. In this case, `mysql` waits for more input:

```
mysql> SELECT USER()
->
```

If this happens to you (you think you've entered a statement but the only response is a `->` prompt), most likely `mysql` is waiting for the semicolon. If you don't notice what the prompt is telling you, you might sit there for a while before realizing what you need to do. Enter a semicolon to complete the statement, and `mysql` executes it:

```
mysql> SELECT USER()
-> ;
+-----+
| USER() |
+-----+
| jon@localhost |
+-----+
```

The `'>` and `">` prompts occur during string collection (another way of saying that MySQL is waiting for completion of a string). In MySQL, you can write strings surrounded by either `'` or `"` characters (for example, `'hello'` or `"goodbye"`), and `mysql` lets you enter strings that span multiple lines. When you see a `'>` or `">` prompt, it means that you have entered a line containing a string that begins with a `'` or `"` quote character, but have not yet entered the matching quote that terminates the string. This often indicates that you have inadvertently left out a quote character. For example:

```
mysql> SELECT * FROM my_table WHERE name = 'Smith AND age < 30;
->
```

If you enter this `SELECT` statement, then press **Enter** and wait for the result, nothing happens. Instead of wondering why this query takes so long, notice the clue provided by the `'>` prompt. It tells you that `mysql` expects to see the rest of an unterminated

string. (Do you see the error in the statement? The string '`Smith`' is missing the second single quotation mark.)

At this point, what do you do? The simplest thing is to cancel the command. However, you cannot just type `\c` in this case, because `mysql` interprets it as part of the string that it is collecting. Instead, enter the closing quote character (so `mysql` knows you've finished the string), then type `\c`:

```
mysql> SELECT * FROM my_table WHERE name = 'Smith AND age < 30;
 '> '\c
mysql>
```

The prompt changes back to `mysql>`, indicating that `mysql` is ready for a new command.

The ``>` prompt is similar to the `'>` and `">` prompts, but indicates that you have begun but not completed a backtick-quoted identifier.

It is important to know what the `'>`, `">`, and ``>` prompts signify, because if you mistakenly enter an unterminated string, any further lines you type appear to be ignored by `mysql`—including a line containing `QUIT`. This can be quite confusing, especially if you do not know that you need to supply the terminating quote before you can cancel the current command.

### 3.3. Creating and Using a Database

Once you know how to enter commands, you are ready to access a database.

Suppose that you have several pets in your home (your menagerie) and you would like to keep track of various types of information about them. You can do so by creating tables to hold your data and loading them with the desired information. Then you can answer different sorts of questions about your animals by retrieving data from the tables. This section shows you how to perform the following operations:

- Create a database
- Create a table
- Load data into the table
- Retrieve data from the table in various ways
- Use multiple tables

The menagerie database is simple (deliberately), but it is not difficult to think of real-world situations in which a similar type of database might be used. For example, a database like this could be used by a farmer to keep track of livestock, or by a veterinarian to keep track of patient records. A menagerie distribution containing some of the queries and sample data used in the following sections can be obtained from the MySQL Web site. It is available in both compressed `tar` file and Zip formats at <http://dev.mysql.com/doc/>.

Use the `SHOW` statement to find out what databases currently exist on the server:

```
mysql> SHOW DATABASES;
+------------+
| Database |
+------------+
| mysql |
| test |
| tmp |
+------------+
```

The `mysql` database describes user access privileges. The `test` database often is available as a workspace for users to try things out.

The list of databases displayed by the statement may be different on your machine; `SHOW DATABASES` does not show databases that you have no privileges for if you do not have the `SHOW DATABASES` privilege. See [Section 12.4.5.15, “SHOW DATABASES Syntax”](#).

If the `test` database exists, try to access it:

```
mysql> USE test
Database changed
```

`USE`, like `QUIT`, does not require a semicolon. (You can terminate such statements with a semicolon if you like; it does no harm.) The `USE` statement is special in another way, too: it must be given on a single line.

You can use the `test` database (if you have access to it) for the examples that follow, but anything you create in that database can

be removed by anyone else with access to it. For this reason, you should probably ask your MySQL administrator for permission to use a database of your own. Suppose that you want to call yours `menagerie`. The administrator needs to execute a command like this:

```
mysql> GRANT ALL ON menagerie.* TO 'your_mysql_name'@'your_client_host';
```

where `your_mysql_name` is the MySQL user name assigned to you and `your_client_host` is the host from which you connect to the server.

### 3.3.1. Creating and Selecting a Database

If the administrator creates your database for you when setting up your permissions, you can begin using it. Otherwise, you need to create it yourself:

```
mysql> CREATE DATABASE menagerie;
```

Under Unix, database names are case sensitive (unlike SQL keywords), so you must always refer to your database as `menagerie`, not as `Menagerie`, `MENAGERIE`, or some other variant. This is also true for table names. (Under Windows, this restriction does not apply, although you must refer to databases and tables using the same lettercase throughout a given query. However, for a variety of reasons, the recommended best practice is always to use the same lettercase that was used when the database was created.)

#### Note

If you get an error such as `ERROR 1044 (42000): ACCESS DENIED FOR USER 'MONTY'@'LOCALHOST' TO DATABASE 'MENAGERIE'` when attempting to create a database, this means that your user account does not have the necessary privileges to do so. Discuss this with the administrator or see [Section 5.4, “The MySQL Access Privilege System”](#).

Creating a database does not select it for use; you must do that explicitly. To make `menagerie` the current database, use this command:

```
mysql> USE menagerie
Database changed
```

Your database needs to be created only once, but you must select it for use each time you begin a `mysql` session. You can do this by issuing a `USE` statement as shown in the example. Alternatively, you can select the database on the command line when you invoke `mysql`. Just specify its name after any connection parameters that you might need to provide. For example:

```
shell> mysql -h host -u user -p menagerie
Enter password: *****
```

#### Important

`menagerie` in the command just shown is **not** your password. If you want to supply your password on the command line after the `-p` option, you must do so with no intervening space (for example, as `-pmypassword`, not as `-p mypassword`). However, putting your password on the command line is not recommended, because doing so exposes it to snooping by other users logged in on your machine.

#### Note

You can see at any time which database is currently selected using `SELECT DATABASE()`.

### 3.3.2. Creating a Table

Creating the database is the easy part, but at this point it is empty, as `SHOW TABLES` tells you:

```
mysql> SHOW TABLES;
Empty set (0.00 sec)
```

The harder part is deciding what the structure of your database should be: what tables you need and what columns should be in each of them.

You want a table that contains a record for each of your pets. This can be called the `pet` table, and it should contain, as a bare minimum, each animal's name. Because the name by itself is not very interesting, the table should contain other information. For example, if more than one person in your family keeps pets, you might want to list each animal's owner. You might also want to record some basic descriptive information such as species and sex.

How about age? That might be of interest, but it is not a good thing to store in a database. Age changes as time passes, which means you'd have to update your records often. Instead, it is better to store a fixed value such as date of birth. Then, whenever you

need age, you can calculate it as the difference between the current date and the birth date. MySQL provides functions for doing date arithmetic, so this is not difficult. Storing birth date rather than age has other advantages, too:

- You can use the database for tasks such as generating reminders for upcoming pet birthdays. (If you think this type of query is somewhat silly, note that it is the same question you might ask in the context of a business database to identify clients to whom you need to send out birthday greetings in the current week or month, for that computer-assisted personal touch.)
- You can calculate age in relation to dates other than the current date. For example, if you store death date in the database, you can easily calculate how old a pet was when it died.

You can probably think of other types of information that would be useful in the `pet` table, but the ones identified so far are sufficient: name, owner, species, sex, birth, and death.

Use a `CREATE TABLE` statement to specify the layout of your table:

```
mysql> CREATE TABLE pet (name VARCHAR(20), owner VARCHAR(20),
-> species VARCHAR(20), sex CHAR(1), birth DATE, death DATE);
```

`VARCHAR` is a good choice for the `name`, `owner`, and `species` columns because the column values vary in length. The lengths in those column definitions need not all be the same, and need not be 20. You can normally pick any length from 1 to 65535, whatever seems most reasonable to you. If you make a poor choice and it turns out later that you need a longer field, MySQL provides an `ALTER TABLE` statement.

Several types of values can be chosen to represent sex in animal records, such as '`m`' and '`f`', or perhaps '`male`' and '`female`'. It is simplest to use the single characters '`m`' and '`f`'.

The use of the `DATE` data type for the `birth` and `death` columns is a fairly obvious choice.

Once you have created a table, `SHOW TABLES` should produce some output:

```
mysql> SHOW TABLES;
+-----+
| Tables in menagerie |
+-----+
| pet |
+-----+
```

To verify that your table was created the way you expected, use a `DESCRIBE` statement:

```
mysql> DESCRIBE pet;
+-----+-----+-----+-----+-----+-----+
| Field | Type | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
name	varchar(20)	YES		NULL	
owner	varchar(20)	YES		NULL	
species	varchar(20)	YES		NULL	
sex	char(1)	YES		NULL	
birth	date	YES		NULL	
death	date	YES		NULL	
+-----+-----+-----+-----+-----+-----+
```

You can use `DESCRIBE` any time, for example, if you forget the names of the columns in your table or what types they have.

For more information about MySQL data types, see [Chapter 10, Data Types](#).

### 3.3.3. Loading Data into a Table

After creating your table, you need to populate it. The `LOAD DATA` and `INSERT` statements are useful for this.

Suppose that your pet records can be described as shown here. (Observe that MySQL expects dates in '`YYYY-MM-DD`' format; this may be different from what you are used to.)

| name   | owner  | species | sex | birth      | death      |
|--------|--------|---------|-----|------------|------------|
| Fluffy | Harold | cat     | f   | 1993-02-04 |            |
| Claws  | Gwen   | cat     | m   | 1994-03-17 |            |
| Buffy  | Harold | dog     | f   | 1989-05-13 |            |
| Fang   | Benny  | dog     | m   | 1990-08-27 |            |
| Bowser | Diane  | dog     | m   | 1979-08-31 | 1995-07-29 |
| Chirpy | Gwen   | bird    | f   | 1998-09-11 |            |

|          |       |       |   |            |  |
|----------|-------|-------|---|------------|--|
| Whistler | Gwen  | bird  |   | 1997-12-09 |  |
| Slim     | Benny | snake | m | 1996-04-29 |  |

Because you are beginning with an empty table, an easy way to populate it is to create a text file containing a row for each of your animals, then load the contents of the file into the table with a single statement.

You could create a text file `pet.txt` containing one record per line, with values separated by tabs, and given in the order in which the columns were listed in the `CREATE TABLE` statement. For missing values (such as unknown sexes or death dates for animals that are still living), you can use `NULL` values. To represent these in your text file, use `\N` (backslash, capital-N). For example, the record for Whistler the bird would look like this (where the whitespace between values is a single tab character):

```
Whistler Gwen bird \N 1997-12-09 \N
```

To load the text file `pet.txt` into the `pet` table, use this statement:

```
mysql> LOAD DATA LOCAL INFILE '/path/pet.txt' INTO TABLE pet;
```

If you created the file on Windows with an editor that uses `\r\n` as a line terminator, you should use this statement instead:

```
mysql> LOAD DATA LOCAL INFILE '/path/pet.txt' INTO TABLE pet
-> LINES TERMINATED BY '\r\n';
```

(On an Apple machine running OS X, you would likely want to use `LINES TERMINATED BY '\r'`.)

You can specify the column value separator and end of line marker explicitly in the `LOAD DATA` statement if you wish, but the defaults are tab and linefeed. These are sufficient for the statement to read the file `pet.txt` properly.

If the statement fails, it is likely that your MySQL installation does not have local file capability enabled by default. See [Section 5.3.5, “Security Issues with LOAD DATA LOCAL”](#), for information on how to change this.

When you want to add new records one at a time, the `INSERT` statement is useful. In its simplest form, you supply values for each column, in the order in which the columns were listed in the `CREATE TABLE` statement. Suppose that Diane gets a new hamster named “Puffball.” You could add a new record using an `INSERT` statement like this:

```
mysql> INSERT INTO pet
-> VALUES ('Puffball','Diane','hamster','f','1999-03-30',NULL);
```

String and date values are specified as quoted strings here. Also, with `INSERT`, you can insert `NULL` directly to represent a missing value. You do not use `\N` like you do with `LOAD DATA`.

From this example, you should be able to see that there would be a lot more typing involved to load your records initially using several `INSERT` statements rather than a single `LOAD DATA` statement.

### 3.3.4. Retrieving Information from a Table

The `SELECT` statement is used to pull information from a table. The general form of the statement is:

```
SELECT what_to_select
FROM which_table
WHERE conditions_to_satisfy;
```

`what_to_select` indicates what you want to see. This can be a list of columns, or `*` to indicate “all columns.” `which_table` indicates the table from which you want to retrieve data. The `WHERE` clause is optional. If it is present, `conditions_to_satisfy` specifies one or more conditions that rows must satisfy to qualify for retrieval.

#### 3.3.4.1. Selecting All Data

The simplest form of `SELECT` retrieves everything from a table:

```
mysql> SELECT * FROM pet;
+-----+-----+-----+-----+-----+-----+
| name | owner | species | sex | birth | death |
+-----+-----+-----+-----+-----+-----+
Fluffy	Harold	cat	f	1993-02-04	NULL
Claws	Gwen	cat	m	1994-03-17	NULL
Buffy	Harold	dog	f	1989-05-13	NULL
Fang	Benny	dog	m	1990-08-27	NULL
Bowser	Diane	dog	m	1979-08-31	1995-07-29
Chirpy	Gwen	bird	f	1998-09-11	NULL
Whistler	Gwen	bird	NULL	1997-12-09	NULL
```

|          |       |         |   |            |      |
|----------|-------|---------|---|------------|------|
| Slim     | Benny | snake   | m | 1996-04-29 | NULL |
| Puffball | Diane | hamster | f | 1999-03-30 | NULL |

This form of `SELECT` is useful if you want to review your entire table, for example, after you've just loaded it with your initial data set. For example, you may happen to think that the birth date for Bowser doesn't seem quite right. Consulting your original pedigree papers, you find that the correct birth year should be 1989, not 1979.

There are at least two ways to fix this:

- Edit the file `pet.txt` to correct the error, then empty the table and reload it using `DELETE` and `LOAD DATA`:

```
mysql> DELETE FROM pet;
mysql> LOAD DATA LOCAL INFILE 'pet.txt' INTO TABLE pet;
```

However, if you do this, you must also re-enter the record for Puffball.

- Fix only the erroneous record with an `UPDATE` statement:

```
mysql> UPDATE pet SET birth = '1989-08-31' WHERE name = 'Bowser';
```

The `UPDATE` changes only the record in question and does not require you to reload the table.

### 3.3.4.2. Selecting Particular Rows

As shown in the preceding section, it is easy to retrieve an entire table. Just omit the `WHERE` clause from the `SELECT` statement. But typically you don't want to see the entire table, particularly when it becomes large. Instead, you're usually more interested in answering a particular question, in which case you specify some constraints on the information you want. Let's look at some selection queries in terms of questions about your pets that they answer.

You can select only particular rows from your table. For example, if you want to verify the change that you made to Bowser's birth date, select Bowser's record like this:

```
mysql> SELECT * FROM pet WHERE name = 'Bowser';
+-----+-----+-----+-----+-----+
| name | owner | species | sex | birth | death |
+-----+-----+-----+-----+-----+
| Bowser | Diane | dog | m | 1989-08-31 | 1995-07-29 |
+-----+-----+-----+-----+-----+
```

The output confirms that the year is correctly recorded as 1989, not 1979.

String comparisons normally are case-insensitive, so you can specify the name as '`bowser`', '`BOWSER`', and so forth. The query result is the same.

You can specify conditions on any column, not just `name`. For example, if you want to know which animals were born during or after 1998, test the `birth` column:

```
mysql> SELECT * FROM pet WHERE birth >= '1998-1-1';
+-----+-----+-----+-----+-----+
| name | owner | species | sex | birth | death |
+-----+-----+-----+-----+-----+
| Chirpy | Gwen | bird | f | 1998-09-11 | NULL |
| Puffball | Diane | hamster | f | 1999-03-30 | NULL |
+-----+-----+-----+-----+-----+
```

You can combine conditions, for example, to locate female dogs:

```
mysql> SELECT * FROM pet WHERE species = 'dog' AND sex = 'f';
+-----+-----+-----+-----+-----+
| name | owner | species | sex | birth | death |
+-----+-----+-----+-----+-----+
| Buffy | Harold | dog | f | 1989-05-13 | NULL |
+-----+-----+-----+-----+-----+
```

The preceding query uses the `AND` logical operator. There is also an `OR` operator:

```
mysql> SELECT * FROM pet WHERE species = 'snake' OR species = 'bird';
+-----+-----+-----+-----+-----+
| name | owner | species | sex | birth | death |
+-----+-----+-----+-----+-----+
Chirpy	Gwen	bird	f	1998-09-11	NULL
Whistler	Gwen	bird	NULL	1997-12-09	NULL
Slim	Benny	snake	m	1996-04-29	NULL
+-----+-----+-----+-----+-----+
```

```
+-----+-----+-----+-----+
| name | owner | species | sex | birth | death |
+-----+-----+-----+-----+
| Claws | Gwen | cat | m | 1994-03-17 | NULL |
| Buffy | Harold | dog | f | 1989-05-13 | NULL |
+-----+-----+-----+-----+
```

`AND` and `OR` may be intermixed, although `AND` has higher precedence than `OR`. If you use both operators, it is a good idea to use parentheses to indicate explicitly how conditions should be grouped:

```
mysql> SELECT * FROM pet WHERE (species = 'cat' AND sex = 'm')
-> OR (species = 'dog' AND sex = 'f');
+-----+-----+-----+-----+
| name | owner | species | sex | birth | death |
+-----+-----+-----+-----+
| Claws | Gwen | cat | m | 1994-03-17 | NULL |
| Buffy | Harold | dog | f | 1989-05-13 | NULL |
+-----+-----+-----+-----+
```

### 3.3.4.3. Selecting Particular Columns

If you do not want to see entire rows from your table, just name the columns in which you are interested, separated by commas. For example, if you want to know when your animals were born, select the `name` and `birth` columns:

```
mysql> SELECT name, birth FROM pet;
+-----+-----+
| name | birth |
+-----+-----+
Fluffy	1993-02-04
Claws	1994-03-17
Buffy	1989-05-13
Fang	1990-08-27
Bowser	1989-08-31
Chirpy	1998-09-11
Whistler	1997-12-09
Slim	1996-04-29
Puffball	1999-03-30
+-----+-----+
```

To find out who owns pets, use this query:

```
mysql> SELECT owner FROM pet;
+-----+
| owner |
+-----+
| Harold |
| Gwen |
| Harold |
| Benny |
| Diane |
| Gwen |
| Gwen |
| Benny |
| Diane |
+-----+
```

Notice that the query simply retrieves the `owner` column from each record, and some of them appear more than once. To minimize the output, retrieve each unique output record just once by adding the keyword `DISTINCT`:

```
mysql> SELECT DISTINCT owner FROM pet;
+-----+
| owner |
+-----+
| Benny |
| Diane |
| Gwen |
| Harold |
+-----+
```

You can use a `WHERE` clause to combine row selection with column selection. For example, to get birth dates for dogs and cats only, use this query:

```
mysql> SELECT name, species, birth FROM pet
-> WHERE species = 'dog' OR species = 'cat';
+-----+-----+-----+
| name | species | birth |
+-----+-----+-----+
Fluffy	cat	1993-02-04
Claws	cat	1994-03-17
Buffy	dog	1989-05-13
Fang	dog	1990-08-27
Bowser	dog	1989-08-31
+-----+-----+-----+
```

### 3.3.4.4. Sorting Rows

You may have noticed in the preceding examples that the result rows are displayed in no particular order. It is often easier to exam-

ine query output when the rows are sorted in some meaningful way. To sort a result, use an `ORDER BY` clause.

Here are animal birthdays, sorted by date:

```
mysql> SELECT name, birth FROM pet ORDER BY birth;
+-----+-----+
| name | birth |
+-----+-----+
Buffy	1989-05-13
Bowser	1989-08-31
Fang	1990-08-27
Fluffy	1993-02-04
Claws	1994-03-17
Slim	1996-04-29
Whistler	1997-12-09
Chirpy	1998-09-11
Puffball	1999-03-30
+-----+-----+
```

On character type columns, sorting—like all other comparison operations—is normally performed in a case-insensitive fashion. This means that the order is undefined for columns that are identical except for their case. You can force a case-sensitive sort for a column by using `BINARY` like so: `ORDER BY BINARY col_name`.

The default sort order is ascending, with smallest values first. To sort in reverse (descending) order, add the `DESC` keyword to the name of the column you are sorting by:

```
mysql> SELECT name, birth FROM pet ORDER BY birth DESC;
+-----+-----+
| name | birth |
+-----+-----+
Puffball	1999-03-30
Chirpy	1998-09-11
Whistler	1997-12-09
Slim	1996-04-29
Claws	1994-03-17
Fluffy	1993-02-04
Fang	1990-08-27
Bowser	1989-08-31
Buffy	1989-05-13
+-----+-----+
```

You can sort on multiple columns, and you can sort different columns in different directions. For example, to sort by type of animal in ascending order, then by birth date within animal type in descending order (youngest animals first), use the following query:

```
mysql> SELECT name, species, birth FROM pet
-> ORDER BY species, birth DESC;
+-----+-----+-----+
| name | species | birth |
+-----+-----+-----+
Chirpy	bird	1998-09-11
Whistler	bird	1997-12-09
Claws	cat	1994-03-17
Fluffy	cat	1993-02-04
Fang	dog	1990-08-27
Bowser	dog	1989-08-31
Buffy	dog	1989-05-13
Puffball	hamster	1999-03-30
Slim	snake	1996-04-29
+-----+-----+-----+
```

The `DESC` keyword applies only to the column name immediately preceding it (`birth`); it does not affect the `species` column sort order.

### 3.3.4.5. Date Calculations

MySQL provides several functions that you can use to perform calculations on dates, for example, to calculate ages or extract parts of dates.

To determine how many years old each of your pets is, compute the difference in the year part of the current date and the birth date, then subtract one if the current date occurs earlier in the calendar year than the birth date. The following query shows, for each pet, the birth date, the current date, and the age in years.

```
mysql> SELECT name, birth, CURDATE(),
-> (YEAR(CURDATE())-YEAR(birth))
-> - (RIGHT(CURDATE(),5)<RIGHT(birth,5))
-> AS age
-> FROM pet;
+-----+-----+-----+-----+
| name | birth | CURDATE() | age |
+-----+-----+-----+-----+
Fluffy	1993-02-04	2003-08-19	10
Claws	1994-03-17	2003-08-19	9
Buffy	1989-05-13	2003-08-19	14
+-----+-----+-----+-----+
```

|          |            |            |    |
|----------|------------|------------|----|
| Fang     | 1990-08-27 | 2003-08-19 | 12 |
| Bowser   | 1989-08-31 | 2003-08-19 | 13 |
| Chirpy   | 1998-09-11 | 2003-08-19 | 4  |
| Whistler | 1997-12-09 | 2003-08-19 | 5  |
| Slim     | 1996-04-29 | 2003-08-19 | 7  |
| Puffball | 1999-03-30 | 2003-08-19 | 4  |

Here, `YEAR()` pulls out the year part of a date and `RIGHT()` pulls off the rightmost five characters that represent the `MM-DD` (calendar year) part of the date. The part of the expression that compares the `MM-DD` values evaluates to 1 or 0, which adjusts the year difference down a year if `CURDATE()` occurs earlier in the year than `birth`. The full expression is somewhat ungainly, so an alias (`age`) is used to make the output column label more meaningful.

The query works, but the result could be scanned more easily if the rows were presented in some order. This can be done by adding an `ORDER BY name` clause to sort the output by name:

| name     | birth      | CURDATE()  | age |
|----------|------------|------------|-----|
| Bowser   | 1989-08-31 | 2003-08-19 | 13  |
| Buffy    | 1989-05-13 | 2003-08-19 | 14  |
| Chirpy   | 1998-09-11 | 2003-08-19 | 4   |
| Claws    | 1994-03-17 | 2003-08-19 | 9   |
| Fang     | 1990-08-27 | 2003-08-19 | 12  |
| Fluffy   | 1993-02-04 | 2003-08-19 | 10  |
| Puffball | 1999-03-30 | 2003-08-19 | 4   |
| Slim     | 1996-04-29 | 2003-08-19 | 7   |
| Whistler | 1997-12-09 | 2003-08-19 | 5   |

To sort the output by `age` rather than `name`, just use a different `ORDER BY` clause:

| name     | birth      | CURDATE()  | age |
|----------|------------|------------|-----|
| Chirpy   | 1998-09-11 | 2003-08-19 | 4   |
| Puffball | 1999-03-30 | 2003-08-19 | 4   |
| Whistler | 1997-12-09 | 2003-08-19 | 5   |
| Slim     | 1996-04-29 | 2003-08-19 | 7   |
| Claws    | 1994-03-17 | 2003-08-19 | 9   |
| Fluffy   | 1993-02-04 | 2003-08-19 | 10  |
| Fang     | 1990-08-27 | 2003-08-19 | 12  |
| Bowser   | 1989-08-31 | 2003-08-19 | 13  |
| Buffy    | 1989-05-13 | 2003-08-19 | 14  |

A similar query can be used to determine age at death for animals that have died. You determine which animals these are by checking whether the `death` value is `NULL`. Then, for those with non-`NULL` values, compute the difference between the `death` and `birth` values:

| name   | birth      | death      | age |
|--------|------------|------------|-----|
| Bowser | 1989-08-31 | 1995-07-29 | 5   |

The query uses `death IS NOT NULL` rather than `death <> NULL` because `NULL` is a special value that cannot be compared using the usual comparison operators. This is discussed later. See [Section 3.3.4.6, “Working with NULL Values”](#).

What if you want to know which animals have birthdays next month? For this type of calculation, year and day are irrelevant; you simply want to extract the month part of the `birth` column. MySQL provides several functions for extracting parts of dates, such as `YEAR()`, `MONTH()`, and `DAYOFMONTH()`. `MONTH()` is the appropriate function here. To see how it works, run a simple query that displays the value of both `birth` and `MONTH(birth)`:

| name   | birth      | MONTH(birth) |
|--------|------------|--------------|
| Fluffy | 1993-02-04 | 2            |
| Claws  | 1994-03-17 | 3            |

|          |            |    |
|----------|------------|----|
| Buffy    | 1989-05-13 | 5  |
| Fang     | 1990-08-27 | 8  |
| Bowser   | 1989-08-31 | 8  |
| Chirpy   | 1998-09-11 | 9  |
| Whistler | 1997-12-09 | 12 |
| Slim     | 1996-04-29 | 4  |
| Puffball | 1999-03-30 | 3  |

Finding animals with birthdays in the upcoming month is also simple. Suppose that the current month is April. Then the month value is 4 and you can look for animals born in May (month 5) like this:

```
mysql> SELECT name, birth FROM pet WHERE MONTH(birth) = 5;
+-----+-----+
| name | birth |
+-----+-----+
| Buffy | 1989-05-13 |
+-----+
```

There is a small complication if the current month is December. You cannot merely add one to the month number (12) and look for animals born in month 13, because there is no such month. Instead, you look for animals born in January (month 1).

You can write the query so that it works no matter what the current month is, so that you do not have to use the number for a particular month. `DATE_ADD()` enables you to add a time interval to a given date. If you add a month to the value of `CURDATE()`, then extract the month part with `MONTH()`, the result produces the month in which to look for birthdays:

```
mysql> SELECT name, birth FROM pet
-> WHERE MONTH(birth) = MONTH(DATE_ADD(CURDATE(), INTERVAL 1 MONTH));
```

A different way to accomplish the same task is to add 1 to get the next month after the current one after using the modulo function (`MOD`) to wrap the month value to 0 if it is currently 12:

```
mysql> SELECT name, birth FROM pet
-> WHERE MONTH(birth) = MOD(MONTH(CURDATE()), 12) + 1;
```

`MONTH()` returns a number between 1 and 12. And `MOD(something, 12)` returns a number between 0 and 11. So the addition has to be after the `MOD()`, otherwise we would go from November (11) to January (1).

### 3.3.4.6. Working with `NULL` Values

The `NULL` value can be surprising until you get used to it. Conceptually, `NULL` means “a missing unknown value” and it is treated somewhat differently from other values. To test for `NULL`, you cannot use the arithmetic comparison operators such as `=`, `<`, or `>`. To demonstrate this for yourself, try the following query:

```
mysql> SELECT 1 = NULL, 1 <> NULL, 1 < NULL, 1 > NULL;
+-----+-----+-----+-----+
| 1 = NULL | 1 <> NULL | 1 < NULL | 1 > NULL |
+-----+-----+-----+-----+
| NULL | NULL | NULL | NULL |
+-----+-----+-----+-----+
```

Clearly you get no meaningful results from these comparisons. Use the `IS NULL` and `IS NOT NULL` operators instead:

```
mysql> SELECT 1 IS NULL, 1 IS NOT NULL;
+-----+-----+
| 1 IS NULL | 1 IS NOT NULL |
+-----+-----+
| 0 | 1 |
+-----+-----+
```

In MySQL, 0 or `NULL` means false and anything else means true. The default truth value from a boolean operation is 1.

This special treatment of `NULL` is why, in the previous section, it was necessary to determine which animals are no longer alive using `death IS NOT NULL` instead of `death <> NULL`.

Two `NULL` values are regarded as equal in a `GROUP BY`.

When doing an `ORDER BY`, `NULL` values are presented first if you do `ORDER BY ... ASC` and last if you do `ORDER BY ... DESC`.

A common error when working with `NULL` is to assume that it is not possible to insert a zero or an empty string into a column defined as `NOT NULL`, but this is not the case. These are in fact values, whereas `NULL` means “not having a value.” You can test this easily enough by using `IS [NOT] NULL` as shown:

```
mysql> SELECT 0 IS NULL, 0 IS NOT NULL, '' IS NULL, '' IS NOT NULL;
```

| 0 IS NULL | 0 IS NOT NULL | '' IS NULL | '' IS NOT NULL |
|-----------|---------------|------------|----------------|
| 0         | 1             | 0          | 1              |

Thus it is entirely possible to insert a zero or empty string into a `NOT NULL` column, as these are in fact `NOT NULL`. See [Section B.5.5.3, “Problems with NULL Values”](#).

### 3.3.4.7. Pattern Matching

MySQL provides standard SQL pattern matching as well as a form of pattern matching based on extended regular expressions similar to those used by Unix utilities such as `vi`, `grep`, and `sed`.

SQL pattern matching enables you to use “`_`” to match any single character and “`%`” to match an arbitrary number of characters (including zero characters). In MySQL, SQL patterns are case-insensitive by default. Some examples are shown here. You do not use `=` or `<>` when you use SQL patterns; use the `LIKE` or `NOT LIKE` comparison operators instead.

To find names beginning with “`b`”:

```
mysql> SELECT * FROM pet WHERE name LIKE 'b%';
+-----+-----+-----+-----+-----+
| name | owner | species | sex | birth | death |
+-----+-----+-----+-----+-----+
| Buffy | Harold | dog | f | 1989-05-13 | NULL |
| Bowser | Diane | dog | m | 1989-08-31 | 1995-07-29 |
+-----+-----+-----+-----+-----+
```

To find names ending with “`fy`”:

```
mysql> SELECT * FROM pet WHERE name LIKE '%fy';
+-----+-----+-----+-----+-----+
| name | owner | species | sex | birth | death |
+-----+-----+-----+-----+-----+
| Fluffy | Harold | cat | f | 1993-02-04 | NULL |
| Buffy | Harold | dog | f | 1989-05-13 | NULL |
+-----+-----+-----+-----+-----+
```

To find names containing a “`w`”:

```
mysql> SELECT * FROM pet WHERE name LIKE '%w%';
+-----+-----+-----+-----+-----+
| name | owner | species | sex | birth | death |
+-----+-----+-----+-----+-----+
Claws	Gwen	cat	m	1994-03-17	NULL
Bowser	Diane	dog	m	1989-08-31	1995-07-29
Whistler	Gwen	bird	NULL	1997-12-09	NULL
+-----+-----+-----+-----+-----+
```

To find names containing exactly five characters, use five instances of the “`_`” pattern character:

```
mysql> SELECT * FROM pet WHERE name LIKE '_____';
+-----+-----+-----+-----+-----+
| name | owner | species | sex | birth | death |
+-----+-----+-----+-----+-----+
| Claws | Gwen | cat | m | 1994-03-17 | NULL |
| Buffy | Harold | dog | f | 1989-05-13 | NULL |
+-----+-----+-----+-----+-----+
```

The other type of pattern matching provided by MySQL uses extended regular expressions. When you test for a match for this type of pattern, use the `REGEXP` and `NOT REGEXP` operators (or `RLIKE` and `NOT RLIKE`, which are synonyms).

The following list describes some characteristics of extended regular expressions:

- “`.`” matches any single character.
- A character class “[ . . . ]” matches any character within the brackets. For example, “[abc]” matches “`a`”, “`b`”, or “`c`”. To name a range of characters, use a dash. “[`a-z`]” matches any letter, whereas “[`0-9`]” matches any digit.
- “`*`” matches zero or more instances of the thing preceding it. For example, “`x*`” matches any number of “`x`” characters, “[`0-9`]\*” matches any number of digits, and “`.*`” matches any number of anything.
- A `REGEXP` pattern match succeeds if the pattern matches anywhere in the value being tested. (This differs from a `LIKE` pattern match, which succeeds only if the pattern matches the entire value.)
- To anchor a pattern so that it must match the beginning or end of the value being tested, use “`^`” at the beginning or “`$`” at the end of the pattern.

To demonstrate how extended regular expressions work, the `LIKE` queries shown previously are rewritten here to use `REGEXP`.

To find names beginning with “`b`”, use “`^`” to match the beginning of the name:

```
mysql> SELECT * FROM pet WHERE name REGEXP '^b';
+-----+-----+-----+-----+-----+
| name | owner | species | sex | birth | death |
+-----+-----+-----+-----+-----+
| Buffy | Harold | dog | f | 1989-05-13 | NULL |
| Bowser | Diane | dog | m | 1989-08-31 | 1995-07-29 |
+-----+-----+-----+-----+-----+
```

If you really want to force a `REGEXP` comparison to be case sensitive, use the `BINARY` keyword to make one of the strings a binary string. This query matches only lowercase “`b`” at the beginning of a name:

```
mysql> SELECT * FROM pet WHERE name REGEXP BINARY '^b';
```

To find names ending with “`fy`”, use “`$`” to match the end of the name:

```
mysql> SELECT * FROM pet WHERE name REGEXP 'fy$';
+-----+-----+-----+-----+-----+
| name | owner | species | sex | birth | death |
+-----+-----+-----+-----+-----+
| Fluffy | Harold | cat | f | 1993-02-04 | NULL |
| Buffy | Harold | dog | f | 1989-05-13 | NULL |
+-----+-----+-----+-----+-----+
```

To find names containing a “`w`”, use this query:

```
mysql> SELECT * FROM pet WHERE name REGEXP 'w';
+-----+-----+-----+-----+-----+
| name | owner | species | sex | birth | death |
+-----+-----+-----+-----+-----+
Claws	Gwen	cat	m	1994-03-17	NULL
Bowser	Diane	dog	m	1989-08-31	1995-07-29
Whistler	Gwen	bird	NULL	1997-12-09	NULL
+-----+-----+-----+-----+-----+
```

Because a regular expression pattern matches if it occurs anywhere in the value, it is not necessary in the previous query to put a wildcard on either side of the pattern to get it to match the entire value like it would be if you used an SQL pattern.

To find names containing exactly five characters, use “`^`” and “`$`” to match the beginning and end of the name, and five instances of “`.`” in between:

```
mysql> SELECT * FROM pet WHERE name REGEXP '^.....$';
+-----+-----+-----+-----+-----+
| name | owner | species | sex | birth | death |
+-----+-----+-----+-----+-----+
| Claws | Gwen | cat | m | 1994-03-17 | NULL |
| Buffy | Harold | dog | f | 1989-05-13 | NULL |
+-----+-----+-----+-----+-----+
```

You could also write the previous query using the `{n}` (“repeat-*n*-times”) operator:

```
mysql> SELECT * FROM pet WHERE name REGEXP '^.{5}$';
+-----+-----+-----+-----+-----+
| name | owner | species | sex | birth | death |
+-----+-----+-----+-----+-----+
| Claws | Gwen | cat | m | 1994-03-17 | NULL |
| Buffy | Harold | dog | f | 1989-05-13 | NULL |
+-----+-----+-----+-----+-----+
```

[Section 11.5.2, “Regular Expressions”](#), provides more information about the syntax for regular expressions.

### 3.3.4.8. Counting Rows

Databases are often used to answer the question, “How often does a certain type of data occur in a table?” For example, you might want to know how many pets you have, or how many pets each owner has, or you might want to perform various kinds of census operations on your animals.

Counting the total number of animals you have is the same question as “How many rows are in the `pet` table?” because there is one record per pet. `COUNT(*)` counts the number of rows, so the query to count your animals looks like this:

```
mysql> SELECT COUNT(*) FROM pet;
+-----+
| COUNT(*) |
+-----+
| 9 |
+-----+
```

```
+-----+
```

Earlier, you retrieved the names of the people who owned pets. You can use `COUNT()` if you want to find out how many pets each owner has:

```
mysql> SELECT owner, COUNT(*) FROM pet GROUP BY owner;
+-----+
| owner | COUNT(*) |
+-----+
Benny	2
Diane	2
Gwen	3
Harold	2
+-----+
```

The preceding query uses `GROUP BY` to group all records for each `owner`. The use of `COUNT()` in conjunction with `GROUP BY` is useful for characterizing your data under various groupings. The following examples show different ways to perform animal census operations.

Number of animals per species:

```
mysql> SELECT species, COUNT(*) FROM pet GROUP BY species;
+-----+
| species | COUNT(*) |
+-----+
bird	2
cat	2
dog	3
hamster	1
snake	1
+-----+
```

Number of animals per sex:

```
mysql> SELECT sex, COUNT(*) FROM pet GROUP BY sex;
+-----+
| sex | COUNT(*) |
+-----+
NULL	1
f	4
m	4
+-----+
```

(In this output, `NULL` indicates that the sex is unknown.)

Number of animals per combination of species and sex:

```
mysql> SELECT species, sex, COUNT(*) FROM pet GROUP BY species, sex;
+-----+
| species | sex | COUNT(*) |
+-----+
bird	NULL	1
bird	f	1
cat	f	1
cat	m	1
dog	f	1
dog	m	2
hamster	f	1
snake	m	1
+-----+
```

You need not retrieve an entire table when you use `COUNT()`. For example, the previous query, when performed just on dogs and cats, looks like this:

```
mysql> SELECT species, sex, COUNT(*) FROM pet
 -> WHERE species = 'dog' OR species = 'cat'
 -> GROUP BY species, sex;
+-----+
| species | sex | COUNT(*) |
+-----+
cat	f	1
cat	m	1
dog	f	1
dog	m	2
+-----+
```

Or, if you wanted the number of animals per sex only for animals whose sex is known:

```
mysql> SELECT species, sex, COUNT(*) FROM pet
 -> WHERE sex IS NOT NULL
 -> GROUP BY species, sex;
+-----+
| species | sex | COUNT(*) |
+-----+
```

| bird    | f |  | 1 |
|---------|---|--|---|
| cat     | f |  | 1 |
| cat     | m |  | 1 |
| dog     | f |  | 1 |
| dog     | m |  | 2 |
| hamster | f |  | 1 |
| snake   | m |  | 1 |

If you name columns to select in addition to the `COUNT()` value, a `GROUP BY` clause should be present that names those same columns. Otherwise, the following occurs:

- If the `ONLY_FULL_GROUP_BY` SQL mode is enabled, an error occurs:

```
mysql> SET sql_mode = 'ONLY_FULL_GROUP_BY';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT owner, COUNT(*) FROM pet;
ERROR 1140 (42000): Mixing of GROUP columns (MIN(),MAX(),COUNT())...
with no GROUP columns is illegal if there is no GROUP BY clause
```

- If `ONLY_FULL_GROUP_BY` is not enabled, the query is processed by treating all rows as a single group, but the value selected for each named column is indeterminate. The server is free to select the value from any row:

```
mysql> SET sql_mode = '';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT owner, COUNT(*) FROM pet;
+-----+-----+
| owner | COUNT(*) |
+-----+-----+
| Harold | 8 |
+-----+-----+
1 row in set (0.00 sec)
```

See also [Section 11.16.3, “`GROUP BY` and `HAVING` with Hidden Columns”](#).

### 3.3.4.9. Using More Than one Table

The `pet` table keeps track of which pets you have. If you want to record other information about them, such as events in their lives like visits to the vet or when litters are born, you need another table. What should this table look like? It needs to contain the following information:

- The pet name so that you know which animal each event pertains to.
- A date so that you know when the event occurred.
- A field to describe the event.
- An event type field, if you want to be able to categorize events.

Given these considerations, the `CREATE TABLE` statement for the `event` table might look like this:

```
mysql> CREATE TABLE event (name VARCHAR(20), date DATE,
-> type VARCHAR(15), remark VARCHAR(255));
```

As with the `pet` table, it is easiest to load the initial records by creating a tab-delimited text file containing the following information.

| name   | date       | type   | remark                      |
|--------|------------|--------|-----------------------------|
| Fluffy | 1995-05-15 | litter | 4 kittens, 3 female, 1 male |
| Buffy  | 1993-06-23 | litter | 5 puppies, 2 female, 3 male |
| Buffy  | 1994-06-19 | litter | 3 puppies, 3 female         |
| Chirpy | 1999-03-21 | vet    | needed beak straightened    |
| Slim   | 1997-08-03 | vet    | broken rib                  |
| Bowser | 1991-10-12 | kennel |                             |
| Fang   | 1991-10-12 | kennel |                             |

|          |            |          |                            |
|----------|------------|----------|----------------------------|
| Fang     | 1998-08-28 | birthday | Gave him a new chew toy    |
| Claws    | 1998-03-17 | birthday | Gave him a new flea collar |
| Whistler | 1998-12-09 | birthday | First birthday             |

Load the records like this:

```
mysql> LOAD DATA LOCAL INFILE 'event.txt' INTO TABLE event;
```

Based on what you have learned from the queries that you have run on the `pet` table, you should be able to perform retrievals on the records in the `event` table; the principles are the same. But when is the `event` table by itself insufficient to answer questions you might ask?

Suppose that you want to find out the ages at which each pet had its litters. We saw earlier how to calculate ages from two dates. The litter date of the mother is in the `event` table, but to calculate her age on that date you need her birth date, which is stored in the `pet` table. This means the query requires both tables:

```
mysql> SELECT pet.name,
-> (YEAR(date)-YEAR(birth)) - (RIGHT(date,5)<RIGHT(birth,5)) AS age,
-> remark
-> FROM pet INNER JOIN event
-> ON pet.name = event.name
-> WHERE event.type = 'litter';
+-----+-----+-----+
| name | age | remark |
+-----+-----+-----+
Fluffy	2	4 kittens, 3 female, 1 male
Buffy	4	5 puppies, 2 female, 3 male
Buffy	5	3 puppies, 3 female
+-----+-----+-----+
```

There are several things to note about this query:

- The `FROM` clause joins two tables because the query needs to pull information from both of them.
- When combining (joining) information from multiple tables, you need to specify how records in one table can be matched to records in the other. This is easy because they both have a `name` column. The query uses an `ON` clause to match up records in the two tables based on the `name` values.

The query uses an `INNER JOIN` to combine the tables. An `INNER JOIN` permits rows from either table to appear in the result if and only if both tables meet the conditions specified in the `ON` clause. In this example, the `ON` clause specifies that the `name` column in the `pet` table must match the `name` column in the `event` table. If a name appears in one table but not the other, the row will not appear in the result because the condition in the `ON` clause fails.

- Because the `name` column occurs in both tables, you must be specific about which table you mean when referring to the column. This is done by prepending the table name to the column name.

You need not have two different tables to perform a join. Sometimes it is useful to join a table to itself, if you want to compare records in a table to other records in that same table. For example, to find breeding pairs among your pets, you can join the `pet` table with itself to produce candidate pairs of males and females of like species:

```
mysql> SELECT p1.name, p1.sex, p2.name, p2.sex, p1.species
-> FROM pet AS p1 INNER JOIN pet AS p2
-> ON p1.species = p2.species AND p1.sex = 'f' AND p2.sex = 'm';
+-----+-----+-----+-----+-----+
| name | sex | name | sex | species |
+-----+-----+-----+-----+-----+
Fluffy	f	Claws	m	cat
Buffy	f	Fang	m	dog
Buffy	f	Bowser	m	dog
+-----+-----+-----+-----+-----+
```

In this query, we specify aliases for the table name to refer to the columns and keep straight which instance of the table each column reference is associated with.

## 3.4. Getting Information About Databases and Tables

What if you forget the name of a database or table, or what the structure of a given table is (for example, what its columns are called)? MySQL addresses this problem through several statements that provide information about the databases and tables it supports.

You have previously seen `SHOW DATABASES`, which lists the databases managed by the server. To find out which database is currently selected, use the `DATABASE()` function:

```
mysql> SELECT DATABASE();
+-----+
| DATABASE() |
+-----+
| menagerie |
+-----+
```

If you have not yet selected any database, the result is `NULL`.

To find out what tables the default database contains (for example, when you are not sure about the name of a table), use this command:

```
mysql> SHOW TABLES;
+-----+
| Tables_in_menagerie |
+-----+
| event |
| pet |
+-----+
```

The name of the column in the output produced by this statement is always `Tables_in_db_name`, where `db_name` is the name of the database. See [Section 12.4.5.39, “SHOW TABLES Syntax”](#), for more information.

If you want to find out about the structure of a table, the `DESCRIBE` statement is useful; it displays information about each of a table's columns:

```
mysql> DESCRIBE pet;
+-----+-----+-----+-----+-----+-----+
| Field | Type | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
name	varchar(20)	YES		NULL	
owner	varchar(20)	YES		NULL	
species	varchar(20)	YES		NULL	
sex	char(1)	YES		NULL	
birth	date	YES		NULL	
death	date	YES		NULL	
+-----+-----+-----+-----+-----+-----+
```

`Field` indicates the column name, `Type` is the data type for the column, `NULL` indicates whether the column can contain `NULL` values, `Key` indicates whether the column is indexed, and `Default` specifies the column's default value. `Extra` displays special information about columns: If a column was created with the `AUTO_INCREMENT` option, the value will be `auto_increment` rather than empty.

`DESC` is a short form of `DESCRIBE`. See [Section 12.8.1, “DESCRIBE Syntax”](#), for more information.

You can obtain the `CREATE TABLE` statement necessary to create an existing table using the `SHOW CREATE TABLE` statement. See [Section 12.4.5.12, “SHOW CREATE TABLE Syntax”](#).

If you have indexes on a table, `SHOW INDEX FROM tbl_name` produces information about them. See [Section 12.4.5.23, “SHOW INDEX Syntax”](#), for more about this statement.

## 3.5. Using `mysql` in Batch Mode

In the previous sections, you used `mysql` interactively to enter queries and view the results. You can also run `mysql` in batch mode. To do this, put the commands you want to run in a file, then tell `mysql` to read its input from the file:

```
shell> mysql < batch-file
```

If you are running `mysql` under Windows and have some special characters in the file that cause problems, you can do this:

```
C:\> mysql -e "source batch-file"
```

If you need to specify connection parameters on the command line, the command might look like this:

```
shell> mysql -h host -u user -p < batch-file
Enter password: *****
```

When you use `mysql` this way, you are creating a script file, then executing the script.

If you want the script to continue even if some of the statements in it produce errors, you should use the `--force` command-line

option.

Why use a script? Here are a few reasons:

- If you run a query repeatedly (say, every day or every week), making it a script enables you to avoid retyping it each time you execute it.
- You can generate new queries from existing ones that are similar by copying and editing script files.
- Batch mode can also be useful while you're developing a query, particularly for multiple-line commands or multiple-statement sequences of commands. If you make a mistake, you don't have to retype everything. Just edit your script to correct the error, then tell `mysql` to execute it again.
- If you have a query that produces a lot of output, you can run the output through a pager rather than watching it scroll off the top of your screen:

```
shell> mysql < batch-file | more
```

- You can catch the output in a file for further processing:

```
shell> mysql < batch-file > mysql.out
```

- You can distribute your script to other people so that they can also run the commands.
- Some situations do not allow for interactive use, for example, when you run a query from a `cron` job. In this case, you must use batch mode.

The default output format is different (more concise) when you run `mysql` in batch mode than when you use it interactively. For example, the output of `SELECT DISTINCT species FROM pet` looks like this when `mysql` is run interactively:

| species |
|---------|
| bird    |
| cat     |
| dog     |
| hamster |
| snake   |

In batch mode, the output looks like this instead:

```
species
bird
cat
dog
hamster
snake
```

If you want to get the interactive output format in batch mode, use `mysql -t`. To echo to the output the commands that are executed, use `mysql -vvv`.

You can also use scripts from the `mysql` prompt by using the `source` command or `\.` command:

```
mysql> source filename;
mysql> \. filename
```

See [Section 4.5.1.5, “Executing SQL Statements from a Text File”](#), for more information.

## 3.6. Examples of Common Queries

Here are examples of how to solve some common problems with MySQL.

Some of the examples use the table `shop` to hold the price of each article (item number) for certain traders (dealers). Supposing that each trader has a single fixed price per article, then (`article`, `dealer`) is a primary key for the records.

Start the command-line tool `mysql` and select a database:

```
shell> mysql your-database-name
```

(In most MySQL installations, you can use the database named `test`).

You can create and populate the example table with these statements:

```
CREATE TABLE shop (
 article INT(4) UNSIGNED ZEROFILL DEFAULT '0000' NOT NULL,
 dealer CHAR(20) DEFAULT '' NOT NULL,
 price DOUBLE(16,2) DEFAULT '0.00' NOT NULL,
 PRIMARY KEY(article, dealer));
INSERT INTO shop VALUES
 (1,'A',3.45),(1,'B',3.99),(2,'A',10.99),(3,'B',1.45),
 (3,'C',1.69),(3,'D',1.25),(4,'D',19.95);
```

After issuing the statements, the table should have the following contents:

```
SELECT * FROM shop;

+-----+-----+-----+
| article | dealer | price |
+-----+-----+-----+
0001	A	3.45
0001	B	3.99
0002	A	10.99
0003	B	1.45
0003	C	1.69
0003	D	1.25
0004	D	19.95
+-----+-----+-----+
```

### 3.6.1. The Maximum Value for a Column

“What is the highest item number?”

```
SELECT MAX(article) AS article FROM shop;

+-----+
| article |
+-----+
| 4 |
+-----+
```

### 3.6.2. The Row Holding the Maximum of a Certain Column

*Task: Find the number, dealer, and price of the most expensive article.*

This is easily done with a subquery:

```
SELECT article, dealer, price
FROM shop
WHERE price=(SELECT MAX(price) FROM shop);

+-----+-----+-----+
| article | dealer | price |
+-----+-----+-----+
| 0004 | D | 19.95 |
+-----+-----+-----+
```

Other solutions are to use a `LEFT JOIN` or to sort all rows descending by price and get only the first row using the MySQL-specific `LIMIT` clause:

```
SELECT s1.article, s1.dealer, s1.price
FROM shop s1
LEFT JOIN shop s2 ON s1.price < s2.price
WHERE s2.article IS NULL;

SELECT article, dealer, price
FROM shop
ORDER BY price DESC
LIMIT 1;
```

#### Note

If there were several most expensive articles, each with a price of 19.95, the `LIMIT` solution would show only one of them.

### 3.6.3. Maximum of Column per Group

*Task: Find the highest price per article.*

```
SELECT article, MAX(price) AS price
FROM shop
```

```
GROUP BY article;
+-----+-----+
| article | price |
+-----+-----+
0001	3.99
0002	10.99
0003	1.69
0004	19.95
+-----+-----+
```

### 3.6.4. The Rows Holding the Group-wise Maximum of a Certain Column

*Task: For each article, find the dealer or dealers with the most expensive price.*

This problem can be solved with a subquery like this one:

```
SELECT article, dealer, price
FROM shop s1
WHERE price=(SELECT MAX(s2.price)
 FROM shop s2
 WHERE s1.article = s2.article);

+-----+-----+-----+
| article | dealer | price |
+-----+-----+-----+
0001	B	3.99
0002	A	10.99
0003	C	1.69
0004	D	19.95
+-----+-----+-----+
```

The preceding example uses a correlated subquery, which can be inefficient (see [Section 12.2.9.7, “Correlated Subqueries”](#)). Other possibilities for solving the problem are to use an uncorrelated subquery in the `FROM` clause or a `LEFT JOIN`:

```
SELECT s1.article, dealer, s1.price
FROM shop s1
JOIN (
 SELECT article, MAX(price) AS price
 FROM shop
 GROUP BY article) AS s2
ON s1.article = s2.article AND s1.price = s2.price;

SELECT s1.article, s1.dealer, s1.price
FROM shop s1
LEFT JOIN shop s2 ON s1.article = s2.article AND s1.price < s2.price
WHERE s2.article IS NULL;
```

The `LEFT JOIN` works on the basis that when `s1.price` is at its maximum value, there is no `s2.price` with a greater value and the `s2` rows values will be `NULL`. See [Section 12.2.8.1, “JOIN Syntax”](#).

### 3.6.5. Using User-Defined Variables

You can employ MySQL user variables to remember results without having to store them in temporary variables in the client. (See [Section 8.4, “User-Defined Variables”](#).)

For example, to find the articles with the highest and lowest price you can do this:

```
mysql> SELECT @min_price:=MIN(price),@max_price:=MAX(price) FROM shop;
mysql> SELECT * FROM shop WHERE price=@min_price OR price=@max_price;
+-----+-----+-----+
| article | dealer | price |
+-----+-----+-----+
| 0003 | D | 1.25 |
| 0004 | D | 19.95 |
+-----+-----+-----+
```

#### Note

It is also possible to store the name of a database object such as a table or a column in a user variable and then to use this variable in an SQL statement; however, this requires the use of a prepared statement. See [Section 12.6, “SQL Syntax for Prepared Statements”](#), for more information.

### 3.6.6. Using Foreign Keys

In MySQL, `InnoDB` tables support checking of foreign key constraints. See [Section 13.6, “The InnoDB Storage Engine”](#), and [Section 1.8.5.4, “Foreign Keys”](#).

A foreign key constraint is not required merely to join two tables. For storage engines other than `InnoDB`, it is possible when defining a column to use a `REFERENCES tbl_name(col_name)` clause, which has no actual effect, and *serves only as a memo or comment to you that the column which you are currently defining is intended to refer to a column in another table*. It is extremely important to realize when using this syntax that:

- MySQL does not perform any sort of `CHECK` to make sure that `col_name` actually exists in `tbl_name` (or even that `tbl_name` itself exists).
- MySQL does not perform any sort of action on `tbl_name` such as deleting rows in response to actions taken on rows in the table which you are defining; in other words, this syntax induces no `ON DELETE` or `ON UPDATE` behavior whatsoever. (Although you can write an `ON DELETE` or `ON UPDATE` clause as part of the `REFERENCES` clause, it is also ignored.)
- This syntax creates a *column*; it does **not** create any sort of index or key.

You can use a column so created as a join column, as shown here:

```

CREATE TABLE person (
 id SMALLINT UNSIGNED NOT NULL AUTO_INCREMENT,
 name CHAR(60) NOT NULL,
 PRIMARY KEY (id)
);

CREATE TABLE shirt (
 id SMALLINT UNSIGNED NOT NULL AUTO_INCREMENT,
 style ENUM('t-shirt', 'polo', 'dress') NOT NULL,
 color ENUM('red', 'blue', 'orange', 'white', 'black') NOT NULL,
 owner SMALLINT UNSIGNED NOT NULL REFERENCES person(id),
 PRIMARY KEY (id)
);

INSERT INTO person VALUES (NULL, 'Antonio Paz');

SELECT @last := LAST_INSERT_ID();

INSERT INTO shirt VALUES
(NULL, 'polo', 'blue', @last),
(NULL, 'dress', 'white', @last),
(NULL, 't-shirt', 'blue', @last);

INSERT INTO person VALUES (NULL, 'Lilliana Angelovska');

SELECT @last := LAST_INSERT_ID();

INSERT INTO shirt VALUES
(NULL, 'dress', 'orange', @last),
(NULL, 'polo', 'red', @last),
(NULL, 'dress', 'blue', @last),
(NULL, 't-shirt', 'white', @last);

SELECT * FROM person;
+----+-----+
| id | name |
+----+-----+
| 1 | Antonio Paz |
| 2 | Lilliana Angelovska |
+----+-----+

SELECT * FROM shirt;
+----+-----+-----+-----+
| id | style | color | owner |
+----+-----+-----+-----+
1	polo	blue	1
2	dress	white	1
3	t-shirt	blue	1
4	dress	orange	2
5	polo	red	2
6	dress	blue	2
7	t-shirt	white	2
+----+-----+-----+-----+

SELECT s.* FROM person p INNER JOIN shirt s
 ON s.owner = p.id
 WHERE p.name LIKE 'Lilliana%'
 AND s.color <> 'white';

+----+-----+-----+-----+
| id | style | color | owner |
+----+-----+-----+-----+
4	dress	orange	2
5	polo	red	2
6	dress	blue	2
+----+-----+-----+-----+

```

When used in this fashion, the `REFERENCES` clause is not displayed in the output of `SHOW CREATE TABLE` or `DESCRIBE`:

```
SHOW CREATE TABLE shirt\G
***** 1. row *****
Table: shirt
Create Table: CREATE TABLE `shirt` (
 `id` smallint(5) unsigned NOT NULL auto_increment,
 `style` enum('t-shirt','polo','dress') NOT NULL,
 `color` enum('red','blue','orange','white','black') NOT NULL,
 `owner` smallint(5) unsigned NOT NULL,
 PRIMARY KEY (`id`)
) ENGINE=MyISAM DEFAULT CHARSET=latin1
```

The use of [REFERENCES](#) in this way as a comment or “reminder” in a column definition works with [MyISAM](#) tables.

### 3.6.7. Searching on Two Keys

An [OR](#) using a single key is well optimized, as is the handling of [AND](#).

The one tricky case is that of searching on two different keys combined with [OR](#):

```
SELECT field1_index, field2_index FROM test_table
WHERE field1_index = '1' OR field2_index = '1'
```

This case is optimized. See [Section 7.3.1.4, “Index Merge Optimization”](#).

You can also solve the problem efficiently by using a [UNION](#) that combines the output of two separate [SELECT](#) statements. See [Section 12.2.8.3, “UNION Syntax”](#).

Each [SELECT](#) searches only one key and can be optimized:

```
SELECT field1_index, field2_index
 FROM test_table WHERE field1_index = '1'
UNION
SELECT field1_index, field2_index
 FROM test_table WHERE field2_index = '1';
```

### 3.6.8. Calculating Visits Per Day

The following example shows how you can use the bit group functions to calculate the number of days per month a user has visited a Web page.

```
CREATE TABLE t1 (year YEAR(4), month INT(2) UNSIGNED ZEROFILL,
 day INT(2) UNSIGNED ZEROFILL);
INSERT INTO t1 VALUES(2000,1,1),(2000,1,20),(2000,1,30),(2000,2,2),
 (2000,2,23),(2000,2,23);
```

The example table contains year-month-day values representing visits by users to the page. To determine how many different days in each month these visits occur, use this query:

```
SELECT year,month,BIT_COUNT(BIT_OR(1<<day)) AS days FROM t1
GROUP BY year,month;
```

Which returns:

| year | month | days |
|------|-------|------|
| 2000 | 01    | 3    |
| 2000 | 02    | 2    |

The query calculates how many different days appear in the table for each year/month combination, with automatic removal of duplicate entries.

### 3.6.9. Using AUTO\_INCREMENT

The [AUTO\\_INCREMENT](#) attribute can be used to generate a unique identity for new rows:

```
CREATE TABLE animals (
 id MEDIUMINT NOT NULL AUTO_INCREMENT,
 name CHAR(30) NOT NULL,
 PRIMARY KEY (id)
);

INSERT INTO animals (name) VALUES
 ('dog'),('cat'),('penguin'),
```

```
('lax'), ('whale'), ('ostrich');
SELECT * FROM animals;
```

Which returns:

| id | name    |
|----|---------|
| 1  | dog     |
| 2  | cat     |
| 3  | penguin |
| 4  | lax     |
| 5  | whale   |
| 6  | ostrich |

You can retrieve the most recent `AUTO_INCREMENT` value with the `LAST_INSERT_ID()` SQL function or the `mysql_insert_id()` C API function. These functions are connection-specific, so their return values are not affected by another connection which is also performing inserts.

### Note

For a multiple-row insert, `LAST_INSERT_ID()` and `mysql_insert_id()` actually return the `AUTO_INCREMENT` key from the *first* of the inserted rows. This enables multiple-row inserts to be reproduced correctly on other servers in a replication setup.

For `MyISAM` tables you can specify `AUTO_INCREMENT` on a secondary column in a multiple-column index. In this case, the generated value for the `AUTO_INCREMENT` column is calculated as `MAX(auto_increment_column) + 1 WHERE prefix=given-prefix`. This is useful when you want to put data into ordered groups.

```
CREATE TABLE animals (
 grp ENUM('fish','mammal','bird') NOT NULL,
 id MEDIUMINT NOT NULL AUTO_INCREMENT,
 name CHAR(30) NOT NULL,
 PRIMARY KEY (grp,id)
) ENGINE=MyISAM;

INSERT INTO animals (grp,name) VALUES
 ('mammal', 'dog'), ('mammal', 'cat'),
 ('bird', 'penguin'), ('fish', 'lax'), ('mammal', 'whale'),
 ('bird', 'ostrich');

SELECT * FROM animals ORDER BY grp,id;
```

Which returns:

| grp    | id | name    |
|--------|----|---------|
| fish   | 1  | lax     |
| mammal | 1  | dog     |
| mammal | 2  | cat     |
| mammal | 3  | whale   |
| bird   | 1  | penguin |
| bird   | 2  | ostrich |

In this case (when the `AUTO_INCREMENT` column is part of a multiple-column index), `AUTO_INCREMENT` values are reused if you delete the row with the biggest `AUTO_INCREMENT` value in any group. This happens even for `MyISAM` tables, for which `AUTO_INCREMENT` values normally are not reused.

If the `AUTO_INCREMENT` column is part of multiple indexes, MySQL will generate sequence values using the index that begins with the `AUTO_INCREMENT` column, if there is one. For example, if the `animals` table contained indexes `PRIMARY KEY (grp, id)` and `INDEX (id)`, MySQL would ignore the `PRIMARY KEY` for generating sequence values. As a result, the table would contain a single sequence, not a sequence per `grp` value.

To start with an `AUTO_INCREMENT` value other than 1, you can set that value with `CREATE TABLE` or `ALTER TABLE`, like this:

```
mysql> ALTER TABLE tbl AUTO_INCREMENT = 100;
```

More information about `AUTO_INCREMENT` is available here:

- How to assign the `AUTO_INCREMENT` attribute to a column: [Section 12.1.17, “CREATE TABLE Syntax”](#), and [Section 12.1.7, “ALTER TABLE Syntax”](#).

- How `AUTO_INCREMENT` behaves depending on the SQL mode: [Section 5.1.7, “Server SQL Modes”](#).
- How to find the row that contains the most recent `AUTO_INCREMENT` value: [Section 11.3.2, “Comparison Functions and Operators”](#).
- Setting the `AUTO_INCREMENT` value to be used: [Section 5.1.4, “Server System Variables”](#).
- `AUTO_INCREMENT` and replication: [Section 16.4.1, “Replication Features and Issues”](#).
- Server-system variables related to `AUTO_INCREMENT` (`auto_increment_increment` and `auto_increment_offset`) that can be used for replication: [Section 5.1.4, “Server System Variables”](#).

## 3.7. Queries from the Twin Project

At the places the early MySQL was developed (Analytikerna and Lventus), the founders did systems and field work for a big research project. This project was a collaboration between the Institute of Environmental Medicine at Karolinska Institutet Stockholm and the Section on Clinical Research in Aging and Psychology at the University of Southern California.

The project involved lots of data collection from all twins in Sweden older than 65 Years (see <http://ki.se/ki/jsp/polopoly.jsp?d=9610&l=en>).

Large parts of the project were administered with a Web interface written using Perl and MySQL.

### 3.7.1. Find All Nondistributed Twins

The following query was used to determine what twins should be studied further after a initial screening. This was written around 1997 using MySQL 3.19.

```

SELECT
 CONCAT(p1.id, p1.tvab) + 0 AS tvid,
 CONCAT(p1.christian_name, ' ', p1.surname) AS Name,
 p1.postal_code AS Code,
 p1.city AS City,
 pg.abrev AS Area,
 IF(td.participation = 'Aborted', 'A', ' ') AS A,
 p1.dead AS dead1,
 l.event AS event1,
 td.suspect AS tsuspect1,
 id.suspect AS isuspect1,
 td.severe AS tseverel,

AND
l.event = 'Finished'
/* Get at area code */
AND SUBSTRING(p1.postal_code, 1, 2) = pg.code
/* Not already distributed */
AND (h.nurse IS NULL OR h.nurse=00 OR h.doctor=00)
/* Has not refused or been aborted */
AND NOT (h.status = 'Refused' OR h.status = 'Aborted'
 OR h.status = 'Died' OR h.status = 'Other')
ORDER BY
 tvid;

```

Some explanations:

- `CONCAT(p1.id, p1.tvab) + 0 AS tvid`

We want to sort on the concatenated `id` and `tvab` in numeric order. Adding `0` to the result causes MySQL to treat the result as a number.

- Column `id`

This identifies a pair of twins. It is an index in all tables.

- Column `tvab`

This identifies a twin in a pair. It has a value of `1` or `2`.

- Column `ptvab`

This is an inverse of `tvab`. When `tvab` is `1` this is `2`, and vice versa. It exists to save typing and to make it easier for MySQL to optimize the query.

This query demonstrates, among other things, how to do lookups on a table from the same table with a join (`p1` and `p2`). In the example, this is used to check whether a twin's partner died before the age of 65. If so, the row is not returned.

All of the above exist in all tables with twin-related information. We have an index on both `id`, `tvab` (all tables), and `id`, `ptvab` (`person_data`) to make queries faster.

When we did this work, our production machine was a 200MHz UltraSPARC, and on that old hardware this query returned about 150 to 200 rows in less than one second. The main table had 70,000 Rows.

### 3.7.2. Show a Table of Twin Pair Status

Each twin has a status code called `event`. The query shown here is used to select all twin pairs combined by event. This indicates in how many pairs both twins are finished, in how many pairs one twin is finished and the other refused, and so on.

```

SELECT
 t1.event,
 t2.event,
 COUNT(*)
FROM
 lensus AS t1,
 lensus AS t2,
 twin_project AS tp
WHERE
 /* We are looking at one pair at a time */
 t1.id = tp.id
 AND t1.tvab=tp.tvab
 AND t1.id = t2.id
 /* Just the screening survey */
 AND tp.survey_no = 5
 /* This makes each pair only appear once */

```

```
 AND t1.tvab='1' AND t2.tvab='2'
GROUP BY
 t1.event, t2.event;
```

## 3.8. Using MySQL with Apache

There are programs that let you authenticate your users from a MySQL database and also let you write your log files into a MySQL table.

You can change the Apache logging format to be easily readable by MySQL by putting the following into the Apache configuration file:

```
LogFormat \
 "%h", "%{Y%m%d%H%M%S}t,%>s, \"%b\", \"%{Content-Type}o\", \
 \"%U\", \"%{Referer}i\", \"%{User-Agent}i\""
```

To load a log file in that format into MySQL, you can use a statement something like this:

```
LOAD DATA INFILE '/local/access_log' INTO TABLE tbl_name
FIELDS TERMINATED BY ',' OPTIONALLY ENCLOSED BY '\"' ESCAPED BY '\\'
```

The named table should be created to have columns that correspond to those that the `LogFormat` line writes to the log file.

---

# Chapter 4. MySQL Programs

This chapter provides a brief overview of the MySQL command-line programs provided by Oracle Corporation. It also discusses the general syntax for specifying options when you run these programs. Most programs have options that are specific to their own operation, but the option syntax is similar for all of them. Finally, the chapter provides more detailed descriptions of individual programs, including which options they recognize.

## 4.1. Overview of MySQL Programs

There are many different programs in a MySQL installation. This section provides a brief overview of them. Later sections provide a more detailed description of each one, with the exception of MySQL Cluster programs. Each program's description indicates its invocation syntax and the options that it supports. [Chapter 17, MySQL Cluster NDB 6.X/7.X](#), describes programs specific to MySQL Cluster.

Most MySQL distributions include all of these programs, except for those programs that are platform-specific. (For example, the server startup scripts are not used on Windows.) The exception is that RPM distributions are more specialized. There is one RPM for the server, another for client programs, and so forth. If you appear to be missing one or more programs, see [Chapter 2, Installing and Upgrading MySQL](#), for information on types of distributions and what they contain. It may be that you have a distribution that does not include all programs and you need to install an additional package.

Each MySQL program takes many different options. Most programs provide a `--help` option that you can use to get a description of the program's different options. For example, try `mysql --help`.

You can override default option values for MySQL programs by specifying options on the command line or in an option file. See [Section 4.2, “Using MySQL Programs”](#), for general information on invoking programs and specifying program options.

The MySQL server, `mysqld`, is the main program that does most of the work in a MySQL installation. The server is accompanied by several related scripts that assist you in starting and stopping the server:

- `mysqld`

The SQL daemon (that is, the MySQL server). To use client programs, `mysqld` must be running, because clients gain access to databases by connecting to the server. See [Section 4.3.1, “mysqld — The MySQL Server”](#).

- `mysqld_safe`

A server startup script. `mysqld_safe` attempts to start `mysqld`. See [Section 4.3.2, “mysqld\\_safe — MySQL Server Startup Script”](#).

- `mysql.server`

A server startup script. This script is used on systems that use System V-style run directories containing scripts that start system services for particular run levels. It invokes `mysqld_safe` to start the MySQL server. See [Section 4.3.3, “mysql.server — MySQL Server Startup Script”](#).

- `mysqld_multi`

A server startup script that can start or stop multiple servers installed on the system. See [Section 4.3.4, “mysqld\\_multi — Manage Multiple MySQL Servers”](#). An alternative to `mysqld_multi` is `mysqlmanager`, the MySQL Instance Manager. See [Section 4.6.10, “mysqlmanager — The MySQL Instance Manager”](#).

There are several programs that perform setup operations during MySQL installation or upgrading:

- `comp_err`

This program is used during the MySQL build/installation process. It compiles error message files from the error source files. See [Section 4.4.1, “comp\\_err — Compile MySQL Error Message File”](#).

- `make_binary_distribution`

This program makes a binary release of a compiled MySQL. This could be sent by FTP to [/pub/mysql/upload/](#) on [ftp.mysql.com](#) for the convenience of other MySQL users.

- `make_win_bin_dist`

This program is used on Windows. It packages a MySQL distribution for installation after the source distribution has been built.

See [Section 4.4.2, “make\\_win\\_bin\\_dist — Package MySQL Distribution as ZIP Archive”](#).

- [mysql\\_fix\\_privilege\\_tables](#)

This program is used after a MySQL upgrade operation. It updates the grant tables with any changes that have been made in newer versions of MySQL. See [Section 4.4.4, “mysql\\_fix\\_privilege\\_tables — Upgrade MySQL System Tables”](#).

Note: As of MySQL 5.1.7, this program has been superseded by [mysql\\_upgrade](#) and should no longer be used.

- [mysql\\_install\\_db](#)

This script creates the MySQL database and initializes the grant tables with default privileges. It is usually executed only once, when first installing MySQL on a system. See [Section 4.4.5, “mysql\\_install\\_db — Initialize MySQL Data Directory”](#), [Section 2.13.1, “Unix Post-Installation Procedures”](#), and [Section 4.4.5, “mysql\\_install\\_db — Initialize MySQL Data Directory”](#).

- [mysql\\_secure\\_installation](#)

This program enables you to improve the security of your MySQL installation. SQL. See [Section 4.4.6, “mysql\\_secure\\_installation — Improve MySQL Installation Security”](#).

- [mysql\\_tzinfo\\_to\\_sql](#)

This program loads the time zone tables in the [mysql](#) database using the contents of the host system *zoneinfo* database (the set of files describing time zones). SQL. See [Section 4.4.7, “mysql\\_tzinfo\\_to\\_sql — Load the Time Zone Tables”](#).

- [mysql\\_upgrade](#)

This program is used after a MySQL upgrade operation. It checks tables for incompatibilities and repairs them if necessary, and updates the grant tables with any changes that have been made in newer versions of MySQL. See [Section 4.4.8, “mysql\\_upgrade — Check Tables for MySQL Upgrade”](#).

MySQL client programs:

- [mysql](#)

The command-line tool for interactively entering SQL statements or executing them from a file in batch mode. See [Section 4.5.1, “mysql — The MySQL Command-Line Tool”](#).

- [mysqladmin](#)

A client that performs administrative operations, such as creating or dropping databases, reloading the grant tables, flushing tables to disk, and reopening log files. [mysqladmin](#) can also be used to retrieve version, process, and status information from the server. See [Section 4.5.2, “mysqladmin — Client for Administering a MySQL Server”](#).

- [mysqlcheck](#)

A table-maintenance client that checks, repairs, analyzes, and optimizes tables. See [Section 4.5.3, “mysqlcheck — A Table Maintenance Program”](#).

- [mysqldump](#)

A client that dumps a MySQL database into a file as SQL, text, or XML. See [Section 4.5.4, “mysqldump — A Database Backup Program”](#).

- [mysqlimport](#)

A client that imports text files into their respective tables using [LOAD DATA INFILE](#). See [Section 4.5.5, “mysqlimport — A Data Import Program”](#).

- [mysqlshow](#)

A client that displays information about databases, tables, columns, and indexes. See [Section 4.5.6, “mysqlshow — Display Database, Table, and Column Information”](#).

- [mysqlslap](#)

A client that is designed to emulate client load for a MySQL server and report the timing of each stage. It works as if multiple clients are accessing the server. See [Section 4.5.7, “mysqlslap — Load Emulation Client”](#).

MySQL administrative and utility programs:

- [innochecksum](#)

An offline InnoDB offline file checksum utility. See [Section 4.6.1, “innochecksum — Offline InnoDB File Checksum Utility”](#).

- [myisam\\_ftdump](#)

A utility that displays information about full-text indexes in MyISAM tables. See [Section 4.6.2, “myisam\\_ftdump — Display Full-Text Index Information”](#).

- [myisamchk](#)

A utility to describe, check, optimize, and repair MyISAM tables. See [Section 4.6.3, “myisamchk — MyISAM Table-Maintenance Utility”](#).

- [myisamlog, isamlog](#)

A utility that processes the contents of a MyISAM log file. See [Section 4.6.4, “myisamlog — Display MyISAM Log File Contents”](#).

- [myisampack](#)

A utility that compresses MyISAM tables to produce smaller read-only tables. See [Section 4.6.5, “myisampack — Generate Compressed, Read-Only MyISAM Tables”](#).

- [mysqlaccess](#)

A script that checks the access privileges for a host name, user name, and database combination. See [Section 4.6.6, “mysqlaccess — Client for Checking Access Privileges”](#).

- [mysqlbinlog](#)

A utility for reading statements from a binary log. The log of executed statements contained in the binary log files can be used to help recover from a crash. See [Section 4.6.7, “mysqlbinlog — Utility for Processing Binary Log Files”](#).

- [mysqldumpslow](#)

A utility to read and summarize the contents of a slow query log. See [Section 4.6.8, “mysqldumpslow — Summarize Slow Query Log Files”](#).

- [mysqlhotcopy](#)

A utility that quickly makes backups of MyISAM tables while the server is running. See [Section 4.6.9, “mysqlhotcopy — A Database Backup Program”](#).

- [mysqlmanager](#)

The MySQL Instance Manager, a program for monitoring and managing MySQL servers. See [Section 4.6.10, “mysqlmanager — The MySQL Instance Manager”](#).

### Important

MySQL Instance Manager has been deprecated and is removed in MySQL 5.5.

- [mysql\\_convert\\_table\\_format](#)

A utility that converts tables in a database to use a given storage engine. See [Section 4.6.11, “mysql\\_convert\\_table\\_format — Convert Tables to Use a Given Storage Engine”](#).

- [mysql\\_find\\_rows](#)

A utility that reads files containing SQL statements (such as update logs) and extracts statements that match a given regular expression. See [Section 4.6.12, “mysql\\_find\\_rows — Extract SQL Statements from Files”](#).

- [mysql\\_fix\\_extensions](#)

A utility that converts the extensions for MyISAM table files to lowercase. This can be useful after transferring the files from a system with case-insensitive file names to a system with case-sensitive file names. See [Section 4.6.13,](#)

[mysql\\_fix\\_extensions](#) — Normalize Table File Name Extensions”.

- [mysql\\_setpermission](#)

A utility for interactively setting permissions in the MySQL grant tables. See [Section 4.6.14, “mysql\\_setpermission — Interactively Set Permissions in Grant Tables”](#).

- [mysql\\_waitpid](#)

A utility that kills the process with a given process ID. See [Section 4.6.15, “mysql\\_waitpid — Kill Process and Wait for Its Termination”](#).

- [mysql\\_zap](#)

A utility that kills processes that match a pattern. See [Section 4.6.16, “mysql\\_zap — Kill Processes That Match a Pattern”](#).

MySQL program-development utilities:

- [mysql2mysql](#)

A shell script that converts [mSQL](#) programs to MySQL. It doesn't handle every case, but it gives a good start when converting. See [Section 4.7.1, “mysql2mysql — Convert mSQL Programs for Use with MySQL”](#).

- [mysql\\_config](#)

A shell script that produces the option values needed when compiling MySQL programs. See [Section 4.7.2, “mysql\\_config — Get Compile Options for Compiling Clients”](#).

- [my\\_print\\_defaults](#)

A utility that shows which options are present in option groups of option files. See [Section 4.7.3, “my\\_print\\_defaults — Display Options from Option Files”](#).

- [resolve\\_stack\\_dump](#)

A utility program that resolves a numeric stack trace dump to symbols. See [Section 4.7.4, “resolve\\_stack\\_dump — Resolve Numeric Stack Trace Dump to Symbols”](#).

Miscellaneous utilities:

- [perror](#)

A utility that displays the meaning of system or MySQL error codes. See [Section 4.8.1, “perror — Explain Error Codes”](#).

- [replace](#)

A utility program that performs string replacement in the input text. See [Section 4.8.2, “replace — A String-Replacement Utility”](#).

- [resolveip](#)

A utility program that resolves a host name to an IP address or vice versa. See [Section 4.8.3, “resolveip — Resolve Host name to IP Address or Vice Versa”](#).

Oracle Corporation also provides several GUI tools for administering and otherwise working with MySQL Server:

- MySQL Workbench: This is the latest graphical tool for working with MySQL databases.
- MySQL Administrator: This tool is used for administering MySQL servers, databases, tables, and user accounts.
- MySQL Query Browser: This graphical tool is used for creating, executing, and optimizing queries on MySQL databases.
- MySQL Migration Toolkit: This tool helps you migrate schemas and data from other relational database management systems for use with MySQL.

These GUI programs are available at <http://dev.mysql.com/downloads/>. Each has its own manual that you can access at <http://dev.mysql.com/doc/>.

MySQL client programs that communicate with the server using the MySQL client/server library use the following environment variables.

|                              |                                                                              |
|------------------------------|------------------------------------------------------------------------------|
| <code>MYSQL_UNIX_PORT</code> | The default Unix socket file; used for connections to <code>localhost</code> |
| <code>MYSQL_TCP_PORT</code>  | The default port number; used for TCP/IP connections                         |
| <code>MYSQL_PWD</code>       | The default password                                                         |
| <code>MYSQL_DEBUG</code>     | Debug trace options when debugging                                           |
| <code>TMPDIR</code>          | The directory where temporary tables and files are created                   |

For a full list of environment variables used by MySQL programs, see [Section 2.14, “Environment Variables”](#).

Use of `MYSQL_PWD` is insecure. See [Section 5.3.2.2, “End-User Guidelines for Password Security”](#).

## 4.2. Using MySQL Programs

### 4.2.1. Invoking MySQL Programs

To invoke a MySQL program from the command line (that is, from your shell or command prompt), enter the program name followed by any options or other arguments needed to instruct the program what you want it to do. The following commands show some sample program invocations. “`shell>`” represents the prompt for your command interpreter; it is not part of what you type. The particular prompt you see depends on your command interpreter. Typical prompts are `$` for `sh` or `bash`, `%` for `csh` or `tcsh`, and `C:\>` for the Windows `command.com` or `cmd.exe` command interpreters.

```
shell> mysql --user=root test
shell> mysqladmin extended-status variables
shell> mysqlshow --help
shell> mysqldump -u root personnel
```

Arguments that begin with a single or double dash (“`-`”, “`--`”) specify program options. Options typically indicate the type of connection a program should make to the server or affect its operational mode. Option syntax is described in [Section 4.2.3, “Specifying Program Options”](#).

Nonoption arguments (arguments with no leading dash) provide additional information to the program. For example, the `mysql` program interprets the first nonoption argument as a database name, so the command `mysql --user=root test` indicates that you want to use the `test` database.

Later sections that describe individual programs indicate which options a program supports and describe the meaning of any additional nonoption arguments.

Some options are common to a number of programs. The most frequently used of these are the `--host` (or `-h`), `--user` (or `-u`), and `--password` (or `-p`) options that specify connection parameters. They indicate the host where the MySQL server is running, and the user name and password of your MySQL account. All MySQL client programs understand these options; they enable you to specify which server to connect to and the account to use on that server. Other connection options are `--port` (or `-P`) to specify a TCP/IP port number and `--socket` (or `-S`) to specify a Unix socket file on Unix (or named pipe name on Windows). For more information on options that specify connection options, see [Section 4.2.2, “Connecting to the MySQL Server”](#).

You may find it necessary to invoke MySQL programs using the path name to the `bin` directory in which they are installed. This is likely to be the case if you get a “program not found” error whenever you attempt to run a MySQL program from any directory other than the `bin` directory. To make it more convenient to use MySQL, you can add the path name of the `bin` directory to your `PATH` environment variable setting. That enables you to run a program by typing only its name, not its entire path name. For example, if `mysql` is installed in `/usr/local/mysql/bin`, you can run the program by invoking it as `mysql`, and it is not necessary to invoke it as `/usr/local/mysql/bin/mysql`.

Consult the documentation for your command interpreter for instructions on setting your `PATH` variable. The syntax for setting environment variables is interpreter-specific. (Some information is given in [Section 4.2.4, “Setting Environment Variables”](#).) After modifying your `PATH` setting, open a new console window on Windows or log in again on Unix so that the setting goes into effect.

### 4.2.2. Connecting to the MySQL Server

For a client program to be able to connect to the MySQL server, it must use the proper connection parameters, such as the name of the host where the server is running and the user name and password of your MySQL account. Each connection parameter has a default value, but you can override them as necessary using program options specified either on the command line or in an option file.

The examples here use the `mysql` client program, but the principles apply to other clients such as `mysqldump`, `mysqladmin`, or `mysqlshow`.

This command invokes `mysql` without specifying any connection parameters explicitly:

```
shell> mysql
```

Because there are no parameter options, the default values apply:

- The default host name is `localhost`. On Unix, this has a special meaning, as described later.
- The default user name is `ODBC` on Windows or your Unix login name on Unix.
- No password is sent if neither `-p` nor `--password` is given.
- For `mysql`, the first nonoption argument is taken as the name of the default database. If there is no such option, `mysql` does not select a default database.

To specify the host name and user name explicitly, as well as a password, supply appropriate options on the command line:

```
shell> mysql --host=localhost --user=myname --password=mypass mydb
shell> mysql -h localhost -u myname -pmypass mydb
```

For password options, the password value is optional:

- If you use a `-p` or `--password` option and specify the password value, there must be *no space* between `-p` or `--password=` and the password following it.
- If you use a `-p` or `--password` option but do not specify the password value, the client program prompts you to enter the password. The password is not displayed as you enter it. This is more secure than giving the password on the command line. Other users on your system may be able to see a password specified on the command line by executing a command such as `ps auxw`. See [Section 5.3.2.2, “End-User Guidelines for Password Security”](#).

As just mentioned, including the password value on the command line can be a security risk. To avoid this problem, specify the `--password` or `-p` option without any following password value:

```
shell> mysql --host=localhost --user=myname --password mydb
shell> mysql -h localhost -u myname -p mydb
```

When the password option has no password value, the client program prints a prompt and waits for you to enter the password. (In these examples, `mydb` is *not* interpreted as a password because it is separated from the preceding password option by a space.)

On some systems, the library routine that MySQL uses to prompt for a password automatically limits the password to eight characters. That is a problem with the system library, not with MySQL. Internally, MySQL does not have any limit for the length of the password. To work around the problem, change your MySQL password to a value that is eight or fewer characters long, or put your password in an option file.

On Unix, MySQL programs treat the host name `localhost` specially, in a way that is likely different from what you expect compared to other network-based programs. For connections to `localhost`, MySQL programs attempt to connect to the local server by using a Unix socket file. This occurs even if a `--port` or `-P` option is given to specify a port number. To ensure that the client makes a TCP/IP connection to the local server, use `--host` or `-h` to specify a host name value of `127.0.0.1`, or the IP address or name of the local server. You can also specify the connection protocol explicitly, even for `localhost`, by using the `--protocol=TCP` option. For example:

```
shell> mysql --host=127.0.0.1
shell> mysql --protocol=TCP
```

The `--protocol` option enables you to establish a particular type of connection even when the other options would normally default to some other protocol.

On Windows, you can force a MySQL client to use a named-pipe connection by specifying the `--pipe` or `--protocol=PIPE` option, or by specifying `.` (period) as the host name. If named-pipe connections are not enabled, an error occurs. Use the `--socket` option to specify the name of the pipe if you do not want to use the default pipe name.

Connections to remote servers always use TCP/IP. This command connects to the server running on `remote.example.com` using the default port number (3306):

```
shell> mysql --host=remote.example.com
```

To specify a port number explicitly, use the `--port` or `-P` option:

```
shell> mysql --host=remote.example.com --port=13306
```

You can specify a port number for connections to a local server, too. However, as indicated previously, connections to `localhost` on Unix will use a socket file by default. You will need to force a TCP/IP connection as already described or any option that specifies a port number will be ignored.

For this command, the program uses a socket file on Unix and the `--port` option is ignored:

```
shell> mysql --port=13306 --host=localhost
```

To cause the port number to be used, invoke the program in either of these ways:

```
shell> mysql --port=13306 --host=127.0.0.1
shell> mysql --port=13306 --protocol=TCP
```

The following list summarizes the options that can be used to control how client programs connect to the server:

- `--host=host_name`, `-h host_name`

The host where the server is running. The default value is `localhost`.

- `--password[=pass_val]`, `-p[pass_val]`

The password of the MySQL account. As described earlier, the password value is optional, but if given, there must be *no space* between `-p` or `--password=` and the password following it. The default is to send no password.

- `--pipe`, `-W`

On Windows, connect to the server using a named pipe. The server must be started with the `--enable-named-pipe` option to enable named-pipe connections.

- `--port=port_num`, `-P port_num`

The port number to use for the connection, for connections made using TCP/IP. The default port number is 3306.

- `--protocol={TCP|SOCKET|PIPE|MEMORY}`

This option explicitly specifies a protocol to use for connecting to the server. It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want. For example, connections on Unix to `localhost` are made using a Unix socket file by default:

```
shell> mysql --host=localhost
```

To force a TCP/IP connection to be used instead, specify a `--protocol` option:

```
shell> mysql --host=localhost --protocol=TCP
```

The following table shows the permissible `--protocol` option values and indicates the platforms on which each value may be used. The values are not case sensitive.

| <code>--protocol</code> Value | Connection Protocol                             | Permissible Operating Systems |
|-------------------------------|-------------------------------------------------|-------------------------------|
| TCP                           | TCP/IP connection to local or remote server     | All                           |
| SOCKET                        | Unix socket file connection to local server     | Unix only                     |
| PIPE                          | Named-pipe connection to local or remote server | Windows only                  |
| MEMORY                        | Shared-memory connection to local server        | Windows only                  |

- `--shared-memory-base-name=name`

On Windows, the shared-memory name to use, for connections made using shared memory to a local server. The default value is `MySQL`. The shared-memory name is case sensitive.

The server must be started with the `--shared-memory` option to enable shared-memory connections.

- `--socket=file_name, -S file_name`

On Unix, the name of the Unix socket file to use, for connections made using a named pipe to a local server. The default Unix socket file name is `/tmp/mysql.sock`.

On Windows, the name of the named pipe to use, for connections to a local server. The default Windows pipe name is `MySQL`. The pipe name is not case sensitive.

The server must be started with the `--enable-named-pipe` option to enable named-pipe connections.

- `--ssl*`

Options that begin with `--ssl` are used for establishing a secure connection to the server using SSL, if the server is configured with SSL support. For details, see [Section 5.5.6.3, “SSL Command Options”](#).

- `--user=user_name, -u user_name`

The user name of the MySQL account you want to use. The default user name is `ODBC` on Windows or your Unix login name on Unix.

It is possible to specify different default values to be used when you make a connection so that you need not enter them on the command line each time you invoke a client program. This can be done in a couple of ways:

- You can specify connection parameters in the `[client]` section of an option file. The relevant section of the file might look like this:

```
[client]
host=host_name
user=user_name
password=your_pass
```

[Section 4.2.3.3, “Using Option Files”](#), discusses option files further.

- You can specify some connection parameters using environment variables. The host can be specified for `mysql` using `MYSQL_HOST`. The MySQL user name can be specified using `USER` (this is for Windows and NetWare only). The password can be specified using `MYSQL_PWD`, although this is insecure; see [Section 5.3.2.2, “End-User Guidelines for Password Security”](#). For a list of variables, see [Section 2.14, “Environment Variables”](#).

## 4.2.3. Specifying Program Options

There are several ways to specify options for MySQL programs:

- List the options on the command line following the program name. This is common for options that apply to a specific invocation of the program.
- List the options in an option file that the program reads when it starts. This is common for options that you want the program to use each time it runs.
- List the options in environment variables (see [Section 4.2.4, “Setting Environment Variables”](#)). This method is useful for options that you want to apply each time the program runs. In practice, option files are used more commonly for this purpose, but [Section 5.6.2, “Running Multiple Servers on Unix”](#), discusses one situation in which environment variables can be very helpful. It describes a handy technique that uses such variables to specify the TCP/IP port number and Unix socket file for the server and for client programs.

Options are processed in order, so if an option is specified multiple times, the last occurrence takes precedence. The following command causes `mysql` to connect to the server running on `localhost`:

```
shell> mysql -h example.com -h localhost
```

If conflicting or related options are given, later options take precedence over earlier options. The following command runs `mysql` in “no column names” mode:

```
shell> mysql --column-names --skip-column-names
```

MySQL programs determine which options are given first by examining environment variables, then by reading option files, and then by checking the command line. This means that environment variables have the lowest precedence and command-line options the highest.

You can take advantage of the way that MySQL programs process options by specifying default option values for a program in an option file. That enables you to avoid typing them each time you run the program while enabling you to override the defaults if necessary by using command-line options.

An option can be specified by writing it in full or as any unambiguous prefix. For example, the `--compress` option can be given to `mysqldump` as `--compr`, but not as `--comp` because the latter is ambiguous:

```
shell> mysqldump --comp
mysqldump: ambiguous option '--comp' (compatible, compress)
```

Be aware that the use of option prefixes can cause problems in the event that new options are implemented for a program. A prefix that is unambiguous now might become ambiguous in the future.

#### 4.2.3.1. Using Options on the Command Line

Program options specified on the command line follow these rules:

- Options are given after the command name.
- An option argument begins with one dash or two dashes, depending on whether it is a short form or long form of the option name. Many options have both short and long forms. For example, `-?` and `--help` are the short and long forms of the option that instructs a MySQL program to display its help message.
- Option names are case sensitive. `-v` and `-V` are both legal and have different meanings. (They are the corresponding short forms of the `--verbose` and `--version` options.)
- Some options take a value following the option name. For example, `-h localhost` or `--host=localhost` indicate the MySQL server host to a client program. The option value tells the program the name of the host where the MySQL server is running.
- For a long option that takes a value, separate the option name and the value by an “`=`” sign. For a short option that takes a value, the option value can immediately follow the option letter, or there can be a space between: `-hlocalhost` and `-h local-host` are equivalent. An exception to this rule is the option for specifying your MySQL password. This option can be given in long form as `--password=pass_val` or as `--password`. In the latter case (with no password value given), the program prompts you for the password. The password option also may be given in short form as `-ppass_val` or as `-p`. However, for the short form, if the password value is given, it must follow the option letter with *no intervening space*. The reason for this is that if a space follows the option letter, the program has no way to tell whether a following argument is supposed to be the password value or some other kind of argument. Consequently, the following two commands have two completely different meanings:

```
shell> mysql -ptest
shell> mysql -p test
```

The first command instructs `mysql` to use a password value of `test`, but specifies no default database. The second instructs `mysql` to prompt for the password value and to use `test` as the default database.

- Within option names, dash (“`-`”) and underscore (“`_`”) may be used interchangeably. For example, `--skip-grant-tables` and `--skip_grant_tables` are equivalent. (However, the leading dashes cannot be given as underscores.)
- For options that take a numeric value, the value can be given with a suffix of `K`, `M`, or `G` (either uppercase or lowercase) to indicate a multiplier of 1024,  $1024^2$  or  $1024^3$ . For example, the following command tells `mysqladmin` to ping the server 1024 times, sleeping 10 seconds between each ping:

```
mysql> mysqladmin --count=1K --sleep=10 ping
```

Option values that contain spaces must be quoted when given on the command line. For example, the `--execute` (or `-e`) option can be used with `mysql` to pass SQL statements to the server. When this option is used, `mysql` executes the statements in the option value and exits. The statements must be enclosed by quotation marks. For example, you can use the following command to obtain a list of user accounts:

```
mysql> mysql -u root -p --execute="SELECT User, Host FROM mysql.user"
Enter password: *****
+-----+-----+
| User | Host |
+-----+-----+
```

```

root	gigan
	gigan
	localhost
jon	localhost
root	localhost
+-----+-----+
shell>

```

Note that the long form (`--execute`) is followed by an equal sign (`=`).

If you wish to use quoted values within a statement, you will either need to escape the inner quotation marks, or use a different type of quotation marks within the statement from those used to quote the statement itself. The capabilities of your command processor dictate your choices for whether you can use single or double quotation marks and the syntax for escaping quote characters. For example, if your command processor supports quoting with single or double quotation marks, you can use double quotation marks around the statement, and single quotation marks for any quoted values within the statement.

Multiple SQL statements may be passed in the option value on the command line, separated by semicolons:

```

shell> mysql -u root -p -e "SELECT VERSION();SELECT NOW()"
Enter password: *****
+-----+
| VERSION() |
+-----+
| 5.1.5-alpha-log |
+-----+
+-----+
| NOW() |
+-----+
| 2006-01-05 21:19:04 |
+-----+

```

The `--execute` or `-e` option may also be used to pass commands in an analogous fashion to the `ndb_mgm` management client for MySQL Cluster. See [Section 17.2.4, “Safe Shutdown and Restart of MySQL Cluster”](#), for an example.

#### 4.2.3.2. Program Option Modifiers

Some options are “boolean” and control behavior that can be turned on or off. For example, the `mysql` client supports a `--column-names` option that determines whether or not to display a row of column names at the beginning of query results. By default, this option is enabled. However, you may want to disable it in some instances, such as when sending the output of `mysql` into another program that expects to see only data and not an initial header line.

To disable column names, you can specify the option using any of these forms:

```

--disable-column-names
--skip-column-names
--column-names=0

```

The `--disable` and `--skip` prefixes and the `=0` suffix all have the same effect: They turn the option off.

The “enabled” form of the option may be specified in any of these ways:

```

--column-names
--enable-column-names
--column-names=1

```

If an option is prefixed by `--loose`, a program does not exit with an error if it does not recognize the option, but instead issues only a warning:

```

shell> mysql --loose-no-such-option
mysql: WARNING: unknown option '--no-such-option'

```

The `--loose` prefix can be useful when you run programs from multiple installations of MySQL on the same machine and list options in an option file. An option that may not be recognized by all versions of a program can be given using the `--loose` prefix (or `loose` in an option file). Versions of the program that recognize the option process it normally, and versions that do not recognize it issue a warning and ignore it.

`mysqld` enables a limit to be placed on how large client programs can set dynamic system variables. To do this, use a `--maximum` prefix with the variable name. For example, `--maximum-query-cache-size=4M` prevents any client from making the query cache size larger than 4MB.

#### 4.2.3.3. Using Option Files

Most MySQL programs can read startup options from option files (also sometimes called configuration files). Option files provide a convenient way to specify commonly used options so that they need not be entered on the command line each time you run a program. For the MySQL server, MySQL provides a number of [preconfigured option files](#).

To determine whether a program reads option files, invoke it with the `--help` option. (For `mysqld`, use `--verbose` and `--help`.) If the program reads option files, the help message indicates which files it looks for and which option groups it recognizes.

### Note

Option files used with MySQL Cluster programs are covered in [Section 17.3, ‘MySQL Cluster Configuration’](#).

On Windows, MySQL programs read startup options from the following files, in the specified order (top items are used first).

| File Name                                                             | Purpose                                                                  |
|-----------------------------------------------------------------------|--------------------------------------------------------------------------|
| <code>WINDIR\my.ini</code> ,<br><code>WINDIR\my.cnf</code>            | Global options                                                           |
| <code>C:\my.ini</code> , <code>C:\my.cnf</code>                       | Global options                                                           |
| <code>INSTALLDIR\my.ini</code> , <code>IN-<br/>STALLDIR\my.cnf</code> | Global options                                                           |
| <code>defaults-extra-file</code>                                      | The file specified with <code>--defaults-extra-file=path</code> , if any |

`WINDIR` represents the location of your Windows directory. This is commonly `C:\WINDOWS`. You can determine its exact location from the value of the `WINDIR` environment variable using the following command:

```
C:\> echo %WINDIR%
```

`INSTALLDIR` represents the MySQL installation directory. This is typically `C:\PROGRAMDIR\MySQL\MySQL 5.1 Server` where `PROGRAMDIR` represents the programs directory (usually `Program Files` on English-language versions of Windows), when MySQL 5.1 has been installed using the installation and configuration wizards. See [The Location of the my.ini File](#).

On Unix, Linux and Mac OS X, MySQL programs read startup options from the following files, in the specified order (top items are used first).

| File Name                        | Purpose                                                                  |
|----------------------------------|--------------------------------------------------------------------------|
| <code>/etc/my.cnf</code>         | Global options                                                           |
| <code>/etc/mysql/my.cnf</code>   | Global options (as of MySQL 5.1.15)                                      |
| <code>SYSCONFDIR/my.cnf</code>   | Global options                                                           |
| <code>\$MYSQL_HOME/my.cnf</code> | Server-specific options                                                  |
| <code>defaults-extra-file</code> | The file specified with <code>--defaults-extra-file=path</code> , if any |
| <code>~/.my.cnf</code>           | User-specific options                                                    |

`~` represents the current user's home directory (the value of `$HOME`).

`SYSCONFDIR` represents the directory specified with the `--sysconfdir` option to `configure` when MySQL was built. By default, this is the `etc` directory located under the compiled-in installation directory. This location is used as of MySQL 5.1.10. (From 5.1.10 to 5.1.22, it was read last, after `~/.my.cnf`.)

`MYSQL_HOME` is an environment variable containing the path to the directory in which the server-specific `my.cnf` file resides.

If `MYSQL_HOME` is not set and you start the server using the `mysqld_safe` program, `mysqld_safe` attempts to set `MYSQL_HOME` as follows:

- Let `BASEDIR` and `DATADIR` represent the path names of the MySQL base directory and data directory, respectively.
- If there is a `my.cnf` file in `DATADIR` but not in `BASEDIR`, `mysqld_safe` sets `MYSQL_HOME` to `DATADIR`.
- Otherwise, if `MYSQL_HOME` is not set and there is no `my.cnf` file in `DATADIR`, `mysqld_safe` sets `MYSQL_HOME` to `BASEDIR`.

In MySQL 5.1, use of `DATADIR` as the location for `my.cnf` is deprecated.

Typically, `DATADIR` is `/usr/local/mysql/data` for a binary installation or `/usr/local/var` for a source installation. Note that this is the data directory location that was specified at configuration time, not the one specified with the `--datadir` option when `mysqld` starts. Use of `--datadir` at runtime has no effect on where the server looks for option files, because it looks

for them before processing any options.

MySQL looks for option files in the order just described and reads any that exist. If an option file that you want to use does not exist, create it with a plain text editor.

If multiple instances of a given option are found, the last instance takes precedence. There is one exception: For `mysqld`, the *first* instance of the `--user` option is used as a security precaution, to prevent a user specified in an option file from being overridden on the command line.

### Note

On Unix platforms, MySQL ignores configuration files that are world-writable. This is intentional as a security measure.

Any long option that may be given on the command line when running a MySQL program can be given in an option file as well. To get the list of available options for a program, run it with the `--help` option.

The syntax for specifying options in an option file is similar to command-line syntax (see [Section 4.2.3.1, “Using Options on the Command Line”](#)). However, in an option file, you omit the leading two dashes from the option name and you specify only one option per line. For example, `--quick` and `--host=localhost` on the command line should be specified as `quick` and `host=localhost` on separate lines in an option file. To specify an option of the form `--loose-opt_name` in an option file, write it as `loose-opt_name`.

Empty lines in option files are ignored. Nonempty lines can take any of the following forms:

- `#comment, ;comment`

Comment lines start with “`#`” or “`;`”. A “`#`” comment can start in the middle of a line as well.

- `[group]`

`group` is the name of the program or group for which you want to set options. After a group line, any option-setting lines apply to the named group until the end of the option file or another group line is given.

- `opt_name`

This is equivalent to `--opt_name` on the command line.

- `opt_name=value`

This is equivalent to `--opt_name=value` on the command line. In an option file, you can have spaces around the “`=`” character, something that is not true on the command line. You can optionally enclose the value within single quotation marks or double quotation marks, which is useful if the value contains a “`#`” comment character.

Leading and trailing spaces are automatically deleted from option names and values.

You can use the escape sequences “`\b`”, “`\t`”, “`\n`”, “`\r`”, “`\\\`”, and “`\s`” in option values to represent the backspace, tab, newline, carriage return, backslash, and space characters. The escaping rules in option files are:

- If a backslash is followed by a valid escape sequence character, the sequence is converted to the character represented by the sequence. For example, “`\s`” is converted to a space.
- If a backslash is not followed by a valid escape sequence character, it remains unchanged. For example, “`\S`” is retained as is.

The preceding rules mean that a literal backslash can be given as “`\\\`”, or as “`\`” if it is not followed by a valid escape sequence character.

The rules for escape sequences in option files differ slightly from the rules for escape sequences in string literals in SQL statements. In the latter context, if “`x`” is not a value escape sequence character, “`\x`” becomes “`x`” rather than “`\x`”. See [Section 8.1.1, “Strings”](#).

The escaping rules for option file values are especially pertinent for Windows path names, which use “`\`” as a path name separator. A separator in a Windows path name must be written as “`\\\`” if it is followed by an escape sequence character. It can be written as “`\\\`” or “`\`” if it is not. Alternatively, “`/`” may be used in Windows path names and will be treated as “`\`”. Suppose that you want to specify a base directory of `C:\Program Files\MySQL\MySQL Server 5.1` in an option file. This can be done several ways. Some examples:

```
basedir="C:\Program Files\MySQL\MySQL Server 5.1"
basedir="C:\\Program Files\\\\MySQL\\\\MySQL Server 5.1"
```

```
basedir="C:/Program Files/MySQL/MySQL Server 5.1"
basedir=C:\\Program\\sFiles\\MySQL\\MySQL\\sServer\\s5.1
```

If an option group name is the same as a program name, options in the group apply specifically to that program. For example, the `[mysqld]` and `[mysql]` groups apply to the `mysqld` server and the `mysql` client program, respectively.

The `[client]` option group is read by all client programs (but *not* by `mysqld`). This enables you to specify options that apply to all clients. For example, `[client]` is the perfect group to use to specify the password that you use to connect to the server. (But make sure that the option file is readable and writable only by yourself, so that other people cannot find out your password.) Be sure not to put an option in the `[client]` group unless it is recognized by *all* client programs that you use. Programs that do not understand the option quit after displaying an error message if you try to run them.

Here is a typical global option file:

```
[client]
port=3306
socket=/tmp/mysql.sock

[mysqld]
port=3306
socket=/tmp/mysql.sock
key_buffer_size=16M
max_allowed_packet=8M

[mysqldump]
quick
```

The preceding option file uses `var_name=value` syntax for the lines that set the `key_buffer_size` and `max_allowed_packet` variables.

Here is a typical user option file:

```
[client]
The following password will be sent to all standard MySQL clients
password="my_password"

[mysql]
no-auto-rehash
connect_timeout=2

[mysqlhotcopy]
interactive_timeout
```

If you want to create option groups that should be read by `mysqld` servers from a specific MySQL release series only, you can do this by using groups with names of `[mysqld-5.0]`, `[mysqld-5.1]`, and so forth. The following group indicates that the `-new` option should be used only by MySQL servers with 5.1.x version numbers:

```
[mysqld-5.1]
new
```

It is possible to use `!include` directives in option files to include other option files and `!includedir` to search specific directories for option files. For example, to include the `/home/mydir/myopt.cnf` file, use the following directive:

```
!include /home/mydir/myopt.cnf
```

To search the `/home/mydir` directory and read option files found there, use this directive:

```
!includedir /home/mydir
```

There is no guarantee about the order in which the option files in the directory will be read.

### Note

Currently, any files to be found and included using the `!includedir` directive on Unix operating systems *must* have file names ending in `.cnf`. On Windows, this directive checks for files with the `.ini` or `.cnf` extension.

Write the contents of an included option file like any other option file. That is, it should contain groups of options, each preceded by a `[group]` line that indicates the program to which the options apply.

While an included file is being processed, only those options in groups that the current program is looking for are used. Other groups are ignored. Suppose that a `my.cnf` file contains this line:

```
!include /home/mydir/myopt.cnf
```

And suppose that `/home/mydir/myopt.cnf` looks like this:

```
[mysqladmin]
force

[mysqld]
key_buffer_size=16M
```

If `my.cnf` is processed by `mysqld`, only the `[mysqld]` group in `/home/mydir/myopt.cnf` is used. If the file is processed by `mysqladmin`, only the `[mysqladmin]` group is used. If the file is processed by any other program, no options in `/home/mydir/myopt.cnf` are used.

The `!includedir` directive is processed similarly except that all option files in the named directory are read.

#### 4.2.3.3.1. Command-Line Options that Affect Option-File Handling

Most MySQL programs that support option files handle the following options. They affect option-file handling, so they must be given on the command line and not in an option file. To work properly, each of these options must immediately follow the command name, with the exception that `--print-defaults` may be used immediately after `--defaults-file` or `--defaults-extra-file`. Also, when specifying file names, you should avoid the use of the “`~`” shell metacharacter because it might not be interpreted as you expect.

- `--defaults-extra-file=file_name`

Read this option file after the global option file but (on Unix) before the user option file. `file_name` is the full path name to the file. If the file does not exist or is otherwise inaccessible, the program will exit with an error.

- `--defaults-file=file_name`

Use only the given option file. `file_name` is the full path name to the file. If the file does not exist or is otherwise inaccessible, the program will exit with an error.

- `--defaults-group-suffix=str`

If this option is given, the program reads not only its usual option groups, but also groups with the usual names and a suffix of `str`. For example, the `mysql` client normally reads the `[client]` and `[mysql]` groups. If the `--defaults-group-suffix=_other` option is given, `mysql` also reads the `[client_other]` and `[mysql_other]` groups.

- `--no-defaults`

Do not read any option files. If a program does not start because it is reading unknown options from an option file, `--no-defaults` can be used to prevent the program from reading them.

- `--print-defaults`

Print the program name and all options that it gets from option files.

#### 4.2.3.3.2. Preconfigured Option Files

MySQL provides a number of preconfigured option files that can be used as a basis for tuning the MySQL server. Look for files such as `my-small.cnf`, `my-medium.cnf`, `my-large.cnf`, and `my-huge.cnf`, which are sample option files for small, medium, large, and very large systems. On Windows, the extension is `.ini` rather than `.cnf`.

##### Note

On Windows, the `.ini` or `.cnf` option file extension might not be displayed.

For a binary distribution, look for the files in or under your installation directory. If you have a source distribution, look in the `support-files` directory. You can rename a copy of a sample file and place it in the appropriate location for use as a base configuration file. Regarding names and appropriate location, see the general information provided in [Section 4.2.3.3, “Using Option Files”](#).

#### 4.2.3.4. Using Options to Set Program Variables

Many MySQL programs have internal variables that can be set at runtime using the `SET` statement. See [Section 12.4.4, “SET Syntax”](#), and [Section 5.1.5, “Using System Variables”](#).

Most of these program variables also can be set at server startup by using the same syntax that applies to specifying program op-

tions. For example, `mysql` has a `max_allowed_packet` variable that controls the maximum size of its communication buffer. To set the `max_allowed_packet` variable for `mysql` to a value of 16MB, use either of the following commands:

```
shell> mysql --max_allowed_packet=16777216
shell> mysql --max_allowed_packet=16M
```

The first command specifies the value in bytes. The second specifies the value in megabytes. For variables that take a numeric value, the value can be given with a suffix of `K`, `M`, or `G` (either uppercase or lowercase) to indicate a multiplier of 1024, 1024<sup>2</sup> or 1024<sup>3</sup>. (For example, when used to set `max_allowed_packet`, the suffixes indicate units of kilobytes, megabytes, or gigabytes.)

In an option file, variable settings are given without the leading dashes:

```
[mysql]
max_allowed_packet=16777216
```

Or:

```
[mysql]
max_allowed_packet=16M
```

If you like, underscores in a variable name can be specified as dashes. The following option groups are equivalent. Both set the size of the server's key buffer to 512MB:

```
[mysqld]
key_buffer_size=512M
[mysqld]
key-buffer-size=512M
```

A variable can be specified by writing it in full or as any unambiguous prefix. For example, the `max_allowed_packet` variable can be set for `mysql` as `--max_a`, but not as `--max` because the latter is ambiguous:

```
shell> mysql --max=1000000
mysql: ambiguous option '--max=1000000' (max_allowed_packet, max_join_size)
```

Be aware that the use of variable prefixes can cause problems in the event that new variables are implemented for a program. A prefix that is unambiguous now might become ambiguous in the future.

Suffixes for specifying a value multiplier can be used when setting a variable at server startup, but not to set the value with `SET` at runtime. On the other hand, with `SET` you can assign a variable's value using an expression, which is not true when you set a variable at server startup. For example, the first of the following lines is legal at server startup, but the second is not:

```
shell> mysql --max_allowed_packet=16M
shell> mysql --max_allowed_packet=16*1024*1024
```

Conversely, the second of the following lines is legal at runtime, but the first is not:

```
mysql> SET GLOBAL max_allowed_packet=16M;
mysql> SET GLOBAL max_allowed_packet=16*1024*1024;
```

### Note

Before MySQL 4.0.2, the only syntax for setting program variables was `--set-variable=option=value` (or `set-variable=option=value` in option files). Underscores cannot be given as dashes, and the variable name must be specified in full. This syntax still is recognized, but is deprecated and is removed in MySQL 5.5.

#### 4.2.3.5. Option Defaults, Options Expecting Values, and the = Sign

By convention, long forms of options that assign a value are written with an equals (=) sign, like this:

```
shell> mysql --host=tonfisk --user=jon
```

For options that require a value (that is, not having a default value), the equal sign is not required, and so the following is also valid:

```
shell> mysql --host tonfisk --user jon
```

In both cases, the `mysql` client attempts to connect to a MySQL server running on the host named "tonfisk" using an account with the user name "jon".

Due to this behavior, problems can occasionally arise when no value is provided for an option that expects one. Consider the following example, where a user connects to a MySQL server running on host `tonfisk` as user `jon`:

```
shell> mysql --host 85.224.35.45 --user jon
Welcome to the MySQL monitor. Commands end with ; or \g.
Your MySQL connection id is 3
Server version: 5.1.52 Source distribution

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SELECT CURRENT_USER();
+-----+
| CURRENT_USER() |
+-----+
| jon@% |
+-----+
1 row in set (0.00 sec)
```

Omitting the required value for one of these option yields an error, such as the one shown here:

```
shell> mysql --host 85.224.35.45 --user
mysqld: Option '--USER' requires an argument
```

In this case, `mysql` was unable to find a value following the `--user` option because nothing came after it on the command line. However, if you omit the value for an option that is *not* the last option to be used, you obtain a different error that you may not be expecting:

```
shell> mysql --host --user jon
ERROR 2005 (HY000): UNKNOWN MySQL SERVER HOST '--USER' (1)
```

Because `mysql` assumes that any string following `--host` on the command line is a host name, `--host --user` is interpreted as `--host--user`, and the client attempts to connect to a MySQL server running on a host named “`--user`”.

Options having default values always require an equal sign when assigning a value; failing to do so causes an error. For example, the MySQL server `--log-error` option has the default value `host_name.err`, where `host_name` is the name of the host on which MySQL is running. Assume that you are running MySQL on a computer whose host name is “`tonfisk`”, and consider the following invocation of `mysqld_safe`:

```
shell> mysqld_safe &
[1] 11699
shell> 080112 12:53:40 mysqld_safe Logging to '/usr/local/mysql/var/tonfisk.err'.
080112 12:53:40 mysqld_safe Starting mysqld daemon with databases from /usr/local/mysql/var
shell>
```

After shutting down the server, restart it as follows:

```
shell> mysqld_safe --log-error &
[1] 11699
shell> 080112 12:53:40 mysqld_safe Logging to '/usr/local/mysql/var/tonfisk.err'.
080112 12:53:40 mysqld_safe Starting mysqld daemon with databases from /usr/local/mysql/var
shell>
```

The result is the same, since `--log-error` is not followed by anything else on the command line, and it supplies its own default value. (The `&` character tells the operating system to run MySQL in the background; it is ignored by MySQL itself.) Now suppose that you wish to log errors to a file named `my-errors.err`. You might try starting the server with `--log-error my-errors`, but this does not have the intended effect, as shown here:

```
shell> mysqld_safe --log-error my-errors &
[1] 31357
shell> 080111 22:53:31 mysqld_safe Logging to '/usr/local/mysql/var/tonfisk.err'.
080111 22:53:32 mysqld_safe Starting mysqld daemon with databases from /usr/local/mysql/var
080111 22:53:34 mysqld_safe mysqld from pid file /usr/local/mysql/var/tonfisk.pid ended
[1]+ Done ./mysqld_safe --log-error my-errors
```

The server attempted to start using `/usr/local/mysql/var/tonfisk.err` as the error log, but then shut down. Examining the last few lines of this file shows the reason:

```
shell> tail /usr/local/mysql/var/tonfisk.err
080111 22:53:32 InnoDB: Started; log sequence number 0 46409
/USR/LOCAL/MYSQL/LIBEXEC/MYSQD: TOO MANY ARGUMENTS (FIRST EXTRA IS 'MY-ERRORS').
USE --VERBOSE --HELP TO GET A LIST OF AVAILABLE OPTIONS
080111 22:53:32 [ERROR] ABORTING

080111 22:53:32 InnoDB: Starting shutdown...
080111 22:53:34 InnoDB: Shutdown completed; log sequence number 0 46409
080111 22:53:34 [Note] /usr/local/mysql/libexec/mysqld: Shutdown complete

080111 22:53:34 mysqld_safe mysqld from pid file /usr/local/mysql/var/tonfisk.pid ended
```

Because the `--log-error` option supplies a default value, you must use an equal sign to assign a different value to it, as shown here:

```
shell> mysqld_safe --log-error=my-errors &
[1] 31437
shell> 080111 22:54:15 mysqld_safe Logging to '/usr/local/mysql/var/my-errors.err'.
```

```
080111 22:54:15 mysqld_safe Starting mysqld daemon with databases from /usr/local/mysql/var
shell>
```

Now the server has been started successfully, and is logging errors to the file `/usr/local/mysql/var/my-errors.err`.

Similar issues can arise when specifying option values in option files. For example, consider a `my.cnf` file that contains the following:

```
[mysql]
host
user
```

When the `mysql` client reads this file, these entries are parsed as `--host --user` or `--host=--user`, with the result shown here:

```
shell> mysql
ERROR 2005 (HY000): UNKNOWN MySQL SERVER HOST '--USER' (1)
```

However, in option files, an equal sign is not assumed. Suppose the `my.cnf` file is as shown here:

```
[mysql]
user jon
```

Trying to start `mysql` in this case causes a different error:

```
shell> mysql
MySQL: UNKNOWN OPTION '--USER JON'
```

A similar error would occur if you were to write `host tonfisk` in the option file rather than `host=tonfisk`. Instead, you must use the equal sign:

```
[mysql]
user=jon
```

```
shell> mysql
Welcome to the MySQL monitor. Commands end with ; or \g.
Your MySQL connection id is 5
Server version: 5.1.52 Source distribution

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SELECT USER();
+-----+
| USER() |
+-----+
| jon@localhost |
+-----+
1 row in set (0.00 sec)
```

This is not the same behavior as with the command line, where the equal sign is not required:

```
shell> mysql --user jon --host tonfisk
Welcome to the MySQL monitor. Commands end with ; or \g.
Your MySQL connection id is 6
Server version: 5.1.52 Source distribution

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SELECT USER();
+-----+
| USER() |
+-----+
| jon@tonfisk |
+-----+
1 row in set (0.00 sec)
```

## 4.2.4. Setting Environment Variables

Environment variables can be set at the command prompt to affect the current invocation of your command processor, or set permanently to affect future invocations. To set a variable permanently, you can set it in a startup file or by using the interface provided by your system for this purpose. Consult the documentation for your command interpreter for specific details. [Section 2.14, “Environment Variables”](#), lists all environment variables that affect MySQL program operation.

To specify a value for an environment variable, use the syntax appropriate for your command processor. For example, on Windows or NetWare, you can set the `USER` variable to specify your MySQL account name. To do so, use this syntax:

```
SET USER=your_name
```

The syntax on Unix depends on your shell. Suppose that you want to specify the TCP/IP port number using the

`MYSQL_TCP_PORT` variable. Typical syntax (such as for `sh`, `bash`, `zsh`, and so on) is as follows:

```
MYSQL_TCP_PORT=3306
export MYSQL_TCP_PORT
```

The first command sets the variable, and the `export` command exports the variable to the shell environment so that its value becomes accessible to MySQL and other processes.

For `csh` and `tcsh`, use `setenv` to make the shell variable available to the environment:

```
setenv MYSQL_TCP_PORT 3306
```

The commands to set environment variables can be executed at your command prompt to take effect immediately, but the settings persist only until you log out. To have the settings take effect each time you log in, use the interface provided by your system or place the appropriate command or commands in a startup file that your command interpreter reads each time it starts.

On Windows, you can set environment variables using the System Control Panel (under Advanced).

On Unix, typical shell startup files are `.bashrc` or `.bash_profile` for `bash`, or `.tcshrc` for `tcsh`.

Suppose that your MySQL programs are installed in `/usr/local/mysql/bin` and that you want to make it easy to invoke these programs. To do this, set the value of the `PATH` environment variable to include that directory. For example, if your shell is `bash`, add the following line to your `.bashrc` file:

```
PATH=${PATH}:/usr/local/mysql/bin
```

`bash` uses different startup files for login and nonlogin shells, so you might want to add the setting to `.bashrc` for login shells and to `.bash_profile` for nonlogin shells to make sure that `PATH` is set regardless.

If your shell is `tcsh`, add the following line to your `.tcshrc` file:

```
setenv PATH ${PATH}:/usr/local/mysql/bin
```

If the appropriate startup file does not exist in your home directory, create it with a text editor.

After modifying your `PATH` setting, open a new console window on Windows or log in again on Unix so that the setting goes into effect.

## 4.3. MySQL Server and Server-Startup Programs

This section describes `mysqld`, the MySQL server, and several programs that are used to start the server.

### 4.3.1. `mysqld` — The MySQL Server

`mysqld`, also known as MySQL Server, is the main program that does most of the work in a MySQL installation. MySQL Server manages access to the MySQL data directory that contains databases and tables. The data directory is also the default location for other information such as log files and status files.

When MySQL server starts, it listens for network connections from client programs and manages access to databases on behalf of those clients.

The `mysqld` program has many options that can be specified at startup. For a complete list of options, run this command:

```
shell> mysqld --verbose --help
```

MySQL Server also has a set of system variables that affect its operation as it runs. System variables can be set at server startup, and many of them can be changed at runtime to effect dynamic server reconfiguration. MySQL Server also has a set of status variables that provide information about its operation. You can monitor these status variables to access runtime performance characteristics.

For a full description of MySQL Server command options, system variables, and status variables, see [Section 5.1, “The MySQL Server”](#). For information about installing MySQL and setting up the initial configuration, see [Chapter 2, Installing and Upgrading MySQL](#).

### 4.3.2. `mysqld_safe` — MySQL Server Startup Script

`mysqld_safe` is the recommended way to start a `mysqld` server on Unix and NetWare. `mysqld_safe` adds some safety features such as restarting the server when an error occurs and logging runtime information to an error log file. Descriptions of error

logging and NetWare-specific behaviors are given later in this section.

### Note

In MySQL 5.1.20 (only), the default error logging behavior with `mysqld_safe` is to write errors to `syslog` on systems that support the `logger` program. This differs from the default behavior of writing an error log file for other versions.

**In 5.1.20, logging to `syslog` may fail to operate correctly in some cases; if so, use `--skip-syslog` to use the default log file or `--log-error=file_name` to specify a log file name explicitly.**

`mysqld_safe` tries to start an executable named `mysqld`. To override the default behavior and specify explicitly the name of the server you want to run, specify a `--mysqld` or `--mysqld-version` option to `mysqld_safe`. You can also use `--ledir` to indicate the directory where `mysqld_safe` should look for the server.

Many of the options to `mysqld_safe` are the same as the options to `mysqld`. See [Section 5.1.2](#), “Server Command Options”.

Options unknown to `mysqld_safe` are passed to `mysqld` if they are specified on the command line, but ignored if they are specified in the `[mysqld_safe]` group of an option file. See [Section 4.2.3.3](#), “Using Option Files”.

`mysqld_safe` reads all options from the `[mysqld]`, `[server]`, and `[mysqld_safe]` sections in option files. For example, if you specify a `[mysqld]` section like this, `mysqld_safe` will find and use the `--log-error` option:

```
[mysqld]
log-error=error.log
```

For backward compatibility, `mysqld_safe` also reads `[safe_mysqld]` sections, although you should rename such sections to `[mysqld_safe]` in MySQL 5.1 installations.

`mysqld_safe` supports the options in the following list. It also reads option files and supports the options for processing them described at [Section 4.2.3.3.1](#), “Command-Line Options that Affect Option-File Handling”.

**Table 4.1. `mysqld_safe` Options**

| Format                                                    | Config File                      | Description                                                                                                             | Introduction | Deprecated | Removed |
|-----------------------------------------------------------|----------------------------------|-------------------------------------------------------------------------------------------------------------------------|--------------|------------|---------|
| <code>--autoclose</code>                                  | <code>autoclose</code>           | On NetWare, <code>mysqld_safe</code> provides a screen presence                                                         |              |            |         |
| <code>--basedir=path</code>                               | <code>basedir</code>             | The path to the MySQL installation directory                                                                            |              |            |         |
| <code>-</code><br><code>core-file-size=size</code>        | <code>core-file-size</code>      | The size of the core file that <code>mysqld</code> should be able to create                                             |              |            |         |
| <code>--datadir=path</code>                               | <code>datadir</code>             | The path to the data directory                                                                                          |              |            |         |
| <code>-</code><br><code>-de-faults-extra-file=path</code> | <code>defaults-extra-file</code> | The name of an option file to be read in addition to the usual option files                                             |              |            |         |
| <code>-</code><br><code>-de-faults-file=file_name</code>  | <code>defaults-file</code>       | The name of an option file to be read instead of the usual option files                                                 |              |            |         |
| <code>--help</code>                                       |                                  | Display a help message and exit                                                                                         |              |            |         |
| <code>--ledir=path</code>                                 | <code>ledir</code>               | Use this option to indicate the path name to the directory where the server is located                                  |              |            |         |
| <code>-</code><br><code>-log-error=file_name</code>       | <code>log-error</code>           | Write the error log to the given file                                                                                   |              |            |         |
| <code>-</code><br><code>-mysqld=prog_name</code>          | <code>mysqld</code>              | The name of the server program (in the ledir directory) that you want to start                                          |              |            |         |
| <code>-</code><br><code>-mysqld-version=suffix</code>     | <code>mysqld-version</code>      | This option is similar to the <code>--mysqld</code> option, but you specify only the suffix for the server program name |              |            |         |

| Format                       | Config File      | Description                                                                                | Introduction | Deprecated | Removed |
|------------------------------|------------------|--------------------------------------------------------------------------------------------|--------------|------------|---------|
| --nice=priority              | nice             | Use the nice program to set the server's scheduling priority to the given value            |              |            |         |
| --no-defaults                | no-defaults      | Do not read any option files                                                               |              |            |         |
| - - open-files-limit=count   | open-files-limit | The number of files that mysqld should be able to open                                     |              |            |         |
| --pid-file                   | pid-file         | The path name of the process ID file                                                       |              |            |         |
| --port=number                | port             | The port number that the server should use when listening for TCP/IP connections           |              |            |         |
| --skip-kill-mysqld           | skip-kill-mysqld | Do not try to kill stray mysqld processes                                                  |              |            |         |
| --skip-syslog                | skip-syslog      | Do not write error messages to syslog; use error log file                                  | 5.1.20       |            |         |
| --socket=path                | socket           | The Unix socket file that the server should use when listening for local connections       |              |            |         |
| --syslog                     | syslog           | Write error messages to syslog                                                             | 5.1.20       |            |         |
| - - timezone=timezone        | timezone         | Set the TZ time zone environment variable to the given option value                        |              |            |         |
| - - user={user_name user_id} | user             | Run the mysqld server as the user having the name user_name or the numeric user ID user_id |              |            |         |

- `--help`

Display a help message and exit.

- `--autoclose`

(NetWare only) On NetWare, `mysqld_safe` provides a screen presence. When you unload (shut down) the `mysqld_safe` NLM, the screen does not by default go away. Instead, it prompts for user input:

```
<NLM has terminated; Press any key to close the screen>
```

If you want NetWare to close the screen automatically instead, use the `--autoclose` option to `mysqld_safe`.

- `--basedir=path`

The path to the MySQL installation directory.

- `--core-file-size=size`

The size of the core file that `mysqld` should be able to create. The option value is passed to `ulimit -c`.

- `--datadir=path`

The path to the data directory.

- `--defaults-extra-file=path`

The name of an option file to be read in addition to the usual option files. This must be the first option on the command line if it is used. If the file does not exist or is otherwise inaccessible, the server will exit with an error.

- `--defaults-file=file_name`

The name of an option file to be read instead of the usual option files. This must be the first option on the command line if it is used.

- `--ledir=path`

If `mysqld_safe` cannot find the server, use this option to indicate the path name to the directory where the server is located.

- `--log-error=file_name`

Write the error log to the given file. See [Section 5.2.2, “The Error Log”](#).

- `--mysqld=prog_name`

The name of the server program (in the `ledir` directory) that you want to start. This option is needed if you use the MySQL binary distribution but have the data directory outside of the binary distribution. If `mysqld_safe` cannot find the server, use the `--ledir` option to indicate the path name to the directory where the server is located.

- `--mysqld-version=suffix`

This option is similar to the `--mysqld` option, but you specify only the suffix for the server program name. The basename is assumed to be `mysqld`. For example, if you use `--mysqld-version=debug`, `mysqld_safe` starts the `mysqld-debug` program in the `ledir` directory. If the argument to `--mysqld-version` is empty, `mysqld_safe` uses `mysqld` in the `ledir` directory.

- `--nice=priority`

Use the `nice` program to set the server's scheduling priority to the given value.

- `--no-defaults`

Do not read any option files. This must be the first option on the command line if it is used.

- `--open-files-limit=count`

The number of files that `mysqld` should be able to open. The option value is passed to `ulimit -n`. Note that you need to start `mysqld_safe` as `root` for this to work properly!

- `--pid-file=file_name`

The path name of the process ID file.

- `--port=port_num`

The port number that the server should use when listening for TCP/IP connections. The port number must be 1024 or higher unless the server is started by the `root` system user.

- `--skip-kill-mysqld`

Do not try to kill stray `mysqld` processes at startup. This option works only on Linux.

- `--socket=path`

The Unix socket file that the server should use when listening for local connections.

- `--syslog, --skip-syslog`

`--syslog` causes error messages to be sent to `syslog` on systems that support the `logger` program. `--skip-syslog` suppresses the use of `syslog`; messages are written to an error log file. These options were added in MySQL 5.1.20.

- `--syslog-tag=tag`

For logging to `syslog`, messages from `mysqld_safe` and `mysqld` are written with a tag of `mysqld_safe` and `mysqld`, respectively. To specify a suffix for the tag, use `--syslog-tag=tag`, which modifies the tags to be `mysqld_safe-tag` and `mysqld-tag`. This option was added in MySQL 5.1.21.

- `--timezone=timezone`

Set the `TZ` time zone environment variable to the given option value. Consult your operating system documentation for legal time zone specification formats.

- `--user={user_name|user_id}`

Run the `mysqld` server as the user having the name `user_name` or the numeric user ID `user_id`. (“User” in this context refers to a system login account, not a MySQL user listed in the grant tables.)

If you execute `mysqld_safe` with the `--defaults-file` or `--defaults-extra-file` option to name an option file, the option must be the first one given on the command line or the option file will not be used. For example, this command will not use the named option file:

```
mysql> mysqld_safe --port=port_num --defaults-file=file_name
```

Instead, use the following command:

```
mysql> mysqld_safe --defaults-file=file_name --port=port_num
```

The `mysqld_safe` script is written so that it normally can start a server that was installed from either a source or a binary distribution of MySQL, even though these types of distributions typically install the server in slightly different locations. (See [Section 2.1.5, “Installation Layouts”](#).) `mysqld_safe` expects one of the following conditions to be true:

- The server and databases can be found relative to the working directory (the directory from which `mysqld_safe` is invoked). For binary distributions, `mysqld_safe` looks under its working directory for `bin` and `data` directories. For source distributions, it looks for `libexec` and `var` directories. This condition should be met if you execute `mysqld_safe` from your MySQL installation directory (for example, `/usr/local/mysql` for a binary distribution).
- If the server and databases cannot be found relative to the working directory, `mysqld_safe` attempts to locate them by absolute path names. Typical locations are `/usr/local/libexec` and `/usr/local/var`. The actual locations are determined from the values configured into the distribution at the time it was built. They should be correct if MySQL is installed in the location specified at configuration time.

Because `mysqld_safe` tries to find the server and databases relative to its own working directory, you can install a binary distribution of MySQL anywhere, as long as you run `mysqld_safe` from the MySQL installation directory:

```
shell> cd mysql_installation_directory
shell> bin/mysqld_safe &
```

If `mysqld_safe` fails, even when invoked from the MySQL installation directory, you can specify the `--ledir` and `--datadir` options to indicate the directories in which the server and databases are located on your system.

When you use `mysqld_safe` to start `mysqld`, `mysqld_safe` arranges for error (and notice) messages from itself and from `mysqld` to go to the same destination.

As of MySQL 5.1.20, there are several `mysqld_safe` options for controlling the destination of these messages:

- `--syslog`: Write error messages to `syslog` on systems that support the `logger` program.
- `--skip-syslog`: Do not write error messages to `syslog`. Messages are written to the default error log file (`host_name.err` in the data directory), or to a named file if the `--log-error` option is given.
- `--log-error=file_name`: Write error messages to the named error file.

If none of these options is given, the default is `--skip-syslog`.

### Note

In MySQL 5.1.20 *only*, the default is `--syslog`. This differs from logging behavior for other versions of MySQL, for which the default is to write messages to the default error log file.

If `--syslog` and `--log-error` are both given, a warning is issued and `--log-error` takes precedence.

When `mysqld_safe` writes a message, notices go to the logging destination (`syslog` or the error log file) and `stdout`. Errors go to the logging destination and `stderr`.

Before MySQL 5.1.20, error logging is controlled only with the `--log-error` option. If it is given, messages go to the named error file. Otherwise, messages go to the default error file.

Normally, you should not edit the `mysqld_safe` script. Instead, configure `mysqld_safe` by using command-line options or options in the `[mysqld_safe]` section of a `my.cnf` option file. In rare cases, it might be necessary to edit `mysqld_safe` to get it to start the server properly. However, if you do this, your modified version of `mysqld_safe` might be overwritten if you upgrade MySQL in the future, so you should make a copy of your edited version that you can reinstall.

On NetWare, `mysqld_safe` is a NetWare Loadable Module (NLM) that is ported from the original Unix shell script. It starts the

server as follows:

1. Runs a number of system and option checks.
2. Runs a check on `MyISAM` tables.
3. Provides a screen presence for the MySQL server.
4. Starts `mysqld`, monitors it, and restarts it if it terminates in error.
5. Sends error messages from `mysqld` to the `host_name.err` file in the data directory.
6. Sends `mysqld_safe` screen output to the `host_name.safe` file in the data directory.

### 4.3.3. `mysql.server` — MySQL Server Startup Script

MySQL distributions on Unix include a script named `mysql.server`. It can be used on systems such as Linux and Solaris that use System V-style run directories to start and stop system services. It is also used by the Mac OS X Startup Item for MySQL.

`mysql.server` can be found in the `support-files` directory under your MySQL installation directory or in a MySQL source distribution.

If you use the Linux server RPM package (`MySQL-server-VERSION.rpm`), the `mysql.server` script will be installed in the `/etc/init.d` directory with the name `mysql`. You need not install it manually. See [Section 2.6.1, “Installing MySQL from RPM Packages on Linux”](#), for more information on the Linux RPM packages.

Some vendors provide RPM packages that install a startup script under a different name such as `mysqld`.

If you install MySQL from a source distribution or using a binary distribution format that does not install `mysql.server` automatically, you can install it manually. Instructions are provided in [Section 2.13.1.2, “Starting and Stopping MySQL Automatically”](#).

`mysql.server` reads options from the `[mysql.server]` and `[mysqld]` sections of option files. For backward compatibility, it also reads `[mysql_server]` sections, although you should rename such sections to `[mysql.server]` when using MySQL 5.1.

`mysql.server` supports the following options.

- `--basedir=path`  
The path to the MySQL installation directory.
- `--datadir=path`  
The path to the MySQL data directory.
- `--pid-file=file_name`  
The path name of the file in which the server should write its process ID.
- `--service-startup-timeout=file_name`  
How long in seconds to wait for confirmation of server startup. If the server does not start within this time, `mysql.server` exits with an error. The default value is 900. A value of 0 means not to wait at all for startup. Negative values mean to wait forever (no timeout). This option was added in MySQL 5.1.17. Before that, a value of 900 is always used.
- `--use-mysqld_safe`  
Use `mysqld_safe` to start the server. This is the default.
- `--use-manager`  
Use Instance Manager to start the server.
- `--user=user_name`  
The login user name to use for running `mysqld`.

## 4.3.4. `mysqld_multi` — Manage Multiple MySQL Servers

`mysqld_multi` is designed to manage several `mysqld` processes that listen for connections on different Unix socket files and TCP/IP ports. It can start or stop servers, or report their current status. The MySQL Instance Manager is an alternative means of managing multiple servers (see [Section 4.6.10, “mysqlmanager — The MySQL Instance Manager”](#)).

`mysqld_multi` searches for groups named `[mysqldN]` in `my.cnf` (or in the file named by the `--config-file` option). `N` can be any positive integer. This number is referred to in the following discussion as the option group number, or `GNR`. Group numbers distinguish option groups from one another and are used as arguments to `mysqld_multi` to specify which servers you want to start, stop, or obtain a status report for. Options listed in these groups are the same that you would use in the `[mysqld]` group used for starting `mysqld`. (See, for example, [Section 2.13.1.2, “Starting and Stopping MySQL Automatically”](#).) However, when using multiple servers, it is necessary that each one use its own value for options such as the Unix socket file and TCP/IP port number. For more information on which options must be unique per server in a multiple-server environment, see [Section 5.6, “Running Multiple MySQL Servers on the Same Machine”](#).

To invoke `mysqld_multi`, use the following syntax:

```
shell> mysqld_multi [options] {start|stop|report} [GNR[,GNR] ...]
```

`start`, `stop`, and `report` indicate which operation to perform. You can perform the designated operation for a single server or multiple servers, depending on the `GNR` list that follows the option name. If there is no list, `mysqld_multi` performs the operation for all servers in the option file.

Each `GNR` value represents an option group number or range of group numbers. The value should be the number at the end of the group name in the option file. For example, the `GNR` for a group named `[mysqld17]` is `17`. To specify a range of numbers, separate the first and last numbers by a dash. The `GNR` value `10-13` represents groups `[mysqld10]` through `[mysqld13]`. Multiple groups or group ranges can be specified on the command line, separated by commas. There must be no whitespace characters (spaces or tabs) in the `GNR` list; anything after a whitespace character is ignored.

This command starts a single server using option group `[mysqld17]`:

```
shell> mysqld_multi start 17
```

This command stops several servers, using option groups `[mysqld8]` and `[mysqld10]` through `[mysqld13]`:

```
shell> mysqld_multi stop 8,10-13
```

For an example of how you might set up an option file, use this command:

```
shell> mysqld_multi --example
```

As of MySQL 5.1.18, `mysqld_multi` searches for option files as follows:

- With `--no-defaults`, no option files are read.
- With `--defaults-file=file_name`, only the named file is read.
- Otherwise, option files in the standard list of locations are read, including any file named by the `--defaults-extra-file=file_name` option, if one is given. (If the option is given multiple times, the last value is used.)

Before MySQL 5.1.18, the preceding options are not recognized. Files in the standard locations are read, and any file named by the `--config-file=file_name` option, if one is given. A file named by `--config-file` is read only for `[mysqldN]` option groups, not the `[mysqld_multi]` group.

Option files read are searched for `[mysqld_multi]` and `[mysqldN]` option groups. The `[mysqld_multi]` group can be used for options to `mysqld_multi` itself. `[mysqldN]` groups can be used for options passed to specific `mysqld` instances.

As of MySQL 5.1.35, the `[mysqld]` or `[mysqld_safe]` groups can be used for common options read by all instances of `mysqld` or `mysqld_safe`. You can specify a `--defaults-file=file_name` option to use a different configuration file for that instance, in which case the `[mysqld]` or `[mysqld_safe]` groups from that file will be used for that instance. Before MySQL 5.1.35, some versions of `mysqld_multi` pass the `--no-defaults` options to instances, so these techniques are inapplicable.

`mysqld_multi` supports the following options.

- `--help`

Display a help message and exit.

- `--config-file=file_name`

As of MySQL 5.1.18, this option is deprecated. If given, it is treated the same way as `--defaults-extra-file`, described earlier. `--config-file` is removed in MySQL 5.5.

Before MySQL 5.1.18, this option specifies the name of an extra option file. It affects where `mysqld_multi` looks for `[mysqldN]` option groups. Without this option, all options are read from the usual `my.cnf` file. The option does not affect where `mysqld_multi` reads its own options, which are always taken from the `[mysqld_multi]` group in the usual `my.cnf` file.

- `--example`

Display a sample option file.

- `--log=file_name`

Specify the name of the log file. If the file exists, log output is appended to it.

- `--mysqladmin=prog_name`

The `mysqladmin` binary to be used to stop servers.

- `--mysqld=prog_name`

The `mysqld` binary to be used. Note that you can specify `mysqld_safe` as the value for this option also. If you use `mysqld_safe` to start the server, you can include the `mysqld` or `ledir` options in the corresponding `[mysqldN]` option group. These options indicate the name of the server that `mysqld_safe` should start and the path name of the directory where the server is located. (See the descriptions for these options in [Section 4.3.2, “mysqld\\_safe — MySQL Server Startup Script”](#).) Example:

```
[mysqld38]
mysqld = mysqld-debug
ledir = /opt/local/mysql/libexec
```

- `--no-log`

Print log information to `stdout` rather than to the log file. By default, output goes to the log file.

- `--password=password`

The password of the MySQL account to use when invoking `mysqladmin`. Note that the password value is not optional for this option, unlike for other MySQL programs.

- `--silent`

Silent mode; disable warnings.

- `--tcp-ip`

Connect to each MySQL server through the TCP/IP port instead of the Unix socket file. (If a socket file is missing, the server might still be running, but accessible only through the TCP/IP port.) By default, connections are made using the Unix socket file. This option affects `stop` and `report` operations.

- `--user=user_name`

The user name of the MySQL account to use when invoking `mysqladmin`.

- `--verbose`

Be more verbose.

- `--version`

Display version information and exit.

Some notes about `mysqld_multi`:

- **Most important:** Before using `mysqld_multi` be sure that you understand the meanings of the options that are passed to the `mysqld` servers and *why* you would want to have separate `mysqld` processes. Beware of the dangers of using multiple `mysqld` servers with the same data directory. Use separate data directories, unless you *know* what you are doing. Starting multiple servers with the same data directory does *not* give you extra performance in a threaded system. See [Section 5.6, “Running Multiple MySQL Servers on the Same Machine”](#).

### Important

Make sure that the data directory for each server is fully accessible to the Unix account that the specific `mysqld` process is started as. *Do not* use the Unix `root` account for this, unless you *know* what you are doing. See [Section 5.3.6, “How to Run MySQL as a Normal User”](#).

- Make sure that the MySQL account used for stopping the `mysqld` servers (with the `mysqladmin` program) has the same user name and password for each server. Also, make sure that the account has the `SHUTDOWN` privilege. If the servers that you want to manage have different user names or passwords for the administrative accounts, you might want to create an account on each server that has the same user name and password. For example, you might set up a common `multi_admin` account by executing the following commands for each server:

```
shell> mysql -u root -S /tmp/mysql.sock -p
Enter password:
mysql> GRANT SHUTDOWN ON *.*
 -> TO 'multi_admin'@'localhost' IDENTIFIED BY 'multipass';
```

See [Section 5.4, “The MySQL Access Privilege System”](#). You have to do this for each `mysqld` server. Change the connection parameters appropriately when connecting to each one. Note that the host name part of the account name must permit you to connect as `multi_admin` from the host where you want to run `mysqld_multi`.

- The Unix socket file and the TCP/IP port number must be different for every `mysqld`. (Alternatively, if the host has multiple network addresses, you can use `--bind-address` to cause different servers to listen to different interfaces.)
- The `--pid-file` option is very important if you are using `mysqld_safe` to start `mysqld` (for example, `-mysqld=mysqld_safe`) Every `mysqld` should have its own process ID file. The advantage of using `mysqld_safe` instead of `mysqld` is that `mysqld_safe` monitors its `mysqld` process and restarts it if the process terminates due to a signal sent using `kill -9` or for other reasons, such as a segmentation fault. Please note that the `mysqld_safe` script might require that you start it from a certain place. This means that you might have to change location to a certain directory before running `mysqld_multi`. If you have problems starting, please see the `mysqld_safe` script. Check especially the lines:

```

MY_PWD=`pwd`
Check if we are starting this relative (for the binary release)
if test -d $MY_PWD/data/mysql -a \
 -f ./share/mysql/englisherrmsg.sys -a \
 -x ./bin/mysqld

```

The test performed by these lines should be successful, or you might encounter problems. See [Section 4.3.2, “mysqld\\_safe — MySQL Server Startup Script”](#).

- You might want to use the `--user` option for `mysqld`, but to do this you need to run the `mysqld_multi` script as the Unix `root` user. Having the option in the option file doesn't matter; you just get a warning if you are not the superuser and the `mysqld` processes are started under your own Unix account.

The following example shows how you might set up an option file for use with `mysqld_multi`. The order in which the `mysqld` programs are started or stopped depends on the order in which they appear in the option file. Group numbers need not form an unbroken sequence. The first and fifth [`mysqldN`] groups were intentionally omitted from the example to illustrate that you can have “gaps” in the option file. This gives you more flexibility.

```
This file should probably be in your home dir (~/.my.cnf)
or /etc/my.cnf
Version 2.1 by Jani Tolonen

[mysqld_multi]
mysqld = /usr/local/bin/mysqld_safe
mysqladmin = /usr/local/bin/mysqladmin
user = multi_admin
password = multipass

[mysqld2]
socket = /tmp/mysql.sock2

language = /usr/local/share/mysql/estonia
user = tonu

[mysqld6]
socket = /tmp/mysql.sock6
port = 3311
pid-file = /usr/local/mysql/var6/hostname.pid6
datadir = /usr/local/mysql/var6
language = /usr/local/share/mysql/japanese
user = jani
```

See [Section 4.2.3.3, “Using Option Files”](#).

## 4.4. MySQL Installation-Related Programs

The programs in this section are used when installing or upgrading MySQL.

### 4.4.1. `comp_err` — Compile MySQL Error Message File

`comp_err` creates the `errmsg.sys` file that is used by `mysqld` to determine the error messages to display for different error codes. `comp_err` normally is run automatically when MySQL is built. It compiles the `errmsg.sys` file from the plaintext file located at `sql/share/errmsg.txt` in MySQL source distributions.

`comp_err` also generates `mysqld_error.h`, `mysqld_ename.h`, and `sql_state.h` header files.

For more information about how error messages are defined, see the MySQL Internals Manual.

Invoke `comp_err` like this:

```
shell> comp_err [options]
```

`comp_err` supports the following options.

- `--help, -?`

Display a help message and exit.

- `--charset=path, -C path`

The character set directory. The default is `../sql/share/charsets`.

- `--debug=debug_options, -# debug_options`

Write a debugging log. A typical `debug_options` string is '`d:t:0,file_name`'. The default is '`d:t:0,/tmp/comp_err.trace`'.

- `--debug-info, -T`

Print some debugging information when the program exits.

- `--header_file=file_name, -H file_name`

The name of the error header file. The default is `mysqld_error.h`.

- `--in_file=file_name, -F file_name`

The name of the input file. The default is `../sql/share/errmsg.txt`.

- `--name_file=file_name, -N file_name`

The name of the error name file. The default is `mysqld_ename.h`.

- `--out_dir=path, -D path`  
The name of the output base directory. The default is `../sql/share/`.
- `--out_file=file_name, -O file_name`  
The name of the output file. The default is `errmsg.sys`.
- `--statefile=file_name, -S file_name`  
The name for the SQLSTATE header file. The default is `sql_state.h`.
- `--version, -V`  
Display version information and exit.

#### 4.4.2. `make_win_bin_dist` — Package MySQL Distribution as ZIP Archive

This script is used on Windows after building a MySQL distribution from source to create executable programs. It packages the binaries and support files into a ZIP archive that can be unpacked at the location where you want to install MySQL.

`make_win_bin_dist` is a shell script, so you must have Cygwin installed to use it.

This program's use is subject to change. Currently, you invoke it as follows from the root directory of your source distribution:

```
shell> make_win_bin_dist [options] package_basename [copy_def ...]
```

The `package_basename` argument provides the basename for the resulting ZIP archive. This name will be the name of the directory that results from unpacking the archive.

Because you might want to include files of directories from other builds, you can instruct this script to copy them in for you, using `copy_def` arguments, which have the form `relative_dest_name=source_name`.

Example:

```
bin/mysqld-max.exe=../my-max-build/sql/release/mysqld.exe
```

If you specify a directory, the entire directory will be copied.

`make_win_bin_dist` supports the following options.

- `--debug`  
Pack the debug binaries and produce an error if they were not built.
- `--embedded`  
Pack the embedded server and produce an error if it was not built. The default is to pack it if it was built.
- `--exe-suffix=suffix`  
Add a suffix to the basename of the `mysql` binary. For example, a suffix of `-abc` produces a binary named `mysqld-abc.exe`.
- `--no-debug`  
Do not pack the debug binaries even if they were built.
- `--no-embedded`  
Do not pack the embedded server even if it was built.
- `--only-debug`  
Use this option when the target for this build was `Debug`, and you just want to replace the normal binaries with debug versions (that is, do not use separate `debug` directories).

## 4.4.3. mysqlbug — Generate Bug Report

This program enables you to generate a bug report and send it to Oracle Corporation. It is a shell script and runs on Unix.

The normal way to report bugs is to visit <http://bugs.mysql.com/>, which is the address for our bugs database. This database is public and can be browsed and searched by anyone. If you log in to the system, you can enter new reports. If you have no Web access, you can generate a bug report by using the `mysqlbug` script.

`mysqlbug` helps you generate a report by determining much of the following information automatically, but if something important is missing, please include it with your message. `mysqlbug` can be found in the `scripts` directory (source distribution) and in the `bin` directory under your MySQL installation directory (binary distribution).

Invoke `mysqlbug` without arguments:

```
shell> mysqlbug
```

The script will place you in an editor with a copy of the report to be sent. Edit the lines near the beginning that indicate the nature of the problem. Then write the file to save your changes, quit the editor, and `mysqlbug` will send the report by email.

## 4.4.4. mysql\_fix\_privilege\_tables — Upgrade MySQL System Tables

### Note

In MySQL 5.1.7, `mysql_fix_privilege_tables` was superseded by `mysql_upgrade`, which should be used instead. See [Section 4.4.8, “mysql\\_upgrade — Check Tables for MySQL Upgrade”](#).

Some releases of MySQL introduce changes to the structure of the system tables in the `mysql` database to add new privileges or support new features. When you update to a new version of MySQL, you should update your system tables as well to make sure that their structure is up to date. Otherwise, there might be capabilities that you cannot take advantage of.

`mysql_fix_privilege_tables` is an older script that previously was used to upgrade the system tables in the `mysql` database after a MySQL upgrade.

Before running `mysql_fix_privilege_tables`, make a backup of your `mysql` database.

On Unix or Unix-like systems, update the system tables by running the `mysql_fix_privilege_tables` script:

```
shell> mysql_fix_privilege_tables
```

You must run this script while the server is running. It attempts to connect to the server running on the local host as `root`. If your `root` account requires a password, indicate the password on the command line like this:

```
shell> mysql_fix_privilege_tables --password=root_password
```

The `mysql_fix_privilege_tables` script performs any actions necessary to convert your system tables to the current format. You might see some `Duplicate column name` warnings as it runs; you can ignore them.

After running the script, stop the server and restart it so that any changes made to the system tables take effect.

On Windows systems, MySQL distributions include a `mysql_fix_privilege_tables.sql` SQL script that you can run using the `mysql` client. For example, if your MySQL installation is located at `C:\Program Files\MySQL\MySQL Server 5.1`, the commands look like this:

```
C:\> cd "C:\Program Files\MySQL\MySQL Server 5.1"
C:\> bin\mysql -u root -p mysql
mysql> SOURCE share/mysql_fix_privilege_tables.sql
```

### Note

Prior to version 5.1.17, the `mysql_fix_privilege_tables.sql` script is found in the `scripts` directory.

The `mysql` command will prompt you for the `root` password; enter it when prompted.

If your installation is located in some other directory, adjust the path names appropriately.

As with the Unix procedure, you might see some `Duplicate column name` warnings as `mysql` processes the statements in the `mysql_fix_privilege_tables.sql` script; you can ignore them.

After running the script, stop the server and restart it.

## 4.4.5. `mysql_install_db` — Initialize MySQL Data Directory

`mysql_install_db` initializes the MySQL data directory and creates the system tables that it contains, if they do not exist.

To invoke `mysql_install_db`, use the following syntax:

```
shell> mysql_install_db [options]
```

Because the MySQL server, `mysqld`, needs to access the data directory when it runs later, you should either run `mysql_install_db` from the same account that will be used for running `mysqld` or run it as `root` and use the `--user` option to indicate the user name that `mysqld` will run as. It might be necessary to specify other options such as `--basedir` or `--datadir` if `mysql_install_db` does not use the correct locations for the installation directory or data directory. For example:

```
shell> bin/mysql_install_db --user=mysql \
 --basedir=/opt/mysql/mysql \
 --datadir=/opt/mysql/mysql/data
```

`mysql_install_db` needs to invoke `mysqld` with the `--bootstrap` and `--skip-grant-tables` options (see [Section 2.3.3, “Typical configure Options”](#)). If MySQL was configured with the `--disable-grant-options` option, `--bootstrap` and `--skip-grant-tables` will be disabled. To handle this, set the `MYSQLD_BOOTSTRAP` environment variable to the full path name of a server that has all options enabled. `mysql_install_db` will use that server.

### Note

If you have set a custom `TMPDIR` variable when performing the installation, and the specified directory is not accessible, the execution of `mysql_install_db` may fail. You should unset `TMPDIR`, or set `TMPDIR` to point to the system temporary directory (usually `/tmp`).

`mysql_install_db` supports the following options, which can be specified on the command line or in the `[mysql_install_db]` and (if they are common to `mysqld`) `[mysqld]` option file groups.

- `--basedir=path`

The path to the MySQL installation directory.

- `--force`

Cause `mysql_install_db` to run even if DNS does not work. In that case, grant table entries that normally use host names will use IP addresses.

- `--datadir=path, --ldata=path`

The path to the MySQL data directory.

- `--rpm`

For internal use. This option is used by RPM files during the MySQL installation process.

- `--skip-name-resolve`

Use IP addresses rather than host names when creating grant table entries. This option can be useful if your DNS does not work.

- `--srcdir=path`

For internal use. The directory under which `mysql_install_db` looks for support files such as the error message file and the file for populating the help tables. This option was added in MySQL 5.1.14.

- `--user=user_name`

The login user name to use for running `mysqld`. Files and directories created by `mysqld` will be owned by this user. You must be `root` to use this option. By default, `mysqld` runs using your current login name and files and directories that it creates will be owned by you.

- `--verbose`

Verbose mode. Print more information about what the program does.

- `--windows`

For internal use. This option is used for creating Windows distributions.

#### 4.4.6. `mysql_secure_installation` — Improve MySQL Installation Security

This program enables you to improve the security of your MySQL installation in the following ways:

- You can set a password for `root` accounts.
- You can remove `root` accounts that are accessible from outside the local host.
- You can remove anonymous-user accounts.
- You can remove the `test` database (which by default can be accessed by all users, even anonymous users), and privileges that permit anyone to access databases with names that start with `test_`.

`mysql_secure_installation` helps you implement security recommendations similar to those described at [Section 2.13.2, “Securing the Initial MySQL Accounts”](#).

Invoke `mysql_secure_installation` without arguments:

```
shell> mysql_secure_installation
```

The script will prompt you to determine which actions to perform.

`mysql_secure_installation` is not available on Windows.

#### 4.4.7. `mysql_tzinfo_to_sql` — Load the Time Zone Tables

The `mysql_tzinfo_to_sql` program loads the time zone tables in the `mysql` database. It is used on systems that have a `zoneinfo` database (the set of files describing time zones). Examples of such systems are Linux, FreeBSD, Solaris, and Mac OS X. One likely location for these files is the `/usr/share/zoneinfo` directory (`/usr/share/lib/zoneinfo` on Solaris). If your system does not have a `zoneinfo` database, you can use the downloadable package described in [Section 9.6, “MySQL Server Time Zone Support”](#).

`mysql_tzinfo_to_sql` can be invoked several ways:

```
shell> mysql_tzinfo_to_sql tz_dir
shell> mysql_tzinfo_to_sql tz_file tz_name
shell> mysql_tzinfo_to_sql --leap tz_file
```

For the first invocation syntax, pass the `zoneinfo` directory path name to `mysql_tzinfo_to_sql` and send the output into the `mysql` program. For example:

```
shell> mysql_tzinfo_to_sql /usr/share/zoneinfo | mysql -u root mysql
```

`mysql_tzinfo_to_sql` reads your system's time zone files and generates SQL statements from them. `mysql` processes those statements to load the time zone tables.

The second syntax causes `mysql_tzinfo_to_sql` to load a single time zone file `tz_file` that corresponds to a time zone name `tz_name`:

```
shell> mysql_tzinfo_to_sql tz_file tz_name | mysql -u root mysql
```

If your time zone needs to account for leap seconds, invoke `mysql_tzinfo_to_sql` using the third syntax, which initializes the leap second information. `tz_file` is the name of your time zone file:

```
shell> mysql_tzinfo_to_sql --leap tz_file | mysql -u root mysql
```

After running `mysql_tzinfo_to_sql`, it is best to restart the server so that it does not continue to use any previously cached time zone data.

#### 4.4.8. `mysql_upgrade` — Check Tables for MySQL Upgrade

`mysql_upgrade` examines all tables in all databases for incompatibilities with the current version of MySQL Server.

`mysql_upgrade` also upgrades the system tables so that you can take advantage of new privileges or capabilities that might have been added.

`mysql_upgrade` should be executed each time you upgrade MySQL. It supersedes the older `mysql_fix_privilege_tables` script, which should no longer be used.

If a table is found to have a possible incompatibility, `mysql_upgrade` performs a table check. If any problems are found, a table repair is attempted. If the table cannot be repaired, see [Section 2.12.4, “Rebuilding or Repairing Tables or Indexes”](#) for manual table repair strategies.

### Note

On Windows Server 2008 and Windows Vista, you must run `mysql_upgrade` with administrator privileges. You can do this by running a Command Prompt as Administrator and running the command. Failure to do so may result in the upgrade failing to execute correctly.

### Caution

You should always back up your current MySQL installation *before* performing an upgrade. See [Section 6.2, “Database Backup Methods”](#).

Some upgrade incompatibilities may require special handling before you upgrade your MySQL installation and run `mysql_upgrade`. See [Section 2.12.1, “Upgrading MySQL”](#), for instructions on determining whether any such incompatibilities apply to your installation and how to handle them.

To use `mysql_upgrade`, make sure that the server is running, and then invoke it like this:

```
shell> mysql_upgrade [options]
```

After running `mysql_upgrade`, stop the server and restart it so that any changes made to the system tables take effect.

`mysql_upgrade` executes the following commands to check and repair tables and to upgrade the system tables:

```
mysqlcheck --all-databases --check-upgrade --auto-repair
mysql < fix_priv_tables
mysqlcheck --all-databases --check-upgrade --fix-db-names --fix-table-names
```

Notes about the preceding commands:

- Because `mysql_upgrade` invokes `mysqlcheck` with the `--all-databases` option, it processes all tables in all databases, which might take a long time to complete. Each table is locked and therefore unavailable to other sessions while it is being processed. Check and repair operations can be time-consuming, particularly for large tables.
- For details about what checks the `--check-upgrade` option entails, see the description of the `FOR UPGRADE` option of the `CHECK TABLE` statement (see [Section 12.4.2.3, “CHECK TABLE Syntax”](#)).
- `fix_priv_tables` represents a script generated internally by `mysql_upgrade` that contains SQL statements to upgrade the tables in the `mysql` database.
- Prior to MySQL 5.1.31, `mysql_upgrade` does not run the second `mysqlcheck` command, which is necessary to re-encode database or table names that contain nonalphanumeric characters. (They still appear after the upgrade with the `#mysql50#` prefix described in [Section 8.2.3, “Mapping of Identifiers to File Names”](#).) If you have such database or table names, execute the second `mysqlcheck` command manually after executing `mysql_upgrade`.

All checked and repaired tables are marked with the current MySQL version number. This ensures that next time you run `mysql_upgrade` with the same version of the server, it can tell whether there is any need to check or repair the table again.

`mysql_upgrade` also saves the MySQL version number in a file named `mysql_upgrade_info` in the data directory. This is used to quickly check whether all tables have been checked for this release so that table-checking can be skipped. To ignore this file and perform the check regardless, use the `--force` option.

If you install MySQL from RPM packages on Linux, you must install the server and client RPMs. `mysql_upgrade` is included in the server RPM but requires the client RPM because the latter includes `mysqlcheck`. (See [Section 2.6.1, “Installing MySQL from RPM Packages on Linux”](#).)

In MySQL 5.1.7, `mysql_upgrade` was added as a shell script and worked only for Unix systems. As of MySQL 5.1.10, `mysql_upgrade` is an executable binary and is available on all systems.

`mysql_upgrade` does not upgrade the contents of the help tables. For upgrade instructions, see [Section 5.1.8, “Server-Side](#)

Help”.

`mysql_upgrade` supports the following options, which can be specified on the command line or in the `[mysql_upgrade]` and `[client]` option file groups. Other options are passed to `mysqlcheck`. For example, it might be necessary to specify the `-password[=password]` option. `mysql_upgrade` also supports the options for processing option files described at Section 4.2.3.3.1, “Command-Line Options that Affect Option-File Handling”.

- `--help`

Display a short help message and exit.

- `--basedir=path`

The path to the MySQL installation directory. This option is accepted for backward compatibility but ignored.

- `--datadir=path`

The path to the data directory. This option is accepted for backward compatibility but ignored.

- `--debug-check`

Print some debugging information when the program exits. This option was added in MySQL 5.1.21.

- `--debug-info, -T`

Print debugging information and memory and CPU usage statistics when the program exits. This option was added in MySQL 5.1.21.

- `--force`

Ignore the `mysql_upgrade_info` file and force execution of `mysqlcheck` even if `mysql_upgrade` has already been executed for the current version of MySQL.

- `--tmpdir=path, -t path`

The path name of the directory to use for creating temporary files. This option was added in MySQL 5.1.25.

- `--user=user_name, -u user_name`

The MySQL user name to use when connecting to the server. The default user name is `root`.

- `--verbose`

Verbose mode. Print more information about what the program does.

- `--write-binlog`

Cause binary logging to be enabled while `mysql_upgrade` runs. This is the default behavior; to disable binary logging during the upgrade, use the inverse of this option (that is, start the program with `--skip-write-binlog`).

This option was introduced in MySQL 5.1.40.

## 4.5. MySQL Client Programs

This section describes client programs that connect to the MySQL server.

### 4.5.1. `mysql` — The MySQL Command-Line Tool

`mysql` is a simple SQL shell (with GNU `readline` capabilities). It supports interactive and noninteractive use. When used interactively, query results are presented in an ASCII-table format. When used noninteractively (for example, as a filter), the result is presented in tab-separated format. The output format can be changed using command options.

If you have problems due to insufficient memory for large result sets, use the `--quick` option. This forces `mysql` to retrieve results from the server a row at a time rather than retrieving the entire result set and buffering it in memory before displaying it. This is done by returning the result set using the `mysql_use_result()` C API function in the client/server library rather than `mysql_store_result()`.

Using `mysql` is very easy. Invoke it from the prompt of your command interpreter as follows:

```
shell> mysql db_name
```

Or:

```
shell> mysql --user=user_name --password=your_password db_name
```

Then type an SQL statement, end it with “`;`”, `\g`, or `\G` and press Enter.

As of MySQL 5.1.10, typing Control-C causes `mysql` to attempt to kill the current statement. If this cannot be done, or Control-C is typed again before the statement is killed, `mysql` exits. Previously, Control-C caused `mysql` to exit in all cases.

You can execute SQL statements in a script file (batch file) like this:

```
shell> mysql db_name < script.sql > output.tab
```

On Unix, the `mysql` client writes a record of executed statements to a history file. See [Section 4.5.1.3, “mysql History File”](#).

#### 4.5.1.1. `mysql` Options

`mysql` supports the following options, which can be specified on the command line or in the `[mysql]` and `[client]` option file groups. `mysql` also supports the options for processing option files described at [Section 4.2.3.3.1, “Command-Line Options that Affect Option-File Handling”](#).

**Table 4.2. `mysql` Options**

| Format                                              | Config File                        | Description                                                                   | Introduction | Deprecated | Removed |
|-----------------------------------------------------|------------------------------------|-------------------------------------------------------------------------------|--------------|------------|---------|
| <code>--auto-rehash</code>                          | <code>auto-rehash</code>           | Enable automatic rehashing                                                    |              |            |         |
| <code>--batch</code>                                | <code>batch</code>                 | Don't use history file                                                        |              |            |         |
| <code>-c -character-sets-dir=name</code>            | <code>character-sets-dir</code>    | Set the default character set                                                 |              |            |         |
| <code>--column-names</code>                         | <code>column-names</code>          | Write column names in results                                                 |              |            |         |
| <code>-c -column-type-info</code>                   | <code>column-type-info</code>      | Display result set metadata                                                   | 5.1.14       |            |         |
| <code>--comments</code>                             | <code>comments</code>              | Whether to retain or strip comments in statements sent to the server          | 5.1.23       |            |         |
| <code>--compress</code>                             | <code>compress</code>              | Compress all information sent between the client and the server               |              |            |         |
| <code>-c -connect_timeout=value</code>              | <code>connect_timeout</code>       | The number of seconds before connection timeout                               |              |            |         |
| <code>-c -database dbname</code>                    | <code>database</code>              | The database to use                                                           |              |            |         |
| <code>-c -debug[=debug_options]</code>              | <code>debug</code>                 | Write a debugging log                                                         |              |            |         |
| <code>--debug-check</code>                          | <code>debug-check</code>           | Print debugging information when the program exits                            | 5.1.21       |            |         |
| <code>--debug-info</code>                           | <code>debug-info</code>            | Print debugging information, memory and CPU statistics when the program exits |              |            |         |
| <code>-c -default-character-set=charset_name</code> | <code>default-character-set</code> | Use <code>charset_name</code> as the default character set                    |              |            |         |
| <code>--delimiter=str</code>                        | <code>delimiter</code>             | Set the statement delimiter                                                   |              |            |         |
| <code>-c -exec=statement</code>                     | <code>execute</code>               | Execute the statement and quit                                                |              |            |         |

| <b>Format</b>                                         | <b>Config File</b> | <b>Description</b>                                                                | <b>Introduction</b> | <b>Deprecated</b> | <b>Removed</b> |
|-------------------------------------------------------|--------------------|-----------------------------------------------------------------------------------|---------------------|-------------------|----------------|
| --force                                               | force              | Continue even if an SQL error occurs                                              |                     |                   |                |
| --help                                                |                    | Display help message and exit                                                     |                     |                   |                |
| --host=host_name                                      | host               | Connect to the MySQL server on the given host                                     |                     |                   |                |
| --html                                                | html               | Produce HTML output                                                               |                     |                   |                |
| --ignore-spaces                                       | ignore-spaces      | Ignore spaces after function names                                                |                     |                   |                |
| --line-numbers                                        | line-numbers       | Write line numbers for errors                                                     |                     |                   |                |
| - -loc-<br>al-infile[={0 1}]                          | local-infile       | Enable or disable for LOCAL capability for LOAD DATA INFILE                       |                     |                   |                |
| - -<br>max_allowed_packet<br>max_allowed_packet=value | max_allowed_packet | The maximum packet length to send to or receive from the server                   |                     |                   |                |
| - -<br>max_join_size=va<br>lue                        | max_join_size      | The automatic limit for rows in a join when using --safe-updates                  |                     |                   |                |
| - -<br>named-commands                                 | named-commands     | Enable named mysql commands                                                       |                     |                   |                |
| - -<br>net_buffer_length<br>=value                    | net_buffer_length  | The buffer size for TCP/IP and socket communication                               |                     |                   |                |
| --no-auto-rehash                                      |                    | Disable automatic rehashing                                                       |                     |                   |                |
| --no-beep                                             | no-beep            | Do not beep when errors occur                                                     |                     |                   |                |
| - -<br>no-<br>named-commands                          | no-named-commands  | Disable named mysql commands                                                      |                     |                   |                |

|--------------------------------------------|--------------------------------------|------------------------------------------------------------------------------------------------------------------------|---------------------|-------------------|----------------|
| <code>lect_limit=value</code>              |                                      |                                                                                                                        |                     |                   |                |
| <code>--show-warnings</code>               | <code>show-warnings</code>           | Show warnings after each statement if there are any                                                                    |                     |                   |                |
| <code>--sigint-ignore</code>               | <code>sigint-ignore</code>           | Ignore SIGINT signals (typically the result of typing Control-C)                                                       |                     |                   |                |
| <code>--silent</code>                      | <code>silent</code>                  | Silent mode                                                                                                            |                     |                   |                |
| <code>--skip-auto-rehash</code>            | <code>skip-auto-rehash</code>        | Disable automatic rehashing                                                                                            |                     |                   |                |
| <code>- - skip-column-names</code>         | <code>skip-column-names</code>       | Do not write column names in results                                                                                   |                     |                   |                |
| <code>- - skip-line-numbers</code>         | <code>skip-line-numbers</code>       | Skip line numbers for errors                                                                                           |                     |                   |                |
| <code>- - skip-named-commands</code>       | <code>skip-named-commands</code>     | Disable named mysql commands                                                                                           |                     |                   |                |
| <code>--skip-pager</code>                  | <code>skip-pager</code>              | Disable paging                                                                                                         |                     |                   |                |
| <code>--skip-reconnect</code>              | <code>skip-reconnect</code>          | Disable reconnecting                                                                                                   |                     |                   |                |
| <code>--socket=path</code>                 | <code>socket</code>                  | For connections to localhost                                                                                           |                     |                   |                |
| <code>- - ssl-ca=file_name</code>          | <code>ssl-ca</code>                  | The path to a file that contains a list of trusted SSL CAs                                                             |                     |                   |                |
| <code>- - ssl-capath=directory_name</code> | <code>ssl-capath</code>              | The path to a directory that contains trusted SSL CA certificates in PEM format                                        |                     |                   |                |
| <code>- - ssl-cert=file_name</code>        | <code>ssl-cert</code>                | The name of the SSL certificate file to use for establishing a secure connection                                       |                     |                   |                |
| <code>- - ssl-cipher=cipher_list</code>    | <code>ssl-cipher</code>              | A list of allowable ciphers to use for SSL encryption                                                                  |                     |                   |                |
| <code>- - ssl-key=file_name</code>         | <code>ssl-key</code>                 | The name of the SSL key file to use for establishing a secure connection                                               |                     |                   |                |
| <code>- - ssl-veri-fy-server-cert</code>   | <code>ssl-veri-fy-server-cert</code> | The server's Common Name value in its certificate is verified against the host name used when connecting to the server |                     |                   |                |
| <code>--table</code>                       | <code>table</code>                   | Display output in tabular format                                                                                       |                     |                   |                |
| <code>--tee=file_name</code>               | <code>tee</code>                     | Append a copy of output to the given file                                                                              |                     |                   |                |
| <code>--unbuffered</code>                  | <code>unbuffered</code>              | Flush the buffer after each query                                                                                      |                     |                   |                |
| <code>--user=user_name</code>              | <code>user</code>                    | The MySQL user name to use when connecting to the server                                                               |                     |                   |                |
| <code>--verbose</code>                     |                                      | Verbose mode                                                                                                           |                     |                   |                |
| <code>--version</code>                     |                                      | Display version information and exit                                                                                   |                     |                   |                |
| <code>--vertical</code>                    | <code>vertical</code>                | Print query output rows vertically (one line per column value)                                                         |                     |                   |                |
| <code>--wait</code>                        | <code>wait</code>                    | If the connection cannot be established, wait and retry instead of aborting                                            |                     |                   |                |
| <code>--xml</code>                         | <code>xml</code>                     | Produce XML output                                                                                                     |                     |                   |                |

- **--help, -?**

Display a help message and exit.

- **--auto-rehash**

Enable automatic rehashing. This option is on by default, which enables database, table, and column name completion. Use `--disable-auto-rehash` to disable rehashing. That causes `mysql` to start faster, but you must issue the `rehash` command if you want to use name completion.

To complete a name, enter the first part and press Tab. If the name is unambiguous, `mysql` completes it. Otherwise, you can press Tab again to see the possible names that begin with what you have typed so far. Completion does not occur if there is no default database.

- **--batch, -B**

Print results using tab as the column separator, with each row on a new line. With this option, `mysql` does not use the history file.

Batch mode results in nontabular output format and escaping of special characters. Escaping may be disabled by using raw mode; see the description for the `--raw` option.

- **--character-sets-dir=path**

The directory where character sets are installed. See [Section 9.5, “Character Set Configuration”](#).

- **--column-names**

Write column names in results.

- **--column-type-info, -m**

Display result set metadata. This option was added in MySQL 5.1.14. (Before that, use `--debug-info`.) The `-m` short option was added in MySQL 5.1.21.

- **--comments, -c**

Whether to preserve comments in statements sent to the server. The default is `--skip-comments` (discard comments), enable with `--comments` (preserve comments). This option was added in MySQL 5.1.23.

- **--compress, -C**

Compress all information sent between the client and the server if both support compression.

- **--database=db\_name, -D db\_name**

The database to use. This is useful primarily in an option file.

- **--debug[=debug\_options], -# [debug\_options]**

Write a debugging log. A typical `debug_options` string is '`d:t:o,file_name`'. The default is '`d:t:o,/tmp/mysql.trace`'.

- **--debug-check**

Print some debugging information when the program exits. This option was added in MySQL 5.1.21.

- **--debug-info, -T**

Before MySQL 5.1.14, this option prints debugging information and memory and CPU usage statistics when the program exits, and also causes display of result set metadata during execution. As of MySQL 5.1.14, use `--column-type-info` to display result set metadata.

- **--default-character-set=charset\_name**

Use `charset_name` as the default character set for the client and connection.

A common issue that can occur when the operating system uses `utf8` or another multi-byte character set is that output from the `mysql` client is formatted incorrectly, due to the fact that the MySQL client uses the `latin1` character set by default. You can usually fix such issues by using this option to force the client to use the system character set instead.

See [Section 9.5, “Character Set Configuration”](#), for more information.

- **--delimiter=str**  
Set the statement delimiter. The default is the semicolon character (“;”).
- **--disable-named-commands**  
Disable named commands. Use the `\*` form only, or use named commands only at the beginning of a line ending with a semi-colon (“;”). `mysql` starts with this option *enabled* by default. However, even with this option, long-format commands still work from the first line. See [Section 4.5.1.2, “mysql Commands”](#).
- **--execute=statement, -e statement**  
Execute the statement and quit. The default output format is like that produced with `--batch`. See [Section 4.2.3.1, “Using Options on the Command Line”](#), for some examples. With this option, `mysql` does not use the history file.
- **--force, -f**  
Continue even if an SQL error occurs.
- **--host=host\_name, -h host\_name**  
Connect to the MySQL server on the given host.
- **--html, -H**  
Produce HTML output.
- **--ignore-spaces, -i**  
Ignore spaces after function names. The effect of this is described in the discussion for the `IGNORE_SPACE` SQL mode (see [Section 5.1.7, “Server SQL Modes”](#)).
- **--line-numbers**  
Write line numbers for errors. Disable this with `--skip-line-numbers`.
- **--local-infile[={0|1}]**  
Enable or disable `LOCAL` capability for `LOAD DATA INFILE`. With no value, the option enables `LOCAL`. The option may be given as `--local-infile=0` or `--local-infile=1` to explicitly disable or enable `LOCAL`. Enabling `LOCAL` has no effect if the server does not also support it.
- **--named-commands, -G**  
Enable named `mysql` commands. Long-format commands are permitted, not just short-format commands. For example, `quit` and `\q` both are recognized. Use `--skip-named-commands` to disable named commands. See [Section 4.5.1.2, “mysql Commands”](#).
- **--no-auto-rehash, -A**  
This has the same effect as `-skip-auto-rehash`. See the description for `--auto-rehash`.
- **--no-beep, -b**  
Do not beep when errors occur.
- **--no-named-commands, -g**  
Deprecated, use `--disable-named-commands` instead. `--no-named-commands` is removed in MySQL 5.5.
- **--no-pager**  
Deprecated form of `--skip-pager`. See the `--pager` option. `--no-pager` is removed in MySQL 5.5.
- **--no-tee**  
Deprecated form of `--skip-tee`. See the `--tee` option. `--no-tee` is removed in MySQL 5.5.
- **--one-database, -o**  
Ignore statements except those that occur while the default database is the one named on the command line. This option is rudimentary and should be used with care. Statement filtering is based only on `USE` statements.

Initially, `mysql` executes statements in the input because specifying a database `db_name` on the command line is equivalent to inserting `USE db_name` at the beginning of the input. Then, for each `USE` statement encountered, `mysql` accepts or rejects following statements depending on whether the database named is the one on the command line. The content of the statements is immaterial.

Suppose that `mysql` is invoked to process this set of statements:

```
DELETE FROM db2.t2;
USE db2;
DROP TABLE db1.t1;
CREATE TABLE db1.t1 (i INT);
USE db1;
INSERT INTO t1 (i) VALUES(1);
CREATE TABLE db2.t1 (j INT);
```

If the command line is `mysql --force --one-database db1`, `mysql` handles the input as follows:

- The `DELETE` statement is executed because the default database is `db1`, even though the statement names a table in a different database.
- The `DROP TABLE` and `CREATE TABLE` statements are not executed because the default database is not `db1`, even though the statements name a table in `db1`.
- The `INSERT` and `CREATE TABLE` statements are executed because the default database is `db1`, even though the `CREATE TABLE` statement names a table in a different database.
- `--pager[=command]`

Use the given command for paging query output. If the command is omitted, the default pager is the value of your `PAGER` environment variable. Valid pagers are `less`, `more`, `cat [> filename]`, and so forth. This option works only on Unix and only in interactive mode. To disable paging, use `--skip-pager`. [Section 4.5.1.2, “mysql Commands”](#), discusses output paging further.

- `--password[=password], -p[password]`

The password to use when connecting to the server. If you use the short option form (`-p`), you *cannot* have a space between the option and the password. If you omit the `password` value following the `--password` or `-p` option on the command line, `mysql` prompts for one.

Specifying a password on the command line should be considered insecure. See [Section 5.3.2.2, “End-User Guidelines for Password Security”](#). You can use an option file to avoid giving the password on the command line.

- `--pipe, -W`

On Windows, connect to the server using a named pipe. This option applies only if the server supports named-pipe connections.

- `--port=port_num, -P port_num`

The TCP/IP port number to use for the connection.

- `--prompt=format_str`

Set the prompt to the specified format. The default is `mysql>`. The special sequences that the prompt can contain are described in [Section 4.5.1.2, “mysql Commands”](#).

- `--protocol={TCP|SOCKET|PIPE|MEMORY}`

The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want. For details on the permissible values, see [Section 4.2.2, “Connecting to the MySQL Server”](#).

- `--quick, -q`

Do not cache each query result, print each row as it is received. This may slow down the server if the output is suspended. With this option, `mysql` does not use the history file.

- `--raw, -r`

For tabular output, the “boxing” around columns enables one column value to be distinguished from another. For nontabular output (such as is produced in batch mode or when the `--batch` or `--silent` option is given), special characters are escaped in the output so they can be identified easily. Newline, tab, `NUL`, and backslash are written as `\n`, `\t`, `\0`, and `\\\`. The `-`

`--raw` option disables this character escaping.

The following example demonstrates tabular versus nontabular output and the use of raw mode to disable escaping:

```
% mysql
mysql> SELECT CHAR(92);
+-----+
| CHAR(92) |
+-----+
| \ |
+-----+

% mysql -s
mysql> SELECT CHAR(92);
CHAR(92)
\\

% mysql -s -r
mysql> SELECT CHAR(92);
CHAR(92)
\
```

- [--reconnect](#)

If the connection to the server is lost, automatically try to reconnect. A single reconnect attempt is made each time the connection is lost. To suppress reconnection behavior, use [--skip-reconnect](#).

- [--safe-updates](#), [--i-am-a-dummy](#), [-U](#)

Permit only those [UPDATE](#) and [DELETE](#) statements that specify which rows to modify by using key values. If you have set this option in an option file, you can override it by using [--safe-updates](#) on the command line. See [Section 4.5.1.6, “mysql Tips”](#), for more information about this option.

- [--secure-auth](#)

Do not send passwords to the server in old (pre-4.1.1) format. This prevents connections except for servers that use the newer password format.

- [--show-warnings](#)

Cause warnings to be shown after each statement if there are any. This option applies to interactive and batch mode.

- [--sigint-ignore](#)

Ignore [SIGINT](#) signals (typically the result of typing Control-C).

- [--silent](#), [-s](#)

Silent mode. Produce less output. This option can be given multiple times to produce less and less output.

This option results in nontabular output format and escaping of special characters. Escaping may be disabled by using raw mode; see the description for the [--raw](#) option.

- [--skip-column-names](#), [-N](#)

Do not write column names in results.

- [--skip-line-numbers](#), [-L](#)

Do not write line numbers for errors. Useful when you want to compare result files that include error messages.

- [--socket=path](#), [-S path](#)

For connections to [localhost](#), the Unix socket file to use, or, on Windows, the name of the named pipe to use.

- [--ssl\\*](#)

Options that begin with [--ssl](#) specify whether to connect to the server using SSL and indicate where to find SSL keys and certificates. See [Section 5.5.6.3, “SSL Command Options”](#).

- [--table](#), [-t](#)

Display output in table format. This is the default for interactive use, but can be used to produce table output in batch mode.

- [--tee=file\\_name](#)

Append a copy of output to the given file. This option works only in interactive mode. [Section 4.5.1.2, “mysql Commands”](#), discusses tee files further.

- **--unbuffered, -n**

Flush the buffer after each query.

- **--user=user\_name, -u user\_name**

The MySQL user name to use when connecting to the server.

- **--verbose, -v**

Verbose mode. Produce more output about what the program does. This option can be given multiple times to produce more and more output. (For example, `-v -v -v` produces table output format even in batch mode.)

- **--version, -V**

Display version information and exit.

- **--vertical, -E**

Print query output rows vertically (one line per column value). Without this option, you can specify vertical output for individual statements by terminating them with `\G`.

- **--wait, -w**

If the connection cannot be established, wait and retry instead of aborting.

- **--xml, -X**

Produce XML output.

### Note

Prior to MySQL 5.1.12, there was no differentiation in the output when using this option between columns containing the `NULL` value and columns containing the string literal '`NULL`'; both were represented as

```
<field name="column_name">NULL</field>
```

Beginning with MySQL 5.1.12, the output when `--xml` is used with `mysql` matches that of `mysqldump --xml`. See [Section 4.5.4, “mysqldump — A Database Backup Program”](#) for details.

Beginning with MySQL 5.1.18, the XML output also uses an XML namespace, as shown here:

```
shell> mysql --xml -uroot -e "SHOW VARIABLES LIKE 'version%'"<?xml version="1.0"?><resultset statement="SHOW VARIABLES LIKE 'version%" xmlns:xsi='http://www.w3.org/2001/XMLSchema-instance'><row><field name="Variable_name">version</field><field name="Value">5.0.40-debug</field></row><row><field name="Variable_name">version_comment</field><field name="Value">Source distribution</field></row><row><field name="Variable_name">version_compile_machine</field><field name="Value">i686</field></row><row><field name="Variable_name">version_compile_os</field><field name="Value">suse-linux-gnu</field></row></resultset>
```

(See [Bug#25946](#).)

You can also set the following variables by using `--var_name=value`. The `--set-variable` format is deprecated and is removed in MySQL 5.5.

- **connect\_timeout**

The number of seconds before connection timeout. (Default value is 0.)

- **max\_allowed\_packet**

The maximum packet length to send to or receive from the server. (Default value is 16MB.)

- **max\_join\_size**

The automatic limit for rows in a join when using `--safe-updates`. (Default value is 1,000,000.)

- **net\_buffer\_length**

The buffer size for TCP/IP and socket communication. (Default value is 16KB.)

- **select\_limit**

The automatic limit for `SELECT` statements when using `--safe-updates`. (Default value is 1,000.)

#### 4.5.1.2. `mysql` Commands

`mysql` sends each SQL statement that you issue to the server to be executed. There is also a set of commands that `mysql` itself interprets. For a list of these commands, type `help` or `\h` at the `mysql>` prompt:

```
mysql> help
List of all MySQL commands:
Note that all text commands must be first on line and end with ';'
? (\?) Synonym for `help'.
clear (\c) Clear command.
connect (\r) Reconnect to the server. Optional arguments are db and host.
delimiter (\d) Set statement delimiter.
edit (\e) Edit command with $EDITOR.
ego (\G) Send command to mysql server, display result vertically.
exit (\q) Exit mysql. Same as quit.
go (\g) Send command to mysql server.
help (\h) Display this help.
nopager (\n) Disable pager, print to stdout.
noteee (\t) Don't write into outfile.
pager (\P) Set PAGER [to_pager]. Print the query results via PAGER.
print (\p) Print current command.
prompt (\R) Change your mysql prompt.
quit (\q) Quit mysql.
rehash (\#\#) Rebuild completion hash.
source (\.) Execute an SQL script file. Takes a file name as an argument.
status (\s) Get status information from the server.
system (\!\!) Execute a system shell command.
tee (\T) Set outfile [to_outfile]. Append everything into given
 outfile.
use (\u) Use another database. Takes database name as argument.
charset (\C) Switch to another charset. Might be needed for processing
 binlog with multi-byte charsets.
warnings (\W) Show warnings after every statement.
nowarning (\w) Don't show warnings after every statement.

For server side help, type 'help contents'
```

Each command has both a long and short form. The long form is not case sensitive; the short form is. The long form can be followed by an optional semicolon terminator, but the short form should not.

The use of short-form commands within multi-line `/* ... */` comments is not supported.

- **help [arg], \h [arg], \? [arg], ? [arg]**

Display a help message listing the available `mysql` commands.

If you provide an argument to the `help` command, `mysql` uses it as a search string to access server-side help from the contents of the MySQL Reference Manual. For more information, see [Section 4.5.1.4, “`mysql` Server-Side Help”](#).

- **charset charset\_name, \C charset\_name**

Change the default character set and issue a `SET NAMES` statement. This enables the character set to remain synchronized on the client and server if `mysql` is run with auto-reconnect enabled (which is not recommended), because the specified character set is used for reconnects. This command was added in MySQL 5.1.7.

- **clear, \c**

Clear the current input. Use this if you change your mind about executing the statement that you are entering.

- `connect [db_name host_name]], \r [db_name host_name]`

Reconnect to the server. The optional database name and host name arguments may be given to specify the default database or the host where the server is running. If omitted, the current values are used.

- `delimiter str, \d str`

Change the string that `mysql` interprets as the separator between SQL statements. The default is the semicolon character (“;”).

The delimiter can be specified as an unquoted or quoted argument. Quoting can be done with either single quote (‘) or double quote (“) characters. To include a quote within a quoted string, either quote the string with the other quote character or escape the quote with a backslash (“\”) character. Backslash should be avoided outside of quoted strings because it is the escape character for MySQL. For an unquoted argument, the delimiter is read up to the first space or end of line. For a quoted argument, the delimiter is read up to the matching quote on the line.

When the delimiter recognized by `mysql` is set to something other than the default of “;”, instances of that character are sent to the server without interpretation. However, the server itself still interprets “;” as a statement delimiter and processes statements accordingly. This behavior on the server side comes into play for multiple-statement execution (see [Section 21.9.12, “C API Support for Multiple Statement Execution”](#)), and for parsing the body of stored procedures and functions, triggers, and events (see [Section 19.1, “Defining Stored Programs”](#)).

- `edit, \e`

Edit the current input statement. `mysql` checks the values of the `EDITOR` and `VISUAL` environment variables to determine which editor to use. The default editor is `vi` if neither variable is set.

The `edit` command works only in Unix.

- `ego, \G`

Send the current statement to the server to be executed and display the result using vertical format.

- `exit, \q`

Exit `mysql`.

- `go, \g`

Send the current statement to the server to be executed.

- `nopager, \n`

Disable output paging. See the description for `pager`.

The `nopager` command works only in Unix.

- `notee, \t`

Disable output copying to the tee file. See the description for `tee`.

- `nowarning, \w`

Enable display of warnings after each statement.

- `pager [command], \P [command]`

Enable output paging. By using the `--pager` option when you invoke `mysql`, it is possible to browse or search query results in interactive mode with Unix programs such as `less`, `more`, or any other similar program. If you specify no value for the option, `mysql` checks the value of the `PAGER` environment variable and sets the pager to that. Pager functionality works only in interactive mode.

Output paging can be enabled interactively with the `pager` command and disabled with `nopager`. The command takes an optional argument; if given, the paging program is set to that. With no argument, the pager is set to the pager that was set on the command line, or `stdout` if no pager was specified.

Output paging works only in Unix because it uses the `popen()` function, which does not exist on Windows. For Windows, the `tee` option can be used instead to save query output, although it is not as convenient as `pager` for browsing output in some situations.

- **print, \p**

Print the current input statement without executing it.

- **prompt [str], \R [str]**

Reconfigure the `mysql` prompt to the given string. The special character sequences that can be used in the prompt are described later in this section.

If you specify the `prompt` command with no argument, `mysql` resets the prompt to the default of `mysql>`.

- **quit, \q**

Exit `mysql`.

- **rehash, \#**

Rebuild the completion hash that enables database, table, and column name completion while you are entering statements. (See the description for the `--auto-rehash` option.)

- **source file\_name, \. file\_name**

Read the named file and executes the statements contained therein. On Windows, you can specify path name separators as `/` or `\`.

- **status, \s**

Provide status information about the connection and the server you are using. If you are running in `--safe-updates` mode, `status` also prints the values for the `mysql` variables that affect your queries.

- **system command, \! command**

Execute the given command using your default command interpreter.

The `system` command works only in Unix.

- **tee [file\_name], \T [file\_name]**

By using the `--tee` option when you invoke `mysql`, you can log statements and their output. All the data displayed on the screen is appended into a given file. This can be very useful for debugging purposes also. `mysql` flushes results to the file after each statement, just before it prints its next prompt. Tee functionality works only in interactive mode.

You can enable this feature interactively with the `tee` command. Without a parameter, the previous file is used. The `tee` file can be disabled with the `notee` command. Executing `tee` again re-enables logging.

- **use db\_name, \u db\_name**

Use `db_name` as the default database.

- **warnings, \W**

Enable display of warnings after each statement (if there are any).

Here are a few tips about the `pager` command:

- You can use it to write to a file and the results go only to the file:

```
mysql> pager cat > /tmp/log.txt
```

You can also pass any options for the program that you want to use as your pager:

```
mysql> pager less -n -i -s
```

- In the preceding example, note the `-S` option. You may find it very useful for browsing wide query results. Sometimes a very wide result set is difficult to read on the screen. The `-S` option to `less` can make the result set much more readable because you can scroll it horizontally using the left-arrow and right-arrow keys. You can also use `-S` interactively within `less` to switch the horizontal-browse mode on and off. For more information, read the `less` manual page:

```
shell> man less
```

- The `-F` and `-X` options may be used with `less` to cause it to exit if output fits on one screen, which is convenient when no scrolling is necessary:

```
mysql> pager less -n -i -s -F -X
```

- You can specify very complex pager commands for handling query output:

```
mysql> pager cat | tee /dr1/tmp/res.txt \
 | tee /dr2/tmp/res2.txt | less -n -i -s
```

In this example, the command would send query results to two files in two different directories on two different file systems mounted on `/dr1` and `/dr2`, yet still display the results onscreen using `less`.

You can also combine the `tee` and `pager` functions. Have a `tee` file enabled and `pager` set to `less`, and you are able to browse the results using the `less` program and still have everything appended into a file the same time. The difference between the Unix `tee` used with the `pager` command and the `mysql` built-in `tee` command is that the built-in `tee` works even if you do not have the Unix `tee` available. The built-in `tee` also logs everything that is printed on the screen, whereas the Unix `tee` used with `pager` does not log quite that much. Additionally, `tee` file logging can be turned on and off interactively from within `mysql`. This is useful when you want to log some queries to a file, but not others.

The `prompt` command reconfigures the default `mysql>` prompt. The string for defining the prompt can contain the following special sequences.

| Option           | Description                                                        |
|------------------|--------------------------------------------------------------------|
| <code>\c</code>  | A counter that increments for each statement you issue             |
| <code>\D</code>  | The full current date                                              |
| <code>\d</code>  | The default database                                               |
| <code>\h</code>  | The server host                                                    |
| <code>\l</code>  | The current delimiter (new in 5.1.12)                              |
| <code>\m</code>  | Minutes of the current time                                        |
| <code>\n</code>  | A newline character                                                |
| <code>\o</code>  | The current month in three-letter format (Jan, Feb, ...)           |
| <code>\O</code>  | The current month in numeric format                                |
| <code>\P</code>  | am/pm                                                              |
| <code>\p</code>  | The current TCP/IP port or socket file                             |
| <code>\R</code>  | The current time, in 24-hour military time (0–23)                  |
| <code>\r</code>  | The current time, standard 12-hour time (1–12)                     |
| <code>\s</code>  | Semicolon                                                          |
| <code>\S</code>  | Seconds of the current time                                        |
| <code>\t</code>  | A tab character                                                    |
| <code>\u</code>  | Your full <code>user_name@host_name</code> account name            |
| <code>\u</code>  | Your user name                                                     |
| <code>\v</code>  | The server version                                                 |
| <code>\w</code>  | The current day of the week in three-letter format (Mon, Tue, ...) |
| <code>\y</code>  | The current year, four digits                                      |
| <code>\Y</code>  | The current year, two digits                                       |
| <code>\_</code>  | A space                                                            |
| <code>\_x</code> | A space (a space follows the backslash)                            |
| <code>\'</code>  | Single quote                                                       |
| <code>\"</code>  | Double quote                                                       |
| <code>\\\</code> | A literal “\” backslash character                                  |
| <code>\x</code>  | <code>x</code> , for any “ <code>x</code> ” not listed above       |

You can set the prompt in several ways:

- *Use an environment variable.* You can set the `MYSQL_PS1` environment variable to a prompt string. For example:

```
shell> export MYSQL_PS1="(\u@\h) [\d]> "
```

- *Use a command-line option.* You can set the `--prompt` option on the command line to `mysql`. For example:

```
shell> mysql --prompt="(\u@\h) [\d]> "
(user@host) [database]>
```

- *Use an option file.* You can set the `prompt` option in the `[mysql]` group of any MySQL option file, such as `/etc/my.cnf` or the `.my.cnf` file in your home directory. For example:

```
[mysql]
prompt=(\u@\h) [\d]>_
```

In this example, note that the backslashes are doubled. If you set the prompt using the `prompt` option in an option file, it is advisable to double the backslashes when using the special prompt options. There is some overlap in the set of permissible prompt options and the set of special escape sequences that are recognized in option files. (The rules for escape sequences in option files are listed in [Section 4.2.3.3, “Using Option Files”](#).) The overlap may cause you problems if you use single backslashes. For example, `\s` is interpreted as a space rather than as the current seconds value. The following example shows how to define a prompt within an option file to include the current time in `HH:MM:SS` format:

```
[mysql]
prompt="\r:\\m:\\s> "
```

- *Set the prompt interactively.* You can change your prompt interactively by using the `prompt` (or `\R`) command. For example:

```
mysql> prompt (\u@\h) [\d]__
PROMPT set to '(\u@\h) [\d]__'
(user@host) [database]>
(user@host) [database]> prompt
Returning to default PROMPT of mysql>
mysql>
```

#### 4.5.1.3. `mysql` History File

On Unix, the `mysql` client writes a record of executed statements to a history file. By default, this file is named `.mysql_history` and is created in your home directory. To specify a different file, set the value of the `MYSQL_HISTFILE` environment variable.

The `.mysql_history` should be protected with a restrictive access mode because sensitive information might be written to it, such as the text of SQL statements that contain passwords. See [Section 5.3.2.2, “End-User Guidelines for Password Security”](#).

It is possible to suppress logging of statements to the history file by using the `--batch` or `--execute` option.

If you do not want to maintain a history file, first remove `.mysql_history` if it exists, and then use either of the following techniques:

- Set the `MYSQL_HISTFILE` variable to `/dev/null`. To cause this setting to take effect each time you log in, put the setting in one of your shell's startup files.
- Create `.mysql_history` as a symbolic link to `/dev/null`:

```
shell> ln -s /dev/null $HOME/.mysql_history
```

You need do this only once.

#### 4.5.1.4. `mysql` Server-Side Help

```
mysql> help search_string
```

If you provide an argument to the `help` command, `mysql` uses it as a search string to access server-side help from the contents of the MySQL Reference Manual. The proper operation of this command requires that the help tables in the `mysql` database be initialized with help topic information (see [Section 5.1.8, “Server-Side Help”](#)).

If there is no match for the search string, the search fails:

```
mysql> help me
Nothing found
Please try to run 'help contents' for a list of all accessible topics
```

Use `help contents` to see a list of the help categories:

```
mysql> help contents
You asked for help about help category: "Contents"
For more information, type 'help <item>', where <item> is one of the
following categories:
 Account Management
 Administration
 Data Definition
 Data Manipulation
 Data Types
 Functions
 Functions and Modifiers for Use with GROUP BY
 Geographic Features
 Language Structure
 Plugins
 Storage Engines
 Stored Routines
 Table Maintenance
 Transactions
 Triggers
```

If the search string matches multiple items, `mysql` shows a list of matching topics:

```
mysql> help logs
Many help items for your request exist.
To make a more specific request, please type 'help <item>',
where <item> is one of the following topics:
 SHOW
 SHOW BINARY LOGS
 SHOW ENGINE
 SHOW LOGS
```

Use a topic as the search string to see the help entry for that topic:

```
mysql> help show binary logs
Name: 'SHOW BINARY LOGS'
Description:
Syntax:
SHOW BINARY LOGS
SHOW MASTER LOGS

Lists the binary log files on the server. This statement is used as
part of the procedure described in [purge-binary-logs], that shows how
to determine which logs can be purged.

mysql> SHOW BINARY LOGS;
+-----+-----+
| Log_name | File_size |
+-----+-----+
| binlog.000015 | 724935
| binlog.000016 | 733481
+-----+-----+
```

#### 4.5.1.5. Executing SQL Statements from a Text File

The `mysql` client typically is used interactively, like this:

```
shell> mysql db_name
```

However, it is also possible to put your SQL statements in a file and then tell `mysql` to read its input from that file. To do so, create a text file `text_file` that contains the statements you wish to execute. Then invoke `mysql` as shown here:

```
shell> mysql db_name < text_file
```

If you place a `USE db_name` statement as the first statement in the file, it is unnecessary to specify the database name on the command line:

```
shell> mysql < text_file
```

If you are already running `mysql`, you can execute an SQL script file using the `source` command or `\.` command:

```
mysql> source file_name
```

```
mysql> \. file_name
```

Sometimes you may want your script to display progress information to the user. For this you can insert statements like this:

```
SELECT '<info_to_display>' AS ' ';
```

The statement shown outputs `<info_to_display>`.

You can also invoke `mysql` with the `--verbose` option, which causes each statement to be displayed before the result that it produces.

As of MySQL 5.1.23, `mysql` ignores Unicode byte order mark (BOM) characters at the beginning of input files. Previously, it read them and sent them to the server, resulting in a syntax error. Presence of a BOM does not cause `mysql` to change its default character set. To do that, invoke `mysql` with an option such as `--default-character-set=utf8`.

For more information about batch mode, see [Section 3.5, “Using mysql in Batch Mode”](#).

#### 4.5.1.6. `mysql` Tips

This section describes some techniques that can help you use `mysql` more effectively.

##### 4.5.1.6.1. Displaying Query Results Vertically

Some query results are much more readable when displayed vertically, instead of in the usual horizontal table format. Queries can be displayed vertically by terminating the query with `\G` instead of a semicolon. For example, longer text values that include newlines often are much easier to read with vertical output:

```
mysql> SELECT * FROM mails WHERE LENGTH(txt) < 300 LIMIT 300,1\G
***** 1. row *****
msg_nro: 3068
 date: 2000-03-01 23:29:50
time_zone: +0200
mail_from: Monty
 reply: monty@no.spam.com
 mail_to: "Thimble Smith" <tim@no.spam.com>
 sbj: UTF-8
 txt: >>>> "Thimble" == Thimble Smith writes:
Thimble> Hi. I think this is a good idea. Is anyone familiar
Thimble> with UTF-8 or Unicode? Otherwise, I'll put this on my
Thimble> TODO list and see what happens.
Yes, please do that.

Regards,
Monty
 file: inbox-jani-1
 hash: 190402944
1 row in set (0.09 sec)
```

##### 4.5.1.6.2. Using the `--safe-updates` Option

For beginners, a useful startup option is `--safe-updates` (or `--i-am-a-dummy`, which has the same effect). It is helpful for cases when you might have issued a `DELETE FROM tbl_name` statement but forgotten the `WHERE` clause. Normally, such a statement deletes all rows from the table. With `--safe-updates`, you can delete rows only by specifying the key values that identify them. This helps prevent accidents.

When you use the `--safe-updates` option, `mysql` issues the following statement when it connects to the MySQL server:

```
SET sql_safe_updates=1, sql_select_limit=1000, sql_max_join_size=1000000;
```

See [Section 5.1.4, “Server System Variables”](#).

The `SET` statement has the following effects:

- You are not permitted to execute an `UPDATE` or `DELETE` statement unless you specify a key constraint in the `WHERE` clause or provide a `LIMIT` clause (or both). For example:

```
UPDATE tbl_name SET not_key_column=val WHERE key_column=val;
UPDATE tbl_name SET not_key_column=val LIMIT 1;
```

- The server limits all large `SELECT` results to 1,000 rows unless the statement includes a `LIMIT` clause.

- The server aborts multiple-table `SELECT` statements that probably need to examine more than 1,000,000 row combinations.

To specify limits different from 1,000 and 1,000,000, you can override the defaults by using the `--select_limit` and `--max_join_size` options:

```
shell> mysql --safe-updates --select_limit=500 --max_join_size=10000
```

#### 4.5.1.6.3. Disabling `mysql` Auto-Reconnect

If the `mysql` client loses its connection to the server while sending a statement, it immediately and automatically tries to reconnect once to the server and send the statement again. However, even if `mysql` succeeds in reconnecting, your first connection has ended and all your previous session objects and settings are lost: temporary tables, the autocommit mode, and user-defined and session variables. Also, any current transaction rolls back. This behavior may be dangerous for you, as in the following example where the server was shut down and restarted between the first and second statements without you knowing it:

```
mysql> SET @a=1;
Query OK, 0 rows affected (0.05 sec)

mysql> INSERT INTO t VALUES(@a);
ERROR 2006: MySQL server has gone away
No connection. Trying to reconnect...
Connection id: 1
Current database: test

Query OK, 1 row affected (1.30 sec)

mysql> SELECT * FROM t;
+----+
| a |
+----+
| NULL |
+----+
1 row in set (0.05 sec)
```

The `@a` user variable has been lost with the connection, and after the reconnection it is undefined. If it is important to have `mysql` terminate with an error if the connection has been lost, you can start the `mysql` client with the `--skip-reconnect` option.

For more information about auto-reconnect and its effect on state information when a reconnection occurs, see [Section 21.9.11, “Controlling Automatic Reconnection Behavior”](#).

#### 4.5.2. `mysqladmin` — Client for Administering a MySQL Server

`mysqladmin` is a client for performing administrative operations. You can use it to check the server's configuration and current status, to create and drop databases, and more.

Invoke `mysqladmin` like this:

```
shell> mysqladmin [options] command [command-arg] [command [command-arg]] ...
```

`mysqladmin` supports the following commands. Some of the commands take an argument following the command name.

- `create db_name`

Create a new database named `db_name`.

- `debug`

Tell the server to write debug information to the error log.

Beginning with MySQL 5.1.12, this includes information about the Event Scheduler. See [Section 19.4.5, “Event Scheduler Status”](#).

- `drop db_name`

Delete the database named `db_name` and all its tables.

- `extended-status`

Display the server status variables and their values.

- `flush-hosts`

Flush all information in the host cache.

- **flush-logs**

Flush all logs.

- **flush-privileges**

Reload the grant tables (same as `reload`).

- **flush-status**

Clear status variables.

- **flush-tables**

Flush all tables.

- **flush-threads**

Flush the thread cache.

- **kill *id,id,...***

Kill server threads. If multiple thread ID values are given, there must be no spaces in the list.

- **old-password *new-password***

This is like the `password` command but stores the password using the old (pre-4.1) password-hashing format. (See [Section 5.3.2.3, “Password Hashing in MySQL”](#).)

- **password *new-password***

Set a new password. This changes the password to `new-password` for the account that you use with `mysqladmin` for connecting to the server. Thus, the next time you invoke `mysqladmin` (or any other client program) using the same account, you will need to specify the new password.

If the `new-password` value contains spaces or other characters that are special to your command interpreter, you need to enclose it within quotation marks. On Windows, be sure to use double quotation marks rather than single quotation marks; single quotation marks are not stripped from the password, but rather are interpreted as part of the password. For example:

```
shell> mysqladmin password "my new password"
```

### Caution

Do not use this command used if the server was started with the `--skip-grant-tables` option. No password change will be applied. This is true even if you precede the `password` command with `flush-privileges` on the same command line to re-enable the grant tables because the flush operation occurs after you connect. However, you can use `mysqladmin flush-privileges` to re-enable the grant table and then use a separate `mysqladmin password` command to change the password.

- **ping**

Check whether the server is available. The return status from `mysqladmin` is 0 if the server is running, 1 if it is not. This is 0 even in case of an error such as `Access denied`, because this means that the server is running but refused the connection, which is different from the server not running.

- **processlist**

Show a list of active server threads. This is like the output of the `SHOW PROCESSLIST` statement. If the `--verbose` option is given, the output is like that of `SHOW FULL PROCESSLIST`. (See [Section 12.4.5.31, “SHOW PROCESSLIST Syntax”](#).)

- **reload**

Reload the grant tables.

- **refresh**

Flush all tables and close and open log files.

- **shutdown**  
Stop the server.
- **start-slave**  
Start replication on a slave server.
- **status**  
Display a short server status message.
- **stop-slave**  
Stop replication on a slave server.
- **variables**  
Display the server system variables and their values.
- **version**  
Display version information from the server.

All commands can be shortened to any unique prefix. For example:

```
shell> mysqladmin proc stat
+-----+-----+-----+-----+-----+-----+-----+
| Id | User | Host | db | Command | Time | State | Info
+-----+-----+-----+-----+-----+-----+-----+
| 51 | monty | localhost | | Query | 0 | | show processlist |
+-----+-----+-----+-----+-----+-----+-----+
Uptime: 1473624 Threads: 1 Questions: 39487
Slow queries: 0 Opens: 541 Flush tables: 1
Open tables: 19 Queries per second avg: 0.0268
```

The `mysqladmin status` command result displays the following values:

- **Uptime**  
The number of seconds the MySQL server has been running.
- **Threads**  
The number of active threads (clients).
- **Questions**  
The number of questions (queries) from clients since the server was started.
- **Slow queries**  
The number of queries that have taken more than `long_query_time` seconds. See [Section 5.2.5, “The Slow Query Log”](#).
- **Opens**  
The number of tables the server has opened.
- **Flush tables**  
The number of `flush-*`, `refresh`, and `reload` commands the server has executed.
- **Open tables**  
The number of tables that currently are open.
- **Memory in use**  
The amount of memory allocated directly by `mysqld`. This value is displayed only when MySQL has been compiled with `--with-debug=full`.
- **Maximum memory used**

The maximum amount of memory allocated directly by `mysqld`. This value is displayed only when MySQL has been compiled with `--with-debug=full`.

If you execute `mysqladmin shutdown` when connecting to a local server using a Unix socket file, `mysqladmin` waits until the server's process ID file has been removed, to ensure that the server has stopped properly.

`mysqladmin` supports the following options, which can be specified on the command line or in the `[mysqladmin]` and `[client]` option file groups. `mysqladmin` also supports the options for processing option files described at [Section 4.2.3.3.1, “Command-Line Options that Affect Option-File Handling”](#).

**Table 4.3. `mysqladmin` Options**

| Format                                                                                                  | Config File                        | Description                                                                                                | Introduction | Deprecated | Removed |
|---------------------------------------------------------------------------------------------------------|------------------------------------|------------------------------------------------------------------------------------------------------------|--------------|------------|---------|
| <code>--compress</code>                                                                                 | <code>compress</code>              | Compress all information sent between the client and the server                                            |              |            |         |
| <code>- -con-</code><br><code>nect_timeout=sec</code><br><code>onds</code>                              | <code>connect_timeout</code>       | The number of seconds before connection timeout                                                            |              |            |         |
| <code>--count=#</code>                                                                                  | <code>count</code>                 | The number of iterations to make for repeated command execution                                            |              |            |         |
| <code>- -de-</code><br><code>bug[=debug_optio</code><br><code>ns]</code>                                | <code>debug</code>                 | Write a debugging log                                                                                      |              |            |         |
| <code>--debug-check</code>                                                                              | <code>debug-check</code>           | Print debugging information when the program exits                                                         | 5.1.21       |            |         |
| <code>--debug-info</code>                                                                               | <code>debug-info</code>            | Print debugging information, memory and CPU statistics when the program exits                              | 5.1.14       |            |         |
| <code>- -de-</code><br><code>fault-charac-</code><br><code>ter-</code><br><code>set=charset_name</code> | <code>default-character-set</code> | Use <code>charset_name</code> as the default character set                                                 |              |            |         |
| <code>--force</code>                                                                                    | <code>force</code>                 | Continue even if an SQL error occurs                                                                       |              |            |         |
| <code>--help</code>                                                                                     |                                    | Display help message and exit                                                                              |              |            |         |
| <code>--host=host_name</code>                                                                           | <code>host</code>                  | Connect to the MySQL server on the given host                                                              |              |            |         |
| <code>--no-beep</code>                                                                                  | <code>no-beep</code>               | Do not beep when errors occur                                                                              | 5.1.17       |            |         |
| <code>- -pass-</code><br><code>word[=password]</code>                                                   | <code>password</code>              | The password to use when connecting to the server                                                          |              |            |         |
| <code>--pipe</code>                                                                                     |                                    | On Windows, connect to server using a named pipe                                                           |              |            |         |
| <code>--port=port_num</code>                                                                            | <code>port</code>                  | The TCP/IP port number to use for the connection                                                           |              |            |         |
| <code>--protocol=type</code>                                                                            | <code>protocol</code>              | The connection protocol to use                                                                             |              |            |         |
| <code>--relative</code>                                                                                 | <code>relative</code>              | Show the difference between the current and previous values when used with the <code>--sleep</code> option |              |            |         |
| <code>- -shut-</code><br><code>down_timeout=se</code><br><code>conds</code>                             | <code>shutdown_timeout</code>      | The maximum number of seconds to wait for server shutdown                                                  |              |            |         |
| <code>--silent</code>                                                                                   | <code>silent</code>                | Silent mode                                                                                                |              |            |         |
| <code>--sleep=delay</code>                                                                              | <code>sleep</code>                 | Execute commands repeatedly, sleeping for delay seconds in between                                         |              |            |         |
| <code>--socket=path</code>                                                                              | <code>socket</code>                | For connections to localhost                                                                               |              |            |         |
| <code>- -ssl-ca=file_name</code>                                                                        | <code>ssl-ca</code>                | The path to a file that contains a list of trusted SSL CAs                                                 |              |            |         |
| <code>-</code>                                                                                          | <code>ssl-capath</code>            | The path to a directory that contains trusted SSL                                                          |              |            |         |

| Format                                  | Config File                          | Description                                                                                                            | Introduction | Deprecated | Removed |
|-----------------------------------------|--------------------------------------|------------------------------------------------------------------------------------------------------------------------|--------------|------------|---------|
| <code>-ssl-capath=directory_name</code> |                                      | CA certificates in PEM format                                                                                          |              |            |         |
| <code>-ssl-cert=file_name</code>        | <code>ssl-cert</code>                | The name of the SSL certificate file to use for establishing a secure connection                                       |              |            |         |
| <code>-ssl-cipher=cipher_list</code>    | <code>ssl-cipher</code>              | A list of allowable ciphers to use for SSL encryption                                                                  |              |            |         |
| <code>-ssl-key=file_name</code>         | <code>ssl-key</code>                 | The name of the SSL key file to use for establishing a secure connection                                               |              |            |         |
| <code>-ssl-veri-fy-server-cert</code>   | <code>ssl-veri-fy-server-cert</code> | The server's Common Name value in its certificate is verified against the host name used when connecting to the server |              |            |         |
| <code>--user=user_name,</code>          | <code>user</code>                    | The MySQL user name to use when connecting to the server                                                               |              |            |         |
| <code>--verbose</code>                  |                                      | Verbose mode                                                                                                           |              |            |         |
| <code>--version</code>                  |                                      | Display version information and exit                                                                                   |              |            |         |
| <code>--vertical</code>                 | <code>vertical</code>                | Print query output rows vertically (one line per column value)                                                         |              |            |         |
| <code>--wait</code>                     | <code>wait</code>                    | If the connection cannot be established, wait and retry instead of aborting                                            |              |            |         |

- `--help, -?`

Display a help message and exit.

- `--character-sets-dir=path`

The directory where character sets are installed. See [Section 9.5, “Character Set Configuration”](#).

- `--compress, -C`

Compress all information sent between the client and the server if both support compression.

- `--count=N, -c N`

The number of iterations to make for repeated command execution if the `--sleep` option is given.

- `--debug[=debug_options], -# [debug_options]`

Write a debugging log. A typical `debug_options` string is '`d:t:o,file_name`'. The default is '`d:t:o,/tmp/mysqladmin.trace`'.

- `--debug-check`

Print some debugging information when the program exits. This option was added in MySQL 5.1.21.

- `--debug-info`

Print debugging information and memory and CPU usage statistics when the program exits. This option was added in MySQL 5.1.14.

- `--default-character-set=charset_name`

Use `charset_name` as the default character set. See [Section 9.5, “Character Set Configuration”](#).

- `--force, -f`

Do not ask for confirmation for the `drop db_name` command. With multiple commands, continue even if an error occurs.

- `--host=host_name, -h host_name`

Connect to the MySQL server on the given host.

- `--no-beep, -b`

Suppress the warning beep that is emitted by default for errors such as a failure to connect to the server. This option was added in MySQL 5.1.17.

- `--password[=password], -p[password]`

The password to use when connecting to the server. If you use the short option form (`-p`), you *cannot* have a space between the option and the password. If you omit the `password` value following the `--password` or `-p` option on the command line, `mysqladmin` prompts for one.

Specifying a password on the command line should be considered insecure. See [Section 5.3.2.2, “End-User Guidelines for Password Security”](#). You can use an option file to avoid giving the password on the command line.

- `--pipe, -W`

On Windows, connect to the server using a named pipe. This option applies only if the server supports named-pipe connections.

- `--port=port_num, -P port_num`

The TCP/IP port number to use for the connection.

- `--protocol={TCP|SOCKET|PIPE|MEMORY}`

The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want. For details on the permissible values, see [Section 4.2.2, “Connecting to the MySQL Server”](#).

- `--relative, -r`

Show the difference between the current and previous values when used with the `--sleep` option. Currently, this option works only with the `extended-status` command.

- `--silent, -s`

Exit silently if a connection to the server cannot be established.

- `--sleep=delay, -i delay`

Execute commands repeatedly, sleeping for `delay` seconds in between. The `--count` option determines the number of iterations. If `--count` is not given, `mysqladmin` executes commands indefinitely until interrupted.

- `--socket=path, -S path`

For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

- `--ssl*`

Options that begin with `--ssl` specify whether to connect to the server using SSL and indicate where to find SSL keys and certificates. See [Section 5.5.6.3, “SSL Command Options”](#).

- `--user=user_name, -u user_name`

The MySQL user name to use when connecting to the server.

- `--verbose, -v`

Verbose mode. Print more information about what the program does.

- `--version, -V`

Display version information and exit.

- `--vertical, -E`

Print output vertically. This is similar to `--relative`, but prints output vertically.

- `--wait[=count]`, `-w[count]`

If the connection cannot be established, wait and retry instead of aborting. If a `count` value is given, it indicates the number of times to retry. The default is one time.

You can also set the following variables by using `--var_name=value`. The `--set-variable` format is deprecated and is removed in MySQL 5.5.

- `connect_timeout`

The maximum number of seconds before connection timeout. The default value is 43200 (12 hours).

- `shutdown_timeout`

The maximum number of seconds to wait for server shutdown. The default value is 3600 (1 hour).

### 4.5.3. `mysqlcheck` — A Table Maintenance Program

The `mysqlcheck` client performs table maintenance: It checks, repairs, optimizes, or analyzes tables.

Each table is locked and therefore unavailable to other sessions while it is being processed, although for check operations, the table is locked with a `READ` lock only (see [Section 12.3.5, “LOCK TABLES and UNLOCK TABLES Syntax”](#), for more information about `READ` and `WRITE` locks). Table maintenance operations can be time-consuming, particularly for large tables. If you use the `--databases` or `--all-databases` option to process all tables in one or more databases, an invocation of `mysqlcheck` might take a long time. (This is also true for `mysql_upgrade` because that program invokes `mysqlcheck` to check all tables and repair them if necessary.)

`mysqlcheck` is similar in function to `myisamchk`, but works differently. The main operational difference is that `mysqlcheck` must be used when the `mysqld` server is running, whereas `myisamchk` should be used when it is not. The benefit of using `mysqlcheck` is that you do not have to stop the server to perform table maintenance.

`mysqlcheck` uses the SQL statements `CHECK TABLE`, `REPAIR TABLE`, `ANALYZE TABLE`, and `OPTIMIZE TABLE` in a convenient way for the user. It determines which statements to use for the operation you want to perform, and then sends the statements to the server to be executed. For details about which storage engines each statement works with, see the descriptions for those statements in [Section 12.4.2, “Table Maintenance Statements”](#).

The `MyISAM` storage engine supports all four maintenance operations, so `mysqlcheck` can be used to perform any of them on `MyISAM` tables. Other storage engines do not necessarily support all operations. In such cases, an error message is displayed. For example, if `test.t` is a `MEMORY` table, an attempt to check it produces this result:

```
shell> mysqlcheck test t
test.t
note : The storage engine for the table doesn't support check
```

If `mysqlcheck` is unable to repair a table, see [Section 2.12.4, “Rebuilding or Repairing Tables or Indexes”](#) for manual table repair strategies. This will be the case, for example, for `InnoDB` tables, which can be checked with `CHECK TABLE`, but not repaired with `REPAIR TABLE`.

The use of `mysqlcheck` with partitioned tables is not supported before MySQL 5.1.27.

#### Caution

It is best to make a backup of a table before performing a table repair operation; under some circumstances the operation might cause data loss. Possible causes include but are not limited to file system errors.

There are three general ways to invoke `mysqlcheck`:

```
shell> mysqlcheck [options] db_name [tbl_name ...]
shell> mysqlcheck [options] --databases db_name ...
shell> mysqlcheck [options] --all-databases
```

If you do not name any tables following `db_name` or if you use the `--databases` or `--all-databases` option, entire databases are checked.

`mysqlcheck` has a special feature compared to other client programs. The default behavior of checking tables (`--check`) can be

changed by renaming the binary. If you want to have a tool that repairs tables by default, you should just make a copy of `mysqlcheck` named `mysqlrepair`, or make a symbolic link to `mysqlcheck` named `mysqlrepair`. If you invoke `mysqlrepair`, it repairs tables.

The following names can be used to change `mysqlcheck` default behavior.

|                            |                                               |
|----------------------------|-----------------------------------------------|
| <code>mysqlrepair</code>   | The default option is <code>--repair</code>   |
| <code>mysqlanalyze</code>  | The default option is <code>--analyze</code>  |
| <code>mysqloptimize</code> | The default option is <code>--optimize</code> |

`mysqlcheck` supports the following options, which can be specified on the command line or in the `[mysqlcheck]` and `[client]` option file groups. `mysqlcheck` also supports the options for processing option files described at [Section 4.2.3.3.1, “Command-Line Options that Affect Option-File Handling”](#).

**Table 4.4. `mysqlcheck` Options**

| Format                                                  | Config File                          | Description                                                                               | Introduction | Deprecated | Removed |
|---------------------------------------------------------|--------------------------------------|-------------------------------------------------------------------------------------------|--------------|------------|---------|
| <code>--all-databases</code>                            | <code>all-databases</code>           | Check all tables in all databases                                                         |              |            |         |
| <code>--all-in-1</code>                                 | <code>all-in-1</code>                | Execute a single statement for each database that names all the tables from that database |              |            |         |
| <code>--analyze</code>                                  | <code>analyze</code>                 | Analyze the tables                                                                        |              |            |         |
| <code>--auto-repair</code>                              | <code>auto-repair</code>             | If a checked table is corrupted, automatically fix it                                     |              |            |         |
| <code>- -charac- ter-sets-dir=path</code>               | <code>character-sets-dir</code>      | The directory where character sets are installed                                          |              |            |         |
| <code>--check</code>                                    | <code>check</code>                   | Check the tables for errors                                                               |              |            |         |
| <code>- -check- only-changed</code>                     | <code>check- only-changed</code>     | Check only tables that have changed since the last check                                  |              |            |         |
| <code>--check-upgrade</code>                            | <code>check-upgrade</code>           | Invoke CHECK TABLE with the FOR UPGRADE option                                            | 5.1.7        |            |         |
| <code>--compress</code>                                 | <code>compress</code>                | Compress all information sent between the client and the server                           |              |            |         |
| <code>--databases</code>                                | <code>databases</code>               | Process all tables in the named databases                                                 |              |            |         |
| <code>- -de- bug[=debug_optio ns]</code>                | <code>debug</code>                   | Write a debugging log                                                                     |              |            |         |
| <code>--debug-check</code>                              | <code>debug-check</code>             | Print debugging information when the program exits                                        | 5.1.21       |            |         |
| <code>--debug-info</code>                               | <code>debug-info</code>              | Print debugging information, memory and CPU statistics when the program exits             | 5.1.14       |            |         |
| <code>- -de- fault-charac- ter- set=charset_name</code> | <code>default-charac- ter-set</code> | Use <code>charset_name</code> as the default character set                                |              |            |         |
| <code>--extended</code>                                 | <code>extended</code>                | Check and repair tables                                                                   |              |            |         |
| <code>--fast</code>                                     | <code>fast</code>                    | Check only tables that have not been closed properly                                      |              |            |         |
| <code>--fix-db-names</code>                             | <code>fix-db-names</code>            | Convert database names to 5.1 format                                                      | 5.1.7        |            |         |
| <code>--fix-table-names</code>                          | <code>fix-table-names</code>         | Convert table names to 5.1 format                                                         | 5.1.7        |            |         |
| <code>--force</code>                                    | <code>force</code>                   | Continue even if an SQL error occurs                                                      |              |            |         |
| <code>--help</code>                                     |                                      | Display help message and exit                                                             |              |            |         |
| <code>--host=host_name</code>                           | <code>host</code>                    | Connect to the MySQL server on the given host                                             |              |            |         |
| <code>--medium-check</code>                             | <code>medium-check</code>            | Do a check that is faster than an --extended opera-                                       |              |            |         |

| Format                                  | Config File                 | Description                                                                                                              | Introduction | Deprecated | Removed |
|-----------------------------------------|-----------------------------|--------------------------------------------------------------------------------------------------------------------------|--------------|------------|---------|
| --optimize                              | optimize                    | Optimize the tables                                                                                                      |              |            |         |
| -<br>-pass-<br>word[=password]          | password                    | The password to use when connecting to the server                                                                        |              |            |         |
| --pipe                                  |                             | On Windows, connect to server using a named pipe                                                                         |              |            |         |
| --port=port_num                         | port                        | The TCP/IP port number to use for the connection                                                                         |              |            |         |
| --protocol=type                         | protocol                    | The connection protocol to use                                                                                           |              |            |         |
| --quick                                 | quick                       | The fastest method of checking                                                                                           |              |            |         |
| --repair                                | repair                      | Perform a repair that can fix almost anything except unique keys that are not unique                                     |              |            |         |
| --silent                                | silent                      | Silent mode                                                                                                              |              |            |         |
| --socket=path                           | socket                      | For connections to localhost                                                                                             |              |            |         |
| -<br>-ssl-ca=file_name                  | ssl-ca                      | The path to a file that contains a list of trusted SSL CAs                                                               |              |            |         |
| -<br>-ssl-<br>capath=directory_<br>name | ssl-capath                  | The path to a directory that contains trusted SSL CA certificates in PEM format                                          |              |            |         |
| -<br>-ssl-<br>cert=file_name            | ssl-cert                    | The name of the SSL certificate file to use for establishing a secure connection                                         |              |            |         |
| -<br>-ssl-<br>cipher=cipher_list        | ssl-cipher                  | A list of allowable ciphers to use for SSL encryption                                                                    |              |            |         |
| -<br>-ssl-key=file_name                 | ssl-key                     | The name of the SSL key file to use for establishing a secure connection                                                 |              |            |         |
| -<br>-ssl-veri-<br>fy-server-cert       | ssl-veri-<br>fy-server-cert | The server's Common Name value in its certificate is verified against the host name used when connecting to the server   |              |            |         |
| --tables                                | tables                      | Overrides the --databases or -B option                                                                                   |              |            |         |
| --usefrm                                | usefrm                      | For repair operations on MyISAM tables                                                                                   |              |            |         |
| -<br>-user=user_name,                   | user                        | The MySQL user name to use when connecting to the server                                                                 |              |            |         |
| --verbose                               |                             | Verbose mode                                                                                                             |              |            |         |
| --version                               |                             | Display version information and exit                                                                                     |              |            |         |
| --write-binlog                          | write-binlog                | Log ANALYZE, OPTIMIZE, REPAIR statements to binary log. --skip-write-binlog adds NO_WRITE_TO_BINLOG to these statements. | 5.1.18       |            |         |

- **--help, -?**

Display a help message and exit.

- **--all-databases, -A**

Check all tables in all databases. This is the same as using the **--databases** option and naming all the databases on the command line.

- **--all-in-1, -1**

Instead of issuing a statement for each table, execute a single statement for each database that names all the tables from that

database to be processed.

- **--analyze, -a**

Analyze the tables.

- **--auto-repair**

If a checked table is corrupted, automatically fix it. Any necessary repairs are done after all tables have been checked.

- **--character-sets-dir=path**

The directory where character sets are installed. See [Section 9.5, “Character Set Configuration”](#).

- **--check, -c**

Check the tables for errors. This is the default operation.

- **--check-only-changed, -C**

Check only tables that have changed since the last check or that have not been closed properly.

- **--check-upgrade, -g**

Invoke `CHECK TABLE` with the `FOR UPGRADE` option to check tables for incompatibilities with the current version of the server. This option automatically enables the `--fix-db-names` and `--fix-table-names` options. `--check-upgrade` was added in MySQL 5.1.7.

- **--compress**

Compress all information sent between the client and the server if both support compression.

- **--databases, -B**

Process all tables in the named databases. Normally, `mysqlcheck` treats the first name argument on the command line as a database name and following names as table names. With this option, it treats all name arguments as database names.

- **--debug[=debug\_options], -# [debug\_options]**

Write a debugging log. A typical `debug_options` string is '`d:t:o,file_name`'. The default is '`d:t:o`'.

- **--debug-check**

Print some debugging information when the program exits. This option was added in MySQL 5.1.21.

- **--debug-info**

Print debugging information and memory and CPU usage statistics when the program exits. This option was added in MySQL 5.1.14.

- **--default-character-set=charset\_name**

Use `charset_name` as the default character set. See [Section 9.5, “Character Set Configuration”](#).

- **--extended, -e**

If you are using this option to check tables, it ensures that they are 100% consistent but takes a long time.

If you are using this option to repair tables, it runs an extended repair that may not only take a long time to execute, but may produce a lot of garbage rows also!

- **--fast, -F**

Check only tables that have not been closed properly.

- **--fix-db-names**

Convert database names to 5.1 format. Only database names that contain special characters are affected. This option was added in MySQL 5.1.7.

- **--fix-table-names**

Convert table names to 5.1 format. Only table names that contain special characters are affected. This option was added in MySQL 5.1.7. As of MySQL 5.1.23, this option also applies to views.

- **--force, -f**

Continue even if an SQL error occurs.

- **--host=host\_name, -h host\_name**

Connect to the MySQL server on the given host.

- **--medium-check, -m**

Do a check that is faster than an **--extended** operation. This finds only 99.99% of all errors, which should be good enough in most cases.

- **--optimize, -o**

Optimize the tables.

- **--password[=password], -p[password]**

The password to use when connecting to the server. If you use the short option form (**-p**), you *cannot* have a space between the option and the password. If you omit the **password** value following the **--password** or **-p** option on the command line, **mysqlcheck** prompts for one.

Specifying a password on the command line should be considered insecure. See [Section 5.3.2.2, “End-User Guidelines for Password Security”](#). You can use an option file to avoid giving the password on the command line.

- **--pipe, -W**

On Windows, connect to the server using a named pipe. This option applies only if the server supports named-pipe connections.

- **--port=port\_num, -P port\_num**

The TCP/IP port number to use for the connection.

- **--protocol={TCP|SOCKET|PIPE|MEMORY}**

The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want. For details on the permissible values, see [Section 4.2.2, “Connecting to the MySQL Server”](#).

- **--quick, -q**

If you are using this option to check tables, it prevents the check from scanning the rows to check for incorrect links. This is the fastest check method.

If you are using this option to repair tables, it tries to repair only the index tree. This is the fastest repair method.

- **--repair, -r**

Perform a repair that can fix almost anything except unique keys that are not unique.

- **--silent, -s**

Silent mode. Print only error messages.

- **--socket=path, -S path**

For connections to **localhost**, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

- **--ssl\***

Options that begin with **--ssl** specify whether to connect to the server using SSL and indicate where to find SSL keys and certificates. See [Section 5.5.6.3, “SSL Command Options”](#).

- **--tables**

Override the **--databases** or **-B** option. All name arguments following the option are regarded as table names.

- `--usefrm`

For repair operations on `MyISAM` tables, get the table structure from the `.frm` file so that the table can be repaired even if the `.MYI` header is corrupted.

- `--user=user_name, -u user_name`

The MySQL user name to use when connecting to the server.

- `--verbose, -v`

Verbose mode. Print information about the various stages of program operation.

- `--version, -V`

Display version information and exit.

- `--write-binlog`

This option is enabled by default, so that `ANALYZE TABLE`, `OPTIMIZE TABLE`, and `REPAIR TABLE` statements generated by `mysqlcheck` are written to the binary log. Use `--skip-write-binlog` to cause `NO_WRITE_TO_BINLOG` to be added to the statements so that they are not logged. Use the `--skip-write-binlog` when these statements should not be sent to replication slaves or run when using the binary logs for recovery from backup. This option was added in MySQL 5.1.18.

#### 4.5.4. `mysqldump` — A Database Backup Program

The `mysqldump` client is a backup program originally written by Igor Romanenko. It can be used to dump a database or a collection of databases for backup or transfer to another SQL server (not necessarily a MySQL server). The dump typically contains SQL statements to create the table, populate it, or both. However, `mysqldump` can also be used to generate files in CSV, other delimited text, or XML format.

If you are doing a backup on the server and your tables all are `MyISAM` tables, consider using the `mysqlhotcopy` instead because it can accomplish faster backups and faster restores. See [Section 4.6.9, “`mysqlhotcopy` — A Database Backup Program”](#).

There are three general ways to invoke `mysqldump`:

```
shell> mysqldump [options] db_name [tbl_name ...]
shell> mysqldump [options] --databases db_name ...
shell> mysqldump [options] --all-databases
```

If you do not name any tables following `db_name` or if you use the `--databases` or `--all-databases` option, entire databases are dumped.

`mysqldump` does not dump the `INFORMATION_SCHEMA` database by default. As of MySQL 5.1.38, `mysqldump` dumps `INFORMATION_SCHEMA` if you name it explicitly on the command line, although currently you must also use the `--skip-lock-tables` option. Before 5.1.38, `mysqldump` silently ignores `INFORMATION_SCHEMA` even if you name it explicitly on the command line.

In MySQL Cluster NDB 7.1.7 and later, the `ndbinfo` information database is ignored and not dumped by `mysqldump`.

To see a list of the options your version of `mysqldump` supports, execute `mysqldump --help`.

Some `mysqldump` options are shorthand for groups of other options:

- Use of `--opt` is the same as specifying `--add-drop-table`, `--add-locks`, `--create-options`, `--disable-keys`, `--extended-insert`, `--lock-tables`, `--quick`, and `--set-charset`. All of the options that `--opt` stands for also are on by default because `--opt` is on by default.
- Use of `--compact` is the same as specifying `--skip-add-drop-table`, `--skip-add-locks`, `--skip-comments`, `--skip-disable-keys`, and `--skip-set-charset` options.

To reverse the effect of a group option, uses its `--skip-xxx` form (`--skip-opt` or `--skip-compact`). It is also possible to select only part of the effect of a group option by following it with options that enable or disable specific features. Here are some examples:

- To select the effect of `--opt` except for some features, use the `--skip` option for each feature. To disable extended inserts and memory buffering, use `--opt --skip-extended-insert --skip-quick`. (Actually, `--`

`--skip-extended-insert --skip-quick` is sufficient because `--opt` is on by default.)

- To reverse `--opt` for all features except index disabling and table locking, use `--skip-opt --disable-keys --lock-tables`.

When you selectively enable or disable the effect of a group option, order is important because options are processed first to last. For example, `--disable-keys --lock-tables --skip-opt` would not have the intended effect; it is the same as `--skip-opt` by itself.

`mysqldump` can retrieve and dump table contents row by row, or it can retrieve the entire content from a table and buffer it in memory before dumping it. Buffering in memory can be a problem if you are dumping large tables. To dump tables row by row, use the `--quick` option (or `--opt`, which enables `--quick`). The `--opt` option (and hence `--quick`) is enabled by default, so to enable memory buffering, use `--skip-quick`.

If you are using a recent version of `mysqldump` to generate a dump to be reloaded into a very old MySQL server, you should not use the `--opt` or `--extended-insert` option. Use `--skip-opt` instead.

### Note

`mysqldump` from MySQL 5.1.21 cannot be used to create dumps from MySQL server 5.1.20 and older. This issue is fixed in MySQL 5.1.22. ([Bug#30123](#))

`mysqldump` supports the following options, which can be specified on the command line or in the `[mysqldump]` and `[client]` option file groups. `mysqldump` also supports the options for processing option files described at [Section 4.2.3.3.1, “Command-Line Options that Affect Option-File Handling”](#).

**Table 4.5. `mysqldump` Options**

| Format                                                                                                          | Config File                    | Description                                                                                           | Introduction     | Deprecated | Removed |
|-----------------------------------------------------------------------------------------------------------------|--------------------------------|-------------------------------------------------------------------------------------------------------|------------------|------------|---------|
| <code>-</code><br><code>-</code><br><code>add-drop-database</code>                                              | <code>add-drop-database</code> | Add a <code>DROP DATABASE</code> statement before each <code>CREATE DATABASE</code> statement         |                  |            |         |
| <code>--add-drop-table</code>                                                                                   | <code>add-drop-table</code>    | Add a <code>DROP TABLE</code> statement before each <code>CREATE TABLE</code> statement               |                  |            |         |
| <code>--add-drop-trigger</code>                                                                                 | <code>add-drop-trigger</code>  | Add a <code>DROP TRIGGER</code> statement before each <code>CREATE TRIGGER</code> statement           | 5.1.47-ndb-7.1.8 |            |         |
| <code>--add-locks</code>                                                                                        | <code>add-locks</code>         | Surround each table dump with <code>LOCK TABLES</code> and <code>UNLOCK TABLES</code> statements      |                  |            |         |
| <code>--all-databases</code>                                                                                    | <code>all-databases</code>     | Dump all tables in all databases                                                                      |                  |            |         |
| <code>--all-tablespaces</code>                                                                                  | <code>all-tablespaces</code>   | Adds to a table dump all SQL statements needed to create any tablespaces used by an NDB Cluster table | 5.1.6            |            |         |
| <code>--allow-keywords</code>                                                                                   | <code>allow-keywords</code>    | Allow creation of column names that are keywords                                                      |                  |            |         |
| <code>--comments</code>                                                                                         | <code>comments</code>          | Add comments to the dump file                                                                         |                  |            |         |
| <code>--compact</code>                                                                                          | <code>compact</code>           | Produce more compact output                                                                           |                  |            |         |
| <code>-</code><br><code>-com-</code><br><code>pat-</code><br><code>ible=name[,name,</code><br><code>...]</code> | <code>compatible</code>        | Produce output that is more compatible with other database systems or with older MySQL servers        |                  |            |         |
| <code>--complete-insert</code>                                                                                  | <code>complete-insert</code>   | Use complete <code>INSERT</code> statements that include column names                                 |                  |            |         |
| <code>--create-options</code>                                                                                   | <code>create-options</code>    | Include all MySQL-specific table options in <code>CREATE TABLE</code> statements                      |                  |            |         |
| <code>--databases</code>                                                                                        | <code>databases</code>         | Dump several databases                                                                                |                  |            |         |
| <code>-</code><br><code>-de-</code><br><code>bug[=debug_optio-</code><br><code>ns]</code>                       | <code>debug</code>             | Write a debugging log                                                                                 |                  |            |         |
| <code>--debug-check</code>                                                                                      | <code>debug-check</code>       | Print debugging information when the program exits                                                    | 5.1.21           |            |         |

| <b>Format</b>                              | <b>Config File</b>             | <b>Description</b>                                                                                                  | <b>Introduction</b> | <b>Deprecated</b> | <b>Removed</b> |
|--------------------------------------------|--------------------------------|---------------------------------------------------------------------------------------------------------------------|---------------------|-------------------|----------------|
| --debug-info                               | debug-info                     | Print debugging information, memory and CPU statistics when the program exits                                       | 5.1.14              |                   |                |
| - -de-fault-character-set=charset_name     | default-character-set          | Use charset_name as the default character set                                                                       |                     |                   |                |
| --delayed-insert                           | delayed-insert                 | Write INSERT DELAYED statements rather than INSERT statements                                                       |                     |                   |                |
| - -de-lete-master-logs                     | delete-master-logs             | On a master replication server, delete the binary logs after performing the dump operation                          |                     |                   |                |
| --disable-keys                             | disable-keys                   | For each table, surround the INSERT statements with statements to disable and enable keys                           |                     |                   |                |
| --dump-date                                | dump-date                      | Include dump date as "Dump completed on" comment if --comments is given                                             | 5.1.23              |                   |                |
| --events                                   | events                         | Dump events from the dumped databases                                                                               | 5.1.8               |                   |                |
| --extended-insert                          | extended-insert                | Use multiple-row INSERT syntax that include several VALUES lists                                                    |                     |                   |                |
| - - fields-en-closed-by=string             | fields-enclosed-by             | This option is used with the --tab option and has the same meaning as the corresponding clause for LOAD DATA INFILE |                     |                   |                |
| - - fields-escaped-by                      | fields-escaped-by              | This option is used with the --tab option and has the same meaning as the corresponding clause for LOAD DATA INFILE |                     |                   |                |
| - - fields-option-ally-en-closed-by=string | fields-option-ally-enclosed-by | This option is used with the --tab option and has the same meaning as the corresponding clause for LOAD DATA INFILE |                     |                   |                |
| - - fields-terminated-by=string            | fields-terminated-by           | This option is used with the --tab option and has the same meaning as the corresponding clause for LOAD DATA INFILE |                     |                   |                |
| --first-slave                              | first-slave                    | Deprecated; use --lock-all-tables instead                                                                           |                     |                   |                |
| --flush-logs                               | flush-logs                     | Flush the MySQL server log files before starting the dump                                                           |                     |                   |                |
| --flush-privileges                         | flush-privileges               | Emit a FLUSH PRIVILEGES statement after dumping the mysql database                                                  |                     |                   |                |
| --help                                     |                                | Display help message and exit                                                                                       |                     |                   |                |
| --hex-blob                                 | hex-blob                       | Dump binary columns using hexadecimal notation (for example, 'abc' becomes 0x616263)                                |                     |                   |                |
| --host                                     | host                           | Host to connect to (IP address or hostname)                                                                         |                     |                   |                |
| - -ig-nore-ta-ble=db_name.tbl_name         | ignore-table                   | Do not dump the given table                                                                                         |                     |                   |                |
| --insert-ignore                            | insert-ignore                  | Write INSERT IGNORE statements rather than INSERT statements                                                        |                     |                   |                |
| - - lines-terminated-by=string             | lines-terminated-by            | This option is used with the --tab option and has the same meaning as the corresponding clause for LOAD DATA INFILE |                     |                   |                |
| --lock-all-tables                          | lock-all-tables                | Lock all tables across all databases                                                                                |                     |                   |                |
| --lock-tables                              | lock-tables                    | Lock all tables before dumping them                                                                                 |                     |                   |                |
| -                                          | log-error                      | Append warnings and errors to the named file                                                                        | 5.1.18              |                   |                |

| Format                                  | Config File         | Description                                                                                                                       | Introduction | Deprecated | Removed |
|-----------------------------------------|---------------------|-----------------------------------------------------------------------------------------------------------------------------------|--------------|------------|---------|
| <code>-log-error=file_name</code>       |                     |                                                                                                                                   |              |            |         |
| <code>--master-data[=value]</code>      | master-data         | Write the binary log file name and position to the output                                                                         |              |            |         |
| <code>--max_allowed_packet=value</code> | max_allowed_packet  | The maximum packet length to send to or receive from the server                                                                   |              |            |         |
| <code>--net_buffer_length=value</code>  | net_buffer_length   | The buffer size for TCP/IP and socket communication                                                                               |              |            |         |
| <code>--no-autocommit</code>            | no-autocommit       | Enclose the INSERT statements for each dumped table within SET autocommit = 0 and COMMIT statements                               |              |            |         |
| <code>--no-create-db</code>             | no-create-db        | This option suppresses the CREATE DATABASE statements                                                                             |              |            |         |
| <code>--no-create-info</code>           | no-create-info      | Do not write CREATE TABLE statements that re-create each dumped table                                                             |              |            |         |
| <code>--no-data</code>                  | no-data             | Do not dump table contents                                                                                                        |              |            |         |
| <code>--no-set-names</code>             | no-set-names        | Same as --skip-set-charset                                                                                                        |              |            |         |
| <code>--no-tablespaces</code>           | no-tablespaces      | Do not write any CREATE LOGFILE GROUP or CREATE TABLESPACE statements in output                                                   | 5.1.14       |            |         |
| <code>--opt</code>                      | opt                 | Shorthand for --add-drop-table --add-locks --create-options --disable-keys --extended-insert --lock-tables --quick --set-charset. |              |            |         |
| <code>--order-by-primary</code>         | order-by-primary    | Dump each table's rows sorted by its primary key, or by its first unique index                                                    |              |            |         |
| <code>--password[=password]</code>      | password            | The password to use when connecting to the server                                                                                 |              |            |         |
| <code>--pipe</code>                     |                     | On Windows, connect to server using a named pipe                                                                                  |              |            |         |
| <code>--port=port_num</code>            | port                | The TCP/IP port number to use for the connection                                                                                  |              |            |         |
| <code>--quick</code>                    | quick               | Retrieve rows for a table from the server a row at a time                                                                         |              |            |         |
| <code>--quote-names</code>              | quote-names         | Quote identifiers within backtick characters                                                                                      |              |            |         |
| <code>--replace</code>                  | replace             | Write REPLACE statements rather than INSERT statements                                                                            | 5.1.3        |            |         |
| <code>--result-file=file</code>         | result-file         | Direct output to a given file                                                                                                     |              |            |         |
| <code>--routines</code>                 | routines            | Dump stored routines (procedures and functions) from the dumped databases                                                         | 5.1.2        |            |         |
| <code>--set-charset</code>              | set-charset         | Add SET NAMES default_character_set to the output                                                                                 |              |            |         |
| <code>--single-transaction</code>       | single-transaction  | This option issues a BEGIN SQL statement before dumping data from the server                                                      |              |            |         |
| <code>--skip-add-drop-table</code>      | skip-add-drop-table | Do not add a DROP TABLE statement before each CREATE TABLE statement                                                              |              |            |         |
| <code>--skip-add-locks</code>           | skip-add-locks      | Do not add locks                                                                                                                  |              |            |         |
| <code>--skip-comments</code>            | skip-comments       | Do not add comments to the dump file                                                                                              |              |            |         |
| <code>--skip-compact</code>             | skip-compact        | Do not produce more compact output                                                                                                |              |            |         |
| <code>--skip-disable-keys</code>        | skip-disable-keys   | Do not disable keys                                                                                                               |              |            |         |

| Format                          | Config File             | Description                                                                                                            | Introduction | Deprecated | Removed |
|---------------------------------|-------------------------|------------------------------------------------------------------------------------------------------------------------|--------------|------------|---------|
| -<br>-<br>skip-extended-insert  | skip-extended-insert    | Turn off extended-insert                                                                                               |              |            |         |
| --skip-opt                      | skip-opt                | Turn off the options set by --opt                                                                                      |              |            |         |
| --skip-quick                    | skip-quick              | Do not retrieve rows for a table from the server a row at a time                                                       |              |            |         |
| -<br>-skip-quote-names          | skip-quote-names        | Do not quote identifiers                                                                                               |              |            |         |
| --skip-set-charset              | skip-set-charset        | Suppress the SET NAMES statement                                                                                       |              |            |         |
| --skip-triggers                 | skip-triggers           | Do not dump triggers                                                                                                   |              |            |         |
| --skip-tz-utc                   | skip-tz-utc             | Turn off tz-utc                                                                                                        | 5.1.2        |            |         |
| -<br>-ssl-ca=file_name          | ssl-ca                  | The path to a file that contains a list of trusted SSL CAs                                                             |              |            |         |
| -<br>-ssl-capath=directory_name | ssl-capath              | The path to a directory that contains trusted SSL CA certificates in PEM format                                        |              |            |         |
| -<br>-ssl-cert=file_name        | ssl-cert                | The name of the SSL certificate file to use for establishing a secure connection                                       |              |            |         |
| -<br>-ssl-cipher=cipher_list    | ssl-cipher              | A list of allowable ciphers to use for SSL encryption                                                                  |              |            |         |
| -<br>-ssl-key=file_name         | ssl-key                 | The name of the SSL key file to use for establishing a secure connection                                               |              |            |         |
| -<br>-ssl-veri-fy-server-cert   | ssl-veri-fy-server-cert | The server's Common Name value in its certificate is verified against the host name used when connecting to the server |              |            |         |
| --tab=path                      | tab                     | Produce tab-separated data files                                                                                       |              |            |         |
| --tables                        | tables                  | Override the --databases or -B option                                                                                  |              |            |         |
| --triggers                      | triggers                | Dump triggers for each dumped table                                                                                    |              |            |         |
| --tz-utc                        | tz-utc                  | Add SET TIME_ZONE='+00:00' to the dump file                                                                            | 5.1.2        |            |         |
| --verbose                       |                         | Verbose mode                                                                                                           |              |            |         |
| --version                       |                         | Display version information and exit                                                                                   |              |            |         |
| -<br>-where='where_condition'   | where                   | Dump only rows selected by the given WHERE condition                                                                   |              |            |         |
| --xml                           | xml                     | Produce XML output                                                                                                     |              |            |         |

- `--help, -?`

Display a help message and exit.

- `--add-drop-database`

Add a `DROP DATABASE` statement before each `CREATE DATABASE` statement. This option is typically used in conjunction with the `--all-databases` or `--databases` option because no `CREATE DATABASE` statements are written unless one of those options is specified.

- `--add-drop-table`

Add a `DROP TABLE` statement before each `CREATE TABLE` statement.

- `--add-drop-trigger`

Add a `DROP TRIGGER` statement before each `CREATE TRIGGER` statement.

### Note

This option is supported only by `mysqldump` as supplied with MySQL Cluster NDB 6.3.38, MySQL Cluster NDB 7.0.19, MySQL Cluster NDB 7.1.8, and later MySQL Cluster release. It is not available when using MySQL 5.1.

- `--add-locks`

Surround each table dump with `LOCK TABLES` and `UNLOCK TABLES` statements. This results in faster inserts when the dump file is reloaded. See [Section 7.3.2.1, “Speed of INSERT Statements”](#).

- `--all-databases, -A`

Dump all tables in all databases. This is the same as using the `--databases` option and naming all the databases on the command line.

- `--all-tablespaces, -Y`

Adds to a table dump all SQL statements needed to create any tablespaces used by an `NDBCLUSTER` table. This information is not otherwise included in the output from `mysqldump`. This option is currently relevant only to MySQL Cluster tables.

This option was added in MySQL 5.1.6.

- `--allow-keywords`

Permit creation of column names that are keywords. This works by prefixing each column name with the table name.

- `--character-sets-dir=path`

The directory where character sets are installed. See [Section 9.5, “Character Set Configuration”](#).

- `--comments, -i`

Write additional information in the dump file such as program version, server version, and host. This option is enabled by default. To suppress this additional information, use `--skip-comments`.

- `--compact`

Produce more compact output. This option enables the `--skip-add-drop-table`, `--skip-add-locks`, `--skip-comments`, `--skip-disable-keys`, and `--skip-set-charset` options.

### Note

Prior to MySQL 5.1.21, this option did not create valid SQL if the database dump contained views. The recreation of views requires the creation and removal of temporary tables and this option suppressed the removal of those temporary tables. As a workaround, use `--compact` with the `--add-drop-table` option and then manually adjust the dump file.

- `--compatible=name`

Produce output that is more compatible with other database systems or with older MySQL servers. The value of `name` can be `ansi`, `mysql323`, `mysql40`, `postgresql`, `oracle`, `mssql`, `db2`, `maxdb`, `no_key_options`, `no_table_options`, or `no_field_options`. To use several values, separate them by commas. These values have the same meaning as the corresponding options for setting the server SQL mode. See [Section 5.1.7, “Server SQL Modes”](#).

This option does not guarantee compatibility with other servers. It only enables those SQL mode values that are currently available for making dump output more compatible. For example, `--compatible=oracle` does not map data types to Oracle types or use Oracle comment syntax.

*This option requires a server version of 4.1.0 or higher.* With older servers, it does nothing.

- `--complete-insert, -c`

Use complete `INSERT` statements that include column names.

- **--compress, -C**

Compress all information sent between the client and the server if both support compression.

- **--create-options**

Include all MySQL-specific table options in the `CREATE TABLE` statements.

- **--databases, -B**

Dump several databases. Normally, `mysqldump` treats the first name argument on the command line as a database name and following names as table names. With this option, it treats all name arguments as database names. `CREATE DATABASE` and `USE` statements are included in the output before each new database.

- **--debug[=debug\_options], -# [debug\_options]**

Write a debugging log. A typical `debug_options` string is '`d:t:o,file_name`'. The default value is '`d:t:o,/tmp/mysqldump.trace`'.

- **--debug-check**

Print some debugging information when the program exits. This option was added in MySQL 5.1.21.

- **--debug-info**

Print debugging information and memory and CPU usage statistics when the program exits. This option was added in MySQL 5.1.14.

- **--default-character-set=charset\_name**

Use `charset_name` as the default character set. See [Section 9.5, “Character Set Configuration”](#). If no character set is specified, `mysqldump` uses `utf8`, and earlier versions use `latin1`.

Prior to MySQL 5.1.38, this option has no effect for output data files produced by using the `--tab` option. See the description for that option.

- **--delayed-insert**

Write `INSERT DELAYED` statements rather than `INSERT` statements.

- **--delete-master-logs**

On a master replication server, delete the binary logs by sending a `PURGE BINARY LOGS` statement to the server after performing the dump operation. This option automatically enables `--master-data`.

- **--disable-keys, -K**

For each table, surround the `INSERT` statements with `/*!40000 ALTER TABLE tbl_name DISABLE KEYS */;` and `/*!40000 ALTER TABLE tbl_name ENABLE KEYS */;` statements. This makes loading the dump file faster because the indexes are created after all rows are inserted. This option is effective only for nonunique indexes of `MyISAM` tables.

- **--dump-date**

If the `--comments` option is given, `mysqldump` produces a comment at the end of the dump of the following form:

```
-- Dump completed on DATE
```

However, the date causes dump files taken at different times to appear to be different, even if the data are otherwise identical. `--dump-date` and `--skip-dump-date` control whether the date is added to the comment. The default is `--dump-date` (include the date in the comment). `--skip-dump-date` suppresses date printing. This option was added in MySQL 5.1.23.

- **--events, -E**

Include Event Scheduler events for the dumped databases in the output. This option was added in MySQL 5.1.8.

- **--extended-insert, -e**

Use multiple-row `INSERT` syntax that include several `VALUES` lists. This results in a smaller dump file and speeds up inserts when the file is reloaded.

- **--fields-terminated-by=..., --fields-enclosed-by=..., -**

`-fields-optionally-enclosed-by=..., --fields-escaped-by=...`

These options are used with the `--tab` option and have the same meaning as the corresponding `FIELDS` clauses for `LOAD DATA INFILE`. See [Section 12.2.6, “LOAD DATA INFILE Syntax”](#).

- `--first-slave`

Deprecated. Use `--lock-all-tables` instead. `--first-slave` is removed in MySQL 5.5.

- `--flush-logs, -F`

Flush the MySQL server log files before starting the dump. This option requires the `RELOAD` privilege. If you use this option in combination with the `--all-databases` option, the logs are flushed *for each database dumped*. The exception is when using `--lock-all-tables` or `--master-data`: In this case, the logs are flushed only once, corresponding to the moment that all tables are locked. If you want your dump and the log flush to happen at exactly the same moment, you should use `--flush-logs` together with either `--lock-all-tables` or `--master-data`.

- `--flush-privileges`

Send a `FLUSH PRIVILEGES` statement to the server after dumping the `mysql` database. This option should be used any time the dump contains the `mysql` database and any other database that depends on the data in the `mysql` database for proper restoration. This option was added in MySQL 5.1.12.

- `--force, -f`

Continue even if an SQL error occurs during a table dump.

One use for this option is to cause `mysqldump` to continue executing even when it encounters a view that has become invalid because the definition refers to a table that has been dropped. Without `--force`, `mysqldump` exits with an error message. With `--force`, `mysqldump` prints the error message, but it also writes an SQL comment containing the view definition to the dump output and continues executing.

- `--host=host_name, -h host_name`

Dump data from the MySQL server on the given host. The default host is `localhost`.

- `--hex-blob`

Dump binary columns using hexadecimal notation (for example, '`abc`' becomes `0x616263`). The affected data types are `BINARY`, `VARBINARY`, the `BLOB` types, and `BIT`.

- `--ignore-table=db_name.tbl_name`

Do not dump the given table, which must be specified using both the database and table names. To ignore multiple tables, use this option multiple times. This option also can be used to ignore views.

- `--insert-ignore`

Write `INSERT IGNORE` statements rather than `INSERT` statements.

- `--lines-terminated-by=...`

This option is used with the `--tab` option and has the same meaning as the corresponding `LINES` clause for `LOAD DATA INFILE`. See [Section 12.2.6, “LOAD DATA INFILE Syntax”](#).

- `--lock-all-tables, -x`

Lock all tables across all databases. This is achieved by acquiring a global read lock for the duration of the whole dump. This option automatically turns off `--single-transaction` and `--lock-tables`.

- `--lock-tables, -l`

For each dumped database, lock all tables to be dumped before dumping them. The tables are locked with `READ LOCAL` to permit concurrent inserts in the case of `MyISAM` tables. For transactional tables such as `InnoDB`, `--single-transaction` is a much better option than `--lock-tables` because it does not need to lock the tables at all.

Because `--lock-tables` locks tables for each database separately, this option does not guarantee that the tables in the dump file are logically consistent between databases. Tables in different databases may be dumped in completely different states.

- `--log-error=file_name`

Log warnings and errors by appending them to the named file. The default is to do no logging. This option was added in MySQL 5.1.18.

- **--master-data[=value]**

Use this option to dump a master replication server to produce a dump file that can be used to set up another server as a slave of the master. It causes the dump output to include a `CHANGE MASTER TO` statement that indicates the binary log coordinates (file name and position) of the dumped server. These are the master server coordinates from which the slave should start replicating after you load the dump file into the slave.

If the option value is 2, the `CHANGE MASTER TO` statement is written as an SQL comment, and thus is informative only; it has no effect when the dump file is reloaded. If the option value is 1, the statement is not written as a comment and takes effect when the dump file is reloaded. If no option value is specified, the default value is 1.

This option requires the `RELOAD` privilege and the binary log must be enabled.

The `--master-data` option automatically turns off `--lock-tables`. It also turns on `--lock-all-tables`, unless `--single-transaction` also is specified, in which case, a global read lock is acquired only for a short time at the beginning of the dump (see the description for `--single-transaction`). In all cases, any action on logs happens at the exact moment of the dump.

It is also possible to set up a slave by dumping an existing slave of the master. To do this, use the following procedure on the existing slave:

1. Stop the slave's SQL thread and get its current status:

```
mysql> STOP SLAVE SQL_THREAD;
mysql> SHOW SLAVE STATUS;
```

2. From the output of the `SHOW SLAVE STATUS` statement, the binary log coordinates of the master server from which the new slave should start replicating are the values of the `Relay_Master_Log_File` and `Exec_Master_Log_Pos` fields. Denote those values as `file_name` and `file_pos`.

3. Dump the slave server:

```
shell> mysqldump --master-data=2 --all-databases > dumpfile
```

4. Restart the slave:

```
mysql> START SLAVE;
```

5. On the new slave, load the dump file:

```
shell> mysql < dumpfile
```

6. On the new slave, set the replication coordinates to those of the master server obtained earlier:

```
mysql> CHANGE MASTER TO
-> MASTER_LOG_FILE = 'file_name', MASTER_LOG_POS = file_pos;
```

The `CHANGE MASTER TO` statement might also need other parameters, such as `MASTER_HOST` to point the slave to the correct master server host. Add any such parameters as necessary.

- **--no-autocommit**

Enclose the `INSERT` statements for each dumped table within `SET autocommit = 0` and `COMMIT` statements.

- **--no-create-db, -n**

This option suppresses the `CREATE DATABASE` statements that are otherwise included in the output if the `--databases` or `--all-databases` option is given.

- **--no-create-info, -t**

Do not write `CREATE TABLE` statements that re-create each dumped table.

### Note

This option does not exclude statements creating log file groups or tablespaces from `mysqldump` output; in

■ MySQL 5.1.14 and later, you can use the `--no-tablespaces` option for this purpose.

- **`--no-data, -d`**

Do not write any table row information (that is, do not dump table contents). This is useful if you want to dump only the `CREATE TABLE` statement for the table (for example, to create an empty copy of the table by loading the dump file).

- **`--no-set-names, -N`**

This has the same effect as `--skip-set-charset`.

- **`--no-tablespaces, -y`**

This option suppresses all `CREATE LOGFILE GROUP` and `CREATE TABLESPACE` statements in the output of `mysqldump`.

This option was added in MySQL 5.1.14.

- **`--opt`**

This option is shorthand. It is the same as specifying `--add-drop-table --add-locks --create-options --disable-keys --extended-insert --lock-tables --quick --set-charset`. It should give you a fast dump operation and produce a dump file that can be reloaded into a MySQL server quickly.

The `--opt` option is enabled by default. Use `--skip-opt` to disable it. See the discussion at the beginning of this section for information about selectively enabling or disabling a subset of the options affected by `--opt`.

- **`--order-by-primary`**

Dump each table's rows sorted by its primary key, or by its first unique index, if such an index exists. This is useful when dumping a `MyISAM` table to be loaded into an `InnoDB` table, but will make the dump operation take considerably longer.

- **`--password[=password], -p[password]`**

The password to use when connecting to the server. If you use the short option form (`-p`), you *cannot* have a space between the option and the password. If you omit the `password` value following the `--password` or `-p` option on the command line, `mysqldump` prompts for one.

Specifying a password on the command line should be considered insecure. See [Section 5.3.2.2, “End-User Guidelines for Password Security”](#). You can use an option file to avoid giving the password on the command line.

- **`--pipe, -W`**

On Windows, connect to the server using a named pipe. This option applies only if the server supports named-pipe connections.

- **`--port=port_num, -P port_num`**

The TCP/IP port number to use for the connection.

- **`--protocol={TCP|SOCKET|PIPE|MEMORY}`**

The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want. For details on the permissible values, see [Section 4.2.2, “Connecting to the MySQL Server”](#).

- **`--quick, -q`**

This option is useful for dumping large tables. It forces `mysqldump` to retrieve rows for a table from the server a row at a time rather than retrieving the entire row set and buffering it in memory before writing it out.

- **`--quote-names, -Q`**

Quote identifiers (such as database, table, and column names) within “`” characters. If the `ANSI_QUOTES` SQL mode is enabled, identifiers are quoted within ““” characters. This option is enabled by default. It can be disabled with `--skip-quote-names`, but this option should be given after any option such as `--compatible` that may enable `--quote-names`.

- **`--replace`**

Write `REPLACE` statements rather than `INSERT` statements. This option was added in MySQL 5.1.3.

- **`--result-file=file_name, -r file_name`**

Direct output to a given file. This option should be used on Windows to prevent newline “`\n`” characters from being converted to “`\r\n`” carriage return/newline sequences. The result file is created and its previous contents overwritten, even if an error occurs while generating the dump.

- `--routines, -R`

Included stored routines (procedures and functions) for the dumped databases in the output. Use of this option requires the `SELECT` privilege for the `mysql.proc` table. The output generated by using `--routines` contains `CREATE PROCEDURE` and `CREATE FUNCTION` statements to re-create the routines. However, these statements do not include attributes such as the routine creation and modification timestamps. This means that when the routines are reloaded, they will be created with the timestamps equal to the reload time.

If you require routines to be re-created with their original timestamp attributes, do not use `--routines`. Instead, dump and reload the contents of the `mysql.proc` table directly, using a MySQL account that has appropriate privileges for the `mysql` database.

This option was added in MySQL 5.1.2. Before that, stored routines are not dumped. Routine `DEFINER` values are not dumped until MySQL 5.1.8. This means that before 5.1.8, when routines are reloaded, they will be created with the definer set to the reloading user. If you require routines to be re-created with their original definer, dump and load the contents of the `mysql.proc` table directly as described earlier.

- `--set-charset`

Add `SET NAMES default_character_set` to the output. This option is enabled by default. To suppress the `SET NAMES` statement, use `--skip-set-charset`.

- `--single-transaction`

This option sends a `START TRANSACTION` SQL statement to the server before dumping data. It is useful only with transactional tables such as `InnoDB`, because then it dumps the consistent state of the database at the time when `BEGIN` was issued without blocking any applications.

When using this option, you should keep in mind that only `InnoDB` tables are dumped in a consistent state. For example, any `MyISAM` or `MEMORY` tables dumped while using this option may still change state.

While a `--single-transaction` dump is in process, to ensure a valid dump file (correct table contents and binary log coordinates), no other connection should use the following statements: `ALTER TABLE`, `CREATE TABLE`, `DROP TABLE`, `RENAME TABLE`, `TRUNCATE TABLE`. A consistent read is not isolated from those statements, so use of them on a table to be dumped can cause the `SELECT` that is performed by `mysqldump` to retrieve the table contents to obtain incorrect contents or fail.

The `--single-transaction` option and the `--lock-tables` option are mutually exclusive because `LOCK TABLES` causes any pending transactions to be committed implicitly.

This option is not supported for MySQL Cluster tables; the results cannot be guaranteed to be consistent due to the fact that the `NDBCLUSTER` storage engine supports only the `READ_COMMITTED` transaction isolation level. You should always use `NDB` backup and restore instead.

To dump large tables, you should combine the `--single-transaction` option with `--quick`.

- `--skip-comments`

See the description for the `--comments` option.

- `--skip-opt`

See the description for the `--opt` option.

- `--socket=path, -S path`

For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

- `--ssl*`

Options that begin with `--ssl` specify whether to connect to the server using SSL and indicate where to find SSL keys and certificates. See [Section 5.5.6.3, “SSL Command Options”](#).

- `--tab=path, -T path`

Produce tab-separated text-format data files. For each dumped table, `mysqldump` creates a `tbl_name.sql` file that contains

the `CREATE TABLE` statement that creates the table, and the server writes a `tbl_name.txt` file that contains its data. The option value is the directory in which to write the files.

### Note

This option should be used only when `mysqldump` is run on the same machine as the `mysqld` server. You must have the `FILE` privilege, and the server must have permission to write files in the directory that you specify.

By default, the `.txt` data files are formatted using tab characters between column values and a newline at the end of each line. The format can be specified explicitly using the `--fields-xxx` and `--lines-terminated-by` options.

As of MySQL 5.1.38, column values are converted to the character set specified by the `--default-character-set` option. Prior to 5.1.38 or if no such option is present, values are dumped using the `binary` character set. In effect, there is no character set conversion. If a table contains columns in several character sets, the output data file will as well and you may not be able to reload the file correctly.

- `--tables`

Override the `--databases` or `-B` option. `mysqldump` regards all name arguments following the option as table names.

- `--triggers`

Include triggers for each dumped table in the output. This option is enabled by default; disable it with `--skip-triggers`.

- `--tz-utc`

This option enables `TIMESTAMP` columns to be dumped and reloaded between servers in different time zones. `mysqldump` sets its connection time zone to UTC and adds `SET TIME_ZONE='+00:00'` to the dump file. Without this option, `TIMESTAMP` columns are dumped and reloaded in the time zones local to the source and destination servers, which can cause the values to change if the servers are in different time zones. `--tz-utc` also protects against changes due to daylight saving time. `--tz-utc` is enabled by default. To disable it, use `--skip-tz-utc`. This option was added in MySQL 5.1.2.

- `--user=user_name, -u user_name`

The MySQL user name to use when connecting to the server.

- `--verbose, -v`

Verbose mode. Print more information about what the program does.

- `--version, -V`

Display version information and exit.

- `--where='where_condition', -w 'where_condition'`

Dump only rows selected by the given `WHERE` condition. Quotes around the condition are mandatory if it contains spaces or other characters that are special to your command interpreter.

Examples:

```
--where="user='jimf'"
-w"userid>1"
-w"userid<1"
```

- `--xml, -X`

Write dump output as well-formed XML.

**NULL, 'NULL', and Empty Values:** For a column named `column_name`, the `NULL` value, an empty string, and the string value `'NULL'` are distinguished from one another in the output generated by this option as follows.

| Value:                                      | XML Representation:                                             |
|---------------------------------------------|-----------------------------------------------------------------|
| <code>NULL</code> ( <i>unknown value</i> )  | <code>&lt;field name="column_name" xsi:nil="true" /&gt;</code>  |
| <code>''</code> ( <i>empty string</i> )     | <code>&lt;field name="column_name"&gt;&lt;/field&gt;</code>     |
| <code>'NULL'</code> ( <i>string value</i> ) | <code>&lt;field name="column_name"&gt;NULL&lt;/field&gt;</code> |

Beginning with MySQL 5.1.12, the output from the `mysql` client when run using the `--xml` option also follows the preceding rules. (See [Section 4.5.1.1, “mysql Options”](#).)

Beginning with MySQL 5.1.18, XML output from `mysqldump` includes the XML namespace, as shown here:

```
shell> mysqldump --xml -u root world City
<?xml version="1.0"?>
<mysqldump xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
<database name="world">
<table_structure name="City">
<field Field="ID" Type="int(11)" Null="NO" Key="PRI" Extra="auto_increment" />
<field Field="Name" Type="char(35)" Null="NO" Key="" Default="" Extra="" />
<field Field="CountryCode" Type="char(3)" Null="NO" Key="" Default="" Extra="" />
<field Field="District" Type="char(20)" Null="NO" Key="" Default="" Extra="" />
<field Field="Population" Type="int(11)" Null="NO" Key="" Default="0" Extra="" />
<key Table="City" Non_unique="0" Key_name="PRIMARY" Seq_in_index="1" Column_name="ID"
 Collation="A" Cardinality="4079" Null="" Index_type="BTREE" Comment="" />
<options Name="City" Engine="MyISAM" Version="10" Row_format="Fixed" Rows="4079"
 Avg_row_length="67" Data_length="273293" Max_data_length="18858823439613951"
 Index_length="43008" Data_free="0" Auto_increment="4080"
 Create_time="2007-03-31 01:47:01" Update_time="2007-03-31 01:47:02"
 Collation="latin1_swedish_ci" Create_options="" Comment="" />
</table_structure>
<table_data name="City">
<row>
<field name="ID">1</field>
<field name="Name">Kabul</field>
<field name="CountryCode">AFG</field>
<field name="District">Kabul</field>
<field name="Population">1780000</field>
</row>
...
<row>
<field name="ID">4079</field>
<field name="Name">Rafah</field>
<field name="CountryCode">PSE</field>
<field name="District">Rafah</field>
<field name="Population">92020</field>
</row>
</table_data>
</database>
</mysqldump>
```

You can also set the following variables by using `--var_name=value` syntax:

- `max_allowed_packet`

The maximum size of the buffer for client/server communication. The maximum is 1GB.

- `net_buffer_length`

The initial size of the buffer for client/server communication. When creating multiple-row `INSERT` statements (as with the `--extended-insert` or `--opt` option), `mysqldump` creates rows up to `net_buffer_length` length. If you increase this variable, you should also ensure that the `net_buffer_length` variable in the MySQL server is at least this large.

A common use of `mysqldump` is for making a backup of an entire database:

```
shell> mysqldump db_name > backup-file.sql
```

You can load the dump file back into the server like this:

```
shell> mysql db_name < backup-file.sql
```

Or like this:

```
shell> mysql -e "source /path-to-backup/backup-file.sql" db_name
```

`mysqldump` is also very useful for populating databases by copying data from one MySQL server to another:

```
shell> mysqldump --opt db_name | mysql --host=remote_host -C db_name
```

It is possible to dump several databases with one command:

```
shell> mysqldump --databases db_name1 [db_name2 ...] > my_databases.sql
```

To dump all databases, use the `--all-databases` option:

```
shell> mysqldump --all-databases > all_databases.sql
```

For [InnoDB](#) tables, `mysqldump` provides a way of making an online backup:

```
shell> mysqldump --all-databases --single-transaction > all_databases.sql
```

This backup acquires a global read lock on all tables (using `FLUSH TABLES WITH READ LOCK`) at the beginning of the dump. As soon as this lock has been acquired, the binary log coordinates are read and the lock is released. If long updating statements are running when the `FLUSH` statement is issued, the MySQL server may get stalled until those statements finish. After that, the dump becomes lock free and does not disturb reads and writes on the tables. If the update statements that the MySQL server receives are short (in terms of execution time), the initial lock period should not be noticeable, even with many updates.

For point-in-time recovery (also known as “roll-forward,” when you need to restore an old backup and replay the changes that happened since that backup), it is often useful to rotate the binary log (see [Section 5.2.4, “The Binary Log”](#)) or at least know the binary log coordinates to which the dump corresponds:

```
shell> mysqldump --all-databases --master-data=2 > all_databases.sql
```

Or:

```
shell> mysqldump --all-databases --flush-logs --master-data=2 > all_databases.sql
```

The `--master-data` and `--single-transaction` options can be used simultaneously, which provides a convenient way to make an online backup suitable for use prior to point-in-time recovery if tables are stored using the [InnoDB](#) storage engine.

For more information on making backups, see [Section 6.2, “Database Backup Methods”](#), and [Section 6.3, “Example Backup and Recovery Strategy”](#).

If you encounter problems backing up views, please read the section that covers restrictions on views which describes a work-around for backing up views when this fails due to insufficient privileges. See [Section D.4, “Restrictions on Views”](#).

## 4.5.5. `mysqlimport` — A Data Import Program

The `mysqlimport` client provides a command-line interface to the `LOAD DATA INFILE` SQL statement. Most options to `mysqlimport` correspond directly to clauses of `LOAD DATA INFILE` syntax. See [Section 12.2.6, “LOAD DATA INFILE Syntax”](#).

Invoke `mysqlimport` like this:

```
shell> mysqlimport [options] db_name textfile1 [textfile2 ...]
```

For each text file named on the command line, `mysqlimport` strips any extension from the file name and uses the result to determine the name of the table into which to import the file's contents. For example, files named `patient.txt`, `patient.text`, and `patient` all would be imported into a table named `patient`.

For additional information about `mysqldump`, see [Section 6.4, “Using `mysqldump` for Backups”](#).

`mysqlimport` supports the following options, which can be specified on the command line or in the `[mysqlimport]` and `[client]` option file groups. `mysqlimport` also supports the options for processing option files described at [Section 4.2.3.3.1, “Command-Line Options that Affect Option-File Handling”](#).

**Table 4.6. `mysqlimport` Options**

Format	Config File	Description	Introduction	Deprecated	Removed
<code>-</code> <code>-</code> <code>columns=column_list</code>	<code>columns</code>	This option takes a comma-separated list of column names as its value			
<code>--compress</code>	<code>compress</code>	Compress all information sent between the client and the server			
<code>-</code> <code>-de-</code>	<code>debug</code>	Write a debugging log			

<b>Format</b>	<b>Config File</b>	<b>Description</b>	<b>Introduction</b>	<b>Deprecated</b>	<b>Removed</b>
<code>bug[=debug_options]</code>					
<code>--debug-check</code>	<code>debug-check</code>	Print debugging information when the program exits	5.1.21		
<code>--debug-info</code>	<code>debug-info</code>	Print debugging information, memory and CPU statistics when the program exits	5.1.14		
<code>- -de- -efault-cha- -racter- -set=charset_name</code>	<code>default-charac- -ter-set</code>	Use charset_name as the default character set			
<code>--delete</code>	<code>delete</code>	Empty the table before importing the text file			
<code>- - fields-en- closed-by=string</code>	<code>fields-enclosed-by</code>	This option has the same meaning as the corresponding clause for LOAD DATA INFILE			
<code>- - fields-escaped-by=string</code>	<code>fields-escaped-by</code>	This option has the same meaning as the corresponding clause for LOAD DATA INFILE			
<code>- - fields-option- ally-en- closed-by=string</code>	<code>fields-option- ally-enclosed-by</code>	This option has the same meaning as the corresponding clause for LOAD DATA INFILE			
<code>- - fields-ter- minated-by=string</code>	<code>fields-ter- minated-by</code>	-- This option has the same meaning as the corresponding clause for LOAD DATA INFILE			
<code>--force</code>	<code>force</code>	Continue even if an SQL error occurs			
<code>--help</code>		Display help message and exit			
<code>--host=host_name</code>	<code>host</code>	Connect to the MySQL server on the given host			
<code>--ignore</code>	<code>ignore</code>	See the description for the --replace option			
<code>--ignore-lines=#</code>	<code>ignore-lines</code>	Ignore the first N lines of the data file			
<code>- - lines-ter- minated-by=string</code>	<code>lines-ter- minated-by</code>	This option has the same meaning as the corresponding clause for LOAD DATA INFILE			
<code>--local</code>	<code>local</code>	Read input files locally from the client host			
<code>--lock-tables</code>	<code>lock-tables</code>	Lock all tables for writing before processing any text files			
<code>--low-priority</code>	<code>low-priority</code>	Use LOW_PRIORITY when loading the table.			
<code>- -pass- word[=password]</code>	<code>password</code>	The password to use when connecting to the server			
<code>--pipe</code>		On Windows, connect to server using a named pipe			
<code>--port=port_num</code>	<code>port</code>	The TCP/IP port number to use for the connection			
<code>--protocol=type</code>	<code>protocol</code>	The connection protocol to use			
<code>--replace</code>	<code>replace</code>	The --replace and --ignore options control handling of input rows that duplicate existing rows on unique key values			
<code>--silent</code>	<code>silent</code>	Produce output only when errors occur			
<code>--socket=path</code>	<code>socket</code>	For connections to localhost			
<code>- -ssl-ca=file_name</code>	<code>ssl-ca</code>	The path to a file that contains a list of trusted SSL CAs			
<code>- -ssl-</code>	<code>ssl-capath</code>	The path to a directory that contains trusted SSL CA certificates in PEM format			

Format	Config File	Description	Introduction	Deprecated	Removed
<code>capath=directory_name</code>					
<code>- - ssl-cert=file_name</code>	<code>ssl-cert</code>	The name of the SSL certificate file to use for establishing a secure connection			
<code>- - ssl-cipher=cipher_list</code>	<code>ssl-cipher</code>	A list of allowable ciphers to use for SSL encryption			
<code>- - ssl-key=file_name</code>	<code>ssl-key</code>	The name of the SSL key file to use for establishing a secure connection			
<code>- - ssl-veri-fy-server-cert</code>	<code>ssl-veri-fy-server-cert</code>	The server's Common Name value in its certificate is verified against the host name used when connecting to the server			
<code>--use-threads=#</code>	<code>use-threads</code>	The number of threads for parallel file-loading	5.1.7		
<code>- -user=user_name,</code>	<code>user</code>	The MySQL user name to use when connecting to the server			
<code>--verbose</code>		Verbose mode			
<code>--version</code>		Display version information and exit			

- `--help, -?`

Display a help message and exit.

- `--character-sets-dir=path`

The directory where character sets are installed. See [Section 9.5, “Character Set Configuration”](#).

- `--columns=column_list, -c column_list`

This option takes a comma-separated list of column names as its value. The order of the column names indicates how to match data file columns with table columns.

- `--compress, -C`

Compress all information sent between the client and the server if both support compression.

- `--debug[=debug_options], -# [debug_options]`

Write a debugging log. A typical `debug_options` string is '`d:t:o,file_name`'. The default is '`d:t:o`'.

- `--debug-check`

Print some debugging information when the program exits. This option was added in MySQL 5.1.21.

- `--debug-info`

Print debugging information and memory and CPU usage statistics when the program exits. This option was added in MySQL 5.1.14.

- `--default-character-set=charset_name`

Use `charset_name` as the default character set. See [Section 9.5, “Character Set Configuration”](#).

- `--delete, -D`

Empty the table before importing the text file.

- `--fields-terminated-by=..., --fields-enclosed-by=..., --fields-optionally-enclosed-by=..., --fields-escaped-by=...`

These options have the same meaning as the corresponding clauses for `LOAD DATA INFILE`. See [Section 12.2.6, “LOAD DATA INFILE Syntax”](#).

- `--force, -f`

Ignore errors. For example, if a table for a text file does not exist, continue processing any remaining files. Without `--force`, `mysqlimport` exits if a table does not exist.

- `--host=host_name, -h host_name`

Import data to the MySQL server on the given host. The default host is `localhost`.

- `--ignore, -i`

See the description for the `--replace` option.

- `--ignore-lines=N`

Ignore the first `N` lines of the data file.

- `--lines-terminated-by=...`

This option has the same meaning as the corresponding clause for `LOAD DATA INFILE`. For example, to import Windows files that have lines terminated with carriage return/linefeed pairs, use `--lines-terminated-by="\r\n"`. (You might have to double the backslashes, depending on the escaping conventions of your command interpreter.) See [Section 12.2.6, “LOAD DATA INFILE Syntax”](#).

- `--local, -L`

Read input files locally from the client host.

- `--lock-tables, -l`

Lock *all* tables for writing before processing any text files. This ensures that all tables are synchronized on the server.

- `--low-priority`

Use `LOW_PRIORITY` when loading the table. This affects only storage engines that use only table-level locking (such as `MYISAM`, `MEMORY`, and `MERGE`).

- `--password[=password], -p[password]`

The password to use when connecting to the server. If you use the short option form (`-p`), you *cannot* have a space between the option and the password. If you omit the `password` value following the `--password` or `-p` option on the command line, `mysqlimport` prompts for one.

Specifying a password on the command line should be considered insecure. See [Section 5.3.2.2, “End-User Guidelines for Password Security”](#). You can use an option file to avoid giving the password on the command line.

- `--pipe, -W`

On Windows, connect to the server using a named pipe. This option applies only if the server supports named-pipe connections.

- `--port=port_num, -P port_num`

The TCP/IP port number to use for the connection.

- `--protocol={TCP|SOCKET|PIPE|MEMORY}`

The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want. For details on the permissible values, see [Section 4.2.2, “Connecting to the MySQL Server”](#).

- `--replace, -r`

The `--replace` and `--ignore` options control handling of input rows that duplicate existing rows on unique key values. If you specify `--replace`, new rows replace existing rows that have the same unique key value. If you specify `--ignore`, input rows that duplicate an existing row on a unique key value are skipped. If you do not specify either option, an error occurs when a duplicate key value is found, and the rest of the text file is ignored.

- `--silent, -s`

Silent mode. Produce output only when errors occur.

- `--socket=path, -S path`

For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

- `--ssl*`

Options that begin with `--ssl` specify whether to connect to the server using SSL and indicate where to find SSL keys and certificates. See [Section 5.5.6.3, “SSL Command Options”](#).

- `--user=user_name, -u user_name`

The MySQL user name to use when connecting to the server.

- `--use-threads=N`

Load files in parallel using `N` threads. This option was added in MySQL 5.1.7.

- `--verbose, -v`

Verbose mode. Print more information about what the program does.

- `--version, -V`

Display version information and exit.

Here is a sample session that demonstrates use of `mysqlimport`:

```
shell> mysql -e 'CREATE TABLE imptest(id INT, n VARCHAR(30))' test
shell> ed
a
100 Max Sydow
101 Count Dracula
.
w imptest.txt
32
q
shell> od -c imptest.txt
0000000 1 0 0 \t M a x S y d o w \n 1 0
0000020 1 \t C o u n t D r a c u l a \n 1 a \n
0000040
shell> mysqlimport --local test imptest.txt
test.imptest: Records: 2 Deleted: 0 Skipped: 0 Warnings: 0
shell> mysql -e 'SELECT * FROM imptest' test
+-----+
| id | n |
+-----+
| 100 | Max Sydow |
| 101 | Count Dracula |
+-----+
```

## 4.5.6. `mysqlshow` — Display Database, Table, and Column Information

The `mysqlshow` client can be used to quickly see which databases exist, their tables, or a table's columns or indexes.

`mysqlshow` provides a command-line interface to several SQL `SHOW` statements. See [Section 12.4.5, “SHOW Syntax”](#). The same information can be obtained by using those statements directly. For example, you can issue them from the `mysql` client program.

Invoke `mysqlshow` like this:

```
shell> mysqlshow [options] [db_name [tbl_name [col_name]]]
```

- If no database is given, a list of database names is shown.
- If no table is given, all matching tables in the database are shown.
- If no column is given, all matching columns and column types in the table are shown.

The output displays only the names of those databases, tables, or columns for which you have some privileges.

If the last argument contains shell or SQL wildcard characters (“`*`”, “`?`”, “`%`”, or “`_`”), only those names that are matched by the

wildcard are shown. If a database name contains any underscores, those should be escaped with a backslash (some Unix shells require two) to get a list of the proper tables or columns. “\*” and “?” characters are converted into SQL “%” and “\_” wildcard characters. This might cause some confusion when you try to display the columns for a table with a “\_” in the name, because in this case, `mysqlshow` shows you only the table names that match the pattern. This is easily fixed by adding an extra “%” last on the command line as a separate argument.

`mysqlshow` supports the following options, which can be specified on the command line or in the [`mysqlshow`] and [`client`] option file groups. `mysqlshow` also supports the options for processing option files described at [Section 4.2.3.3.1, “Command-Line Options that Affect Option-File Handling”](#).

**Table 4.7. `mysqlshow` Options**

Format	Config File	Description	Introduction	Deprecated	Removed
<code>--compress</code>	<code>compress</code>	Compress all information sent between the client and the server			
<code>--count</code>	<code>count</code>	Show the number of rows per table			
<code>- -de- bug[=debug_options]</code>	<code>debug</code>	Write a debugging log			
<code>--debug-check</code>	<code>debug-check</code>	Print debugging information when the program exits	5.1.21		
<code>--debug-info</code>	<code>debug-info</code>	Print debugging information, memory and CPU statistics when the program exits	5.1.14		
<code>- -de- fault-charac- ter-set=charset_name</code>	<code>default-character-set</code>	Use <code>charset_name</code> as the default character set			
<code>--help</code>		Display help message and exit			
<code>--host=host_name</code>	<code>host</code>	Connect to the MySQL server on the given host			
<code>--keys</code>	<code>keys</code>	Show table indexes			
<code>- -pass- word[=password]</code>	<code>password</code>	The password to use when connecting to the server			
<code>--pipe</code>		On Windows, connect to server using a named pipe			
<code>--port=port_num</code>	<code>port</code>	The TCP/IP port number to use for the connection			
<code>--protocol=type</code>	<code>protocol</code>	The connection protocol to use			
<code>--show-table-type</code>		Show a column indicating the table type			
<code>--socket=path</code>	<code>socket</code>	For connections to localhost			
<code>- -ssl-ca=file_name</code>	<code>ssl-ca</code>	The path to a file that contains a list of trusted SSL CAs			
<code>- -ssl- capath=directory_name</code>	<code>ssl-capath</code>	The path to a directory that contains trusted SSL CA certificates in PEM format			
<code>- -ssl- cert=file_name</code>	<code>ssl-cert</code>	The name of the SSL certificate file to use for establishing a secure connection			
<code>- -ssl- cipher=cipher_list</code>	<code>ssl-cipher</code>	A list of allowable ciphers to use for SSL encryption			
<code>- -ssl-key=file_name</code>	<code>ssl-key</code>	The name of the SSL key file to use for establishing a secure connection			
<code>- -ssl-veri- fy-server-cert</code>	<code>ssl-verify-server-cert</code>	The server's Common Name value in its certificate is verified against the host name used when con-			

Format	Config File	Description	Introduction	Deprecated	Removed
<code>ssl-verify-server-cert</code>		necting to the server			
<code>--status</code>	<code>status</code>	Display extra information about each table			
<code>-user=user_name,</code>	<code>user</code>	The MySQL user name to use when connecting to the server			
<code>--verbose</code>		Verbose mode			
<code>--version</code>		Display version information and exit			

- `--help, -?`

Display a help message and exit.
- `--character-sets-dir=path`

The directory where character sets are installed. See [Section 9.5, “Character Set Configuration”](#).
- `--compress, -C`

Compress all information sent between the client and the server if both support compression.
- `--count`

Show the number of rows per table. This can be slow for non-[MyISAM](#) tables.
- `--debug[=debug_options], -# [debug_options]`

Write a debugging log. A typical `debug_options` string is '`d:t:o,file_name`'. The default is '`d:t:o`'.
- `--debug-check`

Print some debugging information when the program exits. This option was added in MySQL 5.1.21.
- `--debug-info`

Print debugging information and memory and CPU usage statistics when the program exits. This option was added in MySQL 5.1.14.
- `--default-character-set=charset_name`

Use `charset_name` as the default character set. See [Section 9.5, “Character Set Configuration”](#).
- `--host=host_name, -h host_name`

Connect to the MySQL server on the given host.
- `--keys, -k`

Show table indexes.
- `--password[=password], -p[password]`

The password to use when connecting to the server. If you use the short option form (`-p`), you *cannot* have a space between the option and the password. If you omit the `password` value following the `--password` or `-p` option on the command line, `mysqlshow` prompts for one.

Specifying a password on the command line should be considered insecure. See [Section 5.3.2.2, “End-User Guidelines for Password Security”](#). You can use an option file to avoid giving the password on the command line.
- `--pipe, -W`

On Windows, connect to the server using a named pipe. This option applies only if the server supports named-pipe connections.
- `--port=port_num, -P port_num`

The TCP/IP port number to use for the connection.

- `--protocol={TCP|SOCKET|PIPE|MEMORY}`

The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want. For details on the permissible values, see [Section 4.2.2, “Connecting to the MySQL Server”](#).

- `--show-table-type, -t`

Show a column indicating the table type, as in `SHOW FULL TABLES`. The type is `BASE TABLE` or `VIEW`.

- `--socket=path, -S path`

For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

- `--ssl*`

Options that begin with `--ssl` specify whether to connect to the server using SSL and indicate where to find SSL keys and certificates. See [Section 5.5.6.3, “SSL Command Options”](#).

- `--status, -i`

Display extra information about each table.

- `--user=user_name, -u user_name`

The MySQL user name to use when connecting to the server.

- `--verbose, -v`

Verbose mode. Print more information about what the program does. This option can be used multiple times to increase the amount of information.

- `--version, -V`

Display version information and exit.

## 4.5.7. `mysqlslap` — Load Emulation Client

`mysqlslap` is a diagnostic program designed to emulate client load for a MySQL server and to report the timing of each stage. It works as if multiple clients are accessing the server. `mysqlslap` is available as of MySQL 5.1.4.

Invoke `mysqlslap` like this:

```
shell> mysqlslap [options]
```

Some options such as `--create` or `--query` enable you to specify a string containing an SQL statement or a file containing statements. If you specify a file, by default it must contain one statement per line. (That is, the implicit statement delimiter is the newline character.) Use the `--delimiter` option to specify a different delimiter, which enables you to specify statements that span multiple lines or place multiple statements on a single line. You cannot include comments in a file; `mysqlslap` does not understand them.

`mysqlslap` runs in three stages:

1. Create schema, table, and optionally any stored programs or data you want to use for the test. This stage uses a single client connection.
2. Run the load test. This stage can use many client connections.
3. Clean up (disconnect, drop table if specified). This stage uses a single client connection.

Examples:

Supply your own create and query SQL statements, with 50 clients querying and 200 selects for each:

```
mysqlslap --delimiter=";" \
--create="CREATE TABLE a (b int);INSERT INTO a VALUES (23)" \
--query="SELECT * FROM a" --concurrency=50 --iterations=200
```

Let `mysqslap` build the query SQL statement with a table of two `INT` columns and three `VARCHAR` columns. Use five clients querying 20 times each. Do not create the table or insert the data (that is, use the previous test's schema and data):

```
mysqslap --concurrency=5 --iterations=20 \
--number-int-cols=2 --number-char-cols=3 \
--auto-generate-sql
```

Tell the program to load the create, insert, and query SQL statements from the specified files, where the `create.sql` file has multiple table creation statements delimited by '`;`' and multiple insert statements delimited by '`;`'. The `--query` file will have multiple queries delimited by '`;`'. Run all the load statements, then run all the queries in the query file with five clients (five times each):

```
mysqslap --concurrency=5 \
--iterations=5 --query=query.sql --create=create.sql \
--delimiter=";"
```

`mysqslap` supports the following options, which can be specified on the command line or in the [`mysqslap`] and [`client`] option file groups. `mysqslap` also supports the options for processing option files described at [Section 4.2.3.3.1, “Command-Line Options that Affect Option-File Handling”](#).

**Table 4.8. `mysqslap` Options**

Format	Config File	Description	Introduction	Deprecated	Removed
<code>- -auto-generate-sql</code>	<code>auto-generate-sql</code>	Generate SQL statements automatically when they are not supplied in files or using command options			
<code>- -auto-gener-ate-sql-add-autoincrement</code>	<code>auto-gener-ate-sql-add-autoincrement</code>	Add AUTO_INCREMENT column to automatically generated tables	5.1.18		
<code>- -auto-gener-ate-sql-ex-e-ecute-number=#</code>	<code>auto-gener-ate-sql-ex-e-ecute-number</code>	Specify how many queries to generate automatically	5.1.18		
<code>- -auto-gener-ate-sql-guid-primary</code>	<code>auto-gener-ate-sql-guid-primary</code>	Add a GUID-based primary key to automatically generated tables	5.1.18		
<code>- -auto-gener-ate-sql-load-type</code>	<code>auto-gener-ate-sql-load-type</code>	Specify how many queries to generate automatically	5.1.16		
<code>- -auto-gener-ate-sql-sec-ondary-indexes=#</code>	<code>auto-gener-ate-sql-sec-ondary-indexes</code>	Specify how many secondary indexes to add to automatically generated tables	5.1.18		
<code>- -auto-gener-ate-sql-unique-query-number=#</code>	<code>auto-gener-ate-sql-unique-query-number</code>	How many different queries to generate for automatic tests.	5.1.18		
<code>- -auto-gener-</code>	<code>auto-gener-ate-sql-</code>	How many different queries to generate for <code>--auto-generate-sql-write-number</code>	5.1.18		

<b>Format</b>	<b>Config File</b>	<b>Description</b>	<b>Introduction</b>	<b>Deprecated</b>	<b>Removed</b>
ate-sql-unique-write-number=#	unique-write-number				
- - auto-generate-sql-write-number=#	auto-generate-sql-write-number	How many row inserts to perform on each thread	5.1.16		
--commit=#	commit	How many statements to execute before committing.	5.1.21		
--compress	compress	Compress all information sent between the client and the server			
--concurrency=#	concurrency	The number of clients to simulate when issuing the SELECT statement			
--create=value	create	The file or string containing the statement to use for creating the table			
- - create-schema	create-schema	The schema in which to run the tests	5.1.5		
--csv=[file]	csv	Generate output in comma-separated values format			
- - debug[=debug_options]	debug	Write a debugging log			
--debug-check	debug-check	Print debugging information when the program exits	5.1.21		
--debug-info	debug-info	Print debugging information, memory and CPU statistics when the program exits	5.1.21		
--delimiter=str	delimiter	The delimiter to use in SQL statements			
--detach=#	detach	Detach (close and reopen) each connection after each N statements	5.1.21		
- - engine=engine_name	engine	The storage engine to use for creating the table			
--help		Display help message and exit			
--host=host_name	host	Connect to the MySQL server on the given host			
--iterations=#	iterations	The number of times to run the tests			
- - lock-directory	lock-directory	The directory to use for storing locks	5.1.5		5.1.18
- - number-char-cols=#	number-char-cols	The number of VARCHAR columns to use if --auto-generate-sql is specified			
- - number-int-cols=#	number-int-cols	The number of INT columns to use if --auto-generate-sql is specified			
- - number-of-queries=#	number-of-queries	Limit each client to approximately this number of queries	5.1.5		
--only-print	only-print	Do not connect to databases. mysqlslap only prints what it would have done	5.1.5		
- - password[=password]	password	The password to use when connecting to the server			

<b>Format</b>	<b>Config File</b>	<b>Description</b>	<b>Introduc-tion</b>	<b>Deprec-ated</b>	<b>Removed</b>
--pipe		On Windows, connect to server using a named pipe			
--port=port_num	port	The TCP/IP port number to use for the connection			
- -post-query=value	post-query	The file or string containing the statement to execute after the tests have completed	5.1.18		
--post-system=str	post-system	The string to execute using system() after the tests have completed	5.1.21		
--pre-query=value	pre-query	The file or string containing the statement to execute before running the tests	5.1.18		
--pre-system=str	pre-system	The string to execute using system() before running the tests	5.1.21		
--preserve-schema	preserve-schema	Preserve the schema from the mysqlslap run	5.1.5		5.1.23
--protocol=type	protocol	The connection protocol to use			
--query=value	query	The file or string containing the SELECT statement to use for retrieving data			
--silent	silent	Silent mode			
--slave	slave	Follow master locks for other mysqlslap clients	5.1.5		5.1.18
--socket=path	socket	For connections to localhost			
- -ssl-ca=file_name	ssl-ca	The path to a file that contains a list of trusted SSL CAs			
- -ssl-capath=directory_name	ssl-capath	The path to a directory that contains trusted SSL CA certificates in PEM format			
- -ssl-cert=file_name	ssl-cert	The name of the SSL certificate file to use for establishing a secure connection			
- -ssl-cipher=cipher_list	ssl-cipher	A list of allowable ciphers to use for SSL encryption			
- -ssl-key=file_name	ssl-key	The name of the SSL key file to use for establishing a secure connection			
- -ssl-veri-fy-server-cert	ssl-veri-fy-server-cert	The server's Common Name value in its certificate is verified against the host name used when connecting to the server			
--use-threads	use-threads	On Unix, the default is to use fork() calls	5.1.6		5.1.18
- -user=user_name,	user	The MySQL user name to use when connecting to the server			
--verbose		Verbose mode			
--version		Display version information and exit			

- **--help, -?**

Display a help message and exit.

- **--auto-generate-sql, -a**

Generate SQL statements automatically when they are not supplied in files or using command options.

- **--auto-generate-sql-add-autoincrement**

Add an **AUTO\_INCREMENT** column to automatically generated tables. This option was added in MySQL 5.1.18.

- **--auto-generate-sql-execute-number=N**

Specify how many queries to generate automatically. This option was added in MySQL 5.1.18.

- **--auto-generate-sql-guid-primary**

Add a GUID-based primary key to automatically generated tables. This option was added in MySQL 5.1.18.

- **--auto-generate-sql-load-type=type**

Specify the test load type. The permissible values are `read` (scan tables), `write` (insert into tables), `key` (read primary keys), `update` (update primary keys), or `mixed` (half inserts, half scanning selects). The default is `mixed`. This option was added in MySQL 5.1.16.

- **--auto-generate-sql-secondary-indexes=N**

Specify how many secondary indexes to add to automatically generated tables. By default, none are added. This option was added in MySQL 5.1.18.

- **--auto-generate-sql-unique-query-number=N**

How many different queries to generate for automatic tests. For example, if you run a `key` test that performs 1000 selects, you can use this option with a value of 1000 to run 1000 unique queries, or with a value of 50 to perform 50 different selects. The default is 10. This option was added in MySQL 5.1.18.

- **--auto-generate-sql-unique-write-number=N**

How many different queries to generate for `--auto-generate-sql-write-number`. The default is 10. This option was added in MySQL 5.1.18.

- **--auto-generate-sql-write-number=N**

How many row inserts to perform on each thread. The default is 100. This option was added in MySQL 5.1.16.

- **--commit=N**

How many statements to execute before committing. The default is 0 (no commits are done). This option was added in MySQL 5.1.21.

- **--compress, -C**

Compress all information sent between the client and the server if both support compression.

- **--concurrency=N, -c N**

The number of clients to simulate when issuing the `SELECT` statement.

- **--create=value**

The file or string containing the statement to use for creating the table.

- **--create-schema=value**

The schema in which to run the tests. This option was added in MySQL 5.1.5.

- **--csv[=file\_name]**

Generate output in comma-separated values format. The output goes to the named file, or to the standard output if no file is given. This option was added in MySQL 5.1.5.

- **--debug[=debug\_options], -# [debug\_options]**

Write a debugging log. A typical `debug_options` string is '`d:t:o,file_name`'. The default is '`d:t:o,/tmp/mysqlslap.trace`'.

- **--debug-check**

Print some debugging information when the program exits. This option was added in MySQL 5.1.21.

- **--debug-info, -T**

Print debugging information and memory and CPU usage statistics when the program exits. This option was added in MySQL

## 5.1.21.

- `--delimiter=str, -F str`

The delimiter to use in SQL statements supplied in files or using command options.

- `--detach=N`

Detach (close and reopen) each connection after each `N` statements. The default is 0 (connections are not detached). This option was added in MySQL 5.1.21.

- `--engine=engine_name, -e engine_name`

The storage engine to use for creating tables.

- `--host=host_name, -h host_name`

Connect to the MySQL server on the given host.

- `--iterations=N, -i N`

The number of times to run the tests.

- `--lock-directory=path`

The directory to use for storing locks. This option was added in MySQL 5.1.5 and removed in 5.1.18.

- `--number-char-cols=N, -x N`

The number of `VARCHAR` columns to use if `--auto-generate-sql` is specified.

- `--number-int-cols=N, -y N`

The number of `INT` columns to use if `--auto-generate-sql` is specified.

- `--number-of-queries=N`

Limit each client to approximately this many queries. Query counting takes into account the statement delimiter. For example, if you invoke `mysqlslap` as follows, the `;` delimiter is recognized so that each instance of the query string counts as two queries. As a result, 5 rows (not 10) are inserted.

```
shell> mysqlslap --delimiter=";" --number-of-queries=10
 --query="use test;insert into t values(null)"
```

This option was added in MySQL 5.1.5.

- `--only-print`

Do not connect to databases. `mysqlslap` only prints what it would have done. This option was added in MySQL 5.1.5.

- `--password[=password], -p[password]`

The password to use when connecting to the server. If you use the short option form (`-p`), you *cannot* have a space between the option and the password. If you omit the `password` value following the `--password` or `-p` option on the command line, `mysqlslap` prompts for one.

Specifying a password on the command line should be considered insecure. See [Section 5.3.2.2, “End-User Guidelines for Password Security”](#). You can use an option file to avoid giving the password on the command line.

- `--pipe, -W`

On Windows, connect to the server using a named pipe. This option applies only if the server supports named-pipe connections.

- `--port=port_num, -P port_num`

The TCP/IP port number to use for the connection.

- `--post-query=value`

The file or string containing the statement to execute after the tests have completed. This execution is not counted for timing purposes. This option was added in MySQL 5.1.18.

- `--shared-memory-base-name=name`

On Windows, the shared-memory name to use, for connections made using shared memory to a local server. This option applies only if the server supports shared-memory connections.

- `--post-system=str`

The string to execute using `system()` after the tests have completed. This execution is not counted for timing purposes. This option was added in MySQL 5.1.21.

- `--pre-query=value`

The file or string containing the statement to execute before running the tests. This execution is not counted for timing purposes. This option was added in MySQL 5.1.18.

- `--pre-system=str`

The string to execute using `system()` before running the tests. This execution is not counted for timing purposes. This option was added in MySQL 5.1.21.

- `--preserve-schema`

Preserve the schema from the `mysqlslap` run. The `--auto-generate-sql` and `--create` options disable this option. This option was added in MySQL 5.1.5 and removed in MySQL 5.1.23.

- `--protocol={TCP|SOCKET|PIPE|MEMORY}`

The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want. For details on the permissible values, see [Section 4.2.2, “Connecting to the MySQL Server”](#).

- `--query=value, -q value`

The file or string containing the `SELECT` statement to use for retrieving data.

- `--silent, -s`

Silent mode. No output.

- `--slave`

Follow master locks for other `mysqlslap` clients. Use this option if you are trying to synchronize around one master server with `--lock-directory` plus NFS. This option was added in MySQL 5.1.5 and removed in 5.1.18.

- `--socket=path, -S path`

For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

- `--ssl*`

Options that begin with `--ssl` specify whether to connect to the server using SSL and indicate where to find SSL keys and certificates. See [Section 5.5.6.3, “SSL Command Options”](#).

- `--use-threads`

On Unix, the default is to use `fork()` calls and this option causes `pthread` calls to be used instead. (On Windows, the default is to use `pthread` calls and the option has no effect.) This option was added in MySQL 5.1.6 and removed in 5.1.18.

- `--user=user_name, -u user_name`

The MySQL user name to use when connecting to the server.

- `--verbose, -v`

Verbose mode. Print more information about what the program does. This option can be used multiple times to increase the amount of information.

- `--version, -V`

Display version information and exit.

## 4.6. MySQL Administrative and Utility Programs

This section describes administrative programs and programs that perform miscellaneous utility operations.

### 4.6.1. `innochecksum` — Offline InnoDB File Checksum Utility

`innochecksum` prints checksums for `InnoDB` files. This tool reads an `InnoDB` tablespace file, calculates the checksum for each page, compares the calculated checksum to the stored checksum, and reports mismatches, which indicate damaged pages. It was originally developed to speed up verifying the integrity of tablespace files after power outages but can also be used after file copies. Because checksum mismatches will cause `InnoDB` to deliberately shut down a running server, it can be preferable to use this tool rather than waiting for a server in production usage to encounter the damaged pages.

`innochecksum` cannot be used on tablespace files that the server already has open. For such files, you should use `CHECK TABLE` to check tables within the tablespace.

If checksum mismatches are found, you would normally restore the tablespace from backup or start the server and attempt to use `mysqldump` to make a backup of the tables within the tablespace.

Invoke `innochecksum` like this:

```
shell> innocentsum [options] file_name
```

`innochecksum` supports the following options. For options that refer to page numbers, the numbers are zero-based.

- `-c`  
Print a count of the number of pages in the file.
- `-d`  
Debug mode; prints checksums for each page.
- `-e num`  
End at this page number.
- `-p num`  
Check only this page number.
- `-s num`  
Start at this page number.
- `-v`  
Verbose mode; print a progress indicator every five seconds.

### 4.6.2. `myisam_ftdump` — Display Full-Text Index information

`myisam_ftdump` displays information about `FULLTEXT` indexes in `MyISAM` tables. It reads the `MyISAM` index file directly, so it must be run on the server host where the table is located. Before using `myisam_ftdump`, be sure to issue a `FLUSH TABLES` statement first if the server is running.

`myisam_ftdump` scans and dumps the entire index, which is not particularly fast. On the other hand, the distribution of words changes infrequently, so it need not be run often.

Invoke `myisam_ftdump` like this:

```
shell> myisam_ftdump [options] tbl_name index_num
```

The `tbl_name` argument should be the name of a `MyISAM` table. You can also specify a table by naming its index file (the file with the `.MYI` suffix). If you do not invoke `myisam_ftdump` in the directory where the table files are located, the table or index file name must be preceded by the path name to the table's database directory. Index numbers begin with 0.

Example: Suppose that the `test` database contains a table named `mytexttable1` that has the following definition:

```
CREATE TABLE mytexttable1
```

```
(
 id INT NOT NULL,
 txt TEXT NOT NULL,
 PRIMARY KEY (id),
 FULLTEXT (txt)
)
```

The index on `id` is index 0 and the `FULLTEXT` index on `txt` is index 1. If your working directory is the `test` database directory, invoke `myisam_ftdump` as follows:

```
shell> myisam_ftdump mytexttable 1
```

If the path name to the `test` database directory is `/usr/local/mysql/data/test`, you can also specify the table name argument using that path name. This is useful if you do not invoke `myisam_ftdump` in the database directory:

```
shell> myisam_ftdump /usr/local/mysql/data/test/mytexttable 1
```

You can use `myisam_ftdump` to generate a list of index entries in order of frequency of occurrence like this:

```
shell> myisam_ftdump -c mytexttable 1 | sort -r
```

`myisam_ftdump` supports the following options:

- `--help, -h -?`

Display a help message and exit.

- `--count, -c`

Calculate per-word statistics (counts and global weights).

- `--dump, -d`

Dump the index, including data offsets and word weights.

- `--length, -l`

Report the length distribution.

- `--stats, -s`

Report global index statistics. This is the default operation if no other operation is specified.

- `--verbose, -v`

Verbose mode. Print more output about what the program does.

### 4.6.3. `myisamchk` — MyISAM Table-Maintenance Utility

The `myisamchk` utility gets information about your database tables or checks, repairs, or optimizes them. `myisamchk` works with MyISAM tables (tables that have `.MYD` and `.MYI` files for storing data and indexes).

You can also use the `CHECK TABLE` and `REPAIR TABLE` statements to check and repair MyISAM tables. See [Section 12.4.2.3, “`CHECK TABLE` Syntax”](#), and [Section 12.4.2.6, “`REPAIR TABLE` Syntax”](#).

The use of `myisamchk` with partitioned tables is not supported.

#### Caution

It is best to make a backup of a table before performing a table repair operation; under some circumstances the operation might cause data loss. Possible causes include but are not limited to file system errors.

Invoke `myisamchk` like this:

```
shell> myisamchk [options] tbl_name ...
```

The `options` specify what you want `myisamchk` to do. They are described in the following sections. You can also get a list of options by invoking `myisamchk --help`.

With no options, `myisamchk` simply checks your table as the default operation. To get more information or to tell `myisamchk` to take corrective action, specify options as described in the following discussion.

`tbl_name` is the database table you want to check or repair. If you run `myisamchk` somewhere other than in the database directory, you must specify the path to the database directory, because `myisamchk` has no idea where the database is located. In fact, `myisamchk` does not actually care whether the files you are working on are located in a database directory. You can copy the files that correspond to a database table into some other location and perform recovery operations on them there.

You can name several tables on the `myisamchk` command line if you wish. You can also specify a table by naming its index file (the file with the `.MYI` suffix). This enables you to specify all tables in a directory by using the pattern `*.MYI`. For example, if you are in a database directory, you can check all the `MyISAM` tables in that directory like this:

```
shell> myisamchk *.MYI
```

If you are not in the database directory, you can check all the tables there by specifying the path to the directory:

```
shell> myisamchk /path/to/database_dir/*.MYI
```

You can even check all tables in all databases by specifying a wildcard with the path to the MySQL data directory:

```
shell> myisamchk /path/to/datadir/**/*.MYI
```

The recommended way to quickly check all `MyISAM` tables is:

```
shell> myisamchk --silent --fast /path/to/datadir/**/*.MYI
```

If you want to check all `MyISAM` tables and repair any that are corrupted, you can use the following command:

```
shell> myisamchk --silent --force --fast --update-state \
 --key_buffer_size=64M --sort_buffer_size=64M \
 --read_buffer_size=1M --write_buffer_size=1M \
 /path/to/datadir/**/*.MYI
```

This command assumes that you have more than 64MB free. For more information about memory allocation with `myisamchk`, see [Section 4.6.3.6, “`myisamchk` Memory Usage”](#).

For additional information about using `myisamchk`, see [Section 6.6, “MyISAM Table Maintenance and Crash Recovery”](#).

### Important

*You must ensure that no other program is using the tables while you are running `myisamchk`.* The most effective means of doing so is to shut down the MySQL server while running `myisamchk`, or to lock all tables that `myisamchk` is being used on.

Otherwise, when you run `myisamchk`, it may display the following error message:

```
warning: clients are using or haven't closed the table properly
```

This means that you are trying to check a table that has been updated by another program (such as the `mysqld` server) that hasn't yet closed the file or that has died without closing the file properly, which can sometimes lead to the corruption of one or more `MyISAM` tables.

If `mysqld` is running, you must force it to flush any table modifications that are still buffered in memory by using `FLUSH TABLES`. You should then ensure that no one is using the tables while you are running `myisamchk`.

However, the easiest way to avoid this problem is to use `CHECK TABLE` instead of `myisamchk` to check tables. See [Section 12.4.2.3, “`CHECK TABLE` Syntax”](#).

`myisamchk` supports the following options, which can be specified on the command line or in the `[myisamchk]` option file group. `myisamchk` also supports the options for processing option files described at [Section 4.2.3.3.1, “Command-Line Options that Affect Option-File Handling”](#).

**Table 4.9. `myisamchk` Options**

Format	Config File	Description	Introduction	Deprecated	Removed
<code>--analyze</code>	<code>analyze</code>	Analyze the distribution of key values			
<code>--backup</code>	<code>backup</code>	Make a backup of the .MYD file as			

<b>Format</b>	<b>Config File</b>	<b>Description</b>	<b>Introduction</b>	<b>Deprecated</b>	<b>Removed</b>
		file_name-time.BAK			
<code>- - block- search=offset</code>	<code>block-search</code>	Find the record that a block at the given offset belongs to			
<code>--check</code>	<code>check</code>	Check the table for errors			
<code>- - check- only-changed</code>	<code>check- only-changed</code>	Check only tables that have changed since the last check			
<code>- -correct-checksum</code>	<code>correct-checksum</code>	Correct the checksum information for the table			
<code>- - data- file-length=len</code>	<code>data-file-length</code>	Maximum length of the data file (when re-creating data file when it is full)			
<code>- -de- bug[=debug_optio ns]</code>	<code>debug</code>	Write a debugging log			
<code>decode_bits=#</code>	<code>decode_bits</code>	Decode_bits			
<code>--description</code>	<code>description</code>	Print some descriptive information about the table			
<code>--extend-check</code>	<code>extend-check</code>	Do a repair that tries to recover every possible row from the data file			
<code>--extended-check</code>	<code>extended-check</code>	Check the table very thoroughly			
<code>--fast</code>	<code>fast</code>	Check only tables that haven't been closed properly			
<code>--force</code>	<code>force</code>	Do a repair operation automatically if myisamchk finds any errors in the table			
<code>--force</code>	<code>force-recover</code>	Overwrite old temporary files. For use with the -r or -o option			
<code>ft_max_word_len =#</code>	<code>ft_max_word_len</code>	Maximum word length for FULLTEXT indexes			
<code>ft_min_word_len =#</code>	<code>ft_min_word_len</code>	Minimum word length for FULLTEXT indexes			
<code>ft_stopword_file= value</code>	<code>ft_stopword_file</code>	Use stopwords from this file instead of built-in list			
<code>--HELP</code>		Display help message and exit			
<code>--help</code>		Display help message and exit			
<code>--information</code>	<code>information</code>	Print informational statistics about the table that is checked			
<code>key_buffer_size= #</code>	<code>key_buffer_size</code>	The size of the buffer used for index blocks for MyISAM tables			
<code>--keys-used=val</code>	<code>keys-used</code>	A bit-value that indicates which indexes to update			
<code>- - max-re- cord-length=len</code>	<code>max-record-length</code>	Skip rows larger than the given length if myisamchk cannot allocate memory to hold them			
<code>--medium-check</code>	<code>medium-check</code>	Do a check that is faster than an --extend-check operation			
<code>myis- am_block_size=#</code>	<code>myis- am_block_size</code>	Block size to be used for MyISAM index pages			
<code>--parallel-recover</code>	<code>parallel-recover</code>	Uses the same technique as -r and -n, but creates all the keys in parallel, using different threads (beta)			
<code>--quick</code>	<code>quick</code>	Achieve a faster repair by not modifying the data file.			

Format	Config File	Description	Introduction	Deprecated	Removed
read_buffer_size= #	read_buffer_size	Each thread that does a sequential scan allocates a buffer of this size for each table it scans			
--read-only	read-only	Don't mark the table as checked			
--recover	recover	Do a repair that can fix almost any problem except unique keys that aren't unique			
--safe-recover	safe-recover	Do a repair using an old recovery method that reads through all rows in order and updates all index trees based on the rows found			
- - set-auto-increment[=value]	set-auto-increment	Force AUTO_INCREMENT numbering for new records to start at the given value			
- - set-collation=name	set-collation	Specify the collation to use for sorting table indexes			
--silent	silent	Silent mode			
sort_buffer_size= #	sort_buffer_size	The buffer that is allocated when sorting the index when doing a REPAIR or when creating indexes with CREATE INDEX or ALTER TABLE			
--sort-index	sort-index	Sort the index tree blocks in high-low order			
sort_key_blocks= #	sort_key_blocks	sort_key_blocks			
--sort-records=#	sort-records	Sort records according to a particular index			
--sort-recover	sort-recover	Force myisamchk to use sorting to resolve the keys even if the temporary files would be very large			
stats_method=value	stats_method	Specifies how MyISAM index statistics collection code should treat NULLs			
--tmpdir=path	tmpdir	Path of the directory to be used for storing temporary files			
--unpack	unpack	Unpack a table that was packed with myisampack			
--update-state	update-state	Store information in the .MYI file to indicate when the table was checked and whether the table crashed			
--verbose		Verbose mode			
--version		Display version information and exit			
write_buffer_size =#	write_buffer_size	Write buffer size			

#### 4.6.3.1. `myisamchk` General Options

The options described in this section can be used for any type of table maintenance operation performed by `myisamchk`. The sections following this one describe options that pertain only to specific operations, such as table checking or repairing.

- `--help`, `-?`

Display a help message and exit. Options are grouped by type of operation.

- `--HELP`, `-H`

Display a help message and exit. Options are presented in a single list.

- `--debug=debug_options`, `-# debug_options`

Write a debugging log. A typical `debug_options` string is '`d:t:o,file_name`'. The default is '`d:t:o,/tmp/myisamchk.trace`'.

- **--silent, -s**

Silent mode. Write output only when errors occur. You can use `-s` twice (`-ss`) to make `myisamchk` very silent.

- **--verbose, -v**

Verbose mode. Print more information about what the program does. This can be used with `-d` and `-e`. Use `-v` multiple times (`-vv`, `-vvv`) for even more output.

- **--version, -V**

Display version information and exit.

- **--wait, -w**

Instead of terminating with an error if the table is locked, wait until the table is unlocked before continuing. If you are running `mysqld` with external locking disabled, the table can be locked only by another `myisamchk` command.

You can also set the following variables by using `--var_name=value` syntax:

Variable	Default Value
<code>decode_bits</code>	9
<code>ft_max_word_len</code>	version-dependent
<code>ft_min_word_len</code>	4
<code>ft_stopword_file</code>	built-in list
<code>key_buffer_size</code>	523264
<code>myisam_block_size</code>	1024
<code>read_buffer_size</code>	262136
<code>sort_buffer_size</code>	2097144
<code>sort_key_blocks</code>	16
<code>stats_method</code>	<code>nulls_unequal</code>
<code>write_buffer_size</code>	262136

The possible `myisamchk` variables and their default values can be examined with `myisamchk --help`:

`sort_buffer_size` is used when the keys are repaired by sorting keys, which is the normal case when you use `--recover`.

`key_buffer_size` is used when you are checking the table with `--extend-check` or when the keys are repaired by inserting keys row by row into the table (like when doing normal inserts). Repairing through the key buffer is used in the following cases:

- You use `--safe-recover`.
- The temporary files needed to sort the keys would be more than twice as big as when creating the key file directly. This is often the case when you have large key values for `CHAR`, `VARCHAR`, or `TEXT` columns, because the sort operation needs to store the complete key values as it proceeds. If you have lots of temporary space and you can force `myisamchk` to repair by sorting, you can use the `--sort-recover` option.

Repairing through the key buffer takes much less disk space than using sorting, but is also much slower.

If you want a faster repair, set the `key_buffer_size` and `sort_buffer_size` variables to about 25% of your available memory. You can set both variables to large values, because only one of them is used at a time.

`myisam_block_size` is the size used for index blocks.

`stats_method` influences how `NULL` values are treated for index statistics collection when the `--analyze` option is given. It acts like the `myisam_stats_method` system variable. For more information, see the description of `myisam_stats_method` in Section 5.1.4, “Server System Variables”, and Section 7.5.4, “MyISAM Index Statistics Collection”.

`ft_min_word_len` and `ft_max_word_len` indicate the minimum and maximum word length for `FULLTEXT` indexes. `ft_stopword_file` names the stopword file. These need to be set under the following circumstances.

If you use `myisamchk` to perform an operation that modifies table indexes (such as repair or analyze), the `FULLTEXT` indexes are rebuilt using the default full-text parameter values for minimum and maximum word length and the stopword file unless you specify otherwise. This can result in queries failing.

The problem occurs because these parameters are known only by the server. They are not stored in `MyISAM` index files. To avoid the problem if you have modified the minimum or maximum word length or the stopword file in the server, specify the same `ft_min_word_len`, `ft_max_word_len`, and `ft_stopword_file` values to `myisamchk` that you use for `mysqld`. For example, if you have set the minimum word length to 3, you can repair a table with `myisamchk` like this:

```
shell> myisamchk --recover --ft_min_word_len=3 tbl_name.MYI
```

To ensure that `myisamchk` and the server use the same values for full-text parameters, you can place each one in both the `[mysqld]` and `[myisamchk]` sections of an option file:

```
[mysqld]
ft_min_word_len=3

[myisamchk]
ft_min_word_len=3
```

An alternative to using `myisamchk` is to use the `REPAIR TABLE`, `ANALYZE TABLE`, `OPTIMIZE TABLE`, or `ALTER TABLE`. These statements are performed by the server, which knows the proper full-text parameter values to use.

#### 4.6.3.2. `myisamchk` Check Options

`myisamchk` supports the following options for table checking operations:

- `--check`, `-c`

Check the table for errors. This is the default operation if you specify no option that selects an operation type explicitly.

- `--check-only-changed`, `-C`

Check only tables that have changed since the last check.

- `--extend-check`, `-e`

Check the table very thoroughly. This is quite slow if the table has many indexes. This option should only be used in extreme cases. Normally, `myisamchk` or `myisamchk --medium-check` should be able to determine whether there are any errors in the table.

If you are using `--extend-check` and have plenty of memory, setting the `key_buffer_size` variable to a large value helps the repair operation run faster.

For a description of the output format, see [Section 4.6.3.5, “Obtaining Table Information with myisamchk”](#).

- `--fast`, `-F`

Check only tables that haven't been closed properly.

- `--force`, `-f`

Do a repair operation automatically if `myisamchk` finds any errors in the table. The repair type is the same as that specified with the `--recover` or `-r` option.

- `--information`, `-i`

Print informational statistics about the table that is checked.

- `--medium-check`, `-m`

Do a check that is faster than an `--extend-check` operation. This finds only 99.99% of all errors, which should be good enough in most cases.

- `--read-only`, `-T`

Do not mark the table as checked. This is useful if you use `myisamchk` to check a table that is in use by some other application that does not use locking, such as `mysqld` when run with external locking disabled.

- `--update-state`, `-U`

Store information in the `.MYI` file to indicate when the table was checked and whether the table crashed. This should be used to get full benefit of the `--check-only-changed` option, but you shouldn't use this option if the `mysqld` server is using the table and you are running it with external locking disabled.

#### 4.6.3.3. `myisamchk` Repair Options

`myisamchk` supports the following options for table repair operations (operations performed when an option such as `-recover` or `--safe-recover` is given):

- `--backup, -B`

Make a backup of the `.MYD` file as `file_name-time.BAK`

- `--character-sets-dir=path`

The directory where character sets are installed. See [Section 9.5, “Character Set Configuration”](#).

- `--correct-checksum`

Correct the checksum information for the table.

- `--data-file-length=len, -D len`

The maximum length of the data file (when re-creating data file when it is “full”).

- `--extend-check, -e`

Do a repair that tries to recover every possible row from the data file. Normally, this also finds a lot of garbage rows. Do not use this option unless you are desperate.

For a description of the output format, see [Section 4.6.3.5, “Obtaining Table Information with `myisamchk`”](#).

- `--force, -f`

Overwrite old intermediate files (files with names like `tbl_name.TMD`) instead of aborting.

- `--keys-used=val, -k val`

For `myisamchk`, the option value is a bit-value that indicates which indexes to update. Each binary bit of the option value corresponds to a table index, where the first index is bit 0. An option value of 0 disables updates to all indexes, which can be used to get faster inserts. Deactivated indexes can be reactivated by using `myisamchk -r`.

- `--no-symlinks, -l`

Do not follow symbolic links. Normally `myisamchk` repairs the table that a symlink points to. This option does not exist as of MySQL 4.0 because versions from 4.0 on do not remove symlinks during repair operations.

- `--max-record-length=len`

Skip rows larger than the given length if `myisamchk` cannot allocate memory to hold them.

- `--parallel-recover, -p`

Use the same technique as `-r` and `-n`, but create all the keys in parallel, using different threads. *This is beta-quality code. Use at your own risk!*

- `--quick, -q`

Achieve a faster repair by modifying only the index file, not the data file. You can specify this option twice to force `myisamchk` to modify the original data file in case of duplicate keys.

- `--recover, -r`

Do a repair that can fix almost any problem except unique keys that are not unique (which is an extremely unlikely error with MyISAM tables). If you want to recover a table, this is the option to try first. You should try `--safe-recover` only if `myisamchk` reports that the table cannot be recovered using `--recover`. (In the unlikely case that `--recover` fails, the data file remains intact.)

If you have lots of memory, you should increase the value of `sort_buffer_size`.

- `--safe-recover, -o`

Do a repair using an old recovery method that reads through all rows in order and updates all index trees based on the rows found. This is an order of magnitude slower than `--recover`, but can handle a couple of very unlikely cases that `--recover` cannot. This recovery method also uses much less disk space than `--recover`. Normally, you should repair first using `--recover`, and then with `--safe-recover` only if `--recover` fails.

If you have lots of memory, you should increase the value of `key_buffer_size`.

- `--set-character-set=name`

Change the character set used by the table indexes. This option was replaced by `--set-collation` in MySQL 5.0.3.

- `--set-collation=name`

Specify the collation to use for sorting table indexes. The character set name is implied by the first part of the collation name.

- `--sort-recover, -n`

Force `myisamchk` to use sorting to resolve the keys even if the temporary files would be very large.

- `--tmpdir=path, -t path`

The path of the directory to be used for storing temporary files. If this is not set, `myisamchk` uses the value of the `TMPDIR` environment variable. `--tmpdir` can be set to a list of directory paths that are used successively in round-robin fashion for creating temporary files. The separator character between directory names is the colon (“`:`”) on Unix and the semicolon (“`;`”) on Windows, NetWare, and OS/2.

- `--unpack, -u`

Unpack a table that was packed with `myisampack`.

#### 4.6.3.4. Other `myisamchk` Options

`myisamchk` supports the following options for actions other than table checks and repairs:

- `--analyze, -a`

Analyze the distribution of key values. This improves join performance by enabling the join optimizer to better choose the order in which to join the tables and which indexes it should use. To obtain information about the key distribution, use a `myisamchk --description --verbose tbl_name` command or the `SHOW INDEX FROM tbl_name` statement.

- `--block-search=offset, -b offset`

Find the record that a block at the given offset belongs to.

- `--description, -d`

Print some descriptive information about the table. Specifying the `--verbose` option once or twice produces additional information. See [Section 4.6.3.5, “Obtaining Table Information with myisamchk”](#).

- `--set-auto-increment [=value], -A[value]`

Force `AUTO_INCREMENT` numbering for new records to start at the given value (or higher, if there are existing records with `AUTO_INCREMENT` values this large). If `value` is not specified, `AUTO_INCREMENT` numbers for new records begin with the largest value currently in the table, plus one.

- `--sort-index, -S`

Sort the index tree blocks in high-low order. This optimizes seeks and makes table scans that use indexes faster.

- `--sort-records=N, -R N`

Sort records according to a particular index. This makes your data much more localized and may speed up range-based `SELECT` and `ORDER BY` operations that use this index. (The first time you use this option to sort a table, it may be very slow.) To determine a table's index numbers, use `SHOW INDEX`, which displays a table's indexes in the same order that `myisamchk`

sees them. Indexes are numbered beginning with 1.

If keys are not packed (`PACK_KEYS=0`), they have the same length, so when `myisamchk` sorts and moves records, it just overwrites record offsets in the index. If keys are packed (`PACK_KEYS=1`), `myisamchk` must unpack key blocks first, then re-create indexes and pack the key blocks again. (In this case, re-creating indexes is faster than updating offsets for each index.)

#### 4.6.3.5. Obtaining Table Information with `myisamchk`

To obtain a description of a `MyISAM` table or statistics about it, use the commands shown here. The output from these commands is explained later in this section.

- `myisamchk -d tbl_name`

Runs `myisamchk` in “describe mode” to produce a description of your table. If you start the MySQL server with external locking disabled, `myisamchk` may report an error for a table that is updated while it runs. However, because `myisamchk` does not change the table in describe mode, there is no risk of destroying data.

- `myisamchk -dv tbl_name`

Adding `-v` runs `myisamchk` in verbose mode so that it produces more information about the table. Adding `-vv` a second time produces even more information.

- `myisamchk -eis tbl_name`

Shows only the most important information from a table. This operation is slow because it must read the entire table.

- `myisamchk -eiv tbl_name`

This is like `-eis`, but tells you what is being done.

The `tbl_name` argument can be either the name of a `MyISAM` table or the name of its index file, as described in [Section 4.6.3, “myisamchk — MyISAM Table-Maintenance Utility”](#). Multiple `tbl_name` arguments can be given.

Suppose that a table named `person` has the following structure. (The `MAX_ROWS` table option is included so that in the example output from `myisamchk` shown later, some values are smaller and fit the output format more easily.)

```
CREATE TABLE person
(
 id INT NOT NULL AUTO_INCREMENT,
 last_name VARCHAR(20) NOT NULL,
 first_name VARCHAR(20) NOT NULL,
 birth DATE,
 death DATE,
 PRIMARY KEY (id),
 INDEX (last_name, first_name),
 INDEX (birth)
) MAX_ROWS = 1000000;
```

Suppose also that the table has these data and index file sizes:

```
-rw-rw---- 1 mysql mysql 9347072 Aug 19 11:47 person.MYD
-rw-rw---- 1 mysql mysql 6066176 Aug 19 11:47 person.MYI
```

Example of `myisamchk -dv` output:

```
MyISAM file: person
Record format: Packed
Character set: latin1_swedish_ci (8)
File-version: 1
Creation time: 2009-08-19 16:47:41
Recover time: 2009-08-19 16:47:56
Status: checked,analyzed,optimized keys
Auto increment key: 1 Last value: 306688
Data records: 306688 Deleted blocks: 0
Datafile parts: 306688 Deleted data: 0
Datafile pointer (bytes): 4 Keyfile pointer (bytes): 3
Datafile length: 9347072 Keyfile length: 6066176
Max datafile length: 4294967294 Max keyfile length: 17179868159
Recordlength: 54

table description:
Key Start Len Index Type Rec/key Root Blocksize
1 2 4 unique long 1 99328 1024
2 6 20 multip. varchar prefix 512 3563520 1024
27 20 20 varchar 512
3 48 3 multip. uint24 NULL 306688 6065152 1024
```

Field	Start	Length	Nullpos	Nullbit	Type
1	1	1			
2	2	4			no zeros
3	6	21			varchar
4	27	21			varchar
5	48	3	1	1	no zeros
6	51	3	1	2	no zeros

Explanations for the types of information `myisamchk` produces are given here. “Keyfile” refers to the index file. “Record” and “row” are synonymous, as are “field” and “column.”

The initial part of the table description contains these values:

- [MyISAM file](#)

Name of the [MyISAM](#) (index) file.

- [Record format](#)

The format used to store table rows. The preceding examples use [Fixed length](#). Other possible values are [Compressed](#) and [Packed](#). ([Packed](#) corresponds to what `SHOW TABLE STATUS` reports as [Dynamic](#).)

- [Character set](#)

The table default character set.

- [File-version](#)

Version of [MyISAM](#) format. Currently always 1.

- [Creation time](#)

When the data file was created.

- [Recover time](#)

When the index/data file was last reconstructed.

- [Status](#)

Table status flags. Possible values are [crashed](#), [open](#), [changed](#), [analyzed](#), [optimized keys](#), and [sorted index pages](#).

- [Auto increment key, Last value](#)

The key number associated the table's [AUTO\\_INCREMENT](#) column, and the most recently generated value for this column. These fields do not appear if there is no such column.

- [Data records](#)

The number of rows in the table.

- [Deleted blocks](#)

How many deleted blocks still have reserved space. You can optimize your table to minimize this space. See [Section 6.6.4, “MyISAM Table Optimization”](#).

- [Datafile parts](#)

For dynamic-row format, this indicates how many data blocks there are. For an optimized table without fragmented rows, this is the same as [Data records](#).

- [Deleted data](#)

How many bytes of unreclaimed deleted data there are. You can optimize your table to minimize this space. See [Section 6.6.4, “MyISAM Table Optimization”](#).

- [Datafile pointer](#)

The size of the data file pointer, in bytes. It is usually 2, 3, 4, or 5 bytes. Most tables manage with 2 bytes, but this cannot be controlled from MySQL yet. For fixed tables, this is a row address. For dynamic tables, this is a byte address.

- **Keyfile pointer**

The size of the index file pointer, in bytes. It is usually 1, 2, or 3 bytes. Most tables manage with 2 bytes, but this is calculated automatically by MySQL. It is always a block address.

- **Max datafile length**

How long the table data file can become, in bytes.

- **Max keyfile length**

How long the table index file can become, in bytes.

- **Recordlength**

How much space each row takes, in bytes.

The `table description` part of the output includes a list of all keys in the table. For each key, `myisamchk` displays some low-level information:

- **Key**

This key's number. This value is shown only for the first column of the key. If this value is missing, the line corresponds to the second or later column of a multiple-column key. For the table shown in the example, there are two `table description` lines for the second index. This indicates that it is a multiple-part index with two parts.

- **Start**

Where in the row this portion of the index starts.

- **Len**

How long this portion of the index is. For packed numbers, this should always be the full length of the column. For strings, it may be shorter than the full length of the indexed column, because you can index a prefix of a string column. The total length of a multiple-part key is the sum of the `Len` values for all key parts.

- **Index**

Whether a key value can exist multiple times in the index. Possible values are `unique` or `multip`. (multiple).

- **Type**

What data type this portion of the index has. This is a `MyISAM` data type with the possible values `packed`, `stripped`, or `empty`.

- **Root**

Address of the root index block.

- **Blocksize**

The size of each index block. By default this is 1024, but the value may be changed at compile time when MySQL is built from source.

- **Rec/key**

This is a statistical value used by the optimizer. It tells how many rows there are per value for this index. A unique index always has a value of 1. This may be updated after a table is loaded (or greatly changed) with `myisamchk -a`. If this is not updated at all, a default value of 30 is given.

The last part of the output provides information about each column:

- **Field**

The column number.

- **Start**

The byte position of the column within table rows.

- **Length**

The length of the column in bytes.

- **Nullpos, Nullbit**

For columns that can be **NULL**, MyISAM stores **NULL** values as a flag in a byte. Depending on how many nullable columns there are, there can be one or more bytes used for this purpose. The **Nullpos** and **Nullbit** values, if nonempty, indicate which byte and bit contains that flag indicating whether the column is **NULL**.

The position and number of bytes used to store **NULL** flags is shown in the line for field 1. This is why there are six **Field** lines for the **person** table even though it has only five columns.

- **Type**

The data type. The value may contain any of the following descriptors:

- **constant**

All rows have the same value.

- **noendspace**

Do not store endspace.

- **noendspace, not\_always**

Do not store endspace and do not do endspace compression for all values.

- **noendspace, noempty**

Do not store endspace. Do not store empty values.

- **table-lookup**

The column was converted to an **ENUM**.

- **zerofill(N)**

The most significant **N** bytes in the value are always 0 and are not stored.

- **nozeros**

Do not store zeros.

- **alwayszero**

Zero values are stored using one bit.

- **Huff tree**

The number of the Huffman tree associated with the column.

- **Bits**

The number of bits used in the Huffman tree.

The **Huff tree** and **Bits** fields are displayed if the table has been compressed with **myisampack**. See [Section 4.6.5, “myisampack — Generate Compressed, Read-Only MyISAM Tables”](#), for an example of this information.

Example of **myisamchk -eiv** output:

```
Checking MyISAM file: person
Data records: 306688 Deleted blocks: 0
- check file-size
- check record delete-chain
No recordlinks

Record data: 7934464 Deleted data: 0
Lost space: 256512 Linkdata: 1156096

User time 43.08, System time 1.68
Maximum resident set size 0, Integral resident set size 0
Non-physical pagefaults 0, Physical pagefaults 0, Swaps 0
Blocks in 0 out 7, Messages in 0 out 0, Signals 0
Voluntary context switches 0, Involuntary context switches 0
Maximum memory usage: 1046926 bytes (1023k)
```

`myisamchk -eiv` output includes the following information:

- **Data records**

The number of rows in the table.

- **Deleted blocks**

How many deleted blocks still have reserved space. You can optimize your table to minimize this space. See [Section 6.6.4, “MyISAM Table Optimization”](#).

- **Key**

The key number.

- **Keyblocks used**

What percentage of the keyblocks are used. When a table has just been reorganized with `myisamchk`, the values are very high (very near theoretical maximum).

- **Packed**

MySQL tries to pack key values that have a common suffix. This can only be used for indexes on `CHAR` and `VARCHAR` columns. For long indexed strings that have similar leftmost parts, this can significantly reduce the space used. In the preceding example, the second key is 40 bytes long and a 97% reduction in space is achieved.

- **Max levels**

How deep the B-tree for this key is. Large tables with long key values get high values.

- **Records**

How many rows are in the table.

- **M.recordlength**

The average row length. This is the exact row length for tables with fixed-length rows, because all rows have the same length.

- **Packed**

MySQL strips spaces from the end of strings. The `Packed` value indicates the percentage of savings achieved by doing this.

- **Recordspace used**

What percentage of the data file is used.

- **Empty space**

What percentage of the data file is unused.

- **Blocks/Record**

Average number of blocks per row (that is, how many links a fragmented row is composed of). This is always 1.0 for fixed-

format tables. This value should stay as close to 1.0 as possible. If it gets too large, you can reorganize the table. See [Section 6.6.4, “MyISAM Table Optimization”](#).

- [Recordblocks](#)

How many blocks (links) are used. For fixed-format tables, this is the same as the number of rows.

- [Deleteblocks](#)

How many blocks (links) are deleted.

- [Recorddata](#)

How many bytes in the data file are used.

- [Deleted data](#)

How many bytes in the data file are deleted (unused).

- [Lost space](#)

If a row is updated to a shorter length, some space is lost. This is the sum of all such losses, in bytes.

- [Linkdata](#)

When the dynamic table format is used, row fragments are linked with pointers (4 to 7 bytes each). [Linkdata](#) is the sum of the amount of storage used by all such pointers.

#### 4.6.3.6. [myisamchk](#) Memory Usage

Memory allocation is important when you run [myisamchk](#). [myisamchk](#) uses no more memory than its memory-related variables are set to. If you are going to use [myisamchk](#) on very large tables, you should first decide how much memory you want it to use. The default is to use only about 3MB to perform repairs. By using larger values, you can get [myisamchk](#) to operate faster. For example, if you have more than 512MB RAM available, you could use options such as these (in addition to any other options you might specify):

```
shell> myisamchk --sort_buffer_size=256M \
 --key_buffer_size=512M \
 --read_buffer_size=64M \
 --write_buffer_size=64M ...
```

Using [--sort\\_buffer\\_size=16M](#) is probably enough for most cases.

Be aware that [myisamchk](#) uses temporary files in [TMPDIR](#). If [TMPDIR](#) points to a memory file system, out of memory errors can easily occur. If this happens, run [myisamchk](#) with the [--tmpdir=path](#) option to specify a directory located on a file system that has more space.

When performing repair operations, [myisamchk](#) also needs a lot of disk space:

- Twice the size of the data file (the original file and a copy). This space is not needed if you do a repair with [--quick](#); in this case, only the index file is re-created. *This space must be available on the same file system as the original data file*, as the copy is created in the same directory as the original.
- Space for the new index file that replaces the old one. The old index file is truncated at the start of the repair operation, so you usually ignore this space. This space must be available on the same file system as the original data file.
- When using [--recover](#) or [--sort-recover](#) (but not when using [--safe-recover](#)), you need space on disk for sorting. This space is allocated in the temporary directory (specified by [TMPDIR](#) or [--tmpdir=path](#)). The following formula yields the amount of space required:

```
(largest_key + row_pointer_length) * number_of_rows * 2
```

You can check the length of the keys and the [row\\_pointer\\_length](#) with [myisamchk -dv tbl\\_name](#) (see [Section 4.6.3.5, “Obtaining Table Information with myisamchk”](#)). The [row\\_pointer\\_length](#) and [number\\_of\\_rows](#) values are the [Datafile pointer](#) and [Data records](#) values in the table description. To determine the [largest\\_key](#) value, check the [Key](#) lines in the table description. The [Len](#) column indicates the number of bytes for each key part. For a multiple-column index, the key size is the sum of the [Len](#) values for all key parts.

If you have a problem with disk space during repair, you can try `--safe-recover` instead of `--recover`.

#### 4.6.4. `myisamlog` — Display MyISAM Log File Contents

`myisamlog` processes the contents of a MyISAM log file.

Invoke `myisamlog` like this:

```
shell> myisamlog [options] [log_file [tbl_name] ...]
shell> isamlog [options] [log_file [tbl_name] ...]
```

The default operation is update (`-u`). If a recovery is done (`-r`), all writes and possibly updates and deletes are done and errors are only counted. The default log file name is `myisam.log` for `myisamlog` and `isam.log` for `isamlog` if no `log_file` argument is given. If tables are named on the command line, only those tables are updated.

`myisamlog` supports the following options:

- `-?, -I`

Display a help message and exit.

- `-c N`

Execute only `N` commands.

- `-f N`

Specify the maximum number of open files.

- `-i`

Display extra information before exiting.

- `-o offset`

Specify the starting offset.

- `-p N`

Remove `N` components from path.

- `-r`

Perform a recovery operation.

- `-R record_pos_file record_pos`

Specify record position file and record position.

- `-u`

Perform an update operation.

- `-v`

Verbose mode. Print more output about what the program does. This option can be given multiple times to produce more and more output.

- `-w write_file`

Specify the write file.

- `-V`

Display version information.

#### 4.6.5. `myisampack` — Generate Compressed, Read-Only MyISAM Tables

The `myisampack` utility compresses MyISAM tables. `myisampack` works by compressing each column in the table separately.

Usually, `myisampack` packs the data file 40% to 70%.

When the table is used later, the server reads into memory the information needed to decompress columns. This results in much better performance when accessing individual rows, because you only have to uncompress exactly one row.

MySQL uses `mmap()` when possible to perform memory mapping on compressed tables. If `mmap()` does not work, MySQL falls back to normal read/write file operations.

Please note the following:

- If the `mysqld` server was invoked with external locking disabled, it is not a good idea to invoke `myisampack` if the table might be updated by the server during the packing process. It is safest to compress tables with the server stopped.
- After packing a table, it becomes read only. This is generally intended (such as when accessing packed tables on a CD).

Invoke `myisampack` like this:

```
shell> myisampack [options] file_name ...
```

Each file name argument should be the name of an index (`.MYI`) file. If you are not in the database directory, you should specify the path name to the file. It is permissible to omit the `.MYI` extension.

After you compress a table with `myisampack`, you should use `myisamchk -rq` to rebuild its indexes. [Section 4.6.3, “myisamchk — MyISAM Table-Maintenance Utility”](#).

`myisampack` supports the following options. It also reads option files and supports the options for processing them described at [Section 4.2.3.3.1, “Command-Line Options that Affect Option-File Handling”](#).

- `--help, -?`

Display a help message and exit.

- `--backup, -b`

Make a backup of each table's data file using the name `tbl_name.OLD`.

- `--character-sets-dir=path`

The directory where character sets are installed. See [Section 9.5, “Character Set Configuration”](#).

- `--debug[=debug_options], -# [debug_options]`

Write a debugging log. A typical `debug_options` string is '`d:t:o,file_name`'. The default is '`d:t:o`'.

- `--force, -f`

Produce a packed table even if it becomes larger than the original or if the intermediate file from an earlier invocation of `myisampack` exists. (`myisampack` creates an intermediate file named `tbl_name.TMD` in the database directory while it compresses the table. If you kill `myisampack`, the `.TMD` file might not be deleted.) Normally, `myisampack` exits with an error if it finds that `tbl_name.TMD` exists. With `--force`, `myisampack` packs the table anyway.

- `--join=big_tbl_name, -j big_tbl_name`

Join all tables named on the command line into a single packed table `big_tbl_name`. All tables that are to be combined *must* have identical structure (same column names and types, same indexes, and so forth).

`big_tbl_name` must not exist prior to the join operation. All source tables named on the command line to be merged into `big_tbl_name` must exist. The source tables are read for the join operation but not modified. The join operation does not create a `.frm` file for `big_tbl_name`, so after the join operation finishes, copy the `.frm` file from one of the source tables and name it `big_tbl_name.frm`.

- `--silent, -s`

Silent mode. Write output only when errors occur.

- `--test, -t`

Do not actually pack the table, just test packing it.

- **--tmpdir=path, -T path**

Use the named directory as the location where `myisampack` creates temporary files.

- **--verbose, -v**

Verbose mode. Write information about the progress of the packing operation and its result.

- **--version, -V**

Display version information and exit.

- **--wait, -w**

Wait and retry if the table is in use. If the `mysqld` server was invoked with external locking disabled, it is not a good idea to invoke `myisampack` if the table might be updated by the server during the packing process.

The following sequence of commands illustrates a typical table compression session:

```
shell> ls -l station.*
-rw-rw-r-- 1 monty my 994128 Apr 17 19:00 station.MYD
-rw-rw-r-- 1 monty my 53248 Apr 17 19:00 station.MYI

56	827	4	no zeros, zerofill(2)	2	9
57	831	4	no zeros, zerofill(1)	2	9

`myisampack` displays the following kinds of information:

- **normal**

The number of columns for which no extra packing is used.

- **empty-space**

The number of columns containing values that are only spaces. These occupy one bit.

- **empty-zero**

The number of columns containing values that are only binary zeros. These occupy one bit.

- **empty-fill**

The number of integer columns that do not occupy the full byte range of their type. These are changed to a smaller type. For example, a `BIGINT` column (eight bytes) can be stored as a `TINYINT` column (one byte) if all its values are in the range from `-128` to `127`.

- **pre-space**

The number of decimal columns that are stored with leading spaces. In this case, each value contains a count for the number of leading spaces.

- **end-space**

The number of columns that have a lot of trailing spaces. In this case, each value contains a count for the number of trailing spaces.

- **table-lookup**

The column had only a small number of different values, which were converted to an `ENUM` before Huffman compression.

- **zero**

The number of columns for which all values are zero.

- **Original trees**

The initial number of Huffman trees.

- **After join**

The number of distinct Huffman trees left after joining trees to save some header space.

After a table has been compressed, the `Field` lines displayed by `myisamchk -dvv` include additional information about each column:

- **Type**

The data type. The value may contain any of the following descriptors:

- **constant**

All rows have the same value.

- **noendspace**

Do not store endspace.

- **noendspace, notalways**

Do not store endspace and do not do endspace compression for all values.

- `noendspace, noempty`  
Do not store endspace. Do not store empty values.
  - `table-lookup`  
The column was converted to an `ENUM`.
  - `zerofill(N)`  
The most significant `N` bytes in the value are always 0 and are not stored.
  - `nozeros`  
Do not store zeros.
  - `alwayszero`  
Zero values are stored using one bit.
- `Huff tree`  
The number of the Huffman tree associated with the column.
  - `Bits`  
The number of bits used in the Huffman tree.

After you run `myisampack`, you must run `myisamchk` to re-create any indexes. At this time, you can also sort the index blocks and create statistics needed for the MySQL optimizer to work more efficiently:

```
shell> myisamchk -rq --sort-index --analyze tbl_name.MYI
```

After you have installed the packed table into the MySQL database directory, you should execute `mysqladmin flush-tables` to force `mysqld` to start using the new table.

To unpack a packed table, use the `--unpack` option to `myisamchk`.

#### 4.6.6. `mysqlaccess` — Client for Checking Access Privileges

`mysqlaccess` is a diagnostic tool that Yves Carlier has provided for the MySQL distribution. It checks the access privileges for a host name, user name, and database combination. Note that `mysqlaccess` checks access using only the `user`, `db`, and `host` tables. It does not check table, column, or routine privileges specified in the `tables_priv`, `columns_priv`, or `procs_priv` tables.

Invoke `mysqlaccess` like this:

```
shell> mysqlaccess [host_name [user_name [db_name]]] [options]
```

`mysqlaccess` supports the following options.

**Table 4.10. `mysqlaccess` Options**

Format	Config File	Description	Introduction	Deprecated	Removed
<code>-brief</code>	<code>brief</code>	Generate reports in single-line tabular format			
<code>--commit</code>	<code>commit</code>	Copy the new access privileges from the temporary tables to the original grant tables			
<code>--copy</code>	<code>copy</code>	Reload the temporary grant tables from original ones			
<code>--db=db_name</code>	<code>db</code>	Specify the database name			
<code>--debug=#</code>	<code>debug</code>	Specify the debug level			
<code>--help</code>		Display help message and exit			
<code>--host=host_name</code>	<code>host</code>	Connect to the MySQL server on the given host			

Format	Config File	Description	Introduction	Deprecated	Removed
--howto	howto	Display some examples that show how to use <code>mysqlaccess</code>			
--old_server	old_server	Assume that the server is an old MySQL server (prior to MySQL 3.21)			
- -pass- word[=password]	password	The password to use when connecting to the server			
--plan	plan	Display suggestions and ideas for future releases			
--preview	preview	Show the privilege differences after making changes to the temporary grant tables			
--relnotes	relnotes	Display the release notes			
- -rhost=host_name	rhost	Connect to the MySQL server on the given host			
--rollback	rollback	Undo the most recent changes to the temporary grant tables.			
- -spass- word[=password]	spassword	The password to use when connecting to the server as the superuser			
- -super- user=user_name	superuser	Specify the user name for connecting as the superuser			
--table	table	Generate reports in table format			
- -user=user_name,	user	The MySQL user name to use when connecting			
--version		Display version information and exit			

- **--help, -?**

Display a help message and exit.

- **--brief, -b**

Generate reports in single-line tabular format.

- **--commit**

Copy the new access privileges from the temporary tables to the original grant tables. The grant tables must be flushed for the new privileges to take effect. (For example, execute a `mysqladmin reload` command.)

- **--copy**

Reload the temporary grant tables from original ones.

- **--db=db\_name, -d db\_name**

Specify the database name.

- **--debug=N**

Specify the debug level. *N* can be an integer from 0 to 3.

- **--host=host\_name, -h host\_name**

The host name to use in the access privileges.

- **--howto**

Display some examples that show how to use `mysqlaccess`.

- **--old\_server**

Assume that the server is an old MySQL server (before MySQL 3.21) that does not yet know how to handle full `WHERE`

clauses.

- `--password[=password], -p[password]`

The password to use when connecting to the server. If you omit the `password` value following the `--password` or `-p` option on the command line, `mysqlaccess` prompts for one.

Specifying a password on the command line should be considered insecure. See [Section 5.3.2.2, “End-User Guidelines for Password Security”](#).

- `--plan`

Display suggestions and ideas for future releases.

- `--preview`

Show the privilege differences after making changes to the temporary grant tables.

- `--relnotes`

Display the release notes.

- `--rhost=host_name, -H host_name`

Connect to the MySQL server on the given host.

- `--rollback`

Undo the most recent changes to the temporary grant tables.

- `--spassword[=password], -P[password]`

The password to use when connecting to the server as the superuser. If you omit the `password` value following the `--spassword` or `-P` option on the command line, `mysqlaccess` prompts for one.

Specifying a password on the command line should be considered insecure. See [Section 5.3.2.2, “End-User Guidelines for Password Security”](#).

- `--superuser=user_name, -U user_name`

Specify the user name for connecting as the superuser.

- `--table, -t`

Generate reports in table format.

- `--user=user_name, -u user_name`

The user name to use in the access privileges.

- `--version, -v`

Display version information and exit.

If your MySQL distribution is installed in some nonstandard location, you must change the location where `mysqlaccess` expects to find the `mysql` client. Edit the `mysqlaccess` script at approximately line 18. Search for a line that looks like this:

```
$MYSQL = '/usr/local/bin/mysql'; # path to mysql executable
```

Change the path to reflect the location where `mysql` actually is stored on your system. If you do not do this, a `Broken pipe` error will occur when you run `mysqlaccess`.

## 4.6.7. `mysqlbinlog` — Utility for Processing Binary Log Files

The server's binary log consists of files containing “events” that describe modifications to database contents. The server writes these files in binary format. To display their contents in text format, use the `mysqlbinlog` utility. You can also use `mysqlbinlog` to display the contents of relay log files written by a slave server in a replication setup because relay logs have the same format as binary logs. The binary log and relay log are discussed further in [Section 5.2.4, “The Binary Log”](#), and [Section 16.2.2, “Replication Relay and Status Files”](#).

Invoke `mysqlbinlog` like this:

```
shell> mysqlbinlog [options] log_file ...
```

For example, to display the contents of the binary log file named `binlog.000003`, use this command:

```
shell> mysqlbinlog binlog.000003
```

The output includes events contained in `binlog.000003`. For statement-based logging, event information includes the SQL statement, the ID of the server on which it was executed, the timestamp when the statement was executed, how much time it took, and so forth. For row-based logging, the event indicates a row change rather than an SQL statement. See [Section 16.1.2, “Replication Formats”](#), for information about logging modes.

Events are preceded by header comments that provide additional information. For example:

```
at 141
#100309 9:28:36 server id 123 end_log_pos 245
 Query thread_id=3350 exec_time=11 error_code=0
```

In the first line, the number following `at` indicates the starting position of the event in the binary log file.

The second line starts with a date and time indicating when the statement started on the server where the event originated. For replication, this timestamp is propagated to slave servers. `server id` is the `server_id` value of the server where the event originated. `end_log_pos` indicates where the next event starts (that is, it is the end position of the current event + 1). `thread_id` indicates which thread executed the event. `exec_time` is the time spent executing the event, on a master server. On a slave, it is the difference of the end execution time on the slave minus the beginning execution time on the master. The difference serves as an indicator of how much replication lags behind the master. `error_code` indicates the result from executing the event. Zero means that no error occurred.

The output from `mysqlbinlog` can be re-executed (for example, by using it as input to `mysql`) to redo the statements in the log. This is useful for recovery operations after a server crash. For other usage examples, see the discussion later in this section and in [Section 6.5, “Point-in-Time \(Incremental\) Recovery Using the Binary Log”](#).

Normally, you use `mysqlbinlog` to read binary log files directly and apply them to the local MySQL server. It is also possible to read binary logs from a remote server by using the `--read-from-remote-server` option. To read remote binary logs, the connection parameter options can be given to indicate how to connect to the server. These options are `--host`, `--password`, `--port`, `--protocol`, `--socket`, and `--user`; they are ignored except when you also use the `--read-from-remote-server` option.

`mysqlbinlog` supports the following options, which can be specified on the command line or in the `[mysqlbinlog]` and `[client]` option file groups. `mysqlbinlog` also supports the options for processing option files described at [Section 4.2.3.3.1, “Command-Line Options that Affect Option-File Handling”](#).

**Table 4.11. `mysqlbinlog` Options**

Format	Config File	Description	Introduction	Deprecated	Removed
<code>-</code> <code>-base64-output[=value]</code>	<code>base64-output</code>	Print binary log entries using base-64 encoding	5.1.5		
<code>-character-sets-dir=path</code>	<code>character-sets-dir</code>	The directory where character sets are installed			
<code>-database=db_name</code>	<code>database</code>	List entries for just this database			
<code>-debug[=debug_options]</code>	<code>debug</code>	Write a debugging log			
<code>--debug-check</code>	<code>debug-check</code>	Print debugging information when the program exits	5.1.21		
<code>--debug-info</code>	<code>debug-info</code>	Print debugging information, memory and CPU statistics when the program exits	5.1.21		
<code>--disable-log-bin</code>	<code>disable-log-bin</code>	Disable binary logging			

Format	Config File	Description	Introduction	Deprecated	Removed
--force-read	force-read	If mysqlbinlog reads a binary log event that it does not recognize, it prints a warning			
--help		Display help message and exit			
--hexdump	hexdump	Display a hex dump of the log in comments	5.1.2		
--host=host_name	host	Connect to the MySQL server on the given host			
--local-load=path	local-load	Prepare local temporary files for LOAD DATA INFILE in the specified directory			
--offset=#	offset	Skip the first N entries in the log			
- - -pass- word[=password]	password	The password to use when connecting to the server			
--port=port_num	port	The TCP/IP port number to use for the connection			
--position=#	position	Deprecated. Use --start-position			
--protocol=type	protocol	The connection protocol to use			
- - read- from-re- mote-server	read- from-re- mote-server	Read the binary log from a MySQL server rather than reading a local log file			
--result-file=name	result-file	Direct output to the given file			
--server-id=id	server-id	Extract only those events created by the server having the given server ID	5.1.4		
--server-id-bits=#	server-id-bits	Tell mysqlbinlog how to interpret the server IDs in the binary log when the binary log was written by a mysqld having its server-id-bits set to less than the maximum. Supported only by the MySQL Cluster version of mysqlbinlog.	5.1.47-ndb- 7.1.6		
- - set-char- set=charset_name	set-charset	Add a SET NAMES charset_name statement to the output	5.1.12		
--short-form	short-form	Display only the statements contained in the log			
--socket=path	socket	For connections to localhost			
- - start-date- time=datetime	start-datetime	Start reading the binary log at the first event having a timestamp equal to or later than the datetime argument			
--start-position=#	start-position	Start reading the binary log at the first event having a position equal to or greater than the argument			
- - stop-date- time=datetime	stop-datetime	Stop reading the binary log at the first event having a timestamp equal to or greater than the datetime argument			
--stop-position=#	stop-position	Stop reading the binary log at the first event having a position equal to or greater than the argument			
--to-last-log	to-last-log	Do not stop at the end of the requested binary log from a MySQL server, but rather continue printing until the end of the last binary log			
- -user=user_name,	user	The MySQL user name to use when connecting to the server			
--verbose		Reconstruct row events as SQL statements	5.1.28		
--version		Display version information and exit			

- `--help, -?`

Display a help message and exit.

- `--base64-output[=value]`

This option determines when events should be displayed encoded as base-64 strings using `BINLOG` statements. The option has these permissible values (not case sensitive):

- `AUTO` ("automatic") or `UNSPEC` ("unspecified") displays `BINLOG` statements automatically when necessary (that is, for format description events and row events). This is the default if no `--base64-output` option is given.

### Note

Automatic `BINLOG` display is the only safe behavior if you intend to use the output of `mysqlbinlog` to re-execute binary log file contents. The other option values are intended only for debugging or testing purposes because they may produce output that does not include all events in executable form.

- `ALWAYS` displays `BINLOG` statements whenever possible. This is the implied value if the option is given as `--base64-output` without a value.
- `NEVER` causes `BINLOG` statements not to be displayed. `mysqlbinlog` exits with an error if a row event is found that must be displayed using `BINLOG`.
- `DECODE-ROWS` specifies to `mysqlbinlog` that you intend for row events to be decoded and displayed as commented SQL statements by also specifying the `--verbose` option. Like `NEVER`, `DECODE-ROWS` suppresses display of `BINLOG` statements, but unlike `NEVER`, it does not exit with an error if a row event is found.

The `--base64-output` option was introduced in MySQL 5.1.5, to be given as `--base64-output` or `--skip-base64-output` (with the sense of `AUTO` or `NEVER`). The option values described in the preceding list may be used as of MySQL 5.1.24, with the exception of `UNSPEC` and `DECODE-ROWS`, which are available as of MySQL 5.1.28.

For examples that show the effect of `--base64-output` and `--verbose` on row event output, see [Section 4.6.7.2, “mysqlbinlog Row Event Display”](#).

- `--character-sets-dir=path`

The directory where character sets are installed. See [Section 9.5, “Character Set Configuration”](#).

- `--database=db_name, -d db_name`

This option causes `mysqlbinlog` to output entries from the binary log (local log only) that occur while `db_name` is been selected as the default database by `USE`.

The `--database` option for `mysqlbinlog` is similar to the `--binlog-do-db` option for `mysqld`, but can be used to specify only one database. If `--database` is given multiple times, only the last instance is used.

The effects of this option depend on whether the statement-based or row-based logging format is in use, in the same way that the effects of `--binlog-do-db` depend on whether statement-based or row-based logging is in use.

**Statement-based logging.** The `--database` option works as follows:

- While `db_name` is the default database, statements are output whether they modify tables in `db_name` or a different database.
- Unless `db_name` is selected as the default database, statements are not output, even if they modify tables in `db_name`.
- There is an exception for `CREATE DATABASE`, `ALTER DATABASE`, and `DROP DATABASE`. The database being *created, altered, or dropped* is considered to be the default database when determining whether to output the statement.

Suppose that the binary log was created by executing these statements using statement-based-logging:

```
INSERT INTO test.t1 (i) VALUES(100);
INSERT INTO db2.t2 (j) VALUES(200);
USE test;
INSERT INTO test.t1 (i) VALUES(101);
INSERT INTO t1 (i) VALUES(102);
INSERT INTO db2.t2 (j) VALUES(201);
USE db2;
INSERT INTO test.t1 (i) VALUES(103);
INSERT INTO db2.t2 (j) VALUES(202);
INSERT INTO t2 (j) VALUES(203);
```

`mysqlbinlog --database=test` does not output the first two `INSERT` statements because there is no default database.

It outputs the three `INSERT` statements following `USE test`, but not the three `INSERT` statements following `USE db2`.

`mysqlbinlog --database=db2` does not output the first two `INSERT` statements because there is no default database. It does not output the three `INSERT` statements following `USE test`, but does output the three `INSERT` statements following `USE db2`.

**Row-based logging.** `mysqlbinlog` outputs only entries that change tables belonging to `db_name`. The default database has no effect on this. Suppose that the binary log just described was created using row-based logging rather than statement-based logging. `mysqlbinlog --database=test` outputs only those entries that modify `t1` in the test database, regardless of whether `USE` was issued or what the default database is.

If a server is running with `binlog_format` set to `MIXED` and you want it to be possible to use `mysqlbinlog` with the `--database` option, you must ensure that tables that are modified are in the database selected by `USE`. (In particular, no cross-database updates should be used.)

### Note

This option did not work correctly for `mysqlbinlog` with row-based logging prior to MySQL 5.1.37. ([Bug#42941](#))

- `--debug[=debug_options], -# [debug_options]`

Write a debugging log. A typical `debug_options` string is '`d:t:o,file_name`'. The default is '`d:t:o,/tmp/mysqlbinlog.trace`'.

- `--debug-check`

Print some debugging information when the program exits. This option was added in MySQL 5.1.21.

- `--debug-info`

Print debugging information and memory and CPU usage statistics when the program exits. This option was added in MySQL 5.1.21.

- `--disable-log-bin, -D`

Disable binary logging. This is useful for avoiding an endless loop if you use the `--to-last-log` option and are sending the output to the same MySQL server. This option also is useful when restoring after a crash to avoid duplication of the statements you have logged.

This option requires that you have the `SUPER` privilege. It causes `mysqlbinlog` to include a `SET sql_log_bin = 0` statement in its output to disable binary logging of the remaining output. The `SET` statement is ineffective unless you have the `SUPER` privilege.

- `--force-read, -f`

With this option, if `mysqlbinlog` reads a binary log event that it does not recognize, it prints a warning, ignores the event, and continues. Without this option, `mysqlbinlog` stops if it reads such an event.

- `--hexdump, -H`

Display a hex dump of the log in comments, as described in [Section 4.6.7.1, “mysqlbinlog Hex Dump Format”](#). The hex output can be helpful for replication debugging. This option was added in MySQL 5.1.2.

- `--host=host_name, -h host_name`

Get the binary log from the MySQL server on the given host.

- `--local-load=path, -l path`

Prepare local temporary files for `LOAD DATA INFILE` in the specified directory.

### Important

These temporary files are not automatically removed by `mysqlbinlog` or any other MySQL program.

- `--offset=N, -o N`

Skip the first `N` entries in the log.

- `--password[=password], -p[password]`

The password to use when connecting to the server. If you use the short option form (`-p`), you *cannot* have a space between the option and the password. If you omit the `password` value following the `--password` or `-p` option on the command line, `mysqlbinlog` prompts for one.

Specifying a password on the command line should be considered insecure. See [Section 5.3.2.2, “End-User Guidelines for Password Security”](#). You can use an option file to avoid giving the password on the command line.

- `--port=port_num, -P port_num`

The TCP/IP port number to use for connecting to a remote server.

- `--position=N`

Deprecated. Use `--start-position` instead. `--position` is removed in MySQL 5.5.

- `--protocol={TCP|SOCKET|PIPE|MEMORY}`

The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want. For details on the permissible values, see [Section 4.2.2, “Connecting to the MySQL Server”](#).

- `--read-from-remote-server, -R`

Read the binary log from a MySQL server rather than reading a local log file. Any connection parameter options are ignored unless this option is given as well. These options are `--host`, `--password`, `--port`, `--protocol`, `--socket`, and `--user`.

This option requires that the remote server be running. It works only for binary log files on the remote server, not relay log files.

- `--result-file=name, -r name`

Direct output to the given file.

- `--server-id=id`

Display only those events created by the server having the given server ID. This option is available as of MySQL 5.1.4.

- `--server-id-bits=N`

Use only the first `N` bits of the `server_id` to identify the server. If the binary log was written by a `mysqld` with server-id-bits set to less than 32 and user data stored in the most significant bit, running `mysqlbinlog` with `--server-id-bits` set to 32 enables this data to be seen.

This option was added in MySQL Cluster NDB 7.0.17 and MySQL Cluster NDB 7.1.6, and is supported only by the versions of `mysqlbinlog` supplied with these and later releases of MySQL Cluster.

- `--set-charset=charset_name`

Add a `SET NAMES charset_name` statement to the output to specify the character set to be used for processing log files. This option was added in MySQL 5.1.12.

- `--short-form, -s`

Display only the statements contained in the log, without any extra information.

- `--socket=path, -S path`

For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

- `--start-datetime=datetime`

Start reading the binary log at the first event having a timestamp equal to or later than the `datetime` argument. The `datetime` value is relative to the local time zone on the machine where you run `mysqlbinlog`. The value should be in a format accepted for the `DATETIME` or `TIMESTAMP` data types. For example:

```
shell> mysqlbinlog --start-datetime="2005-12-25 11:25:56" binlog.000003
```

This option is useful for point-in-time recovery. See [Section 6.3, “Example Backup and Recovery Strategy”](#).

- **--start-position=N, -j N**

Start reading the binary log at the first event having a position equal to or greater than *N*. This option applies to the first log file named on the command line.

This option is useful for point-in-time recovery. See [Section 6.3, “Example Backup and Recovery Strategy”](#).

- **--stop-datetime=datetime**

Stop reading the binary log at the first event having a timestamp equal to or later than the *datetime* argument. This option is useful for point-in-time recovery. See the description of the [--start-datetime](#) option for information about the *date-time* value.

This option is useful for point-in-time recovery. See [Section 6.3, “Example Backup and Recovery Strategy”](#).

- **--stop-position=N**

Stop reading the binary log at the first event having a position equal to or greater than *N*. This option applies to the last log file named on the command line.

This option is useful for point-in-time recovery. See [Section 6.3, “Example Backup and Recovery Strategy”](#).

- **--to-last-log, -t**

Do not stop at the end of the requested binary log from a MySQL server, but rather continue printing until the end of the last binary log. If you send the output to the same MySQL server, this may lead to an endless loop. This option requires [-read-from-remote-server](#).

- **--user=user\_name, -u user\_name**

The MySQL user name to use when connecting to a remote server.

- **--verbose, -v**

Reconstruct row events and display them as commented SQL statements. If this option is given twice, the output includes comments to indicate column data types and some metadata. This option was added in MySQL 5.1.28.

For examples that show the effect of [--base64-output](#) and [--verbose](#) on row event output, see [Section 4.6.7.2, “mysqlbinlog Row Event Display”](#).

- **--version, -V**

Display version information and exit.

You can also set the following variable by using [--var\\_name=value](#) syntax:

- **open\_files\_limit**

Specify the number of open file descriptors to reserve.

You can pipe the output of [mysqlbinlog](#) into the [mysql](#) client to execute the events contained in the binary log. This technique is used to recover from a crash when you have an old backup (see [Section 6.5, “Point-in-Time \(Incremental\) Recovery Using the Binary Log”](#)). For example:

```
shell> mysqlbinlog binlog.000001 | mysql -u root -p
```

Or:

```
shell> mysqlbinlog binlog.[0-9]* | mysql -u root -p
```

You can also redirect the output of [mysqlbinlog](#) to a text file instead, if you need to modify the statement log first (for example, to remove statements that you do not want to execute for some reason). After editing the file, execute the statements that it contains by using it as input to the [mysql](#) program:

```
shell> mysqlbinlog binlog.000001 > tmpfile
shell> ... edit tmpfile ...
shell> mysql -u root -p < tmpfile
```

When `mysqlbinlog` is invoked with the `--start-position` option, it displays only those events with an offset in the binary log greater than or equal to a given position (the given position must match the start of one event). It also has options to stop and start when it sees an event with a given date and time. This enables you to perform point-in-time recovery using the `-stop-datetime` option (to be able to say, for example, “roll forward my databases to how they were today at 10:30 a.m.”).

If you have more than one binary log to execute on the MySQL server, the safe method is to process them all using a single connection to the server. Here is an example that demonstrates what may be *unsafe*:

```
shell> mysqlbinlog binlog.000001 | mysql -u root -p # DANGER!!
shell> mysqlbinlog binlog.000002 | mysql -u root -p # DANGER!!
```

Processing binary logs this way using multiple connections to the server causes problems if the first log file contains a `CREATE TEMPORARY TABLE` statement and the second log contains a statement that uses the temporary table. When the first `mysql` process terminates, the server drops the temporary table. When the second `mysql` process attempts to use the table, the server reports “unknown table.”

To avoid problems like this, use a *single* `mysql` process to execute the contents of all binary logs that you want to process. Here is one way to do so:

```
shell> mysqlbinlog binlog.000001 binlog.000002 | mysql -u root -p
```

Another approach is to write all the logs to a single file and then process the file:

```
shell> mysqlbinlog binlog.000001 > /tmp/statements.sql
shell> mysqlbinlog binlog.000002 >> /tmp/statements.sql
shell> mysql -u root -p -e "source /tmp/statements.sql"
```

`mysqlbinlog` can produce output that reproduces a `LOAD DATA INFILE` operation without the original data file. `mysql-binlog` copies the data to a temporary file and writes a `LOAD DATA LOCAL INFILE` statement that refers to the file. The default location of the directory where these files are written is system-specific. To specify a directory explicitly, use the `-local-load` option.

Because `mysqlbinlog` converts `LOAD DATA INFILE` statements to `LOAD DATA LOCAL INFILE` statements (that is, it adds `LOCAL`), both the client and the server that you use to process the statements must be configured with the `LOCAL` capability enabled. See [Section 5.3.5, “Security Issues with LOAD DATA LOCAL”](#).

## Warning

The temporary files created for `LOAD DATA LOCAL` statements are *not* automatically deleted because they are needed until you actually execute those statements. You should delete the temporary files yourself after you no longer need the statement log. The files can be found in the temporary file directory and have names like `origin-al_file_name-#-#`.

### 4.6.7.1. `mysqlbinlog` Hex Dump Format

The `--hexdump` option causes `mysqlbinlog` to produce a hex dump of the binary log contents:

```
shell> mysqlbinlog --hexdump master-bin.000001
```

The hex output consists of comment lines beginning with `#`, so the output might look like this for the preceding command:

```
/*!40019 SET @SESSION.max_insert_delayed_threads=0*/;
/*!50003 SET @OLD_COMPLETION_TYPE=@COMPLETION_TYPE,COMPLETION_TYPE=0*/;
at 4
#051024 17:24:13 server id 1 end_log_pos 98
Position Timestamp Type Master ID Size Master Pos Flags
00000004 9d fc 5c 43 Of 01 00 00 00 5e 00 00 00 62 00 00 00 00 00
00000017 04 00 35 2e 30 2e 31 35 2d 64 65 62 75 67 2d 6c | ..5.0.15.debug.1
00000027 6f 67 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00
00000037 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00
00000047 00 00 00 00 00 9d fc 5c 43 13 38 0d 00 08 00 12 00
00000057 04 04 04 04 12 00 00 4b 00 04 1a |C.8....|
Start: binlog v 4, server v 5.0.15-debug-log created 051024 17:24:13
at startup
ROLLBACK;
```

Hex dump output currently contains the elements in the following list. This format is subject to change. (For more information about binary log format, see [http://forge.mysql.com/wiki/MySQL\\_Internals\\_Binary\\_Log](http://forge.mysql.com/wiki/MySQL_Internals_Binary_Log).)

- **Position:** The byte position within the log file.
- **Timestamp:** The event timestamp. In the example shown, '`9d fc 5c 43`' is the representation of '`051024`

17:24:13' in hexadecimal.

- **Type:** The event type code. In the example shown, '0f' indicates a `FORMAT_DESCRIPTION_EVENT`. The following table lists the possible type codes.

Type	Name	Meaning
00	<code>UNKNOWN_EVENT</code>	This event should never be present in the log.
01	<code>START_EVENT_V3</code>	This indicates the start of a log file written by MySQL 4 or earlier.
02	<code>QUERY_EVENT</code>	The most common type of events. These contain statements executed on the master.
03	<code>STOP_EVENT</code>	Indicates that master has stopped.
04	<code>ROTATE_EVENT</code>	Written when the master switches to a new log file.
05	<code>INTVAR_EVENT</code>	Used for <code>AUTO_INCREMENT</code> values or when the <code>LAST_INSERT_ID()</code> function is used in the statement.
06	<code>LOAD_EVENT</code>	Used for <code>LOAD DATA INFILE</code> in MySQL 3.23.
07	<code>SLAVE_EVENT</code>	Reserved for future use.
08	<code>CREATE_FILE_EVENT</code>	Used for <code>LOAD DATA INFILE</code> statements. This indicates the start of execution of such a statement. A temporary file is created on the slave. Used in MySQL 4 only.
09	<code>APPEND_BLOCK_EVENT</code>	Contains data for use in a <code>LOAD DATA INFILE</code> statement. The data is stored in the temporary file on the slave.
0a	<code>EXEC_LOAD_EVENT</code>	Used for <code>LOAD DATA INFILE</code> statements. The contents of the temporary file is stored in the table on the slave. Used in MySQL 4 only.
0b	<code>DELETE_FILE_EVENT</code>	Rollback of a <code>LOAD DATA INFILE</code> statement. The temporary file should be deleted on the slave.
0c	<code>NEW_LOAD_EVENT</code>	Used for <code>LOAD DATA INFILE</code> in MySQL 4 and earlier.
0d	<code>RAND_EVENT</code>	Used to send information about random values if the <code>RAND()</code> function is used in the statement.
0e	<code>USER_VAR_EVENT</code>	Used to replicate user variables.
0f	<code>FORMAT_DESCRIPTION_EVENT</code>	This indicates the start of a log file written by MySQL 5 or later.
10	<code>XID_EVENT</code>	Event indicating commit of an XA transaction.
11	<code>BEGIN_LOAD_QUERY_EVENT</code>	Used for <code>LOAD DATA INFILE</code> statements in MySQL 5 and later.
12	<code>EXECUTE_LOAD_QUERY_EVENT</code>	Used for <code>LOAD DATA INFILE</code> statements in MySQL 5 and later.
13	<code>TABLE_MAP_EVENT</code>	Information about a table definition. Used in MySQL 5.1.5 and later.
14	<code>PRE_GA_WRITE_ROWS_EVENT</code>	Row data for a single table that should be created. Used in MySQL 5.1.5 to 5.1.17.
15	<code>PRE_GA_UPDATE_ROWS_EVENT</code>	Row data for a single table that needs to be updated. Used in MySQL 5.1.5 to 5.1.17.
16	<code>PRE_GA_DELETE_ROWS_EVENT</code>	Row data for a single table that should be deleted. Used in MySQL 5.1.5 to 5.1.17.
17	<code>WRITE_ROWS_EVENT</code>	Row data for a single table that should be created. Used in MySQL 5.1.18 and later.
18	<code>UPDATE_ROWS_EVENT</code>	Row data for a single table that needs to be updated. Used in MySQL 5.1.18 and later.
19	<code>DELETE_ROWS_EVENT</code>	Row data for a single table that should be deleted. Used in MySQL 5.1.18 and later.
1a	<code>INCIDENT_EVENT</code>	Something out of the ordinary happened. Added in MySQL 5.1.18.

- **Master ID:** The server ID of the master that created the event.
- **Size:** The size in bytes of the event.
- **Master Pos:** The position of the next event in the original master log file.
- **Flags:** 16 flags. Currently, the following flags are used. The others are reserved for future use.

Flag	Name	Meaning
------	------	---------

01	<code>LOG_EVENT_BINLOG_IN_USE_F</code>	Log file correctly closed. (Used only in <code>FORMAT_DESCRIPTION_EVENT</code> .) If this flag is set (if the flags are, for example, ' <code>01 00</code> ') in a <code>FORMAT_DESCRIPTION_EVENT</code> , the log file has not been properly closed. Most probably this is because of a master crash (for example, due to power failure).
02		Reserved for future use.
04	<code>LOG_EVENT_THREAD_SPECIFIC_F</code>	Set if the event is dependent on the connection it was executed in (for example, ' <code>04 00</code> '), for example, if the event uses temporary tables.
08	<code>LOG_EVENT_SUPPRESS_USE_F</code>	Set in some circumstances when the event is not dependent on the default database.

#### 4.6.7.2. `mysqlbinlog` Row Event Display

The following examples illustrate how `mysqlbinlog` displays row events that specify data modifications. These correspond to events with the `WRITE_ROWS_EVENT`, `UPDATE_ROWS_EVENT`, and `DELETE_ROWS_EVENT` type codes. The `-base64-output=DECODE-ROWS` and `--verbose` options may be used to affect row event output. These options are available as of MySQL 5.1.28.

Suppose that the server is using row-based binary logging and that you execute the following sequence of statements:

```
CREATE TABLE t
(
 id INT NOT NULL,
 name VARCHAR(20) NOT NULL,
 date DATE NULL
) ENGINE = InnoDB;

START TRANSACTION;
INSERT INTO t VALUES(1, 'apple', NULL);
UPDATE t SET name = 'pear', date = '2009-01-01' WHERE id = 1;
DELETE FROM t WHERE id = 1;
COMMIT;
```

By default, `mysqlbinlog` displays row events encoded as base-64 strings using `BINLOG` statements. Omitting extraneous lines, the output for the row events produced by the preceding statement sequence looks like this:

```
shell> mysqlbinlog log_file
...
at 218
#080828 15:03:08 server id 1 end_log_pos 258 Write_rows: table id 17 flags: STMT_END_F
BINLOG '
fAS3SBMBAAAALAAAAnoAAAAABEAAAAAAAABHrlc3QAXQAAwMPCgIUAAQ=
fAS3SBcBAAAAlAAAIBAAAQABEAAAAAAEAA//8AQAAAAvhcHBsZQ=='
/*!*/;
...
at 302
#080828 15:03:08 server id 1 end_log_pos 356 Update_rows: table id 17 flags: STMT_END_F
BINLOG '
fAS3SBMBAAAALAAAAC4BAAAABEAAAAAAAABHrlc3QAXQAAwMPCgIUAAQ=
fAS3SBgBAAAAnGAAAGQBAAAQABEAAAAAAEAA///AEAAAAYXBwbGX4AQAAAARwZWfylbIP
/*!*/;
...
at 400
#080828 15:03:08 server id 1 end_log_pos 442 Delete_rows: table id 17 flags: STMT_END_F
BINLOG '
fAS3SBMBAAAALAAAAlAAAABAAAABEAAAAAAAABHrlc3QAXQAAwMPCgIUAAQ=
fAS3SBkBAAAAlgAAALoBAAAQABEAAAAAAEAA//4AQAAAARwZWfylbIP
/*!*/;
```

To see the row events as comments in the form of “pseudo-SQL” statements, run `mysqlbinlog` with the `--verbose` or `-v` option. The output will contain lines beginning with `###`:

```
shell> mysqlbinlog -v log_file
...
at 218
#080828 15:03:08 server id 1 end_log_pos 258 Write_rows: table id 17 flags: STMT_END_F
BINLOG '
fAS3SBMBAAAALAAAAnoAAAAABEAAAAAAAABHrlc3QAXQAAwMPCgIUAAQ=
fAS3SBcBAAAAlAAAIBAAAQABEAAAAAAEAA//8AQAAAAvhcHBsZQ=='
/*!*/;
INSERT INTO test.t
SET
@1=1
@2='apple'
```

```
@3=NULL
...
at 302
#080828 15:03:08 server id 1 end_log_pos 356 Update_rows: table id 17 flags: STMT_END_F
BINLOG '
fAS3SBMBAAAALAAAAC4BAAAAABAAAAAAAABHrlc3QAXQAAwMPCgIUAAQ=
fAS3SBgBAAAAnGAAAGQBAAQABEAAAAAAEAA///AEAAAAYXBwbGX4AQAAAARwZWfYIbIP
'/*!*/;
UPDATE test.t
WHERE
@1=1
@2='apple'
@3=NULL
SET
@1=1
@2='pear'
@3='2009:01:01'
...
at 400
#080828 15:03:08 server id 1 end_log_pos 442 Delete_rows: table id 17 flags: STMT_END_F
BINLOG '
fAS3SBMBAAAALAAAABAAAAABAAAAAAAABHrlc3QAXQAAwMPCgIUAAQ=
fAS3SBkBAAAAnGAAALoBAAQABEAAAAAAEAA//4AQAAAARwZWfYIbIP
'/*!*/;
DELETE FROM test.t
WHERE
@1=1
@2='pear'
@3='2009:01:01'
```

Specify `--verbose` or `-v` twice to also display data types and some metadata for each column. The output will contain an additional comment following each column change:

```
shell> mysqlbinlog -vv log_file
...
at 218
#080828 15:03:08 server id 1 end_log_pos 258 Write_rows: table id 17 flags: STMT_END_F
BINLOG '
fAS3SBMBAAAALAAAAnOAAAAABAAAAAAAABHrlc3QAXQAAwMPCgIUAAQ=
fAS3SBcBAAAAnGAAAIABAAQABEAAAAAAEAA//8AQAAAAvhchHBsZQ==
'/*!*/;
INSERT INTO test.t
SET
@1=1 /* INT meta=0 nullable=0 is_null=0 */
@2='apple' /* VARSTRING(20) meta=20 nullable=0 is_null=0 */
@3=NULL /* VARSTRING(20) meta=0 nullable=1 is_null=1 */
...
at 302
#080828 15:03:08 server id 1 end_log_pos 356 Update_rows: table id 17 flags: STMT_END_F
BINLOG '
fAS3SBMBAAAALAAAAC4BAAAAABAAAAAAAABHrlc3QAXQAAwMPCgIUAAQ=
fAS3SBgBAAAAnGAAAGQBAAQABEAAAAAAEAA///AEAAAAYXBwbGX4AQAAAARwZWfYIbIP
'/*!*/;
UPDATE test.t
WHERE
@1=1 /* INT meta=0 nullable=0 is_null=0 */
@2='apple' /* VARSTRING(20) meta=20 nullable=0 is_null=0 */
@3=NULL /* VARSTRING(20) meta=0 nullable=1 is_null=1 */
SET
@1=1 /* INT meta=0 nullable=0 is_null=0 */
@2='pear' /* VARSTRING(20) meta=20 nullable=0 is_null=0 */
@3='2009:01:01' /* DATE meta=0 nullable=1 is_null=0 */
...
at 400
#080828 15:03:08 server id 1 end_log_pos 442 Delete_rows: table id 17 flags: STMT_END_F
BINLOG '
fAS3SBMBAAAALAAAABAAAAABAAAAAAAABHrlc3QAXQAAwMPCgIUAAQ=
fAS3SBkBAAAAnGAAALoBAAQABEAAAAAAEAA//4AQAAAARwZWfYIbIP
'/*!*/;
DELETE FROM test.t
WHERE
@1=1 /* INT meta=0 nullable=0 is_null=0 */
@2='pear' /* VARSTRING(20) meta=20 nullable=0 is_null=0 */
@3='2009:01:01' /* DATE meta=0 nullable=1 is_null=0 */
```

You can tell `mysqlbinlog` to suppress the `BINLOG` statements for row events by using the `-base64-output=DECODE-ROWS` option. This is similar to `--base64-output=NEVER` but does not exit with an error if a row event is found. The combination of `--base64-output=DECODE-ROWS` and `--verbose` provides a convenient way to see row events only as SQL statements:

```
shell> mysqlbinlog -v --base64-output=DECODE-ROWS log_file
...
at 218
#080828 15:03:08 server id 1 end_log_pos 258 Write_rows: table id 17 flags: STMT_END_F
INSERT INTO test.t
SET
@1=1
```

```
@2='apple'
@3=NULL
...
at 302
#080828 15:03:08 server id 1 end_log_pos 356 Update_rows: table id 17 flags: STMT_END_F
UPDATE test.t
WHERE
@1=1
@2='apple'
@3=NULL
SET
@1=1
@2='pear'
@3='2009:01:01'
...
at 400
#080828 15:03:08 server id 1 end_log_pos 442 Delete_rows: table id 17 flags: STMT_END_F
DELETE FROM test.t
WHERE
@1=1
@2='pear'
@3='2009:01:01'
```

### Note

You should not suppress `BINLOG` statements if you intend to re-execute `mysqlbinlog` output.

The SQL statements produced by `--verbose` for row events are much more readable than the corresponding `BINLOG` statements. However, they do not correspond exactly to the original SQL statements that generated the events. The following limitations apply:

- The original column names are lost and replaced by `@N`, where `N` is a column number.
- Character set information is not available in the binary log, which affects string column display:
  - There is no distinction made between corresponding binary and nonbinary string types (`BINARY` and `CHAR`, `VARBINARY` and `VARCHAR`, `BLOB` and `TEXT`). The output uses a data type of `STRING` for fixed-length strings and `VARSTRING` for variable-length strings.
  - For multi-byte character sets, the maximum number of bytes per character is not present in the binary log, so the length for string types is displayed in bytes rather than in characters. For example, `STRING(4)` will be used as the data type for values from either of these column types:

```
CHAR(4) CHARACTER SET latin1
CHAR(2) CHARACTER SET ucs2
```

- Due to the storage format for events of type `UPDATE_ROWS_EVENT`, `UPDATE` statements are displayed with the `WHERE` clause preceding the `SET` clause.

Proper interpretation of row events requires the information from the format description event at the beginning of the binary log. Because `mysqlbinlog` does not know in advance whether the rest of the log contains row events, by default it displays the format description event using a `BINLOG` statement in the initial part of the output.

If the binary log is known not to contain any events requiring a `BINLOG` statement (that is, no row events), the `-base64-output=NEVER` option can be used to prevent this header from being written.

## 4.6.8. `mysqldumpslow` — Summarize Slow Query Log Files

The MySQL slow query log contains information about queries that take a long time to execute (see [Section 5.2.5, “The Slow Query Log”](#)). `mysqldumpslow` parses MySQL slow query log files and prints a summary of their contents.

Normally, `mysqldumpslow` groups queries that are similar except for the particular values of number and string data values. It “abstracts” these values to `N` and ‘`S`’ when displaying summary output. The `-a` and `-n` options can be used to modify value abstracting behavior.

Invoke `mysqldumpslow` like this:

```
shell> mysqldumpslow [options] [log_file ...]
```

`mysqldumpslow` supports the following options.

**Table 4.12. `mysqldumpslow` Options**

Format	Config File	Description	Introduction	Deprecated	Removed
<code>-a</code>		Do not abstract all numbers to N and strings to S			
<code>-n num</code>		Abstract numbers with at least the specified digits			
<code>--debug</code>	<code>debug</code>	Write debugging information			
<code>-g pattern</code>		Only consider statements that match the pattern			
<code>--help</code>		Display help message and exit			
<code>-h name</code>		Host name of the server in the log file name			
<code>-i name</code>		Name of the server instance			
<code>-l</code>		Do not subtract lock time from total time			
<code>-r</code>		Reverse the sort order			
<code>-s value</code>		How to sort output			
<code>-t num</code>		Display only first num queries			
<code>--verbose</code>	<code>verbose</code>	Verbose mode			

- `--help`

Display a help message and exit.

- `-a`

Do not abstract all numbers to N and strings to 'S'.

- `--debug, -d`

Run in debug mode.

- `-g pattern`

Consider only queries that match the (`grep`-style) pattern.

- `-h host_name`

Host name of MySQL server for `*-slow.log` file name. The value can contain a wildcard. The default is \* (match all).

- `-i name`

Name of server instance (if using `mysql.server` startup script).

- `-l`

Do not subtract lock time from total time.

- `-n N`

Abstract numbers with at least N digits within names.

- `-r`

Reverse the sort order.

- `-s sort_type`

How to sort the output. The value of `sort_type` should be chosen from the following list:

- `t, at`: Sort by query time or average query time
- `l, al`: Sort by lock time or average lock time
- `s, as`: Sort by rows sent or average rows sent
- `c`: Sort by count

By default, `mysqldumpslow` sorts by average query time (equivalent to `-s at`).

- **-t *N***  
Display only the first *N* queries in the output.
- **--verbose, -v**  
Verbose mode. Print more information about what the program does.

Example of usage:

```
shell> mysqlslow
Reading mysql slow query log from /usr/local/mysql/data/mysqld51-apple-slow.log
Count: 1 Time=4.32s (4s) Lock=0.00s (0s) Rows=0.0 (0), root[root]@localhost
insert into t2 select * from t1

Count: 3 Time=2.53s (7s) Lock=0.00s (0s) Rows=0.0 (0), root[root]@localhost
insert into t2 select * from t1 limit N

Count: 3 Time=2.13s (6s) Lock=0.00s (0s) Rows=0.0 (0), root[root]@localhost
insert into t1 select * from t1
```

## 4.6.9. `mysqlhotcopy` — A Database Backup Program

`mysqlhotcopy` is a Perl script that was originally written and contributed by Tim Bunce. It uses `FLUSH TABLES`, `LOCK TABLES`, and `cp` or `scp` to make a database backup. It is a fast way to make a backup of the database or single tables, but it can be run only on the same machine where the database directories are located. `mysqlhotcopy` works only for backing up `MyISAM` and `ARCHIVE` tables. It runs on Unix and NetWare.

To use `mysqlhotcopy`, you must have read access to the files for the tables that you are backing up, the `SELECT` privilege for those tables, the `RELOAD` privilege (to be able to execute `FLUSH TABLES`), and the `LOCK TABLES` privilege (to be able to lock the tables).

```
shell> mysqlhotcopy db_name [/path/to/new_directory]
```

```
shell> mysqlhotcopy db_name_1 ... db_name_n /path/to/new_directory
```

Back up tables in the given database that match a regular expression:

```
shell> mysqlhotcopy db_name ./regex/
```

The regular expression for the table name can be negated by prefixing it with a tilde (“`~`”):

```
shell> mysqlhotcopy db_name ./~regex/
```

`mysqlhotcopy` supports the following options, which can be specified on the command line or in the [`mysqlhotcopy`] and [`client`] option file groups.

**Table 4.13. `mysqlhotcopy` Options**

Format	Config File	Description	Introduction	Deprecated	Removed
<code>--addtodest</code>	<code>addtodest</code>	Do not rename target directory (if it exists); merely add files to it			
<code>--allowold</code>	<code>allowold</code>	Do not abort if a target exists; rename it by adding an <code>_old</code> suffix			
<code>-check-point=db_name.table_name</code>	<code>checkpoint</code>	Insert checkpoint entries			
<code>--chroot=path</code>	<code>chroot</code>	Base directory of the chroot jail in which mysqld operates			
<code>--debug</code>	<code>debug</code>	Write a debugging log			
<code>--dryrun</code>	<code>dryrun</code>	Report actions without performing them			
<code>--flushlog</code>	<code>flushlog</code>	Flush logs after all tables are locked			
<code>--help</code>		Display help message and exit			

Format	Config File	Description	Introduction	Deprecated	Removed
<code>--host=host_name</code>	<code>host</code>	Connect to the MySQL server on the given host			
<code>--keepold</code>	<code>keepold</code>	Do not delete previous (renamed) target when done			
<code>--noindices</code>	<code>noindices</code>	Do not include full index files in the backup			
<code>-</code> <code>-pass-</code> <code>word[=password]</code>	<code>password</code>	The password to use when connecting to the server			
<code>--port=port_num</code>	<code>port</code>	The TCP/IP port number to use for the connection			
<code>--quiet</code>	<code>quiet</code>	Be silent except for errors			
<code>--regexp</code>	<code>regexp</code>	Copy all databases with names that match the given regular expression			
<code>--resetmaster</code>	<code>resetmaster</code>	Reset the binary log after locking all the tables			
<code>--resetslave</code>	<code>resetslave</code>	Reset the master.info file after locking all the tables			
<code>--socket=path</code>	<code>socket</code>	For connections to localhost			
<code>--tmpdir=path</code>	<code>tmpdir</code>	The temporary directory			
<code>-</code> <code>-user=user_name,</code>	<code>user</code>	The MySQL user name to use when connecting to the server			

- `--help, -?`

Display a help message and exit.

- `--addtodest`

Do not rename target directory (if it exists); merely add files to it.

- `--allowold`

Do not abort if a target exists; rename it by adding an `_old` suffix.

- `--checkpoint=db_name.tbl_name`

Insert checkpoint entries into the specified database `db_name` and table `tbl_name`.

- `--chroot=path`

Base directory of the `chroot` jail in which `mysqld` operates. The `path` value should match that of the `--chroot` option given to `mysqld`.

- `--debug`

Enable debug output.

- `--dryrun, -n`

Report actions without performing them.

- `--flushlog`

Flush logs after all tables are locked.

- `--host=host_name, -h host_name`

The host name of the local host to use for making a TCP/IP connection to the local server. By default, the connection is made to `localhost` using a Unix socket file.

- `--keepold`

Do not delete previous (renamed) target when done.

- `--method=command`

The method for copying files (`cp` or `scp`). The default is `cp`.

- `--noindices`

Do not include full index files for `MyISAM` tables in the backup. This makes the backup smaller and faster. The indexes for re-loaded tables can be reconstructed later with `myisamchk -rq`.

- `--password=password, -ppassword`

The password to use when connecting to the server. The password value is not optional for this option, unlike for other MySQL programs.

Specifying a password on the command line should be considered insecure. See [Section 5.3.2.2, “End-User Guidelines for Password Security”](#). You can use an option file to avoid giving the password on the command line.

- `--port=port_num, -P port_num`

The TCP/IP port number to use when connecting to the local server.

- `--quiet, -q`

Be silent except for errors.

- `--record_log_pos=db_name.tbl_name`

Record master and slave status in the specified database `db_name` and table `tbl_name`.

- `--regexp=expr`

Copy all databases with names that match the given regular expression.

- `--resetmaster`

Reset the binary log after locking all the tables.

- `--resetslave`

Reset the `master.info` file after locking all the tables.

- `--socket=path, -S path`

The Unix socket file to use for connections to `localhost`.

- `--suffix=str`

The suffix to use for names of copied databases.

- `--tmpdir=path`

The temporary directory. The default is `/tmp`.

- `--user=user_name, -u user_name`

The MySQL user name to use when connecting to the server.

Use `perldoc` for additional `mysqlhotcopy` documentation, including information about the structure of the tables needed for the `--checkpoint` and `--record_log_pos` options:

```
shell> perldoc mysqlhotcopy
```

## 4.6.10. `mysqlmanager` — The MySQL Instance Manager

### Important

MySQL Instance Manager has been deprecated and is removed in MySQL 5.5.

`mysqlmanager` is the MySQL Instance Manager (IM). This program monitors and manages MySQL Database Server instances. MySQL Instance Manager is available for Unix-like operating systems, as well as Windows. It runs as a daemon that listens on a TCP/IP port. On Unix, it also listens on a Unix socket file.

MySQL Instance Manager can be used in place of the `mysqld_safe` script to start and stop one or more instances of MySQL Server. Because Instance Manager can manage multiple server instances, it can also be used in place of the `mysqld_multi` script. Instance Manager offers these capabilities:

- Instance Manager can start and stop instances, and report on the status of instances.
- Server instances can be treated as guarded or unguarded:
  - When Instance Manager starts, it starts each guarded instance. If the instance crashes, Instance Manager detects this and restarts it. When Instance Manager stops, it stops the instance.
  - A nonguarded instance is not started when Instance Manager starts or monitored by it. If the instance crashes after being started, Instance Manager does not restart it. When Instance Manager exits, it does not stop the instance if it is running.

Instances are guarded by default. An instance can be designated as nonguarded by including the `nonguarded` option in the configuration file.

- Instance Manager provides an interactive interface for configuring instances, so that the need to edit the configuration file manually is reduced or eliminated.
- Instance Manager provides remote instance management. That is, it runs on the host where you want to control MySQL Server instances, but you can connect to it from a remote host to perform instance-management operations.

The following sections describe MySQL Instance Manager operation in more detail.

#### 4.6.10.1. MySQL Instance Manager Command Options

##### Important

MySQL Instance Manager has been deprecated and is removed in MySQL 5.5.

The MySQL Instance Manager supports a number of command options. For a brief listing, invoke `mysqlmanager` with the `-help` option. Options may be given on the command line or in the Instance Manager configuration file. On Windows, the standard configuration file is `my.ini` in the directory where Instance Manager is installed. On Unix, the standard file is `/etc/my.cnf`. To specify a different configuration file, start Instance Manager with the `--defaults-file` option.

`mysqlmanager` supports the following options. The options for managing entries in the password file are described further in Section 4.6.10.4, “Instance Manager User and Password Management”.

- `--help, -?`  
Display a help message and exit.
- `--add-user`  
Add a new user (specified with the `--username` option) to the password file. This option was added in MySQL 5.1.12.
- `--angel-pid-file=file_name`

The file in which the angel process records its process ID when `mysqlmanager` runs in daemon mode (that is, when the `--run-as-service` option is given). The default file name is `mysqlmanager.angel.pid`.

If the `--angel-pid-file` option is not given, the default angel PID file has the same name as the PID file except that any PID file extension is replaced with an extension of `.angel.pid`. (For example, `mysqlmanager.pid` becomes `mysqlmanager.angel.pid`.)

This option was added in MySQL 5.1.11.

- `--bind-address=IP`  
The IP address to bind to.
- `--check-password-file`  
Check the validity and consistency of the password file. This option was added in MySQL 5.1.12.
- `--clean-password-file`

Drop all users from the password file. This option was added in MySQL 5.1.12.

- `--debug=debug_options, -# debug_options`

Write a debugging log. A typical `debug_options` string is '`d:t:o,file_name`'. This option was added in MySQL 5.1.10.

- `--default-mysqld-path=path`

The path name of the MySQL Server binary. This path name is used for all server instance sections in the configuration file for which no `mysqld-path` option is present. The default value of this option is the compiled-in path name, which depends on how the MySQL distribution was configured. Example: `--default-mysqld-path=/usr/sbin/mysqld`

- `--defaults-file=file_name`

Read Instance Manager and MySQL Server settings from the given file. All configuration changes made by the Instance Manager will be written to this file. This must be the first option on the command line if it is used, and the file must exist.

If this option is not given, Instance Manager uses its standard configuration file. On Windows, the standard file is `my.ini` in the directory where Instance Manager is installed. On Unix, the standard file is `/etc/my.cnf`.

- `--drop-user`

Drop a user (specified with the `--username` option) from the password file. This option was added in MySQL 5.1.12.

- `--edit-user`

Change an entry for an existing user (specified with the `--username` option) in the password file. This option was added in MySQL 5.1.12.

- `--install`

On Windows, install Instance Manager as a Windows service. The service name is `MySQL Manager`.

- `--list-users`

List the users in the password file. This option was added in MySQL 5.1.12.

- `--log=file_name`

The path to the Instance Manager log file. This option has no effect unless the `--run-as-service` option is also given. If the file name specified for the option is a relative name, the log file is created under the directory from which Instance Manager is started. To ensure that the file is created in a specific directory, specify it as a full path name.

If `--run-as-service` is given without `--log`, the log file is `mysqlmanager.log` in the data directory.

If `--run-as-service` is not given, log messages go to the standard output. To capture log output, you can redirect Instance Manager output to a file:

```
mysqlmanager > im.log
```

- `--monitoring-interval=seconds`

The interval in seconds for monitoring server instances. The default value is 20 seconds. Instance Manager tries to connect to each monitored (guarded) instance using the nonexisting `MySQL_Instance_Manager` user account to check whether it is available/not hanging. If the result of the connection attempt indicates that the instance is unavailable, Instance Manager performs several attempts to restart the instance.

Normally, the `MySQL_Instance_Manager` account does not exist, so the connection attempts by Instance Manager cause the monitored instance to produce messages in its general query log similar to the following:

```
Access denied for user 'MySQL_Instance_M'@'localhost' »
(using password: YES)
```

The `nonguarded` option in the appropriate server instance section disables monitoring for a particular instance. If the instance dies after being started, Instance Manager will not restart it. Instance Manager tries to connect to a nonguarded instance only when you request the instance's status (for example, with the `SHOW INSTANCES` status).

See [Section 4.6.10.5, “MySQL Server Instance Status Monitoring”](#), for more information.

- `--mysqld-safe-compatible`

Run in a `mysqld_safe`-compatible manner. For details, see [Section 4.6.10.3, “Starting the MySQL Server with MySQL Instance Manager”](#). This option was added in MySQL 5.1.12.

- `--password=password, -p password`

Specify the password for an entry to be added to or modified in the password file. Unlike the `--password/-P` option for most MySQL programs, the password value is required, not optional. See also [Section 4.6.10.4, “Instance Manager User and Password Management”](#). This option was added in MySQL 5.1.12.

- `--password-file=file_name`

The name of the file where the Instance Manager looks for users and passwords. On Windows, the default is `mysqlmanager.passwd` in the directory where Instance Manager is installed. On Unix, the default file is `/etc/mysqlmanager.passwd`. See also [Section 4.6.10.4, “Instance Manager User and Password Management”](#).

- `--pid-file=file_name`

The process ID file to use. On Windows, the default file is `mysqlmanager.pid` in the directory where Instance Manager is installed. On Unix, the default is `mysqlmanager.pid` in the data directory.

- `--port=port_num`

The port number to use when listening for TCP/IP connections from clients. The default port number (assigned by IANA) is 2273.

- `--print-defaults`

Print the current defaults and exit. This must be the first option on the command line if it is used.

- `--print-password-line`

Prepare an entry for the password file, print it to the standard output, and exit. You can redirect the output from Instance Manager to a file to save the entry in the file.

Prior to MySQL 5.1.12, this option was named `--passwd`.

- `--remove`

On Windows, removes Instance Manager as a Windows service. This assumes that Instance Manager has been run with `-install` previously.

- `--run-as-service`

On Unix, daemonize and start an angel process. The angel process monitors Instance Manager and restarts it if it crashes. (The angel process itself is simple and unlikely to crash.)

- `--socket=path`

On Unix, the socket file to use for incoming connections. The default file is named `/tmp/mysqlmanager.sock`. This option has no meaning on Windows.

- `--standalone`

This option is used on Windows to run Instance Manager in standalone mode. You should specify it when you start Instance Manager from the command line.

- `--user=user_name`

On Unix, the user name of the system account to use for starting and running `mysqlmanager`. This option generates a warning and has no effect unless you start `mysqlmanager` as `root` (so that it can change its effective user ID), or as the named user. It is recommended that you configure `mysqlmanager` to run using the same account used to run the `mysqld` server. (“User” in this context refers to a system login account, not a MySQL user listed in the grant tables.)

- `--username=user_name, -u user_name`

Specify the user name for an entry to be added to or modified in the password file. This option was added in MySQL 5.1.12.

- `--version, -V`

Display version information and exit.

- `--wait-timeout=N`

The number of seconds to wait for activity on an incoming connection before closing it. The default is 28800 seconds (8 hours).

This option was added in MySQL 5.1.7. Before that, the timeout is 30 seconds and cannot be changed.

## 4.6.10.2. MySQL Instance Manager Configuration Files

### Important

MySQL Instance Manager has been deprecated and is removed in MySQL 5.5.

Instance Manager uses its standard configuration file unless it is started with a `--defaults-file` option that specifies a different file. On Windows, the standard file is `my.ini` in the directory where Instance Manager is installed. On Unix, the standard file is `/etc/my.cnf`.

Instance Manager reads options for itself from the `[manager]` section of the configuration file, and options for server instances from `[mysqld]` or `[mysqldN]` sections. The `[manager]` section contains any of the options listed in [Section 4.6.10.1, “MySQL Instance Manager Command Options”](#), except for those specified as having to be given as the first option on the command line. Here is a sample `[manager]` section:

```
MySQL Instance Manager options section
[manager]
default-mysqld-path = /usr/local/mysql/libexec/mysqld
socket=/tmp/manager.sock
pid-file=/tmp/manager.pid
password-file = /home/cps/.mysqlmanager.passwd
monitoring-interval = 2
port = 1999
bind-address = 192.168.1.5
```

Each `[mysqld]` or `[mysqldN]` instance section specifies options given by Instance Manager to a server instance at startup. These are mainly common MySQL Server options (see [Section 5.1.2, “Server Command Options”](#)). In addition, a `[mysqldN]` section can contain the options in the following list, which are specific to Instance Manager. These options are interpreted by Instance Manager itself; it does not pass them to the server when it attempts to start that server.

### Warning

The Instance Manager-specific options must not be used in a `[mysqld]` section. If a server is started without using Instance Manager, it will not recognize these options and will fail to start properly.

- `mysqld-path = path`

The path name of the `mysqld` server binary to use for the server instance.

- `nonguarded`

This option disables Instance Manager monitoring functionality for the server instance. By default, an instance is guarded: At Instance Manager start time, it starts the instance. It also monitors the instance status and attempts to restart it if it fails. At Instance Manager exit time, it stops the instance. None of these things happen for nonguarded instances.

- `shutdown-delay = seconds`

The number of seconds Instance Manager should wait for the server instance to shut down. The default value is 35 seconds. After the delay expires, Instance Manager assumes that the instance is hanging and attempts to terminate it. If you use `InnoDB` with large tables, you should increase this value.

Here are some sample instance sections:

```
[mysqld1]
mysqld-path=/usr/local/mysql/libexec/mysqld
socket=/tmp/mysql.sock
port=3307
server_id=1
skip-stack-trace
core-file
log-bin
log-error
log=mylog
log-slow-queries

[mysqld2]
nonguarded
port=3308
```

```
server_id=2
mysqld-path= /home/cps/mysql/trees/mysql-5.1/sql/mysqld
socket = /tmp/mysql.sock5
pid-file = /tmp/hostname.pid5
datadir= /home/cps/mysql_data/data_dir1
language=/home/cps/mysql/trees/mysql-5.1/sql/share/english
log-bin log=/tmp/forde1.log
```

#### 4.6.10.3. Starting the MySQL Server with MySQL Instance Manager

##### Important

MySQL Instance Manager has been deprecated and is removed in MySQL 5.5.

This section discusses how Instance Manager starts server instances when it starts. However, before you start Instance Manager, you should set up a password file for it. Otherwise, you will not be able to connect to Instance Manager to control it after it starts. For details about creating Instance Manager accounts, see [Section 4.6.10.4, “Instance Manager User and Password Management”](#).

On Unix, the `mysqld` MySQL database server normally is started with the `mysql.server` script, which usually resides in the `/etc/init.d/` folder. That script invokes the `mysqld_safe` script by default. However, you can use Instance Manager instead if you modify the `/etc/my.cnf` configuration file by adding `use-manager` to the `[mysql.server]` section:

```
[mysql.server]
use-manager
```

Before MySQL 5.1.12, Instance Manager always tries to start at least one server instance: When it starts, it reads its configuration file if it exists to find server instance sections and prepare a list of instances. Instance sections have names of the form `[mysqld]` or `[mysqldN]`, where `N` is an unsigned integer (for example, `[mysqld1]`, `[mysqld2]`, and so forth).

After preparing the list of instances, Instance Manager starts the guarded instances in the list. If there are no instances, Instance Manager creates an instance named `mysqld` and attempts to start it with default (compiled-in) configuration values. This means that the Instance Manager cannot find the `mysqld` program if it is not installed in the default location. ([Section 2.1.5, “Installation Layouts”](#), describes default locations for components of MySQL distributions.) If you have installed the MySQL server in a non-standard location, you should create the Instance Manager configuration file.

The startup behavior just described is similar to that of `mysqld_safe`, which always attempts to start a server. However, it lacks the flexibility required for some operations because it is not possible to run Instance Manager in such a way that it refrains from starting any server instances. For example, you cannot invoke Instance Manager for the purpose of configuring an instance without also starting it (a task that a MySQL installer application might want to perform). Consequently, MySQL 5.1.12 introduces the following changes:

- A new option, `--mysqld-safe-compatible`, may be used to cause Instance Manager to run with startup behavior similar to that used before MySQL 5.1.12: If Instance Manager finds a `[mysqld]` instance section in the configuration file, it will start it. If Instance Manager finds no `[mysqld]` section, it creates one using default configuration values, writes a `[mysqld]` section to the configuration file if it is accessible, and starts the `mysqld` instance. Instance Manager also starts any other guarded instances listed in the configuration file.
- Without `--mysqld-safe-compatible`, Instance Manager reads its configuration file if it exists and starts instances for any guarded instance sections that it finds. If there are none, it starts no instances.

Instance Manager also stops all guarded server instances when it shuts down.

The permissible options for `[mysqldN]` server instance sections are described in [Section 4.6.10.2, “MySQL Instance Manager Configuration Files”](#). In these sections, you can use a special `mysqld-path=path-to-mysqld-binary` option that is recognized only by Instance Manager. Use this option to let Instance Manager know where the `mysqld` binary resides. If there are multiple instances, it may also be necessary to set other options such as `datadir` and `port`, to ensure that each instance has a different data directory and TCP/IP port number. [Section 5.6, “Running Multiple MySQL Servers on the Same Machine”](#), discusses the configuration values that must differ for each instance when you run multiple instance on the same machine.

##### Warning

The `[mysqld]` instance section, if it exists, must not contain any Instance Manager-specific options.

The typical Unix startup/shutdown cycle for a MySQL server with the MySQL Instance Manager enabled is as follows:

1. The `/etc/init.d/mysql` script starts MySQL Instance Manager.
2. Instance Manager starts the guarded server instances and monitors them.

3. If a server instance fails, Instance Manager restarts it.
4. If Instance Manager is shut down (for example, with the `/etc/init.d/mysql stop` command), it shuts down all server instances.

#### 4.6.10.4. Instance Manager User and Password Management

##### Important

MySQL Instance Manager has been deprecated and is removed in MySQL 5.5.

The Instance Manager stores its user information in a password file. On Windows, the default is `mysqlmanager.passwd` in the directory where Instance Manager is installed. On Unix, the default file is `/etc/mysqlmanager.passwd`. To specify a different location for the password file, use the `--password-file` option.

If the password file does not exist or contains no password entries, you cannot connect to the Instance Manager.

##### Note

Any Instance Manager process that is running to monitor server instances does not notice changes to the password file. You must stop it and restart it after making password entry changes.

Entries in the password file have the following format, where the two fields are the account user name and encrypted password, separated by a colon:

```
petr:*35110DC9B4D8140F5DE667E28C72DD2597B5C848
```

Instance Manager password encryption is the same as that used by MySQL Server. It is a one-way operation; no means are provided for decrypting encrypted passwords.

Instance Manager accounts differ somewhat from MySQL Server accounts:

- MySQL Server accounts are associated with a host name, user name, and password (see [Section 5.5.1, “User Names and Passwords”](#)).
- Instance Manager accounts are associated with a user name and password only.

This means that a client can connect to Instance Manager with a given user name from any host. To limit connections so that clients can connect only from the local host, start Instance Manager with the `--bind-address=127.0.0.1` option so that it listens only to the local network interface. Remote clients will not be able to connect. Local clients can connect like this:

```
shell> mysql -h 127.0.0.1 -P 2273
```

Before MySQL 5.1.12, the only option for creating password file entries is `--passwd`, which causes Instance Manager to prompt for user name and password values and display the resulting entry. You can save the output in the `/etc/mysqlmanager.passwd` password file to store it. Here is an example:

```
shell> mysqlmanager --passwd >> /etc/mysqlmanager.passwd
Creating record for new user.
Enter user name: mike
Enter password: mikepass
Re-type password: mikepass
```

At the prompts, enter the user name and password for the new Instance Manager user. You must enter the password twice. It does not echo to the screen, so double entry guards against entering a different password than you intend (if the two passwords do not match, no entry is generated).

The preceding command causes the following line to be added to `/etc/mysqlmanager.passwd`:

```
mike:*BBF1F551DD9DD96A01E66EC7DDC073911BAD17BA
```

Use of the `--password` option fails if `mysqlmanager` is invoked directly from an IBM 5250 terminal. To work around this, use a command like the following from the command line to generate the password entry:

```
shell> mysql -B --skip-column-name \
-e 'SELECT CONCAT("user_name",":",PASSWORD("pass_val"));'
```

The output from the command can be used as an entry in the `/etc/mysqlmanager.passwd` file.

Beginning with MySQL 5.1.12, the `--passwd` option is renamed to `--print-password-line` and there are several other options for managing user accounts from the command line. For example, the `--username` and `--password` options are available on the command line for specifying the user name and password for an account entry. You can use them to generate an entry with no prompting like this (type the command on a single line):

```
shell> mysqlmanager --print-password-line
--username=mike --password=mikepass >> /etc/mysqlmanager.passwd
```

If you omit the `--username` or `--password` option, Instance Manager prompts for the required value.

`--print-password-line` causes Instance Manager to send the resulting account entry to its output, which you can append to the password file. The following list describes other account-management options that cause Instance Manager to operate directly on the password file. (These options make Instance Manager scriptable for account-management purposes.) For operations on the password file to succeed, the file must exist and it must be accessible by Instance Manager. (The exception is `--clean-password-file`, which creates the file if it does not exist. Alternatively, if there is no password file, manually create it as an empty file and ensure that its ownership and access modes permit it to be read and written by Instance Manager.) The default password file is used unless you specify a `--password-file` option.

To ensure consistent treatment of the password file, it should be owned by the system account that you use for running Instance Manager to manage server instances, and you should invoke it from that account when you use it to manage accounts in the password file.

- Create a new user:

```
mysqlmanager --add-user --username=user_name [--password=password]
```

This command adds a new entry with the given user name and password to the password file. The `--username` (or `-u`) option is required. `mysqlmanager` prompts for the password if it is not given on the command line with the `--password` (or `-p`) option. The command fails if the user already exists.

- Drop an existing user:

```
mysqlmanager --drop-user --username=user_name
```

This command removes the entry with the given user name from the password file. The user name is required. The command fails if the user does not exist.

- Change the password for an existing user:

```
mysqlmanager --edit-user --username=user_name [--password=password]
```

This command changes the given user's password in the password file. The user name is required. `mysqlmanager` prompts for the password if it is not given on the command line. The command fails if the user does not exist.

- List existing users:

```
mysqlmanager --list-users
```

This command lists the user names of the accounts in the password file.

- Check the password file:

```
mysqlmanager --check-password-file
```

This command performs a consistency and validity check of the password file. The command fails if there is something wrong with the file.

- Empty the password file:

```
mysqlmanager --clean-password-file
```

This command empties the password file, which has the effect of dropping all users listed in it. The option creates the password file if it does not exist, so it can be used to initialize a new password file to be used for other account-management operations. Take care not to use this option to reinitialize a file containing accounts that you do not want to drop.

## 4.6.10.5. MySQL Server Instance Status Monitoring

### Important

MySQL Instance Manager has been deprecated and is removed in MySQL 5.5.

To monitor the status of each guarded server instance, the MySQL Instance Manager attempts to connect to the instance at regular intervals using the `MySQL_Instance_Manager@localhost` user account with a password of `check_connection`.

You are *not* required to create this account for MySQL Server; in fact, it is expected that it will not exist. Instance Manager can tell that a server is operational if the server accepts the connection attempt but refuses access for the account by returning a login error. However, these failed connection attempts are logged by the server to its general query log (see [Section 5.2.3, “The General Query Log”](#)).

Instance Manager also attempts a connection to nonguarded server instances when you use the `SHOW INSTANCES` or `SHOW INSTANCE STATUS` command. This is the only status monitoring done for nonguarded instances.

Instance Manager knows if a server instance fails at startup because it receives a status from the attempt. For an instance that starts but later crashes, Instance Manager receives a signal because it is the parent process of the instance.

Beginning with MySQL 5.1.12, Instance Manager tracks instance states so that it can determine which commands are permitted for each instance. For example, commands that modify an instance's configuration are permitted only while the instance is offline.

Each instance is in one of the states described in the following table. Guarded instances can be in any of the states. Nonguarded instances can only be offline or online. Instance state information is displayed in the `status` column of the `SHOW INSTANCES` and `SHOW INSTANCE STATUS` commands.

State	Meaning
<code>offline</code>	The instance has not been started and is not running.
<code>starting</code>	The instance is starting (initializing). Nonguarded instances cannot be in this state. A nonguarded instance goes directly from offline to online.
<code>stopping</code>	The instance is stopping. Nonguarded instances cannot be in this state. A nonguarded instance goes directly from online to offline, or stays offline if startup fails.
<code>online</code>	The instance has started and is running.
<code>failed</code>	The instance was online but it crashed and is being restarted by Instance Manager, or else the instance failed to start at all and Instance Manager is again attempting to start it. Nonguarded instances cannot be in this state.
<code>crashed</code>	Instance Manager failed to start the instance after several attempts. (Instance Manager will try again later.) Nonguarded instances cannot be in this state.
<code>abandoned</code>	Instance Manager was not able to start the instance, has given up, and will make no further attempts until instructed otherwise. To tell Instance Manager to try again, you must first use <code>STOP INSTANCE</code> to put the instance in offline state, and then use <code>START INSTANCE</code> to start the instance. If it is necessary to make configuration changes for the instance, you must do so after putting the instance offline and before starting it. (Instance Manager accepts configuration-changing commands only for offline instances.) Nonguarded instances cannot be in this state.

## 4.6.10.6. Connecting to MySQL Instance Manager

### Important

MySQL Instance Manager has been deprecated and is removed in MySQL 5.5.

After you set up a password file for the MySQL Instance Manager and Instance Manager is running, you can connect to it. The MySQL client-server protocol is used to communicate with the Instance Manager. For example, you can connect to it using the standard `mysql` client program:

```
shell> mysql --port=2273 --host=im.example.org --user=mysql --password
```

Instance Manager supports the version of the MySQL client-server protocol used by the client tools and libraries distributed with MySQL 4.1 or later, so other programs that use the MySQL C API also can connect to it.

## 4.6.10.7. MySQL Instance Manager Commands

### Important

**MySQL Instance Manager** has been deprecated and is removed in MySQL 5.5.

After you connect to MySQL Instance Manager, you can issue commands. The following general principles apply to Instance Manager command execution:

- Commands that take an instance name fail if the name is not a valid instance name.
- Commands that take an instance name (other than `CREATE INSTANCE`) fail if the instance does not exist.
- As of MySQL 5.1.12, commands for an instance require that the instance be in an appropriate state. You cannot configure or start an instance that is not offline. You cannot start an instance that is online.
- Instance Manager maintains information about instance configuration in an internal (in-memory) cache. Initially, this information comes from the configuration file if it exists, but some commands change the configuration of an instance. Commands that modify the configuration file fail if the file does not exist or is not accessible to Instance Manager.

As of MySQL 5.1.12, configuration-changing commands modify both the in-memory cache and the server instance section recorded in the configuration file to maintain consistency between them. For this to occur, the instance must be offline and the configuration file must be accessible and not malformed. If the configuration file cannot be updated, the command fails and the cache remains unchanged.

- On Windows, the standard file is `my.ini` in the directory where Instance Manager is installed. On Unix, the standard configuration file is `/etc/my.cnf`. To specify a different configuration file, start Instance Manager with the `--defaults-file` option.
- If a `[mysqld]` instance section exists in the configuration file, it must not contain any Instance Manager-specific options (see [Section 4.6.10.2, “MySQL Instance Manager Configuration Files”](#)). Therefore, you must not add any of these options if you change the configuration for an instance named `mysqld`.

The following list describes the commands that Instance Manager accepts, with examples.

- `CREATE INSTANCE instance_name [option_name[=option_value], ...]`

This command configures a new instance by creating an `[instance_name]` section in the configuration file. The command fails if `instance_name` is not a valid instance name or the instance already exists.

The created section instance is empty if no options are given. Otherwise, the options are added to the section. Options should be given in the same format used when you write options in option files. (See [Section 4.2.3.3, “Using Option Files”](#) for a description of the permissible syntax.) If you specify multiple options, separate them by commas.

For example, to create an instance section named `[mysqld98]`, you might write something like this were you to modify the configuration file directly:

```
[mysqld98]
basedir=/var/mysql98
```

To achieve the same effect using `CREATE INSTANCE`, issue this command to Instance Manager:

```
mysql> CREATE INSTANCE mysqld98 basedir="/var/mysql98";
Query OK, 0 rows affected (0,00 sec)
```

`CREATE INSTANCE` creates the instance but does not start it.

If the instance name is the (deprecated) name `mysqld`, the option list cannot include any options that are specific to Instance Manager, such as `nonguarded` (see [Section 4.6.10.2, “MySQL Instance Manager Configuration Files”](#)).

This command was added in MySQL 5.1.12.

- `DROP INSTANCE instance_name`

This command removes the configuration for `instance_name` from the configuration file.

```
mysql> DROP INSTANCE mysqld98;
Query OK, 0 rows affected (0,00 sec)
```

The command fails if `instance_name` is not a valid instance name, the instance does not exist, or is not offline.

This command was added in MySQL 5.1.12.

- `START INSTANCE instance_name`

This command attempts to start an offline instance. The command is asynchronous; it does not wait for the instance to start.

```
mysql> START INSTANCE mysqld4;
Query OK, 0 rows affected (0,00 sec)
```

- `STOP INSTANCE instance_name`

This command attempts to stop an instance. The command is synchronous; it waits for the instance to stop.

```
mysql> STOP INSTANCE mysqld4;
Query OK, 0 rows affected (0,00 sec)
```

- `SHOW INSTANCES`

Shows the names and status of all loaded instances.

```
mysql> SHOW INSTANCES;
+-----+-----+
| instance_name | status |
+-----+-----+
| mysqld3 | offline |
| mysqld4 | online |
| mysqld2 | offline |
+-----+-----+
```

- `SHOW INSTANCE STATUS instance_name`

Shows status and version information for an instance.

```
mysql> SHOW INSTANCE STATUS mysqld3;
+-----+-----+
| instance_name | status | version |
+-----+-----+
| mysqld3 | online | unknown |
+-----+-----+
```

- `SHOW INSTANCE OPTIONS instance_name`

Shows the options used by an instance.

```
mysql> SHOW INSTANCE OPTIONS mysqld3;
+-----+-----+
| option_name | value |
+-----+-----+
| instance_name | mysqld3
| mysqld-path | /home/cps/mysql/trees/mysql-4.1/sql/mysqld
| port | 3309
| socket | /tmp/mysql.sock3
| pid-file | hostname.pid3
| datadir | /home/cps/mysql_data/data_dir1/
| language | /home/cps/mysql/trees/mysql-4.1/sql/share/english
+-----+-----+
```

- `SHOW instance_name LOG FILES`

The command lists all log files used by the instance. The result set contains the path to the log file and the log file size. If no log file path is specified in the instance section of the configuration file (for example, `log=/var/mysql.log`), the Instance Manager tries to guess its placement. If Instance Manager is unable to guess the log file placement you should specify the log file location explicitly by using a log option in the appropriate instance section of the configuration file.

```
mysql> SHOW mysqld LOG FILES;
+-----+-----+-----+
| Logfile | Path | Filesize |
+-----+-----+-----+
| ERROR LOG | /home/cps/var/mysql/owlet.err | 9186
| GENERAL LOG | /home/cps/var/mysql/owlet.log | 471503
| SLOW LOG | /home/cps/var/mysql/owlet-slow.log | 4463
+-----+-----+-----+
```

`SHOW ... LOG FILES` displays information only about log files. If a server instance uses log tables (see [Section 5.2.1, “Selecting General Query and Slow Query Log Output Destinations”](#)), no information about those tables is shown.

Log options are described in [Section 5.1.2, “Server Command Options”](#).

- `SHOW instance_name LOG {ERROR | SLOW | GENERAL} size[,offset_from_end]`

This command retrieves a portion of the specified log file. Because most users are interested in the latest log messages, the `size` parameter defines the number of bytes to retrieve from the end of the log. To retrieve data from the middle of the log file, specify the optional `offset_from_end` parameter. The following example retrieves 21 bytes of data, starting 23 bytes before the end of the log file and ending 2 bytes before the end:

```
mysql> SHOW mysqld LOG GENERAL 21, 2;
+-----+
| Log |
+-----+
| using password: YES |
+-----+
```

- `SET instance_name.option_name[=option_value]`

This command edits the specified instance's configuration section to change or add instance options. The option is added to the section if it is not already present. Otherwise, the new setting replaces the existing one.

```
mysql> SET mysqld2.port=3322;
Query OK, 0 rows affected (0.00 sec)
```

As of MySQL 5.1.12, you can specify multiple options (separated by commas), and `SET` can be used only for offline instances. Each option must indicate the instance name:

```
mysql> SET mysqld2.port=3322, mysqld3.nonguarded;
Query OK, 0 rows affected (0.00 sec)
```

Before MySQL 5.1.12, only a single option can be specified. Also, changes made to the configuration file do not take effect until the MySQL server is restarted. In addition, these changes are not stored in the instance manager's local cache of instance settings until a `FLUSH INSTANCES` command is executed.

- `UNSET instance_name.option_name`

This command removes an option from an instance's configuration section.

```
mysql> UNSET mysqld2.port;
Query OK, 0 rows affected (0.00 sec)
```

As of MySQL 5.1.12, you can specify multiple options (separated by commas), and `UNSET` can be used only for offline instances. Each option must indicate the instance name:

```
mysql> UNSET mysqld2.port, mysqld4.nonguarded;
Query OK, 0 rows affected (0.00 sec)
```

Before MySQL 5.1.12, only a single option can be specified. Also, changes made to the configuration file do not take effect until the MySQL server is restarted. In addition, these changes are not stored in the instance manager's local cache of instance settings until a `FLUSH INSTANCES` command is executed.

- `FLUSH INSTANCES`

As of MySQL 5.1.12, `FLUSH INSTANCES` cannot be used unless all instances are offline. The command causes Instance Manager to reread the configuration file, update its in-memory configuration cache, and start any guarded instances.

Before MySQL 5.1.12, this command forces Instance Manager to reread the configuration file and to refresh internal structures. This command should be performed after editing the configuration file. The command does not restart instances.

```
mysql> FLUSH INSTANCES;
Query OK, 0 rows affected (0.04 sec)
```

## 4.6.11. `mysql_convert_table_format` — Convert Tables to Use a Given Storage Engine

`mysql_convert_table_format` converts the tables in a database to use a particular storage engine (`MyISAM` by default). `mysql_convert_table_format` is written in Perl and requires that the `DBI` and `DBD::mysql` Perl modules be installed (see [Section 2.15, “Perl Installation Notes”](#)).

Invoke `mysql_convert_table_format` like this:

```
shell> mysql_convert_table_format [options]db_name
```

The `db_name` argument indicates the database containing the tables to be converted.

`mysql_convert_table_format` supports the options described in the following list.

- `--help`

Display a help message and exit.

- `--force`

Continue even if errors occur.

- `--host=host_name`

Connect to the MySQL server on the given host.

- `--password=password`

The password to use when connecting to the server. Note that the password value is not optional for this option, unlike for other MySQL programs.

Specifying a password on the command line should be considered insecure. See [Section 5.3.2.2, “End-User Guidelines for Password Security”](#). You can use an option file to avoid giving the password on the command line.

- `--port=port_num`

The TCP/IP port number to use for the connection.

- `--socket=path`

For connections to `localhost`, the Unix socket file to use.

- `--type=engine_name`

Specify the storage engine that the tables should be converted to use. The default is `MyISAM` if this option is not given.

- `--user=user_name`

The MySQL user name to use when connecting to the server.

- `--verbose`

Verbose mode. Print more information about what the program does.

- `--version`

Display version information and exit.

## 4.6.12. `mysql_find_rows` — Extract SQL Statements from Files

`mysql_find_rows` reads files containing SQL statements and extracts statements that match a given regular expression or that contain `USE db_name` or `SET` statements. The utility was written for use with update log files (as used prior to MySQL 5.0) and as such expects statements to be terminated with semicolon (`;`) characters. It may be useful with other files that contain SQL statements as long as statements are terminated with semicolons.

Invoke `mysql_find_rows` like this:

```
shell> mysql_find_rows [options] [file_name ...]
```

Each `file_name` argument should be the name of file containing SQL statements. If no file names are given, `mysql_find_rows` reads the standard input.

Examples:

```
mysql_find_rows --regexp=problem_table --rows=20 < update.log
mysql_find_rows --regexp=problem_table update-log.1 update-log.2
```

`mysql_find_rows` supports the following options:

- **--help, --Information**  
Display a help message and exit.
- **--regexp=pattern**  
Display queries that match the pattern.
- **--rows=N**  
Quit after displaying *N* queries.
- **--skip-use-db**  
Do not include `USE db_name` statements in the output.
- **--start\_row=N**  
Start output from this row.

## 4.6.13. `mysql_fix_extensions` — Normalize Table File Name Extensions

`mysql_fix_extensions` converts the extensions for `MyISAM` (or `ISAM`) table files to their canonical forms. It looks for files with extensions matching any lowercase variant of `.frm`, `.myd`, `.myi`, `.isd`, and `.ism` and renames them to have extensions of `.frm`, `.MYD`, `.MYI`, `.ISD`, and `.ISM`, respectively. This can be useful after transferring the files from a system with case-insensitive file names (such as Windows) to a system with case-sensitive file names.

Invoke `mysql_fix_extensions` like this, where `data_dir` is the path name to the MySQL data directory.

```
shell> mysql_fix_extensions data_dir
```

## 4.6.14. `mysql_setpermission` — Interactively Set Permissions in Grant Tables

`mysql_setpermission` is a Perl script that was originally written and contributed by Luuk de Boer. It interactively sets permissions in the MySQL grant tables. `mysql_setpermission` is written in Perl and requires that the `DBI` and `DBD::mysql` Perl modules be installed (see [Section 2.15, “Perl Installation Notes”](#)).

Invoke `mysql_setpermission` like this:

```
shell> mysql_setpermission [options]
```

`options` should be either `--help` to display the help message, or options that indicate how to connect to the MySQL server. The account used when you connect determines which permissions you have when attempting to modify existing permissions in the grant tables.

`mysql_setpermissions` also reads options from the `[client]` and `[perl]` groups in the `.my.cnf` file in your home directory, if the file exists.

`mysql_setpermission` supports the following options:

- **--help**  
Display a help message and exit.
- **--host=host\_name**  
Connect to the MySQL server on the given host.
- **--password=password**

The password to use when connecting to the server. Note that the password value is not optional for this option, unlike for other MySQL programs.

Specifying a password on the command line should be considered insecure. See [Section 5.3.2.2, “End-User Guidelines for Password Security”](#). You can use an option file to avoid giving the password on the command line.

- `--port=port_num`  
The TCP/IP port number to use for the connection.
- `--socket=path`  
For connections to `localhost`, the Unix socket file to use.
- `--user=user_name`  
The MySQL user name to use when connecting to the server.

## 4.6.15. `mysql_waitpid` — Kill Process and Wait for Its Termination

`mysql_waitpid` signals a process to terminate and waits for the process to exit. It uses the `kill()` system call and Unix signals, so it runs on Unix and Unix-like systems.

Invoke `mysql_waitpid` like this:

```
shell> mysql_waitpid [options] pid wait_time
```

`mysql_waitpid` sends signal 0 to the process identified by `pid` and waits up to `wait_time` seconds for the process to terminate. `pid` and `wait_time` must be positive integers.

If process termination occurs within the wait time or the process does not exist, `mysql_waitpid()` returns 0. Otherwise, it returns 1.

If the `kill()` system call cannot handle signal 0, `mysql_waitpid()` uses signal 1 instead.

`mysql_waitpid` supports the following options:

- `--help, -?, -I`  
Display a help message and exit.
- `--verbose, -v`  
Verbose mode. Display a warning if signal 0 could not be used and signal 1 is used instead.
- `--version, -V`  
Display version information and exit.

## 4.6.16. `mysql_zap` — Kill Processes That Match a Pattern

`mysql_zap` kills processes that match a pattern. It uses the `ps` command and Unix signals, so it runs on Unix and Unix-like systems.

Invoke `mysql_zap` like this:

```
shell> mysql_zap [-signal] [-?If] pattern
```

A process matches if its output line from the `ps` command contains the pattern. By default, `mysql_zap` asks for confirmation for each process. Respond `y` to kill the process, or `q` to exit `mysql_zap`. For any other response, `mysql_zap` does not attempt to kill the process.

If the `-signal` option is given, it specifies the name or number of the signal to send to each process. Otherwise, `mysql_zap` tries first with `TERM` (signal 15) and then with `KILL` (signal 9).

`mysql_zap` supports the following additional options:

- `--help, -?, -I`  
Display a help message and exit.
- `-f`

Force mode. `mysql_zap` attempts to kill each process without confirmation.

- `-t`

Test mode. Display information about each process but do not kill it.

## 4.7. MySQL Program Development Utilities

This section describes some utilities that you may find useful when developing MySQL programs.

In shell scripts, you can use the `my_print_defaults` program to parse option files and see what options would be used by a given program. The following example shows the output that `my_print_defaults` might produce when asked to show the options found in the `[client]` and `[mysql]` groups:

```
shell> my_print_defaults client mysql
--port=3306
--socket=/tmp/mysql.sock
--no-auto-rehash
```

Note for developers: Option file handling is implemented in the C client library simply by processing all options in the appropriate group or groups before any command-line arguments. This works well for programs that use the last instance of an option that is specified multiple times. If you have a C or C++ program that handles multiply specified options this way but that doesn't read option files, you need add only two lines to give it that capability. Check the source code of any of the standard MySQL clients to see how to do this.

Several other language interfaces to MySQL are based on the C client library, and some of them provide a way to access option file contents. These include Perl and Python. For details, see the documentation for your preferred interface.

### 4.7.1. `msql2mysql` — Convert mSQL Programs for Use with MySQL

Initially, the MySQL C API was developed to be very similar to that for the mSQL database system. Because of this, mSQL programs often can be converted relatively easily for use with MySQL by changing the names of the C API functions.

The `msql2mysql` utility performs the conversion of mSQL C API function calls to their MySQL equivalents. `msql2mysql` converts the input file in place, so make a copy of the original before converting it. For example, use `msql2mysql` like this:

```
shell> cp client-prog.c client-prog.c.orig
shell> msql2mysql client-prog.c
client-prog.c converted
```

Then examine `client-prog.c` and make any post-conversion revisions that may be necessary.

`msql2mysql` uses the `replace` utility to make the function name substitutions. See [Section 4.8.2, “`replace` — A String-Replacement Utility”](#).

### 4.7.2. `mysql_config` — Get Compile Options for Compiling Clients

`mysql_config` provides you with useful information for compiling your MySQL client and connecting it to MySQL.

`mysql_config` supports the following options.

- `--cflags`

Compiler flags to find include files and critical compiler flags and defines used when compiling the `libmysqlclient` library. The options returned are tied to the specific compiler that was used when the library was created and might clash with the settings for your own compiler. Use `--include` for more portable options that contain only include paths.

- `--include`

Compiler options to find MySQL include files.

- `--libmysqld-libs, --embedded`

Libraries and options required to link with the MySQL embedded server.

- `--libs`

Libraries and options required to link with the MySQL client library.

- **--libs\_r**

Libraries and options required to link with the thread-safe MySQL client library.

- **--plugindir**

The default plugin directory path name, defined when configuring MySQL. This option was added in MySQL 5.1.24.

- **--port**

The default TCP/IP port number, defined when configuring MySQL.

- **--socket**

The default Unix socket file, defined when configuring MySQL.

- **--version**

Version number for the MySQL distribution.

If you invoke `mysql_config` with no options, it displays a list of all options that it supports, and their values:

```
shell> mysql_config
Usage: /usr/local/mysql/bin/mysql_config [options]
Options:
 --cflags [-I/usr/local/mysql/include/mysql -mcpu=pentiumpro]
 --include [-I/usr/local/mysql/include/mysql]
 --libs [-L/usr/local/mysql/lib/mysql -lmysqlclient -lz
 -lcrypt -lnsl -lm -L/usr/lib -lssl -lcrypto]
 --libs_r [-L/usr/local/mysql/lib/mysql -lmysqlclient_r
 -lpthread -lz -lcrypt -lnsl -lm -lpthread]
 --socket [/tmp/mysql.sock]
 --port [3306]
 --version [4.0.16]
 --libmysqld-libs [-L/usr/local/mysql/lib/mysql -lmysqld -lpthread -lz
 -lcrypt -lnsl -lm -lpthread -lrt]
```

You can use `mysql_config` within a command line to include the value that it displays for a particular option. For example, to compile a MySQL client program, use `mysql_config` as follows:

```
shell> CFG=/usr/local/mysql/bin/mysql_config
shell> sh -c "gcc -o programe `\$CFG --include` programe.c `\$CFG --libs`"
```

When you use `mysql_config` this way, be sure to invoke it within backtick (` `` `) characters. That tells the shell to execute it and substitute its output into the surrounding command.

### 4.7.3. `my_print_defaults` — Display Options from Option Files

`my_print_defaults` displays the options that are present in option groups of option files. The output indicates what options will be used by programs that read the specified option groups. For example, the `mysqlcheck` program reads the `[mysqlcheck]` and `[client]` option groups. To see what options are present in those groups in the standard option files, invoke `my_print_defaults` like this:

```
shell> my_print_defaults mysqlcheck client
--user=username
--password=secret
--host=localhost
```

The output consists of options, one per line, in the form that they would be specified on the command line.

`my_print_defaults` supports the following options.

- **--help, -?**

Display a help message and exit.

- **--config-file=file\_name, --defaults-file=file\_name, -c file\_name**

Read only the given option file.

- `--debug=debug_options, -# debug_options`  
Write a debugging log. A typical `debug_options` string is '`d:t:o,file_name`'. The default is '`d:t:o,/tmp/my_print_defaults.trace`'.
- `--defaults-extra-file=file_name, --extra-file=file_name, -e file_name`  
Read this option file after the global option file but (on Unix) before the user option file.
- `--defaults-group-suffix=suffix, -g suffix`  
In addition to the groups named on the command line, read groups that have the given suffix.
- `--no-defaults, -n`  
Return an empty string.
- `--verbose, -v`  
Verbose mode. Print more information about what the program does.
- `--version, -V`  
Display version information and exit.

#### 4.7.4. `resolve_stack_dump` — Resolve Numeric Stack Trace Dump to Symbols

`resolve_stack_dump` resolves a numeric stack dump to symbols.

Invoke `resolve_stack_dump` like this:

```
shell> resolve_stack_dump [options] symbols_file [numeric_dump_file]
```

The symbols file should include the output from the `nm --numeric-sort mysqld` command. The numeric dump file should contain a numeric stack trace from `mysqld`. If no numeric dump file is named on the command line, the stack trace is read from the standard input.

`resolve_stack_dump` supports the following options.

- `--help, -h`  
Display a help message and exit.
- `--numeric-dump-file=file_name, -n file_name`  
Read the stack trace from the given file.
- `--symbols-file=file_name, -s file_name`  
Use the given symbols file.
- `--version, -V`  
Display version information and exit.

## 4.8. Miscellaneous Programs

### 4.8.1. `perror` — Explain Error Codes

For most system errors, MySQL displays, in addition to an internal text message, the system error code in one of the following styles:

```
message ... (errno: #)
message ... (Errcode: #)
```

You can find out what the error code means by examining the documentation for your system or by using the `perror` utility.

`perror` prints a description for a system error code or for a storage engine (table handler) error code.

Invoke `perror` like this:

```
shell> perror [options] errorcode ...
```

Example:

```
shell> perror 13 64
OS error code 13: Permission denied
OS error code 64: Machine is not on the network
```

To obtain the error message for a MySQL Cluster error code, invoke `perror` with the `--ndb` option:

```
shell> perror --ndb errorcode
```

Note that the meaning of system error messages may be dependent on your operating system. A given error code may mean different things on different operating systems.

`perror` supports the following options.

- `--help, --info, -I, -?`

Display a help message and exit.

- `--ndb`

Print the error message for a MySQL Cluster error code.

- `--silent, -s`

Silent mode. Print only the error message.

- `--verbose, -v`

Verbose mode. Print error code and message. This is the default behavior.

- `--version, -V`

Display version information and exit.

## 4.8.2. `replace` — A String-Replacement Utility

The `replace` utility program changes strings in place in files or on the standard input.

Invoke `replace` in one of the following ways:

```
shell> replace from to [from to] ... -- file_name [file_name] ...
shell> replace from to [from to] ... < file_name
```

`from` represents a string to look for and `to` represents its replacement. There can be one or more pairs of strings.

Use the `--` option to indicate where the string-replacement list ends and the file names begin. In this case, any file named on the command line is modified in place, so you may want to make a copy of the original before converting it. `replace` prints a message indicating which of the input files it actually modifies.

If the `--` option is not given, `replace` reads the standard input and writes to the standard output.

`replace` uses a finite state machine to match longer strings first. It can be used to swap strings. For example, the following command swaps `a` and `b` in the given files, `file1` and `file2`:

```
shell> replace a b b a -- file1 file2 ...
```

The `replace` program is used by `mysql2mysql`. See [Section 4.7.1, “`mysql2mysql` — Convert mSQL Programs for Use with MySQL”](#).

`replace` supports the following options.

- `-?, -I`  
Display a help message and exit.
- `-#debug_options`  
Enable debugging.
- `-s`  
Silent mode. Print less information what the program does.
- `-v`  
Verbose mode. Print more information about what the program does.
- `-V`  
Display version information and exit.

#### 4.8.3. `resolveip` — Resolve Host name to IP Address or Vice Versa

The `resolveip` utility resolves host names to IP addresses and vice versa.

Invoke `resolveip` like this:

```
shell> resolveip [options] {host_name|ip-addr} ...
```

`resolveip` supports the following options.

- `--help, --info, -?, -I`  
Display a help message and exit.
- `--silent, -s`  
Silent mode. Produce less output.
- `--version, -V`  
Display version information and exit.

---

# Chapter 5. MySQL Server Administration

MySQL Server (`mysqld`) is the main program that does most of the work in a MySQL installation. This section provides an overview of MySQL Server and covers topics that deal with administering a MySQL installation:

- Server configuration
- The server log files
- Security issues and user-account management
- Management of multiple servers on a single machine

## 5.1. The MySQL Server

`mysqld` is the MySQL server. The following discussion covers these MySQL server configuration topics:

- Startup options that the server supports
- Server system variables
- Server status variables
- How to set the server SQL mode
- The server shutdown process

### Note

Not all storage engines are supported by all MySQL server binaries and configurations. To find out how to determine which storage engines your MySQL server installation supports, see [Section 12.4.5.17, “SHOW ENGINES Syntax”](#).

### 5.1.1. Server Option and Variable Reference

The following table provides a list of all the command line options, server and status variables applicable within `mysqld`.

The table lists command-line options (Cmd-line), options valid in configuration files (Option file), server system variables (System Var), and status variables (Status var) in one unified list, with notification of where each option/variable is valid. If a server option set on the command line or in an option file differs from the name of the corresponding server system or status variable, the variable name is noted immediately below the corresponding option. For status variables, the scope of the variable is shown (Scope) as either global, session, or both. Please see the corresponding sections for details on setting and using the options and variables. Where appropriate, a direct link to further information on the item as available.

**Table 5.1. Option/Variable Summary**

Name	Cmd-Line	Option file	System Var	Status Var	Var Scope	Dynamic
<code>abort-slave-event-count</code>	Yes	Yes				
<code>Aborted_clients</code>				Yes	Global	No
<code>Aborted_connects</code>				Yes	Global	No
<code>allow-suspicious-udfs</code>	Yes	Yes				
<code>ansi</code>	Yes	Yes				
<code>auto_increment_increment</code>	Yes	Yes	Yes		Both	Yes
<code>auto_increment_offset</code>	Yes	Yes	Yes		Both	Yes
<code>autocommit</code>			Yes		Session	Yes
<code>automatic_sp_privileges</code>			Yes		Global	Yes
<code>back_log</code>	Yes	Yes	Yes		Global	No

Name	Cmd-Line	Option file	System Var	Status Var	Var Scope	Dynamic
<code>basedir</code>	Yes	Yes	Yes		Global	No
<code>big-tables</code>	Yes	Yes			Session	Yes
<code>- Variable: big_tables</code>			Yes		Session	Yes
<code>bind-address</code>	Yes	Yes				
<code>Bin-log_cache_disk_use</code>				Yes	Global	No
<code>binlog_cache_size</code>	Yes	Yes	Yes		Global	Yes
<code>Binlog_cache_use</code>				Yes	Global	No
<code>bin-log_direct_non_transactional_updates</code>	Yes	Yes	Yes		Both	Yes

<sup>a</sup>This option is dynamic, but only the server should set this information. You should not set the value of this variable manually.

<sup>b</sup>This option is dynamic, but only the server should set this information. You should not set the value of this variable manually.

## 5.1.2. Server Command Options

When you start the `mysqld` server, you can specify program options using any of the methods described in [Section 4.2.3, “Specifying Program Options”](#). The most common methods are to provide options in an option file or on the command line. However, in most cases it is desirable to make sure that the server uses the same options each time it runs. The best way to ensure this is to list them in an option file. See [Section 4.2.3.3, “Using Option Files”](#).

`mysqld` reads options from the `[mysqld]` and `[server]` groups. `mysqld_safe` reads options from the `[mysqld]`, `[server]`, `[mysqld_safe]`, and `[safe_mysqld]` groups. `mysql.server` reads options from the `[mysqld]` and `[mysql.server]` groups.

An embedded MySQL server usually reads options from the `[server]`, `[embedded]`, and `[xxxxxx_SERVER]` groups, where `xxxxxx` is the name of the application into which the server is embedded.

`mysqld` accepts many command options. For a brief summary, execute `mysqld --help`. To see the full list, use `mysqld --verbose --help`.

The following list shows some of the most common server options. Additional options are described in other sections:

- Options that affect security: See [Section 5.3.4, “Security-Related mysqld Options”](#).
- SSL-related options: See [Section 5.5.6.3, “SSL Command Options”](#).
- Binary log control options: See [Section 5.2.4, “The Binary Log”](#).
- Replication-related options: See [Section 16.1.3, “Replication and Binary Logging Options and Variables”](#).
- Options for loading plugins such as pluggable storage engines: See [Section 5.1.3, “Server Options for Loading Plugins”](#).
- Options specific to particular storage engines: See [Section 13.5.1, “MyISAM Startup Options”](#), [Section 13.6.3, “InnoDB Startup Options and System Variables”](#), and [Section 17.3.4.2, “mysqld Command Options for MySQL Cluster”](#).

You can also set the values of server system variables by using variable names as options, as described at the end of this section.

Some options control the size of buffers or caches. For a given buffer, the server might need to allocate internal data structures. These structures typically are allocated from the total memory allocated to the buffer, and the amount of space required might be platform dependent. This means that when you assign a value to an option that controls a buffer size, the amount of space actually available might differ from the value assigned. In some cases, the amount might be less than the value assigned. It is also possible that the server will adjust a value upward. For example, if you assign a value of 0 to an option for which the minimal value is 1024, the server will set the value to 1024.

Values for buffer sizes, lengths, and stack sizes are given in bytes unless otherwise specified.

Some options take file name values. Unless otherwise specified, the default file location is the data directory if the value is a relative path name. To specify the location explicitly, use an absolute path name. Suppose that the data directory is `/var/mysql/data`. If a file-valued option is given as a relative path name, it will be located under `/var/mysql/data`. If the value is an absolute path name, its location is as given by the path name.

- `--help`, `-?`

<b>Command-Line Format</b>	<code>-?</code>
	<code>--help</code>
<b>Config-File Format</b>	<code>help</code>

Display a short help message and exit. Use both the `--verbose` and `--help` options to see the full message.

- `--allow-suspicious-udfs`

<b>Command-Line Format</b>	<code>--allow-suspicious-udfs</code>
<b>Config-File Format</b>	<code>allow-suspicious-udfs</code>
<b>Permitted Values</b>	
<b>Type</b>	<code>boolean</code>
<b>Default</b>	<code>FALSE</code>

This option controls whether user-defined functions that have only an `xxx` symbol for the main function can be loaded. By default, the option is off and only UDFs that have at least one auxiliary symbol can be loaded; this prevents attempts at loading functions from shared object files other than those containing legitimate UDFs. See [Section 22.3.2.6, “User-Defined Function Security Precautions”](#).

- `--ansi`

<b>Command-Line Format</b>	<code>--ansi</code>
	<code>-a</code>

<b>Config-File Format</b>	<code>ansi</code>
---------------------------	-------------------

Use standard (ANSI) SQL syntax instead of MySQL syntax. For more precise control over the server SQL mode, use the `--sql-mode` option instead. See [Section 1.8.3, “Running MySQL in ANSI Mode”](#), and [Section 5.1.7, “Server SQL Modes”](#).

- `--basedir=path, -b path`

<b>Command-Line Format</b>	<code>--basedir=name</code>
	<code>-b</code>
<b>Config-File Format</b>	<code>basedir</code>
<b>Option Sets Variable</b>	Yes, <code>basedir</code>
<b>Variable Name</b>	<code>basedir</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No
	<b>Permitted Values</b>
	<b>Type</b> <code>filename</code>

The path to the MySQL installation directory. All paths are usually resolved relative to this directory.

- `--big-tables`

<b>Command-Line Format</b>	<code>--big-tables</code>
<b>Config-File Format</b>	<code>big-tables</code>
<b>Option Sets Variable</b>	Yes, <code>big_tables</code>
<b>Variable Name</b>	<code>big-tables</code>
<b>Variable Scope</b>	Session
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
	<b>Type</b> <code>boolean</code>

Enable large result sets by saving all temporary sets in files. This option prevents most “table full” errors, but also slows down queries for which in-memory tables would suffice. Since MySQL 3.23.2, the server is able to handle large result sets automatically by using memory for small temporary tables and switching to disk tables where necessary.

- `--bind-address=IP`

<b>Command-Line Format</b>	<code>--bind-address=name</code>
<b>Config-File Format</b>	<code>bind-address</code>
	<b>Permitted Values</b>
	<b>Type</b> <code>string</code>
	<b>Default</b> <code>0.0.0.0</code>
	<b>Range</b> <code>0.0.0.0-255.255.255.255</code>

The IP address to bind to. Only one address can be selected. If this option is specified multiple times, the last address given is used.

If no address or `0.0.0.0` is specified, the server listens on all interfaces.

- `--binlog-format={ROW|STATEMENT|MIXED}`

<b>Version Introduced</b>	5.1.5
<b>Command-Line Format</b>	<code>--binlog-format</code>
<b>Config-File Format</b>	<code>binlog-format</code>
<b>Option Sets Variable</b>	Yes, <code>binlog_format</code>

<b>Variable Name</b>	<code>binlog_format</code>
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values (&gt;= 5.1.5, &lt;= 5.1.7)</b>
<b>Type</b>	<code>enumeration</code>
<b>Default</b>	<code>STATEMENT</code>
<b>Valid Values</b>	<code>ROW, STATEMENT</code>
	<b>Permitted Values (&gt;= 5.1.8, &lt;= 5.1.11)</b>
<b>Type</b>	<code>enumeration</code>
<b>Default</b>	<code>STATEMENT</code>
<b>Valid Values</b>	<code>ROW, STATEMENT, MIXED</code>
	<b>Permitted Values (&gt;= 5.1.12, &lt;= 5.1.28)</b>
<b>Type</b>	<code>enumeration</code>
<b>Default</b>	<code>MIXED</code>
<b>Valid Values</b>	<code>ROW, STATEMENT, MIXED</code>
	<b>Permitted Values (&gt;= 5.1.29)</b>
<b>Type</b>	<code>enumeration</code>
<b>Default</b>	<code>STATEMENT</code>
<b>Valid Values</b>	<code>ROW, STATEMENT, MIXED</code>

Specify whether to use row-based, statement-based, or mixed replication (statement-based was the default prior to MySQL 5.1.12; in 5.1.12, the default was changed to mixed replication; in 5.1.29, the default was changed back to statement-based). See [Section 16.1.2, “Replication Formats”](#). This option was added in MySQL 5.1.5.

### Important

Setting the binary logging format without enabling binary logging prevents the MySQL server from starting. This is a known issue in MySQL 5.1 which is fixed in MySQL 5.5. ([Bug#42928](#))

**MySQL Cluster.** The default value for this option in all MySQL Cluster NDB 6.1, 6.2, 6.3, and later 6.x releases is `MIXED`. See [Section 17.6.2, “MySQL Cluster Replication: Assumptions and General Requirements”](#), for more information.

- `--bootstrap`

<b>Command-Line Format</b>	<code>--bootstrap</code>
<b>Config-File Format</b>	<code>bootstrap</code>

This option is used by the `mysql_install_db` script to create the MySQL privilege tables without having to start a full MySQL server.

This option is unavailable if MySQL was configured with the `--disable-grant-options` option. See [Section 2.3.3, “Typical configure Options”](#).

- `--character-sets-dir=path`

<b>Command-Line Format</b>	<code>--character-sets-dir=name</code>
<b>Config-File Format</b>	<code>character-sets-dir</code>
<b>Option Sets Variable</b>	Yes, <code>character_sets_dir</code>
<b>Variable Name</b>	<code>character-sets-dir</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No

	Permitted Values
Type	filename

The directory where character sets are installed. See [Section 9.5, “Character Set Configuration”](#).

- `--character-set-client-handshake`

Command-Line Format	<code>--character-set-client-handshake</code>
Config-File Format	<code>character-set-client-handshake</code>
	Permitted Values
Type	boolean
Default	<code>TRUE</code>

Don't ignore character set information sent by the client. To ignore client information and use the default server character set, use `--skip-character-set-client-handshake`; this makes MySQL behave like MySQL 4.0.

- `--character-set-filesystem=charset_name`

Version Introduced	5.1.6
Command-Line Format	<code>--character-set-filesystem=name</code>
Config-File Format	<code>character-set-filesystem</code>
Option Sets Variable	Yes, <code>character_set_filesystem</code>
Variable Name	<code>character_set_filesystem</code>
Variable Scope	Both
Dynamic Variable	Yes
	Permitted Values
Type	string

The file system character set. This option sets the `character_set_filesystem` system variable. It was added in MySQL 5.1.6.

- `--character-set-server=charset_name, -C charset_name`

Command-Line Format	<code>--character-set-server</code>
Config-File Format	<code>character-set-server</code>
Option Sets Variable	Yes, <code>character_set_server</code>
Variable Name	<code>character_set_server</code>
Variable Scope	Both
Dynamic Variable	Yes
	Permitted Values
Type	string

Use `charset_name` as the default server character set. See [Section 9.5, “Character Set Configuration”](#). If you use this option to specify a nondefault character set, you should also use `--collation-server` to specify the collation.

- `--chroot=path, -r path`

Command-Line Format	<code>--chroot=name</code>
	<code>-r name</code>
Config-File Format	<code>chroot</code>
	Permitted Values
Type	filename

Put the `mysqld` server in a closed environment during startup by using the `chroot()` system call. This is a recommended security measure. Note that use of this option somewhat limits `LOAD DATA INFILE` and `SELECT ... INTO OUTFILE`.

- `--collation-server=collation_name`

<b>Command-Line Format</b>	<code>--collation-server</code>
<b>Config-File Format</b>	<code>collation-server</code>
<b>Option Sets Variable</b>	Yes, <code>collation_server</code>
<b>Variable Name</b>	<code>collation_server</code>
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
	Type <code>string</code>

Use `collation_name` as the default server collation. See [Section 9.5, “Character Set Configuration”](#).

- `--console`

<b>Command-Line Format</b>	<code>--console</code>
<b>Config-File Format</b>	<code>console</code>
<b>Platform Specific</b>	windows

(Windows only.) Write error log messages to `stderr` and `stdout` even if `--log-error` is specified. `mysqld` does not close the console window if this option is used.

- `--core-file`

<b>Command-Line Format</b>	<code>--core-file</code>
<b>Config-File Format</b>	<code>core-file</code>
	<b>Permitted Values</b>
	Type <code>boolean</code>
	Default <code>FALSE</code>

Write a core file if `mysqld` dies. The name and location of the core file is system dependent. On Linux, a core file named `core.pid` is written to the current working directory of the process, which for `mysqld` is the data directory. `pid` represents the process ID of the server process. On Mac OS X, a core file named `core.pid` is written to the `/cores` directory. On Solaris, use the `coreadm` command to specify where to write the core file and how to name it.

For some systems, to get a core file you must also specify the `--core-file-size` option to `mysqld_safe`. See [Section 4.3.2, “mysqld\\_safe — MySQL Server Startup Script”](#). On some systems, such as Solaris, you do not get a core file if you are also using the `--user` option. There might be additional restrictions or limitations. For example, it might be necessary to execute `ulimit -c unlimited` before starting the server. Consult your system documentation.

- `--datadir=path, -h path`

<b>Command-Line Format</b>	<code>--datadir=name</code>
	<code>-h</code>
<b>Config-File Format</b>	<code>datadir</code>
<b>Option Sets Variable</b>	Yes, <code>datadir</code>
<b>Variable Name</b>	<code>datadir</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No
	<b>Permitted Values</b>
	Type <code>filename</code>

The path to the data directory.

- `--debug[=debug_options], -# [debug_options]`

<b>Command-Line Format</b>	<code>--debug[=debug_options]</code>
<b>Config-File Format</b>	<code>debug</code>
<b>Variable Name</b>	<code>debug</code>
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
	<b>Type</b> <code>string</code>
	<b>Default</b> <code>'d:t:o,/tmp/mysqld.trace'</code>

If MySQL is configured with `--with-debug`, you can use this option to get a trace file of what `mysqld` is doing. A typical `debug_options` string is `'d:t:o,file_name'`. The default is `'d:t:i:o,mysqld.trace'`. See [MySQL Internals: Porting](#).

As of MySQL 5.1.12, using `--with-debug` to configure MySQL with debugging support enables you to use the `-debug="d,parser_debug"` option when you start the server. This causes the Bison parser that is used to process SQL statements to dump a parser trace to the server's standard error output. Typically, this output is written to the error log.

This option may be given multiple times. Values that begin with `+` or `-` are added to or subtracted from the previous value. For example, `--debug=T --debug=+P` sets the value to `P:T`.

- `--debug-sync-timeout[=N]`

<b>Version Introduced</b>	5.1.41
<b>Command-Line Format</b>	<code>--debug-sync-timeout[=#]</code>
<b>Config-File Format</b>	<code>debug-sync-timeout</code>
	<b>Permitted Values</b>
	<b>Type</b> <code>numeric</code>

Controls whether the Debug Sync facility for testing and debugging is enabled. Use of Debug Sync requires that MySQL be configured with the `--enable-debug-sync` option (see [Section 2.3.3, “Typical configure Options”](#)). If Debug Sync is not compiled in, this option is not available. The option value is a timeout in seconds. The default value is 0, which disables Debug Sync. To enable it, specify a value greater than 0; this value also becomes the default timeout for individual synchronization points. If the option is given without a value, the timeout is set to 300 seconds.

For a description of the Debug Sync facility and how to use synchronization points, see [MySQL Internals: Test Synchronization](#).

This option was added in MySQL 5.1.41.

- `--default-character-set=charset_name`

<b>Command-Line Format</b>	<code>--default-character-set=name</code>
	<code>-C name</code>
<b>Config-File Format</b>	<code>default-character-set</code>
<b>Deprecated</b>	5.0
	<b>Permitted Values</b>
	<b>Type</b> <code>string</code>

Use `charset_name` as the default character set. This option is deprecated in favor of `--character-set-server`. See [Section 9.5, “Character Set Configuration”](#). `--default-character-set` is removed in MySQL 5.5.

- `--default-collation=collation_name`

<b>Command-Line Format</b>	<code>--default-collation=name</code>
----------------------------	---------------------------------------

<b>Variable Name</b>	<code>default-collation</code>	
<b>Variable Scope</b>		
<b>Dynamic Variable</b>	No	
<b>Deprecated</b>	4.1.3	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>string</code>

Use `collation_name` as the default collation. This option is deprecated in favor of `--collation-server`. See [Section 9.5, “Character Set Configuration”](#). `--default-collation` is removed in MySQL 5.5.

- `--default-storage-engine=type`

<b>Command-Line Format</b>	<code>--default-storage-engine=name</code>	
<b>Config-File Format</b>	<code>default-storage-engine</code>	
<b>Variable Name</b>	<code>default-storage-engine</code>	
<b>Variable Scope</b>	Both	
<b>Dynamic Variable</b>	Yes	

Set the default storage engine (table type) for tables. See [Chapter 13, Storage Engines](#).

- `--default-table-type=type`

<b>Command-Line Format</b>	<code>--default-table-type=name</code>	
<b>Config-File Format</b>	<code>default-table-type</code>	
<b>Deprecated</b>	5.0, by <code>default-storage-engine</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>string</code>

This option is a synonym for `--default-storage-engine`. It is deprecated and removed in MySQL 5.5.

- `--default-time-zone=timezone`

<b>Command-Line Format</b>	<code>--default-time-zone=name</code>	
<b>Config-File Format</b>	<code>default-time-zone</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>string</code>

Set the default server time zone. This option sets the global `time_zone` system variable. If this option is not given, the default time zone is the same as the system time zone (given by the value of the `system_time_zone` system variable).

- `--delay-key-write[={OFF|ON|ALL}]`

<b>Command-Line Format</b>	<code>--delay-key-write[=name]</code>	
<b>Config-File Format</b>	<code>delay-key-write</code>	
<b>Option Sets Variable</b>	Yes, <code>delay_key_write</code>	
<b>Variable Name</b>	<code>delay-key-write</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>enumeration</code>
	<b>Default</b>	<code>ON</code>
	<b>Valid Values</b>	<code>ON, OFF, ALL</code>

Specify how to use delayed key writes. Delayed key writing causes key buffers not to be flushed between writes for [MyISAM](#) tables. `OFF` disables delayed key writes. `ON` enables delayed key writes for those tables that were created with the `DELAY_KEY_WRITE` option. `ALL` delays key writes for all [MyISAM](#) tables. See [Section 7.9.3, “Tuning Server Parameters”](#), and [Section 13.5.1, “MyISAM Startup Options”](#).

### Note

If you set this variable to `ALL`, you should not use [MyISAM](#) tables from within another program (such as another MySQL server or `myisamchk`) when the tables are in use. Doing so leads to index corruption.

- `--des-key-file=file_name`

<b>Command-Line Format</b>	<code>--des-key-file=name</code>
<b>Config-File Format</b>	<code>des-key-file</code>

Read the default DES keys from this file. These keys are used by the `DES_ENCRYPT()` and `DES_DECRYPT()` functions.

- `--enable-named-pipe`

<b>Command-Line Format</b>	<code>--named_pipe</code>
<b>Config-File Format</b>	<code>enable-named-pipe</code>
<b>Platform Specific</b>	windows

Enable support for named pipes. This option applies only on Windows NT, 2000, XP, and 2003 systems. For MySQL 5.1.20 and earlier, this option is available only when using the `mysqld-nt` and `mysqld-debug` servers that support named-pipe connections. For MySQL 5.1.21 and later, `mysqld-nt` is not available, but support is included in the standard `mysqld` and `mysqld-debug` servers.

- `--enable-pstack`

<b>Command-Line Format</b>	<code>--enable-pstack</code>
<b>Config-File Format</b>	<code>enable-pstack</code>
<b>Permitted Values</b>	
<b>Type</b>	<code>boolean</code>
<b>Default</b>	<code>FALSE</code>

Print a symbolic stack trace on failure. This capability is available only on Intel Linux systems, and only if MySQL was configured with the `--with-pstack` option.

- `--engine-condition-pushdown={ON|OFF}`

<b>Command-Line Format</b>	<code>--engine-condition-pushdown</code>
<b>Config-File Format</b>	<code>engine-condition-pushdown</code>
<b>Option Sets Variable</b>	Yes, <code>engine_condition_pushdown</code>
<b>Variable Name</b>	<code>engine_condition_pushdown</code>
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes
<b>Deprecated</b>	5.5.3, by <code>optimizer_switch</code>
<b>Permitted Values (&gt;= 5.1.0)</b>	
<b>Type</b>	<code>boolean</code>
<b>Default</b>	<code>ON</code>

Sets the `engine_condition_pushdown` system variable. For more information, see [Section 7.3.1.5, “Condition Push-down Optimization”](#).

- `--event-scheduler[=value]`

<b>Version Introduced</b>	5.1.6
<b>Command-Line Format</b>	<code>--event-scheduler[=value]</code>
<b>Config-File Format</b>	<code>event-scheduler</code>
<b>Option Sets Variable</b>	Yes, <code>event_scheduler</code>
<b>Variable Name</b>	<code>event_scheduler</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
	<b>Type</b> <code>enumeration</code>
	<b>Default</b> <code>OFF</code>
	<b>Valid Values</b> <code>ON, OFF, DISABLED</code>

Enable or disable, and start or stop, the event scheduler. This option was added in MySQL 5.1.6. Note that its permitted values and behavior changed in MySQL 5.1.11, and again in MySQL 5.1.12.

For detailed information, see [The `--event-scheduler` Option](#).

- `--exit-info[=flags], -T [flags]`

<b>Command-Line Format</b>	<code>--exit-info[=flags]</code>
	<code>-T [flags]</code>
<b>Config-File Format</b>	<code>exit-info</code>
	<b>Permitted Values</b>
	<b>Type</b> <code>numeric</code>

This is a bit mask of different flags that you can use for debugging the `mysqld` server. Do not use this option unless you know exactly what it does!

- `--external-locking`

<b>Command-Line Format</b>	<code>--external-locking</code>
<b>Config-File Format</b>	<code>external-locking</code>
<b>Option Sets Variable</b>	Yes, <code>skip_external_locking</code>
<b>Disabled by</b>	<code>skip-external-locking</code>
	<b>Permitted Values</b>
	<b>Type</b> <code>boolean</code>
	<b>Default</b> <code>FALSE</code>

Enable external locking (system locking), which is disabled by default as of MySQL 4.0. Note that if you use this option on a system on which `lockd` does not fully work (such as Linux), it is easy for `mysqld` to deadlock.

For more information about external locking, including conditions under which it can and cannot be used, see [Section 7.7.4, “External Locking”](#).

- `--flush`

<b>Command-Line Format</b>	<code>--flush</code>
<b>Config-File Format</b>	<code>flush</code>
<b>Variable Name</b>	<code>flush</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes

<b>Permitted Values</b>	
Type	boolean
Default	OFF

Flush (synchronize) all changes to disk after each SQL statement. Normally, MySQL does a write of all changes to disk only after each SQL statement and lets the operating system handle the synchronizing to disk. See [Section B.5.4.2, “What to Do If MySQL Keeps Crashing”](#).

- [--gdb](#)

<b>Command-Line Format</b>	--gdb
<b>Config-File Format</b>	gdb
<b>Permitted Values</b>	
Type	boolean
Default	FALSE

Install an interrupt handler for `SIGINT` (needed to stop `mysqld` with `^C` to set breakpoints) and disable stack tracing and core file handling. See [MySQL Internals: Porting](#).

- [--general-log\[={0|1}\]](#)

<b>Version Introduced</b>	5.1.12
<b>Command-Line Format</b>	--general-log
<b>Config-File Format</b>	general-log
<b>Option Sets Variable</b>	Yes, general_log
<b>Variable Name</b>	general_log
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	
Type	boolean
Default	OFF

Specify the initial general query log state. With no argument or an argument of 1, the [--general-log](#) option enables the log. If omitted or given with an argument of 0, the option disables the log. This option was added in MySQL 5.1.12.

- [--init-file=file\\_name](#)

<b>Command-Line Format</b>	--init-file=name
<b>Config-File Format</b>	init-file
<b>Option Sets Variable</b>	Yes, init_file
<b>Variable Name</b>	init_file
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	
Type	filename

Read SQL statements from this file at startup. Each statement must be on a single line and should not include comments.

This option is unavailable if MySQL was configured with the [--disable-grant-options](#) option. See [Section 2.3.3, “Typical configure Options”](#).

- [--innodb-xxx](#)

The `InnoDB` options are listed in [Section 13.6.3, “InnoDB Startup Options and System Variables”](#).

- `--language=lang_name, -L lang_name`

<b>Command-Line Format</b>	<code>--language=name</code>
	<code>-L</code>
<b>Config-File Format</b>	<code>language</code>
<b>Option Sets Variable</b>	Yes, <code>language</code>
<b>Variable Name</b>	<code>language</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No
<b>Deprecated</b>	5.5.0, by <code>lc-messages-dir</code>
	<b>Permitted Values</b>
	Type <code>filename</code>
	Default <code>/usr/local/mysql/share/mysql/english/</code>

The language to use for error messages. `lang_name` can be given as the language name or as the full path name to the directory where the language files are installed. See [Section 9.2, “Setting the Error Message Language”](#).

- `--large-pages`

<b>Command-Line Format</b>	<code>--large-pages</code>	
<b>Config-File Format</b>	<code>large-pages</code>	
<b>Option Sets Variable</b>	Yes, <code>large_pages</code>	
<b>Variable Name</b>	<code>large_pages</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
<b>Platform Specific</b>	linux	
	<b>Permitted Values</b>	
	Type <code>(linux)</code>	<code>boolean</code>
	Default	<code>FALSE</code>

Some hardware/operating system architectures support memory pages greater than the default (usually 4KB). The actual implementation of this support depends on the underlying hardware and operating system. Applications that perform a lot of memory accesses may obtain performance improvements by using large pages due to reduced Translation Lookaside Buffer (TLB) misses.

Currently, MySQL supports only the Linux implementation of large page support (which is called HugeTLB in Linux). See [Section 7.9.8, “Enabling Large Page Support”](#).

`--large-pages` is disabled by default.

- `--log[=file_name], -l [file_name]`

<b>Version Deprecated</b>	5.1.29
<b>Command-Line Format</b>	<code>--log[=name]</code>
	<code>-l</code>
<b>Config-File Format</b>	<code>log</code>
<b>Option Sets Variable</b>	Yes, <code>log</code>
<b>Variable Name</b>	<code>log</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes
<b>Deprecated</b>	5.1.29, by <code>general-log</code>

Permitted Values	
Type	string
Default	OFF

This option enables logging to the general query log, which contains entries that record client connections and SQL statements received from clients. The log output destination can be selected with the `--log-output` option as of MySQL 5.1.6. Before 5.1.6, logging occurs to the general query log file. If you omit the file name, MySQL uses `host_name.log` as the file name. See [Section 5.2.1, “Selecting General Query and Slow Query Log Output Destinations”](#), and [Section 5.2.3, “The General Query Log”](#).

As of MySQL 5.1.29, the `--log` option is deprecated and will be removed (along with the `log` system variable) in MySQL 7.0. Instead, use the `--general_log` option to enable the general query log and the `--general_log_file=file_name` option to set the general query log file name.

- `--log-error[=file_name]`

<b>Command-Line Format</b>	<code>--log-error[=name]</code>
<b>Config-File Format</b>	<code>log-error</code>
<b>Option Sets Variable</b>	Yes, <code>log_error</code>
<b>Variable Name</b>	<code>log_error</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No
Permitted Values	
Type	filename

Log errors and startup messages to this file. See [Section 5.2.2, “The Error Log”](#). If you omit the file name, MySQL uses `host_name.err`. If the file name has no extension, the server adds an extension of `.err`.

- `--log-isam[=file_name]`

<b>Command-Line Format</b>	<code>--log-isam[=name]</code>
<b>Config-File Format</b>	<code>log-isam</code>
Permitted Values	
Type	filename

Log all `MyISAM` changes to this file (used only when debugging `MyISAM`).

- `--log-long-format`

<b>Command-Line Format</b>	<code>--log-long-format</code>
	<code>-0</code>
<b>Config-File Format</b>	<code>log-long-format</code>
<b>Deprecated</b>	4.1

Log extra information to the binary log and slow query log, if they have been activated. For example, the user name and timestamp are logged for all queries. This option is deprecated, as it now represents the default logging behavior. (See the description for `--log-short-format`.) The `--log-queries-not-using-indexes` option is available for the purpose of logging queries that do not use indexes to the slow query log. `--log-long-format` is removed in MySQL 5.5.

- `--log-output[=value,...]`

<b>Version Introduced</b>	5.1.6
<b>Command-Line Format</b>	<code>--log-output[=name]</code>
<b>Config-File Format</b>	<code>log-output</code>
<b>Option Sets Variable</b>	Yes, <code>log_output</code>

<b>Variable Name</b>	<code>log_output</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
<b>Type</b>	<code>set</code>	
<b>Default</b>	<code>FILE</code>	
<b>Valid Values</b>	<code>TABLE, FILE, NONE</code>	

This option determines the destination for general query log and slow query log output. The option value can be given as one or more of the words `TABLE`, `FILE`, or `NONE`. If the option is given without a value, the default is `FILE`. (For MySQL 5.1.6 through 5.1.20, the default is `TABLE`.) `TABLE` select logging to the `general_log` and `slow_log` tables in the `mysql` database as a destination. `FILE` selects logging to log files as a destination. `NONE` disables logging. If `NONE` is present in the option value, it takes precedence over any other words that are present. `TABLE` and `FILE` can both be given to select to both log output destinations.

This option selects log output destinations, but does not enable log output. To do that, use the `--general_log` and `--slow_query_log` options. For `FILE` logging, the `--general_log_file` and `--slow_query_log_file` options determine the log file location. (Before MySQL 5.1.29, enable the logs with the `--log` and `--log-slow-queries` options. The options take an optional file name argument to specify the log file name.) For more information, see [Section 5.2.1, “Selecting General Query and Slow Query Log Output Destinations”](#).

The `--log-output` option was added in MySQL 5.1.6.

- `--log-queries-not-using-indexes`

<b>Command-Line Format</b>	<code>--log-queries-not-using-indexes</code>	
<b>Config-File Format</b>	<code>log-queries-not-using-indexes</code>	
<b>Option Sets Variable</b>	Yes, <code>log_queries_not_using_indexes</code>	
<b>Variable Name</b>	<code>log_queries_not_using_indexes</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
<b>Type</b>	<code>boolean</code>	

If you are using this option with the slow query log enabled, queries that are expected to retrieve all rows are logged. See [Section 5.2.5, “The Slow Query Log”](#). This option does not necessarily mean that no index is used. For example, a query that uses a full index scan uses an index but would be logged because the index would not limit the number of rows.

- `--log-short-format`

<b>Command-Line Format</b>	<code>--log-short-format</code>	
<b>Config-File Format</b>	<code>log-short-format</code>	
	<b>Permitted Values</b>	
<b>Type</b>	<code>boolean</code>	
<b>Default</b>	<code>FALSE</code>	

Originally intended to log less information to the binary log and slow query log, if they have been activated. However, this option is not operational.

- `--log-slow-admin-statements`

<b>Command-Line Format</b>	<code>--log-slow-admin-statements</code>	
<b>Config-File Format</b>	<code>log-slow-admin-statements</code>	

<b>Permitted Values</b>	
<b>Type</b>	<code>boolean</code>
<b>Default</b>	<code>FALSE</code>

Log slow administrative statements such as `OPTIMIZE TABLE`, `ANALYZE TABLE`, and `ALTER TABLE` to the slow query log.

- `--log-slow-queries[=file_name]`

<b>Version Deprecated</b>	5.1.29
<b>Command-Line Format</b>	<code>--log-slow-queries[=name]</code>
<b>Config-File Format</b>	<code>log-slow-queries</code>
<b>Option Sets Variable</b>	Yes, <code>log_slow_queries</code>
<b>Variable Name</b>	<code>log_slow_queries</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes
<b>Deprecated</b>	5.1.29, by <code>slow-query-log</code>
<b>Permitted Values</b>	
<b>Type</b>	<code>boolean</code>

This option enables logging to the slow query log, which contains entries for all queries that have taken more than `long_query_time` seconds to execute. See the descriptions of the `--log-long-format` and `--log-short-format` options for details.

The log output destination can be selected with the `--log-output` option as of MySQL 5.1.6. Before 5.1.6, logging occurs to the slow query log file. If you omit the file name, MySQL uses `host_name-slow.log` as the file name. See [Section 5.2.1, “Selecting General Query and Slow Query Log Output Destinations”](#), and [Section 5.2.5, “The Slow Query Log”](#).

As of MySQL 5.1.29, the `--log-slow-queries` option is deprecated and will be removed (along with the `log_slow_queries` system variable) in MySQL 7.0. Instead, use the `--slow_query_log` option to enable the slow query log and the `--slow_query_log_file=file_name` option to set the slow query log file name.

- `--log-tc=file_name`

<b>Command-Line Format</b>	<code>--log-tc=name</code>
<b>Config-File Format</b>	<code>log-tc</code>
<b>Permitted Values</b>	
<b>Type</b>	<code>filename</code>
<b>Default</b>	<code>tc.log</code>

The name of the memory-mapped transaction coordinator log file (for XA transactions that affect multiple storage engines when the binary log is disabled). The default name is `tc.log`. The file is created under the data directory if not given as a full path name. Currently, this option is unused.

- `--log-tc-size=size`

<b>Command-Line Format</b>	<code>--log-tc-size=#</code>
<b>Config-File Format</b>	<code>log-tc-size</code>
<b>Permitted Values</b>	
<b>Platform Bit Size</b>	<code>32</code>
<b>Type</b>	<code>numeric</code>
<b>Default</b>	<code>24576</code>
<b>Max Value</b>	<code>4294967295</code>

Permitted Values	
Platform	64
Bit Size	
Type	numeric
Default	24576
Max Value	18446744073709547520

The size in bytes of the memory-mapped transaction coordinator log. The default size is 24KB.

- `--log-warnings[=level], -W [level]`

Command-Line Format	<code>--log-warnings[=#]</code>
	<code>-W [#]</code>
Config-File Format	<code>log-warnings</code>
Option Sets Variable	Yes, <code>log_warnings</code>
Variable Name	<code>log_warnings</code>
Variable Scope	Both
Dynamic Variable	Yes
Disabled by	<code>skip-log-warnings</code>
Permitted Values	
Platform	64
Bit Size	
Type	numeric
Default	1
Range	0-18446744073709547520

Print out warnings such as `Aborted connection...` to the error log. Enabling this option is recommended, for example, if you use replication (you get more information about what is happening, such as messages about network failures and reconnections). This option is enabled (1) by default, and the default `level` value if omitted is 1. To disable this option, use `--log-warnings=0`. If the value is greater than 1, aborted connections are written to the error log. See [Section B.5.2.11, “Communication Errors and Aborted Connections”](#).

If a slave server was started with `--log-warnings` enabled, the slave prints messages to the error log to provide information about its status, such as the binary log and relay log coordinates where it starts its job, when it is switching to another relay log, when it reconnects after a disconnect, and so forth. As of MySQL 5.1.38, the server logs messages about statements that are unsafe for statement-based logging only if `--log-warnings` is enabled.

- `--low-priority-updates`

Command-Line Format	<code>--low-priority-updates</code>
Config-File Format	<code>low-priority-updates</code>
Option Sets Variable	Yes, <code>low_priority_updates</code>
Variable Name	<code>low_priority_updates</code>
Variable Scope	Both
Dynamic Variable	Yes
Permitted Values	
Type	<code>boolean</code>
Default	<code>FALSE</code>

Give table-modifying operations (`INSERT`, `REPLACE`, `DELETE`, `UPDATE`) lower priority than selects. This can also be done using `{ INSERT | REPLACE | DELETE | UPDATE } LOW_PRIORITY ...` to lower the priority of only one query, or by `SET LOW_PRIORITY_UPDATES=1` to change the priority in one thread. This affects only storage engines that use only table-level locking (MyISAM, MEMORY, MERGE). See [Section 7.7.2, “Table Locking Issues”](#).

- `--min-examined-row-limit=number`

<b>Version Introduced</b>	5.1.21
<b>Command-Line Format</b>	<code>--min-examined-row-limit=#</code>
<b>Config-File Format</b>	<code>min-examined-row-limit</code>
<b>Variable Name</b>	<code>min_examined_row_limit</code>
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
	<b>Platform</b> <code>32</code>
	<b>Bit Size</b>
	<b>Type</b> <code>numeric</code>
	<b>Default</b> <code>0</code>
	<b>Range</b> <code>0-4294967295</code>
	<b>Permitted Values</b>
	<b>Platform</b> <code>64</code>
	<b>Bit Size</b>
	<b>Type</b> <code>numeric</code>
	<b>Default</b> <code>0</code>
	<b>Range</b> <code>0-18446744073709547520</code>

When this option is set, queries which examine fewer than `number` rows are not written to the slow query log. The default is 0.

This option was introduced in MySQL 5.1.21.

- `--memlock`

<b>Command-Line Format</b>	<code>--memlock</code>
<b>Config-File Format</b>	<code>memlock</code>
<b>Variable Name</b>	<code>locked_in_memory</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No
	<b>Permitted Values</b>
	<b>Type</b> <code>boolean</code>
	<b>Default</b> <code>FALSE</code>

Lock the `mysqld` process in memory. This option might help if you have a problem where the operating system is causing `mysqld` to swap to disk.

`--memlock` works on systems that support the `mlockall()` system call; this includes Solaris as well as most Linux distributions that use a 2.4 or newer kernel. On Linux systems, you can tell whether or not `mlockall()` (and thus this option) is supported by checking to see whether or not it is defined in the system `mman.h` file, like this:

```
shell> grep mlockall /usr/include/sys/mman.h
```

If `mlockall()` is supported, you should see in the output of the previous command something like the following:

```
extern int mlockall (int __flags) __THROW;
```

## Important

Using this option requires that you run the server as `root`, which, for reasons of security, is normally not a good idea. See [Section 5.3.6, “How to Run MySQL as a Normal User”](#).

You must not try to use this option on a system that does not support the `mlockall()` system call; if you do so, `mysqld` will very likely crash as soon as you try to start it.

- `--myisam-block-size=N`

<b>Command-Line Format</b>	<code>--myisam-block-size=#</code>
<b>Config-File Format</b>	<code>myisam-block-size</code>
<b>Permitted Values</b>	
<b>Type</b>	<code>numeric</code>
<b>Default</b>	<code>1024</code>
<b>Range</b>	<code>1024-16384</code>

The block size to be used for `MyISAM` index pages.

- `--myisam-recover[=option[,option]...]`

<b>Command-Line Format</b>	<code>--myisam-recover[=name]</code>
<b>Config-File Format</b>	<code>myisam-recover</code>
<b>Option Sets Variable</b>	<code>Yes, myisam_recover_options</code>
<b>Permitted Values</b>	
<b>Type</b>	<code>enumeration</code>
<b>Default</b>	<code>OFF</code>
<b>Valid Values</b>	<code>DEFAULT, BACKUP, FORCE, QUICK</code>

Set the `MyISAM` storage engine recovery mode. The option value is any combination of the values of `DEFAULT`, `BACKUP`, `FORCE`, or `QUICK`. If you specify multiple values, separate them by commas. Specifying the option with no argument is the same as specifying `DEFAULT`, and specifying with an explicit value of " " disables recovery (same as not giving the option). If recovery is enabled, each time `mysqld` opens a `MyISAM` table, it checks whether the table is marked as crashed or wasn't closed properly. (The last option works only if you are running with external locking disabled.) If this is the case, `mysqld` runs a check on the table. If the table was corrupted, `mysqld` attempts to repair it.

The following options affect how the repair works.

<b>Option</b>	<b>Description</b>
<code>DEFAULT</code>	Recovery without backup, forcing, or quick checking.
<code>BACKUP</code>	If the data file was changed during recovery, save a backup of the <code>tbl_name.MYD</code> file as <code>tbl_name-datetime.BAK</code> .
<code>FORCE</code>	Run recovery even if we would lose more than one row from the <code>.MYD</code> file.
<code>QUICK</code>	Don't check the rows in the table if there aren't any delete blocks.

Before the server automatically repairs a table, it writes a note about the repair to the error log. If you want to be able to recover from most problems without user intervention, you should use the options `BACKUP`, `FORCE`. This forces a repair of a table even if some rows would be deleted, but it keeps the old data file as a backup so that you can later examine what happened.

See [Section 13.5.1, “MyISAM Startup Options”](#).

- `--old-alter-table`

<b>Command-Line Format</b>	<code>--old-alter-table</code>
<b>Config-File Format</b>	<code>old-alter-table</code>
<b>Option Sets Variable</b>	<code>Yes, old_alter_table</code>
<b>Variable Name</b>	<code>old-alter-table</code>
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	
<b>Type</b>	<code>boolean</code>
<b>Default</b>	<code>OFF</code>

When this option is given, the server does not use the optimized method of processing an `ALTER TABLE` operation. It reverts to using a temporary table, copying over the data, and then renaming the temporary table to the original, as used by MySQL 5.0 and earlier. For more information on the operation of `ALTER TABLE`, see [Section 12.1.7, “ALTER TABLE Syntax”](#).

- `--old-passwords`

<b>Command-Line Format</b>	<code>--old_passwords</code>
<b>Config-File Format</b>	<code>old-passwords</code>
<b>Option Sets Variable</b>	Yes, <code>old_passwords</code>
<b>Variable Name</b>	<code>old_passwords</code>
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	
<b>Type</b>	<code>boolean</code>
<b>Default</b>	<code>FALSE</code>

Force the server to generate short (pre-4.1) password hashes for new passwords. This is useful for compatibility when the server must support older client programs. See [Section 5.3.2.3, “Password Hashing in MySQL”](#).

- `--old-style-user-limits`

<b>Command-Line Format</b>	<code>--old-style-user-limits</code>
<b>Config-File Format</b>	<code>old-style-user-limits</code>
<b>Permitted Values</b>	
<b>Type</b>	<code>boolean</code>
<b>Default</b>	<code>FALSE</code>

Enable old-style user limits. (Before MySQL 5.0.3, account resource limits were counted separately for each host from which a user connected rather than per account row in the `user` table.) See [Section 5.5.4, “Setting Account Resource Limits”](#).

- `--one-thread`

<b>Command-Line Format</b>	<code>--one-thread</code>
<b>Config-File Format</b>	<code>one-thread</code>

Only use one thread (for debugging under Linux). This option is available only if the server is built with debugging enabled. See [MySQL Internals: Porting](#).

As of MySQL 5.1.17, this option is deprecated; use `--thread_handling=no-threads` instead.

- `--open-files-limit=count`

<b>Command-Line Format</b>	<code>--open-files-limit=#</code>
<b>Config-File Format</b>	<code>open-files-limit</code>
<b>Option Sets Variable</b>	Yes, <code>open_files_limit</code>
<b>Variable Name</b>	<code>open_files_limit</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	
<b>Type</b>	<code>numeric</code>
<b>Default</b>	<code>0</code>
<b>Range</b>	<code>0-65535</code>

Changes the number of file descriptors available to `mysqld`. You should try increasing the value of this option if `mysqld`

gives you the error `Too many open files.``mysqld` uses the option value to reserve descriptors with `setrlimit()`. If the requested number of file descriptors cannot be allocated, `mysqld` writes a warning to the error log.

`mysqld` may attempt to allocate more than the requested number of descriptors (if they are available), using the values of `max_connections` and `table_open_cache` to estimate whether more descriptors will be needed.

- `--partition[=value]`

<b>Command-Line Format</b>	<code>--partition</code>
<b>Config-File Format</b>	<code>partition</code>
<b>Option Sets Variable</b>	Yes, <code>have_partitioning</code>
<b>Variable Name</b>	<code>partition</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No
<b>Disabled by</b>	<code>skip-partition</code>
<b>Permitted Values</b>	
<b>Type</b>	<code>boolean</code>
<b>Default</b>	<code>ON</code>

Enables or disables user-defined partitioning support in the MySQL Server.

- `--pid-file=path`

<b>Command-Line Format</b>	<code>--pid-file=name</code>
<b>Config-File Format</b>	<code>pid-file</code>
<b>Option Sets Variable</b>	Yes, <code>pid_file</code>
<b>Variable Name</b>	<code>pid_file</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	
<b>Type</b>	<code>filename</code>

The path name of the process ID file. The server creates the file in the data directory unless an absolute path name is given to specify a different directory. This file is used by other programs such as `mysqld_safe` to determine the server's process ID.

- `--plugin-xxx`

Specifies an option that pertains to a server plugin. For example, many storage engines can be built as plugins, and for such engines, options for them can be specified with a `--plugin` prefix. Thus, the `--innodb_file_per_table` option for `InnoDB` can be specified as `--plugin-innodb_file_per_table`.

For boolean options that can be enabled or disabled, the `--skip` prefix and other alternative formats are supported as well (see [Section 4.2.3.2, “Program Option Modifiers”](#)). For example, `--skip-plugin-innodb_file_per_table` disables `innodb_file_per_table`.

The rationale for the `--plugin` prefix is that it enables plugin options to be specified unambiguously if there is a name conflict with a built-in server option. For example, were a plugin writer to name a plugin “sql” and implement a “mode” option, the option name might be `--sql-mode`, which would conflict with the built-in option of the same name. In such cases, references to the conflicting name are resolved in favor of the built-in option. To avoid the ambiguity, users can specify the plugin option as `--plugin-sql-mode`. Use of the `--plugin` prefix for plugin options is recommended to avoid any question of ambiguity.

- `--plugin-load=plugin_list`

<b>Version Introduced</b>	5.1.18
<b>Command-Line Format</b>	<code>--plugin-load=plugin_list</code>
<b>Config-File Format</b>	<code>plugin-load</code>
<b>Permitted Values</b>	
<b>Type</b>	<code>string</code>

This option tells the server to load the named plugins at startup. The option value is a semicolon-separated list of `name=plugin_library` pairs. Each `name` is the name of the plugin, and `plugin_library` is the name of the shared library that contains the plugin code. Each library file must be located in the directory named by the `plugin_dir` system variable. For example, if plugins named `myplug1` and `myplug2` have library files `myplug1.so` and `myplug2.so`, use this option to load them at startup:

```
shell> mysqld --plugin-load=myplug1=myplug1.so;myplug2=myplug2.so
```

All plugins to load must be named in the same `--plugin-load` option. If multiple `--plugin-load` options are given, only the last one is used.

Each named plugin is loaded for a single invocation of `mysqld` only. After a restart, the plugin is not loaded unless `--plugin-load` is used again. This is in contrast to `INSTALL PLUGIN`, which adds an entry to the `mysql.plugins` table to cause the plugin to be loaded for every normal server startup.

Under normal startup, the server determines which plugins to load by reading the `mysql.plugins` system table. If the server is started with the `--skip-grant-tables` option, it does not consult the `mysql.plugins` table and thus does not load plugins installed with the `INSTALL PLUGIN` statement. `--plugin-load` enables plugins to be loaded even when `--skip-grant-tables` is given. `--plugin-load` also enables plugins to be loaded at startup under configurations when plugins cannot be loaded at runtime.

For additional information about plugin loading, see [Section 12.4.3.1, “Installing and Uninstalling Plugins”](#).

This option was added in MySQL 5.1.18.

- `--port=port_num, -P port_num`

<b>Command-Line Format</b>	<code>--port=#</code>
	<code>-P</code>
<b>Config-File Format</b>	<code>port</code>
<b>Option Sets Variable</b>	Yes, <code>port</code>
<b>Variable Name</b>	<code>port</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No
	<b>Permitted Values</b>
	Type      numeric
	Default   3306

The port number to use when listening for TCP/IP connections. The port number must be 1024 or higher unless the server is started by the `root` system user.

- `--port-open-timeout=num`

<b>Version Introduced</b>	5.1.5
<b>Command-Line Format</b>	<code>--port-open-timeout=#</code>
<b>Config-File Format</b>	<code>port-open-timeout</code>
	<b>Permitted Values</b>
	Type      numeric
	Default   0

On some systems, when the server is stopped, the TCP/IP port might not become available immediately. If the server is restarted quickly afterward, its attempt to reopen the port can fail. This option indicates how many seconds the server should wait for the TCP/IP port to become free if it cannot be opened. The default is not to wait. This option was added in MySQL 5.1.5.

- `--safe-mode`

<b>Command-Line Format</b>	<code>--safe-mode</code>
<b>Config-File Format</b>	<code>safe-mode</code>
<b>Deprecated</b>	5.0

Skip some optimization stages.

- `--safe-show-database`

<b>Command-Line Format</b>	<code>-</code> <code>-</code> <code>safe-</code> <code>show-</code> <code>data-</code> <code>base</code>	(until 4.1.1)	
<b>Config-File Format</b>	<code>safe-show-database</code>		
<b>Variable Name</b>	<code>safe_show_database</code>		
<b>Variable Scope</b>	Global		
<b>Dynamic Variable</b>	Yes		
<b>Deprecated</b>	4.0.2		
	<b>Permitted Values</b>		
	<b>Type</b>	<code>boolean</code>	

This option is deprecated and does not do anything because there is a `SHOW DATABASES` privilege that can be used to control access to database names on a per-account basis. See [Section 5.4.1, “Privileges Provided by MySQL”](#). `-safe-show-database` is removed in MySQL 5.5.

- `--safe-user-create`

<b>Command-Line Format</b>	<code>--safe-user-create</code>
<b>Config-File Format</b>	<code>safe-user-create</code>
	<b>Permitted Values</b>
	<b>Type</b> <code>boolean</code>
	<b>Default</b> <code>FALSE</code>

If this option is enabled, a user cannot create new MySQL users by using the `GRANT` statement unless the user has the `INSERT` privilege for the `mysql.user` table or any column in the table. If you want a user to have the ability to create new users that have those privileges that the user has the right to grant, you should grant the user the following privilege:

```
GRANT INSERT(user) ON mysql.user TO 'user_name'@'host_name';
```

This ensures that the user cannot change any privilege columns directly, but has to use the `GRANT` statement to give privileges to other users.

- `--secure-auth`

<b>Command-Line Format</b>	<code>--secure-auth</code>
<b>Config-File Format</b>	<code>secure-auth</code>
<b>Option Sets Variable</b>	Yes, <code>secure_auth</code>
<b>Variable Name</b>	<code>secure_auth</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
	<b>Type</b> <code>boolean</code>
	<b>Default</b> <code>FALSE</code>

Disallow authentication by clients that attempt to use accounts that have old (pre-4.1) passwords.

- `--secure-file-priv=path`

<b>Version Introduced</b>	5.1.17
---------------------------	--------

<b>Command-Line Format</b>	<code>--secure-file-priv=path</code>
<b>Config-File Format</b>	<code>secure-file-priv=path</code>
<b>Option Sets Variable</b>	Yes, <code>secure_file_priv</code>
<b>Variable Name</b>	<code>secure-file-priv</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No
	<b>Permitted Values</b>
	<b>Type</b> <code>string</code>

This option limits the effect of the `LOAD_FILE()` function and the `LOAD DATA` and `SELECT ... INTO OUTFILE` statements to work only with files in the specified directory.

This option was added in MySQL 5.1.17.

- `--shared-memory`

Enable shared-memory connections by local clients. This option is available only on Windows.

- `--shared-memory-base-name=name`

The name of shared memory to use for shared-memory connections. This option is available only on Windows. The default name is `MYSQL`. The name is case sensitive.

- `--skip-concurrent-insert`

Turn off the ability to select and insert at the same time on `MyISAM` tables. (This is to be used only if you think you have found a bug in this feature.) See [Section 7.7.3, “Concurrent Inserts”](#).

- `--skip-external-locking`

Do not use external locking (system locking). For more information about external locking, including conditions under which it can and cannot be used, see [Section 7.7.4, “External Locking”](#).

External locking has been disabled by default since MySQL 4.0.

- `--skip-event-scheduler`

<b>Command-Line Format</b>	<code>--skip-event-scheduler</code>
	<code>--disable-event-scheduler</code>
<b>Config-File Format</b>	<code>skip-event-scheduler</code>

Turns the Event Scheduler `OFF`. This is not the same as disabling the Event Scheduler, which requires setting `--event-scheduler=DISABLED`; see [The --event-scheduler Option](#), for more information.

- `--skip-grant-tables`

This option causes the server to start without using the privilege system at all, which gives anyone with access to the server *unrestricted access to all databases*. You can cause a running server to start using the grant tables again by executing `mysqladmin flush-privileges` or `mysqladmin reload` command from a system shell, or by issuing a MySQL `FLUSH PRIVILEGES` statement after connecting to the server. This option also suppresses loading of plugins, user-defined functions (UDFs), and, beginning with MySQL 5.1.17, scheduled events. To cause plugins to be loaded anyway, use the `--plugin-load` option.

`--skip-grant-tables` is unavailable if MySQL was configured with the `--disable-grant-options` option. See [Section 2.3.3, “Typical configure Options”](#).

- `--skip-host-cache`

Do not use the internal host name cache for faster name-to-IP resolution. Instead, query the DNS server every time a client connects. See [Section 7.9.9, “How MySQL Uses DNS”](#).

- `--skip-innodb`

Disable the `InnoDB` storage engine. In this case, the server will not start if the default storage engine is set to `InnoDB`. Use `--default-storage-engine` to set the default to some other engine if necessary.

- `--skip-name-resolve`

Do not resolve host names when checking client connections. Use only IP numbers. If you use this option, all `Host` column values in the grant tables must be IP numbers or `localhost`. See [Section 7.9.9, “How MySQL Uses DNS”](#).

- `--skip-networking`

Don't listen for TCP/IP connections at all. All interaction with `mysqld` must be made using named pipes or shared memory (on Windows) or Unix socket files (on Unix). This option is highly recommended for systems where only local clients are permitted. See [Section 7.9.9, “How MySQL Uses DNS”](#).

- `--skip-partition`

<b>Command-Line Format</b>	<code>--skip-partition</code>
	<code>--disable-partition</code>
<b>Config-File Format</b>	<code>skip-partition</code>

Disables user-defined partitioning. Existing partitioned tables cannot be accessed when the server has been started with this option.

- `--ssl*`

Options that begin with `--ssl` specify whether to permit clients to connect using SSL and indicate where to find SSL keys and certificates. See [Section 5.5.6.3, “SSL Command Options”](#).

- `--standalone`

<b>Command-Line Format</b>	<code>--standalone</code>
<b>Config-File Format</b>	<code>standalone</code>
<b>Platform Specific</b>	<code>windows</code>

Available on Windows NT-based systems only; instructs the MySQL server not to run as a service.

- `--symbolic-links, --skip-symbolic-links`

<b>Command-Line Format</b>	<code>--symbolic-links</code>
<b>Config-File Format</b>	<code>symbolic-links</code>

Enable or disable symbolic link support. This option has different effects on Windows and Unix:

- On Windows, enabling symbolic links enables you to establish a symbolic link to a database directory by creating a `db_name.sym` file that contains the path to the real directory. See [Section 7.9.7.3, “Using Symbolic Links for Databases on Windows”](#).
- On Unix, enabling symbolic links means that you can link a `MyISAM` index file or data file to another directory with the `INDEX DIRECTORY` or `DATA DIRECTORY` options of the `CREATE TABLE` statement. If you delete or rename the table, the files that its symbolic links point to also are deleted or renamed. See [Section 7.9.7.2, “Using Symbolic Links for Tables on Unix”](#).

- `--skip-safemalloc`

<b>Command-Line Format</b>	<code>--skip-safemalloc</code>
<b>Config-File Format</b>	<code>skip-safemalloc</code>

If MySQL is configured with `--with-debug=full`, all MySQL programs check for memory overruns during each memory allocation and memory freeing operation. This checking is very slow, so for the server you can avoid it when you don't need it by using the `--skip-safemalloc` option.

- `--skip-show-database`

<b>Command-Line Format</b>	--skip-show-database
<b>Config-File Format</b>	skip-show-database
<b>Option Sets Variable</b>	Yes, skip_show_database
<b>Variable Name</b>	skip_show_database
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No

With this option, the `SHOW DATABASES` statement is permitted only to users who have the `SHOW DATABASES` privilege, and the statement displays all database names. Without this option, `SHOW DATABASES` is permitted to all users, but displays each database name only if the user has the `SHOW DATABASES` privilege or some privilege for the database. Note that *any* global privilege is considered a privilege for the database.

- `--skip-stack-trace`

<b>Command-Line Format</b>	--skip-stack-trace
<b>Config-File Format</b>	skip-stack-trace

Don't write stack traces. This option is useful when you are running `mysqld` under a debugger. On some systems, you also must use this option to get a core file. See [MySQL Internals: Porting](#).

- `--skip-thread-priority`

<b>Version Deprecated</b>	5.1.29
<b>Command-Line Format</b>	--skip-thread-priority
<b>Config-File Format</b>	skip-thread-priority
<b>Deprecated</b>	5.1.29

Disable using thread priorities for faster response time. This option is deprecated as of MySQL 5.1.29.

Prior to MySQL 5.1.29, `mysqld` makes a large number of invalid calls to thread scheduling routines on Linux. These calls do not affect performance noticeably but may be a source of "noise" for debugging tools. For example, they can overwhelm other information of more interest in kernel logs. To avoid these calls, start the server with the `--skip-thread-priority` option.

- `--slow-query-log[={0|1}]`

<b>Version Introduced</b>	5.1.12		
<b>Command-Line Format</b>	- - slow- query- log	5.1.29	
<b>Config-File Format</b>	slow- query- log	5.1.29	
<b>Option Sets Variable</b>	Yes, slow_query_log		
<b>Variable Name</b>	slow_query_log		
<b>Variable Scope</b>	Global		
<b>Dynamic Variable</b>	Yes		
	<b>Permitted Values</b>		
	Type	boolean	
	Default	OFF	

Specify the initial slow query log state. With no argument or an argument of 1, the `--slow-query-log` option enables the log. If omitted or given with an argument of 0, the option disables the log. This option was added in MySQL 5.1.12.

- `--socket=path`

<b>Command-Line Format</b>	<code>--socket=name</code>
<b>Config-File Format</b>	<code>socket</code>
<b>Option Sets Variable</b>	Yes, <code>socket</code>
<b>Variable Name</b>	<code>socket</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	
<b>Type</b>	<code>filename</code>
<b>Default</b>	<code>/tmp/mysql.sock</code>

On Unix, this option specifies the Unix socket file to use when listening for local connections. The default value is `/tmp/mysql.sock`. If this option is given, the server creates the file in the data directory unless an absolute path name is given to specify a different directory. On Windows, the option specifies the pipe name to use when listening for local connections that use a named pipe. The default value is `MySQL` (not case sensitive).

- `--sql-mode=value[,value[,value...]]`

<b>Command-Line Format</b>	<code>--sql-mode=name</code>
<b>Config-File Format</b>	<code>sql-mode</code>
<b>Option Sets Variable</b>	Yes, <code>sql_mode</code>
<b>Variable Name</b>	<code>sql_mode</code>
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	
<b>Type</b>	<code>set</code>
<b>Default</b>	<code>''</code>
<b>Valid Values</b>	<code>ALLOW_INVALID_DATES, ANSI_QUOTES, ER_ROR_FOR_DIVISION_BY_ZERO, HIGH_NOT_PRECEDENCE, IGNORE_SPACE, NO_AUTO_CREATE_USER, NO_AUTO_VALUE_ON_ZERO, NO_BACKSLASH_ESCAPES, NO_DIR_IN_CREATE, NO_ENGINE_SUBSTITUTION, NO_FIELD_OPTIONS, NO_KEY_OPTIONS, NO_TABLE_OPTIONS, NO_UNSIGNED_SUBTRACTION, NO_ZERO_DATE, NO_ZERO_IN_DATE, ONLY_FULL_GROUP_BY, PAD_CHAR_TO_FULL_LENGTH, PIPES_AS_CONCAT, REAL_AS_FLOAT, STRICT_ALL_TABLES, STRICT_TRANS_TABLES</code>

Set the SQL mode. See [Section 5.1.7, “Server SQL Modes”](#).

- `--sysdate-is-now`

<b>Version Introduced</b>	5.1.8
<b>Command-Line Format</b>	<code>--sysdate-is-now</code>
<b>Config-File Format</b>	<code>sysdate-is-now</code>
<b>Permitted Values</b>	
<b>Type</b>	<code>boolean</code>
<b>Default</b>	<code>FALSE</code>

`SYSDATE()` by default returns the time at which it executes, not the time at which the statement in which it occurs begins executing. This differs from the behavior of `NOW()`. This option causes `SYSDATE()` to be an alias for `NOW()`. For information about the implications for binary logging and replication, see the description for `SYSDATE()` in [Section 11.7, “Date and Time Functions”](#) and for `SET TIMESTAMP` in [Section 5.1.4, “Server System Variables”](#).

This option was added in MySQL 5.1.8.

- `--tc-heuristic-recover={COMMIT|ROLLBACK}`

<b>Command-Line Format</b>	<code>--tc-heuristic-recover=name</code>
<b>Config-File Format</b>	<code>tc-heuristic-recover</code>
	<b>Permitted Values</b>
	<b>Type</b> <code>enumeration</code>
	<b>Valid Values</b> <code>COMMIT, RECOVER</code>

The type of decision to use in the heuristic recovery process. Currently, this option is unused.

- `--temp-pool`

<b>Command-Line Format</b>	<code>--temp-pool</code>
<b>Config-File Format</b>	<code>temp-pool</code>
	<b>Permitted Values</b>
	<b>Type</b> <code>boolean</code>
	<b>Default</b> <code>TRUE</code>

This option causes most temporary files created by the server to use a small set of names, rather than a unique name for each new file. This works around a problem in the Linux kernel dealing with creating many new files with different names. With the old behavior, Linux seems to “leak” memory, because it is being allocated to the directory entry cache rather than to the disk cache. As of MySQL 5.1.31, this option is ignored except on Linux.

- `--transaction-isolation=level`

<b>Command-Line Format</b>	<code>--transaction-isolation=name</code>
<b>Config-File Format</b>	<code>transaction-isolation</code>
	<b>Permitted Values</b>
	<b>Type</b> <code>enumeration</code>
	<b>Valid Values</b> <code>READ-UNCOMMITTED, READ-COMMITTED, REPEATABLE-READ, SERIALIZABLE</code>

Sets the default transaction isolation level. The `level` value can be `READ-UNCOMMITTED`, `READ-COMMITTED`, `REPEATABLE-READ`, or `SERIALIZABLE`. See [Section 12.3.6, “SET TRANSACTION Syntax”](#).

- `--tmpdir=path, -t path`

<b>Command-Line Format</b>	<code>--tmpdir=name</code>
	<code>-t</code>
<b>Config-File Format</b>	<code>tmpdir</code>
<b>Option Sets Variable</b>	Yes, <code>tmpdir</code>
<b>Variable Name</b>	<code>tmpdir</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No
	<b>Permitted Values</b>
	<b>Type</b> <code>filename</code>

The path of the directory to use for creating temporary files. It might be useful if your default `/tmp` directory resides on a partition that is too small to hold temporary tables. This option accepts several paths that are used in round-robin fashion. Paths should be separated by colon characters (“`:`”) on Unix and semicolon characters (“`;`”) on Windows, NetWare, and OS/2. If the MySQL server is acting as a replication slave, you should not set `--tmpdir` to point to a directory on a memory-based file system or to a directory that is cleared when the server host restarts. For more information about the storage location of temporary files, see [Section B.5.4.4, “Where MySQL Stores Temporary Files”](#). A replication slave needs some of its temporary files to survive a machine restart so that it can replicate temporary tables or `LOAD DATA INFILE` operations. If files in the temporary file directory are lost when the server restarts, replication fails.

- `--user={user_name|user_id}, -u {user_name|user_id}`

<b>Command-Line Format</b>	<code>--user=name</code>
	<code>-u name</code>
<b>Config-File Format</b>	<code>user</code>
	<b>Permitted Values</b>
<b>Type</b>	<code>string</code>

Run the `mysqld` server as the user having the name `user_name` or the numeric user ID `user_id`. (“User” in this context refers to a system login account, not a MySQL user listed in the grant tables.)

This option is *mandatory* when starting `mysqld` as `root`. The server changes its user ID during its startup sequence, causing it to run as that particular user rather than as `root`. See [Section 5.3.1, “General Security Guidelines”](#).

To avoid a possible security hole where a user adds a `--user=root` option to a `my.cnf` file (thus causing the server to run as `root`), `mysqld` uses only the first `--user` option specified and produces a warning if there are multiple `--user` options. Options in `/etc/my.cnf` and `$MYSQL_HOME/my.cnf` are processed before command-line options, so it is recommended that you put a `--user` option in `/etc/my.cnf` and specify a value other than `root`. The option in `/etc/my.cnf` is found before any other `--user` options, which ensures that the server runs as a user other than `root`, and that a warning results if any other `--user` option is found.

- `--verbose, -v`

Use this option with the `--help` option for detailed help.

- `--version, -V`

Display version information and exit.

You can assign a value to a server system variable by using an option of the form `--var_name=value`. For example, `--key_buffer_size=32M` sets the `key_buffer_size` variable to a value of 32MB.

Note that when you assign a value to a variable, MySQL might automatically correct the value to stay within a given range, or adjust the value to the closest permissible value if only certain values are permitted.

If you want to restrict the maximum value to which a variable can be set at runtime with `SET`, you can define this by using the `--maximum-var_name=value` command-line option.

You can change the values of most system variables for a running server with the `SET` statement. See [Section 12.4.4, “SET Syntax”](#).

[Section 5.1.4, “Server System Variables”](#), provides a full description for all variables, and additional information for setting them at server startup and runtime. [Section 7.9.3, “Tuning Server Parameters”](#), includes information on optimizing the server by tuning system variables.

### 5.1.3. Server Options for Loading Plugins

The server can load plugins under the control of startup options. For example, many storage engines can be built in pluggable form and loaded when the server starts. In the following descriptions, `plugin_name` stands for a plugin name such as `innodb`.

As of MySQL 5.1.36, these options control plugin loading:

- `--plugin_name=OFF`

Do not enable the plugin.

- `--plugin_name[=ON]`

Enable the plugin. If plugin initialization fails, start the server anyway, but with the plugin disabled. Specifying the option as `--plugin_name` without a value also enables the plugin.

- `--plugin_name=FORCE`

Enable the plugin. If plugin initialization fails, do not start the server. In other words, force the server to run with the plugin or not at all.

The values `OFF`, `ON`, and `FORCE` are not case sensitive.

If a plugin is disabled, either explicitly with `OFF` or implicitly because it was enabled with `ON` but failed to initialize, aspects of server operation that require the plugin will change. For example, if the plugin implements a storage engine, existing tables for the storage engine become inaccessible, and attempts to create new tables for the storage engine result in tables that use the default storage engine unless the `NO_ENGINE_SUBSTITUTION` SQL mode has been enabled to cause an error to occur instead.

Suppose that `CSV`, `InnoDB`, and `ARCHIVE` are built as pluggable storage engines and that you want the server to load them at startup, subject to these conditions: The server is permitted to run if `CSV` initialization fails, but must require that `InnoDB` initialization succeed. `ARCHIVE` should be disabled. To accomplish that, use these lines in an option file:

```
[mysqld]
csv=ON
innodb=FORCE
archive=OFF
```

`--enable-plugin_name` is also supported and is the same as `--plugin_name=ON`. `--disable-plugin_name` and `--skip-plugin_name` are also supported and are the same as `--plugin_name=OFF`.

Before MySQL 5.1.36, plugin options are boolean options (see [Section 4.2.3.2, “Program Option Modifiers”](#)). That is, any of these options enable the plugin:

```
--plugin_name
--plugin_name=1
--enable-plugin_name
```

And these options disable the plugin:

```
--plugin_name=0
--disable-plugin_name
--skip-plugin_name
```

If the plugin fails to initialize, the server runs with the plugin disabled.

If you upgrade to MySQL 5.1.36 or later from an older version and previously used options of the form `--plugin_name=0` or `--plugin_name=1`, the equivalent options are now `--plugin_name=OFF` and `--plugin_name=ON`, respectively. You also have the choice of requiring plugins to start successfully by using `--plugin_name=FORCE`.

Plugins can also be loaded at runtime, using the `INSTALL PLUGIN` statement (see [Section 12.4.3.4, “`INSTALL PLUGIN` Syntax”](#)).

## 5.1.4. Server System Variables

The MySQL server maintains many system variables that indicate how it is configured. Each system variable has a default value. System variables can be set at server startup using options on the command line or in an option file. Most of them can be changed dynamically while the server is running by means of the `SET` statement, which enables you to modify operation of the server without having to stop and restart it. You can refer to system variable values in expressions.

There are several ways to see the names and values of system variables:

- To see the values that a server will use based on its compiled-in defaults and any option files that it reads, use this command:

```
mysqld --verbose --help
```

- To see the values that a server will use based on its compiled-in defaults, ignoring the settings in any option files, use this command:

```
mysqld --no-defaults --verbose --help
```

- To see the current values used by a running server, use the `SHOW VARIABLES` statement.

This section provides a description of each system variable. Variables with no version indicated are present in all MySQL 5.1 releases. For historical information concerning their implementation, please see <http://dev.mysql.com/doc/refman/5.0/en/>, and <http://dev.mysql.com/doc/refman/4.1/en/>.

The following table lists all available system variables:

**Table 5.2. System Variable Summary**

Name	Cmd-Line	Option file	System Var	Var Scope	Dynamic
auto_increment_incremen t	Yes	Yes	Yes	Both	Yes
auto_increment_offset	Yes	Yes	Yes	Both	Yes
autocommit			Yes	Session	Yes
automatic_sp_privileges			Yes	Global	Yes
back_log	Yes	Yes	Yes	Global	No
basedir	Yes	Yes	Yes	Global	No
big-tables	Yes	Yes			Yes
- Variable: big_tables			Yes	Session	Yes
binlog_cache_size	Yes	Yes	Yes	Global	Yes
bin- log_direct_non_transactio nal_updates	Yes	Yes	Yes	Both	Yes
binlog-format	Yes	Yes			Yes
- Variable: binlog_format			Yes	Both	Yes
bulk_insert_buffer_size	Yes	Yes	Yes	Both	Yes
character_set_client			Yes	Both	Yes
character_set_connection			Yes	Both	Yes
character_set_database <sup>a</sup>			Yes	Both	Yes
character-set-filesystem	Yes	Yes			Yes
- Variable: charac ter_set_filesystem			Yes	Both	Yes
character_set_results			Yes	Both	Yes
character-set-server	Yes	Yes			Yes
- Variable: charac ter_set_server			Yes	Both	Yes
character_set_system			Yes	Global	No
character-sets-dir	Yes	Yes			No
- Variable: charac ter_sets_dir			Yes	Global	No
collation_connection			Yes	Both	Yes
collation_database <sup>b</sup>			Yes	Both	Yes
collation-server	Yes	Yes			Yes
- Variable: collat ion_server			Yes	Both	Yes

warning_count			Yes	Session	No

<sup>a</sup>This option is dynamic, but only the server should set this information. You should not set the value of this variable manually.

<sup>b</sup>This option is dynamic, but only the server should set this information. You should not set the value of this variable manually.

For additional system variable information, see these sections:

- [Section 5.1.5, “Using System Variables”](#), discusses the syntax for setting and displaying system variable values.
- [Section 5.1.5.2, “Dynamic System Variables”](#), lists the variables that can be set at runtime.
- Information on tuning system variables can be found in [Section 7.9.3, “Tuning Server Parameters”](#).
- [Section 13.6.3, “InnoDB Startup Options and System Variables”](#), lists InnoDB system variables.
- [Section 17.3.4.3, “MySQL Cluster System Variables”](#), lists system variables which are specific to MySQL Cluster.
- For information on server system variables specific to replication, see [Section 16.1.3, “Replication and Binary Logging Options and Variables”](#).

### Note

Some of the following variable descriptions refer to “enabling” or “disabling” a variable. These variables can be enabled with the `SET` statement by setting them to `ON` or `1`, or disabled by setting them to `OFF` or `0`. However, to set such a variable on the command line or in an option file, you must set it to `1` or `0`; setting it to `ON` or `OFF` will not work. For example, on the command line, `--delay_key_write=1` works but `--delay_key_write=ON` does not.

Some system variables control the size of buffers or caches. For a given buffer, the server might need to allocate internal data structures. These structures typically are allocated from the total memory allocated to the buffer, and the amount of space required might be platform dependent. This means that when you assign a value to a system variable that controls a buffer size, the amount of space actually available might differ from the value assigned. In some cases, the amount might be less than the value assigned. It is also possible that the server will adjust a value upward. For example, if you assign a value of 0 to a variable for which the minimal value is 1024, the server will set the value to 1024.

Values for buffer sizes, lengths, and stack sizes are given in bytes unless otherwise specified.

Some system variables take file name values. Unless otherwise specified, the default file location is the data directory if the value is a relative path name. To specify the location explicitly, use an absolute path name. Suppose that the data directory is `/var/mysql/data`. If a file-valued variable is given as a relative path name, it will be located under `/var/mysql/data`. If the

value is an absolute path name, its location is as given by the path name.

- [autocommit](#)

The autocommit mode. If set to 1, all changes to a table take effect immediately. If set to 0, you must use [COMMIT](#) to accept a transaction or [ROLLBACK](#) to cancel it. By default, client connections begin with [autocommit](#) set to 1. If you change [autocommit](#) mode from 0 to 1, MySQL performs an automatic [COMMIT](#) of any open transaction. Another way to begin a transaction is to use a [START TRANSACTION](#) or [BEGIN](#) statement. See [Section 12.3.1, “START TRANSACTION, COMMIT, and ROLLBACK Syntax”](#).

- [automatic\\_sp\\_privileges](#)

<b>Variable Name</b>	<a href="#">automatic_sp_privileges</a>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<a href="#">boolean</a>
	<b>Default</b>	<a href="#">TRUE</a>

When this variable has a value of 1 (the default), the server automatically grants the [EXECUTE](#) and [ALTER ROUTINE](#) privileges to the creator of a stored routine, if the user cannot already execute and alter or drop the routine. (The [ALTER ROUTINE](#) privilege is required to drop the routine.) The server also automatically drops those privileges from the creator when the routine is dropped. If [automatic\\_sp\\_privileges](#) is 0, the server does not automatically add or drop these privileges.

The creator of a routine is the account used to execute the [CREATE](#) statement for it. This might not be the same as the account named as the [DEFINER](#) in the routine definition.

See also [Section 19.2.2, “Stored Routines and MySQL Privileges”](#).

- [back\\_log](#)

<b>Command-Line Format</b>	<code>--back_log=#</code>	
<b>Config-File Format</b>	<code>back_log</code>	
<b>Option Sets Variable</b>	Yes, <a href="#">back_log</a>	
<b>Variable Name</b>	<a href="#">back_log</a>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	<a href="#">numeric</a>
	<b>Default</b>	<a href="#">50</a>
	<b>Range</b>	<a href="#">1-65535</a>

The number of outstanding connection requests MySQL can have. This comes into play when the main MySQL thread gets very many connection requests in a very short time. It then takes some time (although very little) for the main thread to check the connection and start a new thread. The [back\\_log](#) value indicates how many requests can be stacked during this short time before MySQL momentarily stops answering new requests. You need to increase this only if you expect a large number of connections in a short period of time.

In other words, this value is the size of the listen queue for incoming TCP/IP connections. Your operating system has its own limit on the size of this queue. The manual page for the Unix [listen\(\)](#) system call should have more details. Check your OS documentation for the maximum value for this variable. [back\\_log](#) cannot be set higher than your operating system limit.

- [basedir](#)

<b>Command-Line Format</b>	<code>--basedir=name</code>	
	<code>-b</code>	
<b>Config-File Format</b>	<code>basedir</code>	
<b>Option Sets Variable</b>	Yes, <a href="#">basedir</a>	
<b>Variable Name</b>	<a href="#">basedir</a>	

<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No
	<b>Permitted Values</b>
	<b>Type</b> <code>filename</code>

The MySQL installation base directory. This variable can be set with the `--basedir` option. Relative path names for other variables usually are resolved relative to the base directory.

- **`big_tables`**

If set to 1, all temporary tables are stored on disk rather than in memory. This is a little slower, but the error `The table 'tbl_name' is full` does not occur for `SELECT` operations that require a large temporary table. The default value for a new connection is 0 (use in-memory temporary tables). Normally, you should never need to set this variable, because in-memory tables are automatically converted to disk-based tables as required.

**Note**

This variable was formerly named `sql_big_tables`.

- **`bulk_insert_buffer_size`**

<b>Command-Line Format</b>	<code>--bulk_insert_buffer_size=#</code>
<b>Config-File Format</b>	<code>bulk_insert_buffer_size</code>
<b>Option Sets Variable</b>	Yes, <code>bulk_insert_buffer_size</code>
<b>Variable Name</b>	<code>bulk_insert_buffer_size</code>
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
<b>Platform Bit Size</b>	<code>32</code>
<b>Type</b>	<code>numeric</code>
<b>Default</b>	<code>8388608</code>
<b>Range</b>	<code>0-4294967295</code>
	<b>Permitted Values</b>
<b>Platform Bit Size</b>	<code>64</code>
<b>Type</b>	<code>numeric</code>
<b>Default</b>	<code>8388608</code>
<b>Range</b>	<code>0-18446744073709547520</code>

`MyISAM` uses a special tree-like cache to make bulk inserts faster for `INSERT ... SELECT, INSERT ... VALUES (...), (...), ...`, and `LOAD DATA INFILE` when adding data to nonempty tables. This variable limits the size of the cache tree in bytes per thread. Setting it to 0 disables this optimization. The default value is 8MB.

- **`character_set_client`**

<b>Variable Name</b>	<code>character_set_client</code>
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
	<b>Type</b> <code>string</code>

The character set for statements that arrive from the client. The session value of this variable is set using the character set requested by the client when the client connects to the server. (Many clients support a `--default-character-set` option to enable this character set to be specified explicitly. See also [Section 9.1.4, “Connection Character Sets and Collations”](#).) The

global value of the variable is used to set the session value in cases when the client-requested value is unknown or not available, or the server is configured to ignore client requests:

- The client is from a version of MySQL older than MySQL 4.1, and thus does not request a character set.
- The client requests a character set not known to the server. For example, a Japanese-enabled client requests `sjis` when connecting to a server not configured with `sjis` support.
- `mysqld` was started with the `--skip-character-set-client-handshake` option, which causes it to ignore client character set configuration. This reproduces MySQL 4.0 behavior and is useful should you wish to upgrade the server without upgrading all the clients.

- `character_set_connection`

<b>Variable Name</b>	<code>character_set_connection</code>	
<b>Variable Scope</b>	Both	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
<b>Type</b>	<code>string</code>	

The character set for the current connection. Used for literals that do not have an explicit character set specification and for number-to-string conversion.

- `character_set_database`

<b>Variable Name</b>	<code>character_set_database</code>	
<b>Variable Scope</b>	Both	
<b>Dynamic Variable</b>	Yes	
<b>Footnote</b>	This option is dynamic, but only the server should set this information. You should not set the value of this variable manually.	
	<b>Permitted Values</b>	
<b>Type</b>	<code>string</code>	

The character set used by the default database. The server sets this variable whenever the default database changes. If there is no default database, the variable has the same value as `character_set_server`.

- `character_set_filesystem`

<b>Version Introduced</b>	5.1.6	
<b>Command-Line Format</b>	<code>--character-set-filesystem=name</code>	
<b>Config-File Format</b>	<code>character-set-filesystem</code>	
<b>Option Sets Variable</b>	Yes, <code>character_set_filesystem</code>	
<b>Variable Name</b>	<code>character_set_filesystem</code>	
<b>Variable Scope</b>	Both	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
<b>Type</b>	<code>string</code>	

The file system character set. This variable is used to interpret string literals that refer to file names, such as in the `LOAD DATA INFILE` and `SELECT ... INTO OUTFILE` statements and the `LOAD_FILE()` function. Such file names are converted from `character_set_client` to `character_set_filesystem` before the file opening attempt occurs. The default value is `binary`, which means that no conversion occurs. For systems on which multi-byte file names are permitted, a different value may be more appropriate. For example, if the system represents file names using UTF-8, set `character_set_filesystem` to '`utf8`'. This variable was added in MySQL 5.1.6.

- `character_set_results`

<b>Variable Name</b>	<code>character_set_results</code>	

<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
	<b>Type</b> <code>string</code>

The character set used for returning query results such as result sets or error messages to the client.

- `character_set_server`

<b>Command-Line Format</b>	<code>--character-set-server</code>
<b>Config-File Format</b>	<code>character-set-server</code>
<b>Option Sets Variable</b>	Yes, <code>character_set_server</code>
<b>Variable Name</b>	<code>character_set_server</code>
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
	<b>Type</b> <code>string</code>

The server's default character set.

- `character_set_system`

<b>Variable Name</b>	<code>character_set_system</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No
	<b>Permitted Values</b>
	<b>Type</b> <code>string</code>

The character set used by the server for storing identifiers. The value is always `utf8`.

- `character_sets_dir`

<b>Command-Line Format</b>	<code>--character-sets-dir=name</code>
<b>Config-File Format</b>	<code>character-sets-dir</code>
<b>Option Sets Variable</b>	Yes, <code>character_sets_dir</code>
<b>Variable Name</b>	<code>character-sets-dir</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No
	<b>Permitted Values</b>
	<b>Type</b> <code>filename</code>

The directory where character sets are installed.

- `collation_connection`

<b>Variable Name</b>	<code>collation_connection</code>
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
	<b>Type</b> <code>string</code>

The collation of the connection character set.

- `collation_database`

<b>Variable Name</b>	<code>collation_database</code>
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes
<b>Footnote</b>	This option is dynamic, but only the server should set this information. You should not set the value of this variable manually.
	<b>Permitted Values</b>
	<b>Type</b> <code>string</code>

The collation used by the default database. The server sets this variable whenever the default database changes. If there is no default database, the variable has the same value as `collation_server`.

- `collation_server`

<b>Command-Line Format</b>	<code>--collation-server</code>
<b>Config-File Format</b>	<code>collation-server</code>
<b>Option Sets Variable</b>	Yes, <code>collation_server</code>
<b>Variable Name</b>	<code>collation_server</code>
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
	<b>Type</b> <code>string</code>

The server's default collation.

- `completion_type`

<b>Command-Line Format</b>	<code>--completion_type=#</code>
<b>Config-File Format</b>	<code>completion_type</code>
<b>Option Sets Variable</b>	Yes, <code>completion_type</code>
<b>Variable Name</b>	<code>completion_type</code>
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes

The transaction completion type. This variable can take the values shown in the following table.

<b>Value</b>	<b>Description</b>
0	<code>COMMIT</code> and <code>ROLLBACK</code> are unaffected. This is the default value.
1	<code>COMMIT</code> and <code>ROLLBACK</code> are equivalent to <code>COMMIT AND CHAIN</code> and <code>ROLLBACK AND CHAIN</code> , respectively. (A new transaction starts immediately with the same isolation level as the just-terminated transaction.)
2	<code>COMMIT</code> and <code>ROLLBACK</code> are equivalent to <code>COMMIT RELEASE</code> and <code>ROLLBACK RELEASE</code> , respectively. (The server disconnects after terminating the transaction.)

`completion_type` affects transactions that begin with `START TRANSACTION` or `BEGIN` and end with `COMMIT` or `ROLLBACK`. It does not apply to implicit commits resulting from execution of the statements listed in [Section 12.3.3, “Statements That Cause an Implicit Commit”](#). It also does not apply for `XA COMMIT`, `XA ROLLBACK`, or when `autocommit=1`.

- `concurrent_insert`

<b>Command-Line Format</b>	<code>--concurrent_insert[=#]</code>
<b>Config-File Format</b>	<code>concurrent_insert</code>

<b>Option Sets Variable</b>	Yes, <code>concurrent_insert</code>
<b>Variable Name</b>	<code>concurrent_insert</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
	<b>Type</b> <code>boolean</code>
	<b>Default</b> <code>TRUE</code>

If 1 (the default), MySQL permits `INSERT` and `SELECT` statements to run concurrently for `MyISAM` tables that have no free blocks in the middle of the data file. If you start `mysqld` with `--skip-new`, this variable is set to 0.

This variable can take three integer values.

<b>Value</b>	<b>Description</b>
0	Disables concurrent inserts
1	(Default) Enables concurrent insert for <code>MyISAM</code> tables that do not have holes
2	Enables concurrent inserts for all <code>MyISAM</code> tables, even those that have holes. For a table with a hole, new rows are inserted at the end of the table if it is in use by another thread. Otherwise, MySQL acquires a normal write lock and inserts the row into the hole.

See also [Section 7.7.3, “Concurrent Inserts”](#).

- `connect_timeout`

<b>Command-Line Format</b>	<code>--connect_timeout=#</code>
<b>Config-File Format</b>	<code>connect_timeout</code>
<b>Option Sets Variable</b>	Yes, <code>connect_timeout</code>
<b>Variable Name</b>	<code>connect_timeout</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values (&lt;= 5.1.22)</b>
	<b>Type</b> <code>numeric</code>
	<b>Default</b> <code>5</code>
	<b>Permitted Values (&gt;= 5.1.23)</b>
	<b>Type</b> <code>numeric</code>
	<b>Default</b> <code>10</code>

The number of seconds that the `mysqld` server waits for a connect packet before responding with `Bad handshake`. The default value is 10 seconds as of MySQL 5.1.23 and 5 seconds before that.

Increasing the `connect_timeout` value might help if clients frequently encounter errors of the form `Lost connection to MySQL server at 'XXX', system error: errno`.

- `datadir`

<b>Command-Line Format</b>	<code>--datadir=name</code>
	<code>-h</code>
<b>Config-File Format</b>	<code>datadir</code>
<b>Option Sets Variable</b>	Yes, <code>datadir</code>
<b>Variable Name</b>	<code>datadir</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No

<b>Permitted Values</b>	
Type	filename

The MySQL data directory. This variable can be set with the `--datadir` option.

- `date_format`

This variable is unused.

- `datetime_format`

This variable is unused.

- `debug`

<b>Command-Line Format</b>	<code>--debug[=debug_options]</code>
<b>Config-File Format</b>	<code>debug</code>
<b>Variable Name</b>	<code>debug</code>
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
	Type <code>string</code>
	Default <code>'d:t:o,/tmp/mysqld.trace'</code>

This variable indicates the current debugging settings. It is available only for servers built with debugging support. The initial value comes from the value of instances of the `--debug` option given at server startup. The global and session values may be set at runtime; the `SUPER` privilege is required, even for the session value.

Assigning a value that begins with `+` or `-` cause the value to added to or subtracted from the current value:

```
mysql> SET debug = 'T';
mysql> SELECT @@debug;
+-----+
| @@debug |
+-----+
| T |
+-----+

mysql> SET debug = '+P';
mysql> SELECT @@debug;
+-----+
| @@debug |
+-----+
| P:T |
+-----+

mysql> SET debug = '-P';
mysql> SELECT @@debug;
+-----+
| @@debug |
+-----+
| T |
+-----+
```

This variable was added in MySQL 5.1.7.

- `debug_sync`

<b>Version Introduced</b>	5.1.41
<b>Variable Name</b>	<code>debug_sync</code>
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
	Type <code>string</code>

This variable is the user interface to the Debug Sync facility. Use of Debug Sync requires that MySQL be configured with the `--enable-debug-sync` option (see [Section 2.3.3, “Typical configure Options”](#)). If Debug Sync is not compiled in, this system variable is not available.

The global variable value is read only and indicates whether the facility is enabled. By default, Debug Sync is disabled and the value of `debug_sync` is `OFF`. If the server is started with `--debug-sync-timeout=N`, where `N` is a timeout value greater than 0, Debug Sync is enabled and the value of `debug_sync` is `ON - current signal` followed by the signal name. Also, `N` becomes the default timeout for individual synchronization points.

The session value can be read by any user and will have the same value as the global variable. The session value can be set by users that have the `SUPER` privilege to control synchronization points.

For a description of the Debug Sync facility and how to use synchronization points, see [MySQL Internals: Test Synchronization](#).

This variable was added in MySQL 5.1.41.

- `default_week_format`

<b>Command-Line Format</b>	<code>--default_week_format=#</code>
<b>Config-File Format</b>	<code>default_week_format</code>
<b>Option Sets Variable</b>	Yes, <code>default_week_format</code>
<b>Variable Name</b>	<code>default_week_format</code>
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	
<b>Type</b>	<code>numeric</code>
<b>Default</b>	<code>0</code>
<b>Range</b>	<code>0-7</code>

The default mode value to use for the `WEEK( )` function. See [Section 11.7, “Date and Time Functions”](#).

- `delay_key_write`

<b>Command-Line Format</b>	<code>--delay-key-write[=name]</code>
<b>Config-File Format</b>	<code>delay-key-write</code>
<b>Option Sets Variable</b>	Yes, <code>delay_key_write</code>
<b>Variable Name</b>	<code>delay-key-write</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	
<b>Type</b>	<code>enumeration</code>
<b>Default</b>	<code>ON</code>
<b>Valid Values</b>	<code>ON, OFF, ALL</code>

This option applies only to `MyISAM` tables. It can have one of the following values to affect handling of the `DELAY_KEY_WRITE` table option that can be used in `CREATE TABLE` statements.

Option	Description
<code>OFF</code>	<code>DELAY_KEY_WRITE</code> is ignored.
<code>ON</code>	MySQL honors any <code>DELAY_KEY_WRITE</code> option specified in <code>CREATE TABLE</code> statements. This is the default value.
<code>ALL</code>	All new opened tables are treated as if they were created with the <code>DELAY_KEY_WRITE</code> option enabled.

If `DELAY_KEY_WRITE` is enabled for a table, the key buffer is not flushed for the table on every index update, but only when

the table is closed. This speeds up writes on keys a lot, but if you use this feature, you should add automatic checking of all MyISAM tables by starting the server with the `--myisam-recover` option (for example, `--myisam-recover=BACKUP, FORCE`). See [Section 5.1.2, “Server Command Options”](#), and [Section 13.5.1, “MyISAM Startup Options”](#).

### Warning

If you enable external locking with `--external-locking`, there is no protection against index corruption for tables that use delayed key writes.

- `delayed_insert_limit`

<b>Command-Line Format</b>	<code>--delayed_insert_limit=#</code>
<b>Config-File Format</b>	<code>delayed_insert_limit</code>
<b>Option Sets Variable</b>	Yes, <code>delayed_insert_limit</code>
<b>Variable Name</b>	<code>delayed_insert_limit</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	
<b>Platform Bit Size</b>	32
<b>Type</b>	<code>numeric</code>
<b>Default</b>	100
<b>Range</b>	1-4294967295
<b>Permitted Values</b>	
<b>Platform Bit Size</b>	64
<b>Type</b>	<code>numeric</code>
<b>Default</b>	100
<b>Range</b>	1-18446744073709547520

After inserting `delayed_insert_limit` delayed rows, the `INSERT DELAYED` handler thread checks whether there are any `SELECT` statements pending. If so, it permits them to execute before continuing to insert delayed rows.

- `delayed_insert_timeout`

<b>Command-Line Format</b>	<code>--delayed_insert_timeout=#</code>
<b>Config-File Format</b>	<code>delayed_insert_timeout</code>
<b>Option Sets Variable</b>	Yes, <code>delayed_insert_timeout</code>
<b>Variable Name</b>	<code>delayed_insert_timeout</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	
<b>Type</b>	<code>numeric</code>
<b>Default</b>	300

How many seconds an `INSERT DELAYED` handler thread should wait for `INSERT` statements before terminating.

- `delayed_queue_size`

<b>Command-Line Format</b>	<code>--delayed_queue_size=#</code>
<b>Config-File Format</b>	<code>delayed_queue_size</code>
<b>Option Sets Variable</b>	Yes, <code>delayed_queue_size</code>
<b>Variable Name</b>	<code>delayed_queue_size</code>
<b>Variable Scope</b>	Global

<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
<b>Platform</b>	32
<b>Bit Size</b>	
<b>Type</b>	numeric
<b>Default</b>	1000
<b>Range</b>	1-4294967295
	<b>Permitted Values</b>
<b>Platform</b>	64
<b>Bit Size</b>	
<b>Type</b>	numeric
<b>Default</b>	1000
<b>Range</b>	1-18446744073709547520

This is a per-table limit on the number of rows to queue when handling `INSERT DELAYED` statements. If the queue becomes full, any client that issues an `INSERT DELAYED` statement waits until there is room in the queue again.

- `div_precision_increment`

<b>Command-Line Format</b>	--div_precision_increment=#
<b>Config-File Format</b>	<code>div_precision_increment</code>
<b>Option Sets Variable</b>	Yes, <code>div_precision_increment</code>
<b>Variable Name</b>	<code>div_precision_increment</code>
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
<b>Type</b>	numeric
<b>Default</b>	4
<b>Range</b>	0-30

This variable indicates the number of digits by which to increase the scale of the result of division operations performed with the `/` operator. The default value is 4. The minimum and maximum values are 0 and 30, respectively. The following example illustrates the effect of increasing the default value.

```
mysql> SELECT 1/7;
+-----+
| 1/7 |
+-----+
| 0.1429 |
+-----+
mysql> SET div_precision_increment = 12;
mysql> SELECT 1/7;
+-----+
| 1/7 |
+-----+
| 0.142857142857 |
+-----+
```

- `engine_condition_pushdown`

<b>Command-Line Format</b>	--engine-condition-pushdown
<b>Config-File Format</b>	<code>engine-condition-pushdown</code>
<b>Option Sets Variable</b>	Yes, <code>engine_condition_pushdown</code>
<b>Variable Name</b>	<code>engine_condition_pushdown</code>
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes
<b>Deprecated</b>	5.5.3, by <code>optimizer_switch</code>

<b>Permitted Values (&gt;= 5.1.0)</b>	
<b>Type</b>	<code>boolean</code>
<b>Default</b>	<code>ON</code>

The engine condition pushdown optimization enables processing for certain comparisons to be “pushed down” to the storage engine level for more efficient execution. For more information, see [Section 7.3.1.5, “Condition Pushdown Optimization”](#).

Engine condition pushdown is used only by the `NDBCLUSTER` storage engine. Enabling this optimization on a MySQL Server acting as a MySQL Cluster SQL node causes `WHERE` conditions on unindexed columns to be evaluated on the cluster's data nodes and only the rows that match to be sent back to the SQL node that issued the query. This greatly reduces the amount of cluster data that must be sent over the network, increasing the efficiency with which results are returned.

The `engine_condition_pushdown` variable controls whether engine condition pushdown is enabled. By default, this variable is `OFF` (0). Setting it to `ON` (1), enables pushdown.

- `error_count`

The number of errors that resulted from the last statement that generated messages. This variable is read only. See [Section 12.4.5.18, “SHOW ERRORS Syntax”](#).

- `event_scheduler`

<b>Version Introduced</b>	5.1.6
<b>Command-Line Format</b>	<code>--event-scheduler[=value]</code>
<b>Config-File Format</b>	<code>event-scheduler</code>
<b>Option Sets Variable</b>	Yes, <code>event_scheduler</code>
<b>Variable Name</b>	<code>event_scheduler</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	
<b>Type</b>	<code>enumeration</code>
<b>Default</b>	<code>OFF</code>
<b>Valid Values</b>	<code>ON, OFF, DISABLED</code>

This variable indicates the status of the Event Scheduler; as of MySQL 5.1.12, possible values are `ON`, `OFF`, and `DISABLED`, with the default being `OFF`. This variable and its effects on the Event Scheduler's operation are discussed in greater detail in the [Overview section of the Events chapter](#).

This variable was added in MySQL 5.1.6.

- `expire_logs_days`

<b>Command-Line Format</b>	<code>--expire_logs_days=#</code>
<b>Config-File Format</b>	<code>expire_logs_days</code>
<b>Option Sets Variable</b>	Yes, <code>expire_logs_days</code>
<b>Variable Name</b>	<code>expire_logs_days</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	
<b>Type</b>	<code>numeric</code>
<b>Default</b>	<code>0</code>
<b>Range</b>	<code>0-99</code>

The number of days for automatic binary log file removal. The default is 0, which means “no automatic removal.” Possible removals happen at startup and when the binary log is flushed. Log flushing occurs as indicated in [Section 5.2, “MySQL Server](#)

Logs”.

To remove binary log files manually, use the `PURGE BINARY LOGS` statement. See [Section 12.5.1.1, “PURGE BINARY LOGS Syntax”](#).

- `flush`

<b>Command-Line Format</b>	<code>--flush</code>
<b>Config-File Format</b>	<code>flush</code>
<b>Variable Name</b>	<code>flush</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
	<b>Type</b> <code>boolean</code>
	<b>Default</b> <code>OFF</code>

If `ON`, the server flushes (synchronizes) all changes to disk after each SQL statement. Normally, MySQL does a write of all changes to disk only after each SQL statement and lets the operating system handle the synchronizing to disk. See [Section B.5.4.2, “What to Do If MySQL Keeps Crashing”](#). This variable is set to `ON` if you start `mysqld` with the `--flush` option.

- `flush_time`

<b>Command-Line Format</b>	<code>--flush_time=#</code>
<b>Config-File Format</b>	<code>flush_time</code>
<b>Option Sets Variable</b>	Yes, <code>flush_time</code>
<b>Variable Name</b>	<code>flush_time</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
	<b>Type</b> <code>numeric</code>
	<b>Default</b> <code>0</code>
	<b>Min Value</b> <code>0</code>
	<b>Permitted Values</b>
	<b>Type</b> <code>numeric</code> (windows)
	<b>Default</b> <code>1800</code>
	<b>Min Value</b> <code>0</code>

If this is set to a nonzero value, all tables are closed every `flush_time` seconds to free up resources and synchronize unflushed data to disk. This option is best used only on Windows 9x or Me, or on systems with minimal resources.

- `foreign_key_checks`

If set to 1 (the default), foreign key constraints for `InnoDB` tables are checked. If set to 0, they are ignored. Disabling foreign key checking can be useful for reloading `InnoDB` tables in an order different from that required by their parent/child relationships. See [Section 13.6.4.4, “FOREIGN KEY Constraints”](#).

Setting `foreign_key_checks` to 0 also affects data definition statements: `DROP SCHEMA` drops a schema even if it contains tables that have foreign keys that are referred to by tables outside the schema, and `DROP TABLE` drops tables that have foreign keys that are referred to by other tables.

### Note

Setting `foreign_key_checks` to 1 does not trigger a scan of the existing table data. Therefore, rows added to the table while `foreign_key_checks = 0` will not be verified for consistency.

- [ft\\_boolean\\_syntax](#)

<b>Command-Line Format</b>	--ft_boolean_syntax=name
<b>Config-File Format</b>	ft_boolean_syntax
<b>Variable Name</b>	ft_boolean_syntax
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
	Type string
	Default +-><()~*: " " &

The list of operators supported by boolean full-text searches performed using `IN BOOLEAN MODE`. See [Section 11.9.2, “Boolean Full-Text Searches”](#).

The default variable value is `' + -><()~*: " " & | '`. The rules for changing the value are as follows:

- Operator function is determined by position within the string.
- The replacement value must be 14 characters.
- Each character must be an ASCII nonalphanumeric character.
- Either the first or second character must be a space.
- No duplicates are permitted except the phrase quoting operators in positions 11 and 12. These two characters are not required to be the same, but they are the only two that may be.
- Positions 10, 13, and 14 (which by default are set to “`:`”, “`&`”, and “`|`”) are reserved for future extensions.

- [ft\\_max\\_word\\_len](#)

<b>Command-Line Format</b>	--ft_max_word_len=#
<b>Config-File Format</b>	ft_max_word_len
<b>Option Sets Variable</b>	Yes, ft_max_word_len
<b>Variable Name</b>	ft_max_word_len
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No
	<b>Permitted Values</b>
	Type numeric
	Min Value 10

The maximum length of the word to be included in a `FULLTEXT` index.

### Note

`FULLTEXT` indexes must be rebuilt after changing this variable. Use `REPAIR TABLE tbl_name QUICK`.

- [ft\\_min\\_word\\_len](#)

<b>Command-Line Format</b>	--ft_min_word_len=#
<b>Config-File Format</b>	ft_min_word_len
<b>Option Sets Variable</b>	Yes, ft_min_word_len
<b>Variable Name</b>	ft_min_word_len
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No

<b>Permitted Values</b>	
Type	numeric
Default	4
Min Value	1

The minimum length of the word to be included in a `FULLTEXT` index.

### Note

`FULLTEXT` indexes must be rebuilt after changing this variable. Use `REPAIR TABLE tbl_name QUICK`.

- `ft_query_expansion_limit`

<b>Command-Line Format</b>	<code>--ft_query_expansion_limit=#</code>
<b>Config-File Format</b>	<code>ft_query_expansion_limit</code>
<b>Option Sets Variable</b>	Yes, <code>ft_query_expansion_limit</code>
<b>Variable Name</b>	<code>ft_query_expansion_limit</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	
Type	numeric
Default	20
Range	0-1000

The number of top matches to use for full-text searches performed using `WITH QUERY EXPANSION`.

- `ft_stopword_file`

<b>Command-Line Format</b>	<code>--ft_stopword_file=name</code>
<b>Config-File Format</b>	<code>ft_stopword_file</code>
<b>Option Sets Variable</b>	Yes, <code>ft_stopword_file</code>
<b>Variable Name</b>	<code>ft_stopword_file</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	
Type	filename

The file from which to read the list of stopwords for full-text searches. The server looks for the file in the data directory unless an absolute path name is given to specify a different directory. All the words from the file are used; comments are *not* honored. By default, a built-in list of stopwords is used (as defined in the `storage/myisam/ft_static.c` file). Setting this variable to the empty string ('') disables stopword filtering. See also Section 11.9.4, “Full-Text Stopwords”.

### Note

`FULLTEXT` indexes must be rebuilt after changing this variable or the contents of the stopword file. Use `REPAIR TABLE tbl_name QUICK`.

- `general_log`

<b>Version Introduced</b>	5.1.12
<b>Command-Line Format</b>	<code>--general-log</code>
<b>Config-File Format</b>	<code>general-log</code>
<b>Option Sets Variable</b>	Yes, <code>general_log</code>
<b>Variable Name</b>	<code>general_log</code>

<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
	<b>Type</b> boolean
	<b>Default</b> OFF

Whether the general query log is enabled. The value can be 0 (or OFF) to disable the log or 1 (or ON) to enable the log. The default value depends on whether the `--general_log` option is given (`--log` before MySQL 5.1.29). The destination for log output is controlled by the `log_output` system variable; if that value is NONE, no log entries are written even if the log is enabled. The `general_log` variable was added in MySQL 5.1.12.

- [general\\_log\\_file](#)

<b>Version Introduced</b>	5.1.12		
<b>Command-Line Format</b>	- - <code>gener- al- log- file=fi le_name</code>	5.1.29	
<b>Config-File Format</b>	<code>gener- al_log_ file</code>	5.1.29	
<b>Option Sets Variable</b>	Yes, <a href="#">general_log_file</a>		
<b>Variable Name</b>	<a href="#">general_log_file</a>		
<b>Variable Scope</b>	Global		
<b>Dynamic Variable</b>	Yes		
	<b>Permitted Values</b>		
	<b>Type</b>	filename	
	<b>Default</b>	<code>host_name.log</code>	

The name of the general query log file. The default value is `host_name.log`, but the initial value can be changed with the `--general_log_file` option (`--log` before MySQL 5.1.29). This variable was added in MySQL 5.1.12.

- [group\\_concat\\_max\\_len](#)

<b>Command-Line Format</b>	<code>--group_concat_max_len=#</code>
<b>Config-File Format</b>	<code>group_concat_max_len</code>
<b>Option Sets Variable</b>	Yes, <a href="#">group_concat_max_len</a>
<b>Variable Name</b>	<a href="#">group_concat_max_len</a>
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
	<b>Platform Bit Size</b> 32
	<b>Type</b> numeric
	<b>Default</b> 1024
	<b>Range</b> 4-4294967295

Permitted Values	
Platform	64
Bit Size	
Type	numeric
Default	1024
Range	4-18446744073709547520

The maximum permitted result length in bytes for the `GROUP_CONCAT()` function. The default is 1024.

- `have_archive`

`YES` if `mysqld` supports `ARCHIVE` tables, `NO` if not. This variable was removed in MySQL 5.1.14.

- `have_blackhole_engine`

`YES` if `mysqld` supports `BLACKHOLE` tables, `NO` if not. This variable was removed in MySQL 5.1.14.

- `have_compress`

`YES` if the `zlib` compression library is available to the server, `NO` if not. If not, the `COMPRESS()` and `UNCOMPRESS()` functions cannot be used.

- `have_community_features`

`YES` if statement profiling is enabled, `NO` if not. See [Section 12.4.5.32, “SHOW PROFILE Syntax”](#).

This variable is renamed to `have_profiling` in MySQL 5.5.

- `have_crypt`

`YES` if the `crypt()` system call is available to the server, `NO` if not. If not, the `ENCRYPT()` function cannot be used.

- `have_csv`

`YES` if `mysqld` supports `ARCHIVE` tables, `NO` if not.

- `have_dynamic_loading`

`YES` if `mysqld` supports dynamic loading of plugins, `NO` if not. This variable was added in MySQL 5.1.10.

- `have_example_engine`

`YES` if `mysqld` supports `EXAMPLE` tables, `NO` if not. This variable was removed in MySQL 5.1.14.

- `have_federated_engine`

`YES` if `mysqld` supports `FEDERATED` tables, `NO` if not. This variable was removed in MySQL 5.1.14.

- `have_geometry`

`YES` if the server supports spatial data types, `NO` if not.

- `have_innodb`

`YES` if `mysqld` supports `InnoDB` tables. `DISABLED` if `--skip-innodb` is used.

- `have_isam`

In MySQL 5.1, this variable appears only for reasons of backward compatibility. It is always `NO` because `ISAM` tables are no longer supported. This variable was removed in MySQL 5.1.7.

- `have_merge_engine`

`YES` if `mysqld` supports `MERGE` tables. `DISABLED` if `--skip-merge` is used. This variable was removed in MySQL 5.1.3.

- `have_openssl`

`YES` if `mysqld` supports SSL connections, `NO` if not. As of MySQL 5.1.17, this variable is an alias for `have_ssl`.

- [have\\_partitioning](#)

**YES** if `mysqld` supports partitioning. Added in MySQL 5.1.1 as `have_partition_engine` and renamed to `have_partitioning` in 5.1.6.

- [have\\_query\\_cache](#)

**YES** if `mysqld` supports the query cache, **NO** if not.

- [have\\_row\\_based\\_replication](#)

<b>Version Introduced</b>	5.1.5
<b>Version Removed</b>	5.1.15
<b>Variable Name</b>	<a href="#">have_row_based_replication</a>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No
	<b>Permitted Values</b>
	Type <b>boolean</b>

**YES** if the server can perform replication using row-based binary logging. If the value is **NO**, the server can use only statement-based logging. See [Section 16.1.2, “Replication Formats”](#). This variable was added in MySQL 5.1.5 and removed in 5.1.15.

- [have\\_raid](#)

In MySQL 5.1, this variable appears only for reasons of backward compatibility. It is always **NO** because `RAID` tables are no longer supported. This variable was removed in MySQL 5.1.7.

- [have\\_rtree\\_keys](#)

**YES** if `RTREE` indexes are available, **NO** if not. (These are used for spatial indexes in `MyISAM` tables.)

- [have\\_ssl](#)

**YES** if `mysqld` supports SSL connections, **NO** if not. This variable was added in MySQL 5.1.17. Before that, use `have_openssl`.

- [have\\_symlink](#)

**YES** if symbolic link support is enabled, **NO** if not. This is required on Unix for support of the `DATA DIRECTORY` and `INDEX DIRECTORY` table options, and on Windows for support of data directory symlinks.

- [hostname](#)

<b>Version Introduced</b>	5.1.17
<b>Variable Name</b>	<a href="#">hostname</a>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No
	<b>Permitted Values</b>
	Type <b>string</b>

The server sets this variable to the server host name at startup. This variable was added in MySQL 5.1.17.

- [identity](#)

This variable is a synonym for the `last_insert_id` variable. It exists for compatibility with other database systems. You can read its value with `SELECT @@identity`, and set it using `SET identity`.

- [init\\_connect](#)

<b>Command-Line Format</b>	<code>--init-connect=name</code>
<b>Config-File Format</b>	<code>init_connect</code>
<b>Option Sets Variable</b>	Yes, <code>init_connect</code>

<b>Variable Name</b>	<code>init_connect</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>string</code>

A string to be executed by the server for each client that connects. The string consists of one or more SQL statements. To specify multiple statements, separate them by semicolon characters. For example, each client begins by default with autocommit mode enabled. There is no global system variable to specify that autocommit should be disabled by default, but `init_connect` can be used to achieve the same effect:

```
SET GLOBAL init_connect='SET autocommit=0';
```

This variable can also be set on the command line or in an option file. To set the variable as just shown using an option file, include these lines:

```
[mysqld]
init_connect='SET autocommit=0'
```

Note that the content of `init_connect` is not executed for users that have the `SUPER` privilege. This is done so that an erroneous value for `init_connect` does not prevent all clients from connecting. For example, the value might contain a statement that has a syntax error, thus causing client connections to fail. Not executing `init_connect` for users that have the `SUPER` privilege enables them to open a connection and fix the `init_connect` value.

- `init_file`

<b>Command-Line Format</b>	<code>--init-file=name</code>	
<b>Config-File Format</b>	<code>init_file</code>	
<b>Option Sets Variable</b>	Yes, <code>init_file</code>	
<b>Variable Name</b>	<code>init_file</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>filename</code>

The name of the file specified with the `--init-file` option when you start the server. This should be a file containing SQL statements that you want the server to execute when it starts. Each statement must be on a single line and should not include comments. No statement terminator such as `;`, `\g`, or `\G` should be given at the end of each statement.

Note that the `--init-file` option is unavailable if MySQL was configured with the `--disable-grant-options` option. See [Section 2.3.3, “Typical configure Options”](#).

- `innodb_xxx`

`InnoDB` system variables are listed in [Section 13.6.3, “InnoDB Startup Options and System Variables”](#).

- `insert_id`

The value to be used by the following `INSERT` or `ALTER TABLE` statement when inserting an `AUTO_INCREMENT` value. This is mainly used with the binary log.

- `interactive_timeout`

<b>Command-Line Format</b>	<code>--interactive_timeout=#</code>	
<b>Config-File Format</b>	<code>interactive_timeout</code>	
<b>Option Sets Variable</b>	Yes, <code>interactive_timeout</code>	
<b>Variable Name</b>	<code>interactive_timeout</code>	
<b>Variable Scope</b>	Both	
<b>Dynamic Variable</b>	Yes	

<b>Permitted Values</b>	
<b>Type</b>	<code>numeric</code>
<b>Default</b>	<code>28800</code>
<b>Min Value</b>	<code>1</code>

The number of seconds the server waits for activity on an interactive connection before closing it. An interactive client is defined as a client that uses the `CLIENT_INTERACTIVE` option to `mysql_real_connect()`. See also `wait_timeout`.

- [join\\_buffer\\_size](#)

<b>Command-Line Format</b>	<code>--join_buffer_size=#</code>
<b>Config-File Format</b>	<code>join_buffer_size</code>
<b>Option Sets Variable</b>	Yes, <code>join_buffer_size</code>
<b>Variable Name</b>	<code>join_buffer_size</code>
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes

The minimum size of the buffer that is used for plain index scans, range index scans, and joins that do not use indexes and thus perform full table scans. Normally, the best way to get fast joins is to add indexes. Increase the value of `join_buffer_size` to get a faster full join when adding indexes is not possible. One join buffer is allocated for each full join between two tables. For a complex join between several tables for which indexes are not used, multiple join buffers might be necessary. There is no gain from setting the buffer larger than required to hold each matching row, and all joins allocate at least the minimum size, so use caution in setting this variable to a large value globally. It is better to keep the global setting small and change to a larger setting only in sessions that are doing large joins. Memory allocation time can cause substantial performance drops if the global size is larger than needed by most queries that use it.

The maximum permissible setting for `join_buffer_size` is 4GB. As of MySQL 5.1.23, values larger than 4GB are permitted for 64-bit platforms (except 64-bit Windows, for which large values are truncated to 4GB with a warning).

- [keep\\_files\\_on\\_create](#)

<b>Version Introduced</b>	5.1.21
<b>Command-Line Format</b>	<code>--keep_files_on_create=#</code>
<b>Config-File Format</b>	<code>keep_files_on_create</code>
<b>Option Sets Variable</b>	Yes, <code>keep_files_on_create</code>
<b>Variable Name</b>	<code>keep_files_on_create</code>
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
	<b>Type</b> <code>boolean</code>
	<b>Default</b> <code>OFF</code>

If a `MyISAM` table is created with no `DATA DIRECTORY` option, the `.MYD` file is created in the database directory. By default, if `MyISAM` finds an existing `.MYD` file in this case, it overwrites it. The same applies to `.MYI` files for tables created with no `INDEX DIRECTORY` option. To suppress this behavior, set the `keep_files_on_create` variable to `ON` (1), in which case `MyISAM` will not overwrite existing files and returns an error instead. The default value is `OFF` (0).

If a `MyISAM` table is created with a `DATA DIRECTORY` or `INDEX DIRECTORY` option and an existing `.MYD` or `.MYI` file is found, `MyISAM` always returns an error. It will not overwrite a file in the specified directory.

This variable was added in MySQL 5.1.23.

- [key\\_buffer\\_size](#)

<b>Command-Line Format</b>	<code>--key_buffer_size=#</code>
<b>Config-File Format</b>	<code>key_buffer_size</code>

<b>Option Sets Variable</b>	Yes, <code>key_buffer_size</code>
<b>Variable Name</b>	<code>key_buffer_size</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values (&lt;= 5.1.22)</b>
<b>Type</b>	<code>numeric</code>
<b>Default</b>	<code>8388608</code>
<b>Range</b>	<code>8-4294967295</code>
	<b>Permitted Values (&gt;= 5.1.23)</b>
<b>Platform Bit Size</b>	<code>32</code>
<b>Type</b>	<code>numeric</code>
<b>Default</b>	<code>8388608</code>
<b>Range</b>	<code>8-4294967295</code>
	<b>Permitted Values (&gt;= 5.1.23)</b>
<b>Platform Bit Size</b>	<code>64</code>
<b>Type</b>	<code>numeric</code>
<b>Default</b>	<code>8388608</code>
<b>Range</b>	<code>8-OS_PER_PROCESS_LIMIT</code>

Index blocks for `MyISAM` tables are buffered and are shared by all threads. `key_buffer_size` is the size of the buffer used for index blocks. The key buffer is also known as the key cache.

The maximum permissible setting for `key_buffer_size` is 4GB on 32-bit platforms. As of MySQL 5.1.23, values larger than 4GB are permitted for 64-bit platforms, except 64-bit Windows prior to MySQL 5.1.31, for which large values are truncated to 4GB with a warning. As of MySQL 5.1.31, values larger than 4GB are also permitted for 64-bit Windows. The effective maximum size might be less, depending on your available physical RAM and per-process RAM limits imposed by your operating system or hardware platform. The value of this variable indicates the amount of memory requested. Internally, the server allocates as much memory as possible up to this amount, but the actual allocation might be less.

You can increase the value to get better index handling for all reads and multiple writes; on a system whose primary function is to run MySQL using the `MyISAM` storage engine, 25% of the machine's total memory is an acceptable value for this variable. However, you should be aware that, if you make the value too large (for example, more than 50% of the machine's total memory), your system might start to page and become extremely slow. This is because MySQL relies on the operating system to perform file system caching for data reads, so you must leave some room for the file system cache. You should also consider the memory requirements of any other storage engines that you may be using in addition to `MyISAM`.

For even more speed when writing many rows at the same time, use `LOCK TABLES`. See [Section 7.3.2.1, “Speed of INSERT Statements”](#).

You can check the performance of the key buffer by issuing a `SHOW STATUS` statement and examining the `Key_read_requests`, `Key_reads`, `Key_write_requests`, and `Key_writes` status variables. (See [Section 12.4.5, “SHOW Syntax”](#).) The `Key_reads/Key_read_requests` ratio should normally be less than 0.01. The `Key_writes/Key_write_requests` ratio is usually near 1 if you are using mostly updates and deletes, but might be much smaller if you tend to do updates that affect many rows at the same time or if you are using the `DELAY_KEY_WRITE` table option.

The fraction of the key buffer in use can be determined using `key_buffer_size` in conjunction with the `Key_blocks_unused` status variable and the buffer block size, which is available from the `key_cache_block_size` system variable:

```
1 - ((Key_blocks_unused * key_cache_block_size) / key_buffer_size)
```

This value is an approximation because some space in the key buffer is allocated internally for administrative structures. Factors that influence the amount of overhead for these structures include block size and pointer size. As block size increases, the percentage of the key buffer lost to overhead tends to decrease. Larger blocks results in a smaller number of read operations (because more keys are obtained per read), but conversely an increase in reads of keys that are not examined (if not all keys in a block are relevant to a query).

It is possible to create multiple MyISAM key caches. The size limit of 4GB applies to each cache individually, not as a group. See [Section 7.6.1, “The MyISAM Key Cache”](#).

- `key_cache_age_threshold`

<b>Command-Line Format</b>	<code>--key_cache_age_threshold=#</code>
<b>Config-File Format</b>	<code>key_cache_age_threshold</code>
<b>Option Sets Variable</b>	Yes, <code>key_cache_age_threshold</code>
<b>Variable Name</b>	<code>key_cache_age_threshold</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	
<b>Platform Bit Size</b>	32
<b>Type</b>	numeric
<b>Default</b>	300
<b>Range</b>	100–4294967295
<b>Permitted Values</b>	
<b>Platform Bit Size</b>	64
<b>Type</b>	numeric
<b>Default</b>	300
<b>Range</b>	100–18446744073709547520

This value controls the demotion of buffers from the hot sublist of a key cache to the warm sublist. Lower values cause demotion to happen more quickly. The minimum value is 100. The default value is 300. See [Section 7.6.1, “The MyISAM Key Cache”](#).

- `key_cache_block_size`

<b>Command-Line Format</b>	<code>--key_cache_block_size=#</code>
<b>Config-File Format</b>	<code>key_cache_block_size</code>
<b>Option Sets Variable</b>	Yes, <code>key_cache_block_size</code>
<b>Variable Name</b>	<code>key_cache_block_size</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	1024
<b>Range</b>	512–16384

The size in bytes of blocks in the key cache. The default value is 1024. See [Section 7.6.1, “The MyISAM Key Cache”](#).

- `key_cache_division_limit`

<b>Command-Line Format</b>	<code>--key_cache_division_limit=#</code>
<b>Config-File Format</b>	<code>key_cache_division_limit</code>
<b>Option Sets Variable</b>	Yes, <code>key_cache_division_limit</code>
<b>Variable Name</b>	<code>key_cache_division_limit</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes

<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	100
<b>Range</b>	1–100

The division point between the hot and warm sublists of the key cache buffer list. The value is the percentage of the buffer list to use for the warm sublist. Permissible values range from 1 to 100. The default value is 100. See [Section 7.6.1, “The MyISAM Key Cache”](#).

- [language](#)

<b>Command-Line Format</b>	--language=name	
	-L	
<b>Config-File Format</b>	language	
<b>Option Sets Variable</b>	Yes, language	
<b>Variable Name</b>	language	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
<b>Deprecated</b>	5.5.0, by lc-messages-dir	
	<b>Permitted Values</b>	
	<b>Type</b>	filename
	<b>Default</b>	/usr/local/mysql/share/mysql/english/

The directory where error messages are located. See [Section 9.2, “Setting the Error Message Language”](#).

- [large\\_files\\_support](#)

<b>Variable Name</b>	large_files_support
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No

Whether `mysqld` was compiled with options for large file support.

- [large\\_pages](#)

<b>Command-Line Format</b>	--large-pages	
<b>Config-File Format</b>	large-pages	
<b>Option Sets Variable</b>	Yes, large_pages	
<b>Variable Name</b>	large_pages	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
<b>Platform Specific</b>	linux	
	<b>Permitted Values</b>	
	<b>Type</b> (linux)	boolean
	<b>Default</b>	FALSE

Whether large page support is enabled (via the `--large-pages` option). See [Section 7.9.8, “Enabling Large Page Support”](#).

- [large\\_page\\_size](#)

<b>Variable Name</b>	large_page_size
<b>Variable Scope</b>	Global

<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	
<b>Type</b> (linux)	numeric
<b>Default</b>	0

If large page support is enabled, this shows the size of memory pages. Currently, large memory pages are supported only on Linux; on other platforms, the value of this variable is always 0. See [Section 7.9.8, “Enabling Large Page Support”](#).

- [last\\_insert\\_id](#)

The value to be returned from `LAST_INSERT_ID()`. This is stored in the binary log when you use `LAST_INSERT_ID()` in a statement that updates a table. Setting this variable does not update the value returned by the `mysql_insert_id()` C API function.

- [lc\\_time\\_names](#)

<b>Version Introduced</b>	5.1.12
<b>Variable Name</b>	<a href="#">lc_time_names</a>
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	
<b>Type</b>	string

This variable specifies the locale that controls the language used to display day and month names and abbreviations. This variable affects the output from the `DATE_FORMAT()`, `DAYNAME()` and `MONTHNAME()` functions. Locale names are POSIX-style values such as '`ja_JP`' or '`pt_BR`'. The default value is '`en_US`' regardless of your system's locale setting. For further information, see [Section 9.7, “MySQL Server Locale Support”](#). This variable was added in MySQL 5.1.12.

- [license](#)

<b>Variable Name</b>	license
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	
<b>Type</b>	string
<b>Default</b>	GPL

The type of license the server has.

- [local\\_infile](#)

<b>Variable Name</b>	local_infile
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	
<b>Type</b>	boolean

Whether `LOCAL` is supported for `LOAD DATA INFILE` statements. See [Section 5.3.5, “Security Issues with LOAD DATA LOCAL”](#).

- [locked\\_in\\_memory](#)

<b>Variable Name</b>	<a href="#">locked_in_memory</a>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No

Whether `mysqld` was locked in memory with `--memlock`.

- `log`

Whether logging of all statements to the general query log is enabled. See [Section 5.2.3, “The General Query Log”](#).

This variable is deprecated as of MySQL 5.1.29; use `general_log` instead.

- `log_bin`

<b>Variable Name</b>	<code>log_bin</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No

Whether the binary log is enabled. If the `--log-bin` option is used, then the value of this variable is `ON`; otherwise it is `OFF`. This variable reports only on the status of binary logging (enabled or disabled); it does not actually report the value to which `--log-bin` is set.

See [Section 5.2.4, “The Binary Log”](#).

- `log_bin_trust_function_creators`

<b>Command-Line Format</b>	<code>--log-bin-trust-function-creators</code>
<b>Config-File Format</b>	<code>log-bin-trust-function-creators</code>
<b>Option Sets Variable</b>	Yes, <code>log_bin_trust_function_creators</code>
<b>Variable Name</b>	<code>log_bin_trust_function_creators</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
	<b>Type</b> <code>boolean</code>
	<b>Default</b> <code>FALSE</code>

This variable applies when binary logging is enabled. It controls whether stored function creators can be trusted not to create stored functions that will cause unsafe events to be written to the binary log. If set to 0 (the default), users are not permitted to create or alter stored functions unless they have the `SUPER` privilege in addition to the `CREATE ROUTINE` or `ALTER ROUTINE` privilege. A setting of 0 also enforces the restriction that a function must be declared with the `DETERMINISTIC` characteristic, or with the `READS SQL DATA` or `NO SQL` characteristic. If the variable is set to 1, MySQL does not enforce these restrictions on stored function creation. This variable also applies to trigger creation. See [Section 19.7, “Binary Logging of Stored Programs”](#).

- `log_error`

<b>Command-Line Format</b>	<code>--log-error[=name]</code>
<b>Config-File Format</b>	<code>log-error</code>
<b>Option Sets Variable</b>	Yes, <code>log_error</code>
<b>Variable Name</b>	<code>log_error</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No
	<b>Permitted Values</b>
	<b>Type</b> <code>filename</code>

The location of the error log.

- `log_output`

<b>Version Introduced</b>	5.1.6
<b>Command-Line Format</b>	<code>--log-output[=name]</code>

<b>Config-File Format</b>	<code>log_output</code>
<b>Option Sets Variable</b>	Yes, <code>log_output</code>
<b>Variable Name</b>	<code>log_output</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
	Type <code>set</code>
	Default <code>FILE</code>
	Valid Values <code>TABLE, FILE, NONE</code>

The destination for general query log and slow query log output. The value can be a comma-separated list of one or more of the words `TABLE` (log to tables), `FILE` (log to files), or `NONE` (do not log to tables or files). The default value is `TABLE`. `NONE`, if present, takes precedence over any other specifiers. If the value is `NONE` log entries are not written even if the logs are enabled. If the logs are not enabled, no logging occurs even if the value of `log_output` is not `NONE`. For more information, see [Section 5.2.1, “Selecting General Query and Slow Query Log Output Destinations”](#). This variable was added in MySQL 5.1.6.

- `log_queries_not_using_indexes`

<b>Command-Line Format</b>	<code>--log-queries-not-using-indexes</code>
<b>Config-File Format</b>	<code>log-queries-not-using-indexes</code>
<b>Option Sets Variable</b>	Yes, <code>log_queries_not_using_indexes</code>
<b>Variable Name</b>	<code>log_queries_not_using_indexes</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
	Type <code>boolean</code>

Whether queries that do not use indexes are logged to the slow query log. See [Section 5.2.5, “The Slow Query Log”](#). This variable was added in MySQL 5.1.11.

- `log_slave_updates`

Whether updates received by a slave server from a master server should be logged to the slave's own binary log. Binary logging must be enabled on the slave for this variable to have any effect. See [Section 16.1.3, “Replication and Binary Logging Options and Variables”](#).

- `log_slow_queries`

<b>Version Deprecated</b>	5.1.29
<b>Command-Line Format</b>	<code>--log-slow-queries[=name]</code>
<b>Config-File Format</b>	<code>log-slow-queries</code>
<b>Option Sets Variable</b>	Yes, <code>log_slow_queries</code>
<b>Variable Name</b>	<code>log_slow_queries</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes
<b>Deprecated</b>	5.1.29, by <code>slow-query-log</code>
	<b>Permitted Values</b>
	Type <code>boolean</code>

Whether slow queries should be logged. “Slow” is determined by the value of the `long_query_time` variable. See [Section 5.2.5, “The Slow Query Log”](#).

This variable is deprecated as of MySQL 5.1.29; use `slow_query_log` instead.

- `log_warnings`

<b>Command-Line Format</b>	<code>--log-warnings[=#]</code>
	<code>-W [#]</code>
<b>Config-File Format</b>	<code>log-warnings</code>
<b>Option Sets Variable</b>	Yes, <code>log_warnings</code>
<b>Variable Name</b>	<code>log_warnings</code>
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes
<b>Disabled by</b>	<code>skip-log-warnings</code>
<b>Permitted Values</b>	
<b>Platform Bit Size</b>	<code>64</code>
<b>Type</b>	<code>numeric</code>
<b>Default</b>	<code>1</code>
<b>Range</b>	<code>0-18446744073709547520</code>

Whether to produce additional warning messages. It is enabled (1) by default and can be disabled by setting it to 0. Aborted connections are not logged to the error log unless the value is greater than 1. As of MySQL 5.1.38, the server logs messages about statements that are unsafe for statement-based logging only if the value is greater than 0.

- `long_query_time`

<b>Command-Line Format</b>	<code>--long_query_time=#</code>
<b>Config-File Format</b>	<code>long_query_time</code>
<b>Option Sets Variable</b>	Yes, <code>long_query_time</code>
<b>Variable Name</b>	<code>long_query_time</code>
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes
<b>Permitted Values (&gt;= 5.1.21)</b>	
<b>Type</b>	<code>numeric</code>
<b>Default</b>	<code>10</code>
<b>Min Value</b>	<code>0</code>

If a query takes longer than this many seconds, the server increments the `Slow_queries` status variable. If the slow query log is enabled, the query is logged to the slow query log file. This value is measured in real time, not CPU time, so a query that is under the threshold on a lightly loaded system might be above the threshold on a heavily loaded one. Prior to MySQL 5.1.21, the minimum value is 1, and the value for this variable must be an integer. Beginning with MySQL 5.1.21, the minimum is 0, and a resolution of microseconds is supported when logging to a file. However, the microseconds part is ignored and only integer values are written when logging to tables. The default value is 10. See [Section 5.2.5, “The Slow Query Log”](#).

- `low_priority_updates`

<b>Command-Line Format</b>	<code>--low-priority-updates</code>
<b>Config-File Format</b>	<code>low-priority-updates</code>
<b>Option Sets Variable</b>	Yes, <code>low_priority_updates</code>
<b>Variable Name</b>	<code>low_priority_updates</code>
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	
<b>Type</b>	<code>boolean</code>
<b>Default</b>	<code>FALSE</code>

If set to 1, all `INSERT`, `UPDATE`, `DELETE`, and `LOCK TABLE WRITE` statements wait until there is no pending `SELECT` or `LOCK TABLE READ` on the affected table. This affects only storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`). This variable previously was named `sql_low_priority_updates`.

- `lower_case_file_system`

<b>Command-Line Format</b>	<code>--lower_case_file_system[=#]</code>
<b>Config-File Format</b>	<code>lower_case_file_system</code>
<b>Option Sets Variable</b>	Yes, <code>lower_case_file_system</code>
<b>Variable Name</b>	<code>lower_case_file_system</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No
	<b>Permitted Values</b>
	<b>Type</b> <code>boolean</code>

This variable describes the case sensitivity of file names on the file system where the data directory is located. `OFF` means file names are case sensitive, `ON` means they are not case sensitive. This variable is read only because it reflects a file system attribute and setting it would have no effect on the file system.

- `lower_case_table_names`

<b>Command-Line Format</b>	<code>--lower_case_table_names[=#]</code>
<b>Config-File Format</b>	<code>lower_case_table_names</code>
<b>Option Sets Variable</b>	Yes, <code>lower_case_table_names</code>
<b>Variable Name</b>	<code>lower_case_table_names</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No
	<b>Permitted Values</b>
	<b>Type</b> <code>numeric</code>
	<b>Default</b> <code>0</code>
	<b>Range</b> <code>0-2</code>

If set to 0, table names are stored as specified and comparisons are case sensitive. If set to 1, table names are stored in lowercase on disk and comparisons are not case sensitive. If set to 2, table names are stored as given but compared in lowercase. This option also applies to database names and table aliases. For additional information, see [Section 8.2.2, “Identifier Case Sensitivity”](#).

You should *not* set this variable to 0 if you are running MySQL on a system that has case-insensitive file names (such as Windows or Mac OS X). If you set this variable to 0 on such a system and access `MyISAM` tablenames using different lettercases, index corruption may result. On Windows the default value is 1. On Mac OS X, the default value is 2.

If you are using `InnoDB` tables, you should set this variable to 1 on all platforms to force names to be converted to lowercase. Prior to MySQL Cluster NDB 6.3.35, MySQL Cluster NDB 7.0.15, and MySQL Cluster NDB 7.1.4, this is also true for tables using the `NDB` storage engine.

- `max_allowed_packet`

<b>Command-Line Format</b>	<code>--max_allowed_packet=#</code>
<b>Config-File Format</b>	<code>max_allowed_packet</code>
<b>Option Sets Variable</b>	Yes, <code>max_allowed_packet</code>
<b>Variable Name</b>	<code>max_allowed_packet</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes

<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	1048576
<b>Range</b>	1024-1073741824

The maximum size of one packet or any generated/intermediate string.

The packet message buffer is initialized to `net_buffer_length` bytes, but can grow up to `max_allowed_packet` bytes when needed. This value by default is small, to catch large (possibly incorrect) packets.

You must increase this value if you are using large `BLOB` columns or long strings. It should be as big as the largest `BLOB` you want to use. The protocol limit for `max_allowed_packet` is 1GB. The value should be a multiple of 1024; nonmultiples are rounded down to the nearest multiple.

When you change the message buffer size by changing the value of the `max_allowed_packet` variable, you should also change the buffer size on the client side if your client program permits it. On the client side, `max_allowed_packet` has a default of 1GB. Some programs such as `mysql` and `mysqldump` enable you to change the client-side value by setting `max_allowed_packet` on the command line or in an option file.

As of MySQL 5.1.31, the session value of this variable is read only. Before 5.1.31, setting the session value is permitted but has no effect.

- [max\\_connect\\_errors](#)

<b>Command-Line Format</b>	--max_connect_errors=#
<b>Config-File Format</b>	<code>max_connect_errors</code>
<b>Option Sets Variable</b>	Yes, <code>max_connect_errors</code>
<b>Variable Name</b>	<code>max_connect_errors</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	
<b>Platform Bit Size</b>	32
<b>Type</b>	numeric
<b>Default</b>	10
<b>Range</b>	1-4294967295
<b>Permitted Values</b>	
<b>Platform Bit Size</b>	64
<b>Type</b>	numeric
<b>Default</b>	10
<b>Range</b>	1-18446744073709547520

If there are more than this number of interrupted connections from a host, that host is blocked from further connections. You can unblock blocked hosts with the `FLUSH HOSTS` statement. If a connection is established successfully within fewer than `max_connect_errors` attempts after a previous connection was interrupted, the error count for the host is cleared to zero. However, once a host is blocked, the `FLUSH HOSTS` statement is the only way to unblock it.

- [max\\_connections](#)

<b>Command-Line Format</b>	--max_connections=#
<b>Config-File Format</b>	<code>max_connections</code>
<b>Option Sets Variable</b>	Yes, <code>max_connections</code>
<b>Variable Name</b>	<code>max_connections</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes

	<b>Permitted Values (&lt;= 5.1.14)</b>
Type	numeric
Default	100
	<b>Permitted Values (&gt;= 5.1.15)</b>
Type	numeric
Default	151
Range	1-16384
	<b>Permitted Values (&gt;= 5.1.17)</b>
Type	numeric
Default	151
Range	1-100000

The maximum permitted number of simultaneous client connections. By default, this is 151, beginning with MySQL 5.1.15. (Previously, the default was 100.) See [Section B.5.2.7, “Too many connections”](#), for more information.

Increasing this value increases the number of file descriptors that `mysqld` requires. See [Section 7.8.2, “How MySQL Opens and Closes Tables”](#), for comments on file descriptor limits.

- [max\\_delayed\\_threads](#)

<b>Command-Line Format</b>	<code>--max_delayed_threads=#</code>
<b>Config-File Format</b>	<code>max_delayed_threads</code>
<b>Option Sets Variable</b>	Yes, <code>max_delayed_threads</code>
<b>Variable Name</b>	<code>max_delayed_threads</code>
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
Type	numeric
Default	20
Range	0-16384

Do not start more than this number of threads to handle `INSERT DELAYED` statements. If you try to insert data into a new table after all `INSERT DELAYED` threads are in use, the row is inserted as if the `DELAYED` attribute wasn't specified. If you set this to 0, MySQL never creates a thread to handle `DELAYED` rows; in effect, this disables `DELAYED` entirely.

For the `SESSION` value of this variable, the only valid values are 0 or the `GLOBAL` value.

- [max\\_error\\_count](#)

<b>Command-Line Format</b>	<code>--max_error_count=#</code>
<b>Config-File Format</b>	<code>max_error_count</code>
<b>Option Sets Variable</b>	Yes, <code>max_error_count</code>
<b>Variable Name</b>	<code>max_error_count</code>
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
Type	numeric
Default	64
Range	0-65535

The maximum number of error, warning, and note messages to be stored for display by the `SHOW ERRORS` and `SHOW WARNINGS` statements.

- [max\\_heap\\_table\\_size](#)

<b>Command-Line Format</b>	--max_heap_table_size=#
<b>Config-File Format</b>	max_heap_table_size
<b>Option Sets Variable</b>	Yes, <a href="#">max_heap_table_size</a>
<b>Variable Name</b>	<a href="#">max_heap_table_size</a>
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	16777216
<b>Range</b>	16384–4294967295

This variable sets the maximum size to which [MEMORY](#) tables are permitted to grow. The value of the variable is used to calculate [MEMORY](#) table [MAX\\_ROWS](#) values. Setting this variable has no effect on any existing [MEMORY](#) table, unless the table is re-created with a statement such as [CREATE TABLE](#) or altered with [ALTER TABLE](#) or [TRUNCATE TABLE](#). A server restart also sets the maximum size of existing [MEMORY](#) tables to the global [max\\_heap\\_table\\_size](#) value.

### Note

On 64-bit platforms, the maximum value for this variable is 1844674407370954752.

- [max\\_insert\\_delayed\\_threads](#)

<b>Variable Name</b>	<a href="#">max_insert_delayed_threads</a>
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	
<b>Type</b>	numeric

This variable is a synonym for [max\\_delayed\\_threads](#).

- [max\\_join\\_size](#)

<b>Command-Line Format</b>	--max_join_size=#
<b>Config-File Format</b>	max_join_size
<b>Option Sets Variable</b>	Yes, <a href="#">max_join_size</a>
<b>Variable Name</b>	<a href="#">max_join_size</a>
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	4294967295
<b>Range</b>	1–4294967295

Do not permit [SELECT](#) statements that probably need to examine more than [max\\_join\\_size](#) rows (for single-table statements) or row combinations (for multiple-table statements) or that are likely to do more than [max\\_join\\_size](#) disk seeks. By setting this value, you can catch [SELECT](#) statements where keys are not used properly and that would probably take a long time. Set it if your users tend to perform joins that lack a [WHERE](#) clause, that take a long time, or that return millions of rows.

Setting this variable to a value other than [DEFAULT](#) resets the value of [sql\\_big\\_selects](#) to 0. If you set the [sql\\_big\\_selects](#) value again, the [max\\_join\\_size](#) variable is ignored.

If a query result is in the query cache, no result size check is performed, because the result has previously been computed and it does not burden the server to send it to the client.

This variable previously was named `sql_max_join_size`.

- `max_length_for_sort_data`

<b>Command-Line Format</b>	<code>--max_length_for_sort_data=#</code>		
<b>Config-File Format</b>	<code>max_length_for_sort_data</code>		
<b>Option Sets Variable</b>	Yes, <code>max_length_for_sort_data</code>		
<b>Variable Name</b>	<code>max_length_for_sort_data</code>		
<b>Variable Scope</b>	Both		
<b>Dynamic Variable</b>	Yes		
<b>Permitted Values</b>			
<b>Type</b>	<code>numeric</code>		
<b>Default</b>	<code>1024</code>		
<b>Range</b>	<code>4-8388608</code>		

The cutoff on the size of index values that determines which `filesort` algorithm to use. See [Section 7.3.1.11, “ORDER BY Optimization”](#).

- `max_prepared_stmt_count`

<b>Version Introduced</b>	5.1.10		
<b>Command-Line Format</b>	-	5.0.21	
	-		
	<code>max_prepared_stmt_count=#</code>		
<b>Config-File Format</b>	<code>max_prepared_stmt_count</code>	5.0.21	
<b>Option Sets Variable</b>	Yes, <code>max_prepared_stmt_count</code>		
<b>Variable Name</b>	<code>max_prepared_stmt_count</code>		
<b>Variable Scope</b>	Global		
<b>Dynamic Variable</b>	Yes		
<b>Permitted Values</b>			
<b>Type</b>	<code>numeric</code>		
<b>Default</b>	<code>16382</code>		
<b>Range</b>	<code>0-1048576</code>		

This variable limits the total number of prepared statements in the server. It can be used in environments where there is the potential for denial-of-service attacks based on running the server out of memory by preparing huge numbers of statements. If the value is set lower than the current number of prepared statements, existing statements are not affected and can be used, but no new statements can be prepared until the current number drops below the limit. The default value is 16,382. The permissible range of values is from 0 to 1 million. Setting the value to 0 disables prepared statements. This variable was added in MySQL 5.1.10.

- `max_relay_log_size`

<b>Command-Line Format</b>	<code>--max_relay_log_size=#</code>		
<b>Config-File Format</b>	<code>max_relay_log_size</code>		
<b>Option Sets Variable</b>	Yes, <code>max_relay_log_size</code>		
<b>Variable Name</b>	<code>max_relay_log_size</code>		
<b>Variable Scope</b>	Global		
<b>Dynamic Variable</b>	Yes		

<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	0
<b>Range</b>	0–1073741824

If a write by a replication slave to its relay log causes the current log file size to exceed the value of this variable, the slave rotates the relay logs (closes the current file and opens the next one). If `max_relay_log_size` is 0, the server uses `max_binlog_size` for both the binary log and the relay log. If `max_relay_log_size` is greater than 0, it constrains the size of the relay log, which enables you to have different sizes for the two logs. You must set `max_relay_log_size` to between 4096 bytes and 1GB (inclusive), or to 0. The default value is 0. See [Section 16.2.1, “Replication Implementation Details”](#).

- [max\\_seeks\\_for\\_key](#)

<b>Command-Line Format</b>	<code>--max_seeks_for_key=#</code>
<b>Config-File Format</b>	<code>max_seeks_for_key</code>
<b>Option Sets Variable</b>	Yes, <code>max_seeks_for_key</code>
<b>Variable Name</b>	<code>max_seeks_for_key</code>
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	
<b>Platform Bit Size</b>	32
<b>Type</b>	numeric
<b>Default</b>	4294967295
<b>Range</b>	1–4294967295
	<b>Permitted Values</b>
<b>Platform Bit Size</b>	64
<b>Type</b>	numeric
<b>Default</b>	18446744073709547520
<b>Range</b>	1–18446744073709547520

Limit the assumed maximum number of seeks when looking up rows based on a key. The MySQL optimizer assumes that no more than this number of key seeks are required when searching for matching rows in a table by scanning an index, regardless of the actual cardinality of the index (see [Section 12.4.5.23, “SHOW INDEX Syntax”](#)). By setting this to a low value (say, 100), you can force MySQL to prefer indexes instead of table scans.

- [max\\_sort\\_length](#)

<b>Command-Line Format</b>	<code>--max_sort_length=#</code>
<b>Config-File Format</b>	<code>max_sort_length</code>
<b>Option Sets Variable</b>	Yes, <code>max_sort_length</code>
<b>Variable Name</b>	<code>max_sort_length</code>
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	1024
<b>Range</b>	4–8388608

The number of bytes to use when sorting `BLOB` or `TEXT` values. Only the first `max_sort_length` bytes of each value are used; the rest are ignored.

- [max\\_sp\\_recursion\\_depth](#)

<b>Command-Line Format</b>	--max_sp_recursion_depth[=#]
<b>Config-File Format</b>	max_sp_recursion_depth
<b>Option Sets Variable</b>	Yes, max_sp_recursion_depth
<b>Variable Name</b>	max_sp_recursion_depth
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	0
<b>Max Value</b>	255

The number of times that any given stored procedure may be called recursively. The default value for this option is 0, which completely disables recursion in stored procedures. The maximum value is 255.

Stored procedure recursion increases the demand on thread stack space. If you increase the value of `max_sp_recursion_depth`, it may be necessary to increase thread stack size by increasing the value of `thread_stack` at server startup.

- [max\\_tmp\\_tables](#)

<b>Command-Line Format</b>	--max_tmp_tables=#
<b>Config-File Format</b>	max_tmp_tables
<b>Option Sets Variable</b>	Yes, max_tmp_tables
<b>Variable Name</b>	max_tmp_tables
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	
<b>Platform Bit Size</b>	32
<b>Type</b>	numeric
<b>Default</b>	32
<b>Range</b>	1-4294967295
<b>Permitted Values</b>	
<b>Platform Bit Size</b>	64
<b>Type</b>	numeric
<b>Default</b>	32
<b>Range</b>	1-18446744073709547520

The maximum number of temporary tables a client can keep open at the same time. (This variable does not yet do anything.)

- [max\\_user\\_connections](#)

<b>Command-Line Format</b>	--max_user_connections=#
<b>Config-File Format</b>	max_user_connections
<b>Option Sets Variable</b>	Yes, max_user_connections
<b>Variable Name</b>	max_user_connections
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes

<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	0
<b>Range</b>	0–4294967295

The maximum number of simultaneous connections permitted to any given MySQL user account. A value of 0 (the default) means “no limit.”

This variable has a global value that can be set at server startup or runtime. It also has a read-only session value that indicates the effective simultaneous-connection limit that applies to the account associated with the current session. The session value is initialized as follows:

- If the user account has a nonzero `MAX_USER_CONNECTIONS` resource limit, the session `max_user_connections` value is set to that limit.
- Otherwise, the session `max_user_connections` value is set to the global value.

Account resource limits are specified using the `GRANT` statement. See [Section 5.5.4, “Setting Account Resource Limits”](#), and [Section 12.4.1.3, “GRANT Syntax”](#).

- `max_write_lock_count`

<b>Command-Line Format</b>	<code>--max_write_lock_count=#</code>
<b>Config-File Format</b>	<code>max_write_lock_count</code>
<b>Option Sets Variable</b>	Yes, <code>max_write_lock_count</code>
<b>Variable Name</b>	<code>max_write_lock_count</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	
<b>Platform Bit Size</b>	32
<b>Type</b>	numeric
<b>Default</b>	4294967295
<b>Range</b>	1–4294967295
<b>Permitted Values</b>	
<b>Platform Bit Size</b>	64
<b>Type</b>	numeric
<b>Default</b>	18446744073709547520
<b>Range</b>	1–18446744073709547520

After this many write locks, permit some pending read lock requests to be processed in between.

- `min_examined_row_limit`

<b>Version Introduced</b>	5.1.21
<b>Command-Line Format</b>	<code>--min-examined-row-limit=#</code>
<b>Config-File Format</b>	<code>min-examined-row-limit</code>
<b>Variable Name</b>	<code>min_examined_row_limit</code>
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes

<b>Permitted Values</b>	
<b>Platform Bit Size</b>	32
<b>Type</b>	numeric
<b>Default</b>	0
<b>Range</b>	0-4294967295
<b>Permitted Values</b>	
<b>Platform Bit Size</b>	64
<b>Type</b>	numeric
<b>Default</b>	0
<b>Range</b>	0-18446744073709547520

Queries that examine fewer than this number of rows are not logged to the slow query log. This variable was added in MySQL 5.1.21.

- `myisam_data_pointer_size`

<b>Command-Line Format</b>	--myisam_data_pointer_size=#
<b>Config-File Format</b>	myisam_data_pointer_size
<b>Option Sets Variable</b>	Yes, myisam_data_pointer_size
<b>Variable Name</b>	myisam_data_pointer_size
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	6
<b>Range</b>	2-7

The default pointer size in bytes, to be used by `CREATE TABLE` for MyISAM tables when no `MAX_ROWS` option is specified. This variable cannot be less than 2 or larger than 7. The default value is 6. See [Section B.5.2.12, “The table is full”](#).

- `myisam_max_sort_file_size`

<b>Command-Line Format</b>	--myisam_max_sort_file_size=#
<b>Config-File Format</b>	myisam_max_sort_file_size
<b>Option Sets Variable</b>	Yes, myisam_max_sort_file_size
<b>Variable Name</b>	myisam_max_sort_file_size
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	2147483648

The maximum size of the temporary file that MySQL is permitted to use while re-creating a MyISAM index (during `REPAIR TABLE`, `ALTER TABLE`, or `LOAD DATA INFILE`). If the file size would be larger than this value, the index is created using the key cache instead, which is slower. The value is given in bytes.

The default value is 2GB. If MyISAM index files exceed this size and disk space is available, increasing the value may help performance. The space must be available in the file system containing the directory where the original index file is located.

- `myisam_mmap_size`

<b>Version Introduced</b>	5.1.43
---------------------------	--------

<b>Command-Line Format</b>	<code>--myisam_mmap_size=#</code>	
<b>Config-File Format</b>	<code>myisam_mmap_size</code>	
<b>Option Sets Variable</b>	Yes, <code>myisam_mmap_size</code>	
<b>Variable Name</b>	<code>myisam_mmap_size</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
<b>Permitted Values</b>		
<b>Platform Bit Size</b>	<code>32</code>	
<b>Type</b>	<code>numeric</code>	
<b>Default</b>	<code>4294967295</code>	
<b>Range</b>	<code>7-4294967295</code>	
<b>Permitted Values</b>		
<b>Platform Bit Size</b>	<code>64</code>	
<b>Type</b>	<code>numeric</code>	
<b>Default</b>	<code>18446744073709547520</code>	
<b>Range</b>	<code>7-18446744073709547520</code>	

The maximum amount of memory to use for memory mapping compressed `MyISAM` files. If many compressed `MyISAM` tables are used, the value can be decreased to reduce the likelihood of memory-swapping problems. This variable was added in MySQL 5.1.43.

- `myisam_recover_options`

<b>Variable Name</b>	<code>myisam_recover_options</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	

The value of the `--myisam-recover` option. See [Section 5.1.2, “Server Command Options”](#).

- `myisam_repair_threads`

<b>Command-Line Format</b>	<code>--myisam_repair_threads=#</code>	
<b>Config-File Format</b>	<code>myisam_repair_threads</code>	
<b>Option Sets Variable</b>	Yes, <code>myisam_repair_threads</code>	
<b>Variable Name</b>	<code>myisam_repair_threads</code>	
<b>Variable Scope</b>	Both	
<b>Dynamic Variable</b>	Yes	
<b>Permitted Values</b>		
<b>Platform Bit Size</b>	<code>32</code>	
<b>Type</b>	<code>numeric</code>	
<b>Default</b>	<code>1</code>	
<b>Range</b>	<code>1-4294967295</code>	
<b>Permitted Values</b>		
<b>Platform Bit Size</b>	<code>64</code>	
<b>Type</b>	<code>numeric</code>	
<b>Default</b>	<code>1</code>	
<b>Range</b>	<code>1-18446744073709547520</code>	

If this value is greater than 1, [MyISAM](#) table indexes are created in parallel (each index in its own thread) during the [Repair by sorting](#) process. The default value is 1.

### Note

Multi-threaded repair is still *beta-quality* code.

- [myisam\\_sort\\_buffer\\_size](#)

<b>Command-Line Format</b>	--myisam_sort_buffer_size=#
<b>Config-File Format</b>	myisam_sort_buffer_size
<b>Option Sets Variable</b>	Yes, myisam_sort_buffer_size
<b>Variable Name</b>	myisam_sort_buffer_size
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	
<b>Platform Bit Size</b>	32
<b>Type</b>	numeric
<b>Default</b>	8388608
<b>Range</b>	4-4294967295
<b>Permitted Values</b>	
<b>Platform Bit Size</b>	64
<b>Type</b>	numeric
<b>Default</b>	8388608
<b>Range</b>	4-18446744073709547520

The size of the buffer that is allocated when sorting [MyISAM](#) indexes during a [REPAIR TABLE](#) or when creating indexes with [CREATE INDEX](#) or [ALTER TABLE](#).

The maximum permissible setting for [myisam\\_sort\\_buffer\\_size](#) is 4GB. As of MySQL 5.1.23, values larger than 4GB are permitted for 64-bit platforms (except 64-bit Windows, for which large values are truncated to 4GB with a warning).

- [myisam\\_stats\\_method](#)

<b>Command-Line Format</b>	--myisam_stats_method=name
<b>Config-File Format</b>	myisam_stats_method
<b>Option Sets Variable</b>	Yes, myisam_stats_method
<b>Variable Name</b>	myisam_stats_method
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	
<b>Type</b>	enumeration
<b>Valid Values</b>	nulls_equal, nulls_unequal, nulls_ignored

How the server treats [NULL](#) values when collecting statistics about the distribution of index values for [MyISAM](#) tables. This variable has three possible values, [nulls\\_equal](#), [nulls\\_unequal](#), and [nulls\\_ignored](#). For [nulls\\_equal](#), all [NULL](#) index values are considered equal and form a single value group that has a size equal to the number of [NULL](#) values. For [nulls\\_unequal](#), [NULL](#) values are considered unequal, and each [NULL](#) forms a distinct value group of size 1. For [nulls\\_ignored](#), [NULL](#) values are ignored.

The method that is used for generating table statistics influences how the optimizer chooses indexes for query execution, as described in [Section 7.5.4, “MyISAM Index Statistics Collection”](#).

Any unique prefix of a valid value may be used to set the value of this variable.

- [myisam\\_use mmap](#)

<b>Version Introduced</b>	5.1.4
<b>Command-Line Format</b>	<code>--myisam_use mmap</code>
<b>Config-File Format</b>	<code>myisam_use mmap</code>
<b>Option Sets Variable</b>	Yes, <a href="#">myisam_use mmap</a>
<b>Variable Name</b>	<code>myisam_use mmap</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	
<b>Type</b>	<code>boolean</code>
<b>Default</b>	<code>OFF</code>

Use memory mapping for reading and writing [MyISAM](#) tables. This variable was added in MySQL 5.1.4.

- [named\\_pipe](#)

<b>Variable Name</b>	<code>named_pipe</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No
<b>Platform Specific</b>	windows

(Windows only.) Indicates whether the server supports connections over named pipes.

- [net\\_buffer\\_length](#)

<b>Command-Line Format</b>	<code>--net_buffer_length=#</code>
<b>Config-File Format</b>	<code>net_buffer_length</code>
<b>Option Sets Variable</b>	Yes, <a href="#">net_buffer_length</a>
<b>Variable Name</b>	<code>net_buffer_length</code>
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	
<b>Type</b>	<code>numeric</code>
<b>Default</b>	<code>16384</code>
<b>Range</b>	<code>1024-1048576</code>

Each client thread is associated with a connection buffer and result buffer. Both begin with a size given by [net\\_buffer\\_length](#) but are dynamically enlarged up to [max\\_allowed\\_packet](#) bytes as needed. The result buffer shrinks to [net\\_buffer\\_length](#) after each SQL statement.

This variable should not normally be changed, but if you have very little memory, you can set it to the expected length of statements sent by clients. If statements exceed this length, the connection buffer is automatically enlarged. The maximum value to which [net\\_buffer\\_length](#) can be set is 1MB.

As of MySQL 5.1.31, the session value of this variable is read only. Before 5.1.31, setting the session value is permitted but has no effect.

- [net\\_read\\_timeout](#)

<b>Command-Line Format</b>	<code>--net_read_timeout=#</code>
<b>Config-File Format</b>	<code>net_read_timeout</code>
<b>Option Sets Variable</b>	Yes, <a href="#">net_read_timeout</a>

<b>Variable Name</b>	<a href="#">net_read_timeout</a>	
<b>Variable Scope</b>	Both	
<b>Dynamic Variable</b>	Yes	
<b>Permitted Values</b>		
<b>Type</b>	<a href="#">numeric</a>	
<b>Default</b>	<a href="#">30</a>	
<b>Min Value</b>	<a href="#">1</a>	

The number of seconds to wait for more data from a connection before aborting the read. This timeout applies only to TCP/IP connections, not to connections made through Unix socket files, named pipes, or shared memory. When the server is reading from the client, [net\\_read\\_timeout](#) is the timeout value controlling when to abort. When the server is writing to the client, [net\\_write\\_timeout](#) is the timeout value controlling when to abort. See also [slave\\_net\\_timeout](#).

- [net\\_retry\\_count](#)

<b>Command-Line Format</b>	<a href="#">--net_retry_count=#</a>	
<b>Config-File Format</b>	<a href="#">net_retry_count</a>	
<b>Option Sets Variable</b>	Yes, <a href="#">net_retry_count</a>	
<b>Variable Name</b>	<a href="#">net_retry_count</a>	
<b>Variable Scope</b>	Both	
<b>Dynamic Variable</b>	Yes	
<b>Permitted Values</b>		
<b>Platform Bit Size</b>	<a href="#">32</a>	
<b>Type</b>	<a href="#">numeric</a>	
<b>Default</b>	<a href="#">10</a>	
<b>Range</b>	<a href="#">1-4294967295</a>	
<b>Permitted Values</b>		
<b>Platform Bit Size</b>	<a href="#">64</a>	
<b>Type</b>	<a href="#">numeric</a>	
<b>Default</b>	<a href="#">10</a>	
<b>Range</b>	<a href="#">1-18446744073709547520</a>	

If a read on a communication port is interrupted, retry this many times before giving up. This value should be set quite high on FreeBSD because internal interrupts are sent to all threads.

- [net\\_write\\_timeout](#)

<b>Command-Line Format</b>	<a href="#">--net_write_timeout=#</a>	
<b>Config-File Format</b>	<a href="#">net_write_timeout</a>	
<b>Option Sets Variable</b>	Yes, <a href="#">net_write_timeout</a>	
<b>Variable Name</b>	<a href="#">net_write_timeout</a>	
<b>Variable Scope</b>	Both	
<b>Dynamic Variable</b>	Yes	
<b>Permitted Values</b>		
<b>Type</b>	<a href="#">numeric</a>	
<b>Default</b>	<a href="#">60</a>	
<b>Min Value</b>	<a href="#">1</a>	

The number of seconds to wait for a block to be written to a connection before aborting the write. This timeout applies only to TCP/IP connections, not to connections made using Unix socket files, named pipes, or shared memory. See also [net\\_read\\_timeout](#).

- [new](#)

<b>Command-Line Format</b>	--new
	-n
<b>Config-File Format</b>	new
<b>Option Sets Variable</b>	Yes, <a href="#">new</a>
<b>Variable Name</b>	<a href="#">new</a>
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes
<b>Disabled by</b>	<a href="#">skip-new</a>
	<b>Permitted Values</b>
	Type <a href="#">boolean</a>
	Default <a href="#">FALSE</a>

This variable was used in MySQL 4.0 to turn on some 4.1 behaviors, and is retained for backward compatibility. In MySQL 5.1, its value is always [OFF](#).

- [old](#)

<b>Version Introduced</b>	5.1.18
<b>Command-Line Format</b>	--old
<b>Config-File Format</b>	old
<b>Variable Name</b>	old
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No

[old](#) is a compatibility variable. It is disabled by default, but can be enabled at startup to revert the server to behaviors present in older versions.

Currently, when [old](#) is enabled, it changes the default scope of index hints to that used prior to MySQL 5.1.17. That is, index hints with no [FOR](#) clause apply only to how indexes are used for row retrieval and not to resolution of [ORDER BY](#) or [GROUP BY](#) clauses. (See [Section 12.2.8.2, “Index Hint Syntax”](#).) Take care about enabling this in a replication setup. With statement-based binary logging, having different modes for the master and slaves might lead to replication errors.

This variable was added as [old\\_mode](#) in MySQL 5.1.17 and renamed to [old](#) in MySQL 5.1.18.

- [old\\_alter\\_table](#)

<b>Command-Line Format</b>	--old-alter-table
<b>Config-File Format</b>	old-alter-table
<b>Option Sets Variable</b>	Yes, <a href="#">old_alter_table</a>
<b>Variable Name</b>	<a href="#">old-alter-table</a>
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
	Type <a href="#">boolean</a>
	Default <a href="#">OFF</a>

When this variable is enabled, the server does not use the optimized method of processing an [ALTER TABLE](#) operation. It reverts to using a temporary table, copying over the data, and then renaming the temporary table to the original, as used by MySQL 5.0 and earlier. For more information on the operation of [ALTER TABLE](#), see [Section 12.1.7, “ALTER TABLE Syntax”](#).

tax”.

- `old_passwords`

<b>Command-Line Format</b>	-- <code>old_passwords</code>
<b>Config-File Format</b>	<code>old-passwords</code>
<b>Option Sets Variable</b>	Yes, <code>old_passwords</code>
<b>Variable Name</b>	<code>old_passwords</code>
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
	Type <code>boolean</code>
	Default <code>FALSE</code>

Whether the server should use pre-4.1-style passwords for MySQL user accounts. See [Section B.5.2.4, “Client does not support authentication protocol”](#).

- `one_shot`

This is not a variable, but it can be used when setting some variables. It is described in [Section 12.4.4, “SET Syntax”](#).

- `open_files_limit`

<b>Command-Line Format</b>	-- <code>open-files-limit=#</code>
<b>Config-File Format</b>	<code>open-files-limit</code>
<b>Option Sets Variable</b>	Yes, <code>open_files_limit</code>
<b>Variable Name</b>	<code>open_files_limit</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No
	<b>Permitted Values</b>
	Type <code>numeric</code>
	Default <code>0</code>
	Range <code>0-65535</code>

The number of files that the operating system permits `mysqld` to open. This is the real value permitted by the system and might be different from the value you gave using the `--open-files-limit` option to `mysqld` or `mysqld_safe`. The value is 0 on systems where MySQL can't change the number of open files.

- `optimizer_prune_level`

<b>Command-Line Format</b>	-- <code>optimizer_prune_level[=#]</code>
<b>Config-File Format</b>	<code>optimizer_prune_level</code>
<b>Option Sets Variable</b>	Yes, <code>optimizer_prune_level</code>
<b>Variable Name</b>	<code>optimizer_prune_level</code>
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
	Type <code>boolean</code>
	Default <code>1</code>

Controls the heuristics applied during query optimization to prune less-promising partial plans from the optimizer search space. A value of 0 disables heuristics so that the optimizer performs an exhaustive search. A value of 1 causes the optimizer to prune plans based on the number of rows retrieved by intermediate plans.

- `optimizer_search_depth`

<b>Command-Line Format</b>	--optimizer_search_depth[=#]
<b>Config-File Format</b>	optimizer_search_depth
<b>Option Sets Variable</b>	Yes, optimizer_search_depth
<b>Variable Name</b>	optimizer_search_depth
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
	<b>Type</b> numeric
	<b>Default</b> 62

The maximum depth of search performed by the query optimizer. Values larger than the number of relations in a query result in better query plans, but take longer to generate an execution plan for a query. Values smaller than the number of relations in a query return an execution plan quicker, but the resulting plan may be far from being optimal. If set to 0, the system automatically picks a reasonable value. If set to 63, the optimizer switches to the algorithm used in MySQL 5.0.0 (and previous versions) for performing searches. The value of 63 is deprecated and will be treated as invalid in a future MySQL release.

- [optimizer\\_search](#)

<b>Version Introduced</b>	5.1.34		
<b>Command-Line Format</b>	--optimizer_switch=value		
<b>Config-File Format</b>	optimizer_switch		
	optimizer_switch	5.4.2	
	optimizer_switch	6.0.11	
<b>Option Sets Variable</b>	Yes, optimizer_switch		
<b>Variable Name</b>	optimizer_switch		
<b>Variable Scope</b>	Both		
<b>Dynamic Variable</b>	Yes		

The `optimizer_switch` system variable enables control over optimizer behaviors. The value of this variable is a set of flags, each of which has a value of `on` or `off` to indicate whether the corresponding optimizer behavior is enabled or disabled. This variable has global and session values and can be changed at runtime. The global default can be set at server startup.

To see the current set of optimizer flags, select the variable value:

```
mysql> SELECT @@optimizer_switch\G
***** 1. row *****
@@optimizer_switch: index_merge=on,index_merge_union=on,
 index_merge_sort_union=on,index_merge_intersection=on
```

For more information about the syntax of this variable and the optimizer behaviors that it controls, see [Section 7.4.2, “Controlling Switchable Optimizations”](#).

- [pid\\_file](#)

<b>Command-Line Format</b>	--pid-file=name	
<b>Config-File Format</b>	pid-file	
<b>Option Sets Variable</b>	Yes, pid_file	
<b>Variable Name</b>	pid_file	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	filename

The path name of the process ID (PID) file. This variable can be set with the `--pid-file` option.

- `plugin_dir`

<b>Version Introduced</b>	5.1.2
<b>Command-Line Format</b>	<code>--plugin_dir=name</code>
<b>Config-File Format</b>	<code>plugin_dir</code>
<b>Option Sets Variable</b>	Yes, <code>plugin_dir</code>
<b>Variable Name</b>	<code>plugin_dir</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	
<b>Type</b>	<code>filename</code>
<b>Default</b>	<code>/usr/local/mysql/lib/mysql</code>

The path name of the plugin directory. This variable was added in MySQL 5.1.2.

If the plugin directory is writable by the server, it may be possible for a user to write executable code to a file in the directory using `SELECT ... INTO DUMPFILE`. This can be prevented by making `plugin_dir` read only to the server or by setting `--secure-file-priv` to a directory where `SELECT` writes can be made safely.

- `port`

<b>Command-Line Format</b>	<code>--port=#</code>
	<code>-P</code>
<b>Config-File Format</b>	<code>port</code>
<b>Option Sets Variable</b>	Yes, <code>port</code>
<b>Variable Name</b>	<code>port</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	
<b>Type</b>	<code>numeric</code>
<b>Default</b>	<code>3306</code>

The number of the port on which the server listens for TCP/IP connections. This variable can be set with the `--port` option.

- `preload_buffer_size`

<b>Command-Line Format</b>	<code>--preload_buffer_size=#</code>
<b>Config-File Format</b>	<code>preload_buffer_size</code>
<b>Option Sets Variable</b>	Yes, <code>preload_buffer_size</code>
<b>Variable Name</b>	<code>preload_buffer_size</code>
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	
<b>Type</b>	<code>numeric</code>
<b>Default</b>	<code>32768</code>
<b>Range</b>	<code>1024-1073741824</code>

The size of the buffer that is allocated when preloading indexes.

- `prepared_stmt_count`

The current number of prepared statements. (The maximum number of statements is given by the `max_prepared_stmt_count` system variable.) This variable was added in MySQL 5.1.10. In MySQL 5.1.14, it was converted to the global `Prepared_stmt_count` status variable.

- [profiling](#)

If set to 0 (the default), statement profiling is disabled. If set to 1, statement profiling is enabled and the `SHOW PROFILES` and `SHOW PROFILE` statements provide access to profiling information. See [Section 12.4.5.33, “SHOW PROFILES Syntax”](#). This variable was added in MySQL 5.1.24.

- [profiling\\_history\\_size](#)

The number of statements for which to maintain profiling information if `profiling` is enabled. The default value is 15. The maximum value is 100. Setting the value to 0 effectively disables profiling. See [Section 12.4.5.33, “SHOW PROFILES Syntax”](#). This variable was added in MySQL 5.1.24.

- [protocol\\_version](#)

<b>Variable Name</b>	<code>protocol_version</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No
	<b>Permitted Values</b>
	<b>Type</b> <code>numeric</code>

The version of the client/server protocol used by the MySQL server.

- [pseudo\\_thread\\_id](#)

<b>Variable Name</b>	<code>pseudo_thread_id</code>
<b>Variable Scope</b>	Session
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
	<b>Type</b> <code>numeric</code>

This variable is for internal server use.

- [query\\_alloc\\_block\\_size](#)

<b>Command-Line Format</b>	<code>--query_alloc_block_size=#</code>
<b>Config-File Format</b>	<code>query_alloc_block_size</code>
<b>Option Sets Variable</b>	Yes, <code>query_alloc_block_size</code>
<b>Variable Name</b>	<code>query_alloc_block_size</code>
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
	<b>Platform Bit Size</b> <code>32</code>
	<b>Type</b> <code>numeric</code>
	<b>Default</b> <code>8192</code>
	<b>Range</b> <code>1024-4294967295</code>
	<b>Block Size</b> <code>1024</code>

<b>Permitted Values</b>	
<b>Platform</b>	64
<b>Bit Size</b>	
<b>Type</b>	numeric
<b>Default</b>	8192
<b>Range</b>	1024-18446744073709547520
<b>Block Size</b>	1024

The allocation size of memory blocks that are allocated for objects created during statement parsing and execution. If you have problems with memory fragmentation, it might help to increase this parameter.

- [query\\_cache\\_limit](#)

<b>Command-Line Format</b>	--query_cache_limit=#	
<b>Config-File Format</b>	query_cache_limit	
<b>Option Sets Variable</b>	Yes, query_cache_limit	
<b>Variable Name</b>	query_cache_limit	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
<b>Permitted Values</b>		
<b>Platform</b>	32	
<b>Bit Size</b>		
<b>Type</b>	numeric	
<b>Default</b>	1048576	
<b>Range</b>	0-4294967295	
	<b>Permitted Values</b>	
	<b>Platform</b>	64
	<b>Bit Size</b>	
	<b>Type</b>	numeric
	<b>Default</b>	1048576
	<b>Range</b>	0-18446744073709547520

Don't cache results that are larger than this number of bytes. The default value is 1MB.

- [query\\_cache\\_min\\_res\\_unit](#)

<b>Command-Line Format</b>	--query_cache_min_res_unit=#
<b>Config-File Format</b>	query_cache_min_res_unit
<b>Option Sets Variable</b>	Yes, query_cache_min_res_unit
<b>Variable Name</b>	query_cache_min_res_unit
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	
<b>Platform</b>	32
<b>Bit Size</b>	
<b>Type</b>	numeric
<b>Default</b>	4096
<b>Range</b>	512-4294967295

<b>Permitted Values</b>	
<b>Platform Bit Size</b>	64
<b>Type</b>	numeric
<b>Default</b>	4096
<b>Range</b>	512-18446744073709547520

The minimum size (in bytes) for blocks allocated by the query cache. The default value is 4096 (4KB). Tuning information for this variable is given in [Section 7.6.3.3, “Query Cache Configuration”](#).

- [query\\_cache\\_size](#)

<b>Command-Line Format</b>	--query_cache_size=#
<b>Config-File Format</b>	query_cache_size
<b>Option Sets Variable</b>	Yes, query_cache_size
<b>Variable Name</b>	query_cache_size
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	
<b>Platform Bit Size</b>	32
<b>Type</b>	numeric
<b>Default</b>	0
<b>Range</b>	0-4294967295
	<b>Permitted Values</b>
<b>Platform Bit Size</b>	64
<b>Type</b>	numeric
<b>Default</b>	0
<b>Range</b>	0-18446744073709547520

The amount of memory allocated for caching query results. The default value is 0, which disables the query cache. The permissible values are multiples of 1024; other values are rounded down to the nearest multiple. Note that `query_cache_size` bytes of memory are allocated even if `query_cache_type` is set to 0. See [Section 7.6.3.3, “Query Cache Configuration”](#), for more information.

The query cache needs a minimum size of about 40KB to allocate its structures. (The exact size depends on system architecture.) If you set the value of `query_cache_size` too small, you'll get a warning, as described in [Section 7.6.3.3, “Query Cache Configuration”](#).

- [query\\_cache\\_type](#)

<b>Command-Line Format</b>	--query_cache_type=#
<b>Config-File Format</b>	query_cache_type
<b>Option Sets Variable</b>	Yes, query_cache_type
<b>Variable Name</b>	query_cache_type
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	
<b>Type</b>	enumeration
<b>Default</b>	1
<b>Valid Values</b>	0, 1, 2

Set the query cache type. Setting the `GLOBAL` value sets the type for all clients that connect thereafter. Individual clients can set the `SESSION` value to affect their own use of the query cache. Possible values are shown in the following table.

Option	Description
<code>0</code> or <code>OFF</code>	Don't cache results in or retrieve results from the query cache. Note that this does not deallocate the query cache buffer. To do that, you should set <code>query_cache_size</code> to 0.
<code>1</code> or <code>ON</code>	Cache all cacheable query results except for those that begin with <code>SELECT SQL_NO_CACHE</code> .
<code>2</code> or <code>DEMAND</code>	Cache results only for cacheable queries that begin with <code>SELECT SQL_CACHE</code> .

This variable defaults to `ON`.

Any unique prefix of a valid value may be used to set the value of this variable.

- `query_cache_wlock_invalidate`

<b>Command-Line Format</b>	-- <code>query_cache_wlock_invalidate</code>
<b>Config-File Format</b>	<code>query_cache_wlock_invalidate</code>
<b>Option Sets Variable</b>	Yes, <code>query_cache_wlock_invalidate</code>
<b>Variable Name</b>	<code>query_cache_wlock_invalidate</code>
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
	<b>Type</b> boolean
	<b>Default</b> FALSE

Normally, when one client acquires a `WRITE` lock on a `MyISAM` table, other clients are not blocked from issuing statements that read from the table if the query results are present in the query cache. Setting this variable to 1 causes acquisition of a `WRITE` lock for a table to invalidate any queries in the query cache that refer to the table. This forces other clients that attempt to access the table to wait while the lock is in effect.

- `query_prealloc_size`

<b>Command-Line Format</b>	-- <code>query_prealloc_size=#</code>
<b>Config-File Format</b>	<code>query_prealloc_size</code>
<b>Option Sets Variable</b>	Yes, <code>query_prealloc_size</code>
<b>Variable Name</b>	<code>query_prealloc_size</code>
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
	<b>Platform Bit Size</b> 32
	<b>Type</b> numeric
	<b>Default</b> 8192
	<b>Range</b> 8192-4294967295
	<b>Block Size</b> 1024
	<b>Permitted Values</b>
	<b>Platform Bit Size</b> 64
	<b>Type</b> numeric
	<b>Default</b> 8192
	<b>Range</b> 8192-18446744073709547520
	<b>Block Size</b> 1024

The size of the persistent buffer used for statement parsing and execution. This buffer is not freed between statements. If you are running complex queries, a larger `query_prealloc_size` value might be helpful in improving performance, because it can reduce the need for the server to perform memory allocation during query execution operations.

- `rand_seed1`

The `rand_seed1` and `rand_seed2` variables exist as session variables only, and can be set but not read. Beginning with MySQL 5.1.18, the variables—but not their values—are shown in the output of `SHOW VARIABLES`.

The purpose of these variables is to support replication of the `RAND()` function. For statements that invoke `RAND()`, the master passes two values to the slave, where they are used to seed the random number generator. The slave uses these values to set the session variables `rand_seed1` and `rand_seed2` so that `RAND()` on the slave generates the same value as on the master.

- `rand_seed2`

See the description for `rand_seed1`.

- `range_alloc_block_size`

<b>Command-Line Format</b>	<code>--range_alloc_block_size=#</code>
<b>Config-File Format</b>	<code>range_alloc_block_size</code>
<b>Option Sets Variable</b>	Yes, <code>range_alloc_block_size</code>
<b>Variable Name</b>	<code>range_alloc_block_size</code>
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	
<b>Platform Bit Size</b>	32
<b>Type</b>	numeric
<b>Default</b>	4096
<b>Range</b>	4096-4294967295
<b>Block Size</b>	1024

The size of blocks that are allocated when doing range optimization.

- `read_buffer_size`

<b>Command-Line Format</b>	<code>--read_buffer_size=#</code>
<b>Config-File Format</b>	<code>read_buffer_size</code>
<b>Option Sets Variable</b>	Yes, <code>read_buffer_size</code>
<b>Variable Name</b>	<code>read_buffer_size</code>
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	131072
<b>Range</b>	8200-2147479552

Each thread that does a sequential scan allocates a buffer of this size (in bytes) for each table it scans. If you do many sequential scans, you might want to increase this value, which defaults to 131072. The value of this variable should be a multiple of 4KB. If it is set to a value that is not a multiple of 4KB, its value will be rounded down to the nearest multiple of 4KB.

The maximum permissible setting for `read_buffer_size` is 2GB.

`read_buffer_size` and `read_rnd_buffer_size` are not specific to any storage engine and apply in a general manner for optimization. See [Section 7.9.5, “How MySQL Uses Memory”](#), for example.

- [read\\_only](#)

<b>Command-Line Format</b>	--read_only
<b>Config-File Format</b>	read_only
<b>Option Sets Variable</b>	Yes, <a href="#">read_only</a>
<b>Variable Name</b>	<a href="#">read_only</a>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	0

This variable is off by default. When it is enabled, the server permits no updates except from users that have the [SUPER](#) privilege or (on a slave server) from updates performed by slave threads. In replication setups, it can be useful to enable [read\\_only](#) on slave servers to ensure that slaves accept updates only from the master server and not from clients.

[read\\_only](#) does not apply to [TEMPORARY](#) tables, nor does it prevent the server from inserting rows into the log tables (see [Section 5.2.1, “Selecting General Query and Slow Query Log Output Destinations”](#)). This variable does not prevent the use of [ANALYZE TABLE](#) or [OPTIMIZE TABLE](#) statements because its purpose is to prevent changes to table structure or contents. Analysis and optimization do not qualify as such changes. This means, for example, that consistency checks on read-only slaves can be performed with `mysqlcheck --all-databases --analyze`.

[read\\_only](#) exists only as a [GLOBAL](#) variable, so changes to its value require the [SUPER](#) privilege. Changes to [read\\_only](#) on a master server are not replicated to slave servers. The value can be set on a slave server independent of the setting on the master.

As of MySQL 5.1.15, the following conditions apply:

- If you attempt to enable [read\\_only](#) while you have any explicit locks (acquired with [LOCK TABLES](#)) or have a pending transaction, an error occurs.
- If you attempt to enable [read\\_only](#) while other clients hold explicit table locks or have pending transactions, the attempt blocks until the locks are released and the transactions end. While the attempt to enable [read\\_only](#) is pending, requests by other clients for table locks or to begin transactions also block until [read\\_only](#) has been set.
- [read\\_only](#) can be enabled while you hold a global read lock (acquired with [FLUSH TABLES WITH READ LOCK](#)) because that does not involve table locks.

- [read\\_rnd\\_buffer\\_size](#)

<b>Command-Line Format</b>	--read_rnd_buffer_size=#
<b>Config-File Format</b>	read_rnd_buffer_size
<b>Option Sets Variable</b>	Yes, <a href="#">read_rnd_buffer_size</a>
<b>Variable Name</b>	<a href="#">read_rnd_buffer_size</a>
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	262144
<b>Range</b>	8200-4294967295

When reading rows in sorted order following a key-sorting operation, the rows are read through this buffer to avoid disk seeks. See [Section 7.3.1.11, “ORDER BY Optimization”](#). Setting the variable to a large value can improve [ORDER BY](#) performance by a lot. However, this is a buffer allocated for each client, so you should not set the global variable to a large value. Instead, change the session variable only from within those clients that need to run large queries.

The maximum permissible setting for [read\\_rnd\\_buffer\\_size](#) is 2GB.

[read\\_buffer\\_size](#) and [read\\_rnd\\_buffer\\_size](#) are not specific to any storage engine and apply in a general manner for optimization. See [Section 7.9.5, “How MySQL Uses Memory”](#), for example.

- `relay_log_purge`

<b>Command-Line Format</b>	<code>--relay_log_purge</code>
<b>Config-File Format</b>	<code>relay_log_purge</code>
<b>Option Sets Variable</b>	Yes, <code>relay_log_purge</code>
<b>Variable Name</b>	<code>relay_log_purge</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
	<b>Type</b> <code>boolean</code>
	<b>Default</b> <code>TRUE</code>

Disables or enables automatic purging of relay log files as soon as they are not needed any more. The default value is 1 ([ON](#)).

- `relay_log_space_limit`

<b>Command-Line Format</b>	<code>--relay_log_space_limit=#</code>
<b>Config-File Format</b>	<code>relay_log_space_limit</code>
<b>Option Sets Variable</b>	Yes, <code>relay_log_space_limit</code>
<b>Variable Name</b>	<code>relay_log_space_limit</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No
	<b>Permitted Values</b>
	<b>Platform Bit Size</b> <code>32</code>
	<b>Type</b> <code>numeric</code>
	<b>Default</b> <code>0</code>
	<b>Range</b> <code>0-4294967295</code>
	<b>Permitted Values</b>
	<b>Platform Bit Size</b> <code>64</code>
	<b>Type</b> <code>numeric</code>
	<b>Default</b> <code>0</code>
	<b>Range</b> <code>0-18446744073709547520</code>

The maximum amount of space to use for all relay logs.

- `report_host`

The value of the `--report-host` option. This variable was added in MySQL 5.1.24.

- `report_password`

The value of the `--report-password` option. This variable was added in MySQL 5.1.24.

- `report_port`

The value of the `--report-port` option. This variable was added in MySQL 5.1.24.

- `report_user`

The value of the `--report-user` option. This variable was added in MySQL 5.1.24.

- `secure_auth`

<b>Command-Line Format</b>	<code>--secure-auth</code>
<b>Config-File Format</b>	<code>secure-auth</code>

<b>Option Sets Variable</b>	Yes, <code>secure_auth</code>
<b>Variable Name</b>	<code>secure_auth</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
	<b>Type</b> <code>boolean</code>
	<b>Default</b> <code>FALSE</code>

If the MySQL server has been started with the `--secure-auth` option, it blocks connections from all accounts that have passwords stored in the old (pre-4.1) format. In that case, the value of this variable is `ON`, otherwise it is `OFF`.

You should enable this option if you want to prevent all use of passwords employing the old format (and hence insecure communication over the network).

Server startup fails with an error if this option is enabled and the privilege tables are in pre-4.1 format. See [Section B.5.2.4, “Client does not support authentication protocol”](#).

- `secure_file_priv`

<b>Version Introduced</b>	5.1.17
<b>Command-Line Format</b>	<code>--secure-file-priv=path</code>
<b>Config-File Format</b>	<code>secure-file-priv=path</code>
<b>Option Sets Variable</b>	Yes, <code>secure_file_priv</code>
<b>Variable Name</b>	<code>secure-file-priv</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No
	<b>Permitted Values</b>
	<b>Type</b> <code>string</code>

By default, this variable is empty. If set to the name of a directory, it limits the effect of the `LOAD_FILE()` function and the `LOAD DATA` and `SELECT ... INTO OUTFILE` statements to work only with files in that directory.

This variable was added in MySQL 5.1.17.

- `server_id`

<b>Command-Line Format</b>	<code>--server-id=#</code>
<b>Config-File Format</b>	<code>server-id</code>
<b>Option Sets Variable</b>	Yes, <code>server_id</code>
<b>Variable Name</b>	<code>server_id</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
	<b>Type</b> <code>numeric</code>
	<b>Default</b> <code>0</code>
	<b>Range</b> <code>0-4294967295</code>

The server ID, used in replication to give each master and slave a unique identity. This variable is set by the `--server-id` option. For each server participating in replication, you should pick a positive integer in the range from 1 to  $2^{32} - 1$  to act as that server's ID.

- `shared_memory`

<b>Variable Name</b>	<code>shared_memory</code>
<b>Variable Scope</b>	Global

<b>Dynamic Variable</b>	No
<b>Platform Specific</b>	windows

(Windows only.) Whether the server permits shared-memory connections.

- [shared\\_memory\\_base\\_name](#)

<b>Variable Name</b>	<a href="#">shared_memory_base_name</a>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No
<b>Platform Specific</b>	windows

(Windows only.) The name of shared memory to use for shared-memory connections. This is useful when running multiple MySQL instances on a single physical machine. The default name is [MYSQL](#). The name is case sensitive.

- [skip\\_external\\_locking](#)

This is [OFF](#) if [mysqld](#) uses external locking, [ON](#) if external locking is disabled.

- [skip\\_name\\_resolve](#)

This variable is set from the value of the [--skip-name-resolve](#) option. If it is [ON](#), [mysqld](#) resolves host names when checking client connections. If [OFF](#), [mysqld](#) uses only IP numbers and all [Host](#) column values in the grant tables must be IP numbers or [localhost](#). See [Section 7.9.9, “How MySQL Uses DNS”](#).

This variable was added in MySQL 5.1.46.

- [skip\\_networking](#)

This is [ON](#) if the server permits only local (non-TCP/IP) connections. On Unix, local connections use a Unix socket file. On Windows, local connections use a named pipe or shared memory. On NetWare, only TCP/IP connections are supported, so do not set this variable to [ON](#). This variable can be set to [ON](#) with the [--skip-networking](#) option.

- [skip\\_show\\_database](#)

This prevents people from using the [SHOW DATABASES](#) statement if they do not have the [SHOW DATABASES](#) privilege. This can improve security if you have concerns about users being able to see databases belonging to other users. Its effect depends on the [SHOW DATABASES](#) privilege: If the variable value is [ON](#), the [SHOW DATABASES](#) statement is permitted only to users who have the [SHOW DATABASES](#) privilege, and the statement displays all database names. If the value is [OFF](#), [SHOW DATABASES](#) is permitted to all users, but displays the names of only those databases for which the user has the [SHOW DATABASES](#) or other privilege.

- [slow\\_launch\\_time](#)

<b>Command-Line Format</b>	<a href="#">--slow_launch_time=#</a>
<b>Config-File Format</b>	<a href="#">slow_launch_time</a>
<b>Option Sets Variable</b>	Yes, <a href="#">slow_launch_time</a>
<b>Variable Name</b>	<a href="#">slow_launch_time</a>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
	Type <a href="#">numeric</a>
	Default <a href="#">2</a>

If creating a thread takes longer than this many seconds, the server increments the [Slow\\_launch\\_threads](#) status variable.

- [slow\\_query\\_log](#)

Whether the slow query log is enabled. The value can be 0 (or [OFF](#)) to disable the log or 1 (or [ON](#)) to enable the log. The default value depends on whether the [--slow\\_query\\_log](#) option is given ([--log-slow-queries](#) before MySQL 5.1.29).

The destination for log output is controlled by the `log_output` system variable; if that value is `NONE`, no log entries are written even if the log is enabled. The `slow_query_log` variable was added in MySQL 5.1.12.

- `slow_query_log_file`

<b>Version Introduced</b>	5.1.12
<b>Command-Line Format</b>	<code>--slow-query-log-file=file_name</code>
<b>Config-File Format</b>	<code>slow_query_log_file</code>
<b>Option Sets Variable</b>	Yes, <code>slow_query_log_file</code>
<b>Variable Name</b>	<code>slow_query_log_file</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
	<b>Type</b> <code>filename</code>

The name of the slow query log file. The default value is `host_name-slow.log`, but the initial value can be changed with the `--slow_query_log_file` option (`--log-slow-queries` before MySQL 5.1.29). This variable was added in MySQL 5.1.12.

- `socket`

<b>Command-Line Format</b>	<code>--socket=name</code>
<b>Config-File Format</b>	<code>socket</code>
<b>Option Sets Variable</b>	Yes, <code>socket</code>
<b>Variable Name</b>	<code>socket</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No
	<b>Permitted Values</b>
	<b>Type</b> <code>filename</code>
	<b>Default</b> <code>/tmp/mysql.sock</code>

On Unix platforms, this variable is the name of the socket file that is used for local client connections. The default is `/tmp/mysql.sock`. (For some distribution formats, the directory might be different, such as `/var/lib/mysql` for RPMs.)

On Windows, this variable is the name of the named pipe that is used for local client connections. The default value is `MySQL` (not case sensitive).

- `sort_buffer_size`

<b>Command-Line Format</b>	<code>--sort_buffer_size=#</code>
<b>Config-File Format</b>	<code>sort_buffer_size</code>
<b>Option Sets Variable</b>	Yes, <code>sort_buffer_size</code>
<b>Variable Name</b>	<code>sort_buffer_size</code>
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
	<b>Platform Bit Size</b> <code>32</code>
	<b>Type</b> <code>numeric</code>
	<b>Default</b> <code>2097144</code>
	<b>Max Value</b> <code>4294967295</code>

Permitted Values	
Platform Bit Size	64
Type	numeric
Default	2097144
Max Value	18446744073709547520

Each session that needs to do a sort allocates a buffer of this size. `sort_buffer_size` is not specific to any storage engine and applies in a general manner for optimization. See [Section 7.3.1.11, “ORDER BY Optimization”](#), for example.

If you see many `Sort_merge_passes` per second in `SHOW GLOBAL STATUS` output, you can consider increasing the `sort_buffer_size` value to speed up `ORDER BY` or `GROUP BY` operations that cannot be improved with query optimization or improved indexing. The entire buffer is allocated even if it is not all needed, so setting it larger than required globally will slow down most queries that sort. It is best to increase it as a session setting, and only for the sessions that need a larger size. On Linux, there are thresholds of 256KB and 2MB where larger values may significantly slow down memory allocation, so you should consider staying below one of those values. Experiment to find the best value for your workload. See [Section B.5.4.4, “Where MySQL Stores Temporary Files”](#).

The maximum permissible setting for `sort_buffer_size` is 4GB. As of MySQL 5.1.23, values larger than 4GB are permitted for 64-bit platforms (except 64-bit Windows, for which large values are truncated to 4GB with a warning).

- [`sql\_auto\_is\_null`](#)

If this variable is set to 1 (the default), then after a statement that successfully inserts an automatically generated `AUTO_INCREMENT` value, you can find that value by issuing a statement of the following form:

```
SELECT * FROM tbl_name WHERE auto_col IS NULL
```

If the statement returns a row, the value returned is the same as if you invoked the `LAST_INSERT_ID()` function. For details, including the return value after a multiple-row insert, see [Section 11.14, “Information Functions”](#). If no `AUTO_INCREMENT` value was successfully inserted, the `SELECT` statement returns no row.

The behavior of retrieving an `AUTO_INCREMENT` value by using an `IS NULL` comparison is used by some ODBC programs, such as Access. See [Section 21.1.7.1.1, “Obtaining Auto-Increment Values”](#). This behavior can be disabled by setting `sql_auto_is_null` to 0.

- [`sql\_big\_selects`](#)

If set to 0, MySQL aborts `SELECT` statements that are likely to take a very long time to execute (that is, statements for which the optimizer estimates that the number of examined rows exceeds the value of `max_join_size`). This is useful when an inadvisable `WHERE` statement has been issued. The default value for a new connection is 1, which permits all `SELECT` statements.

If you set the `max_join_size` system variable to a value other than `DEFAULT`, `sql_big_selects` is set to 0.

- [`sql\_buffer\_result`](#)

If set to 1, `sql_buffer_result` forces results from `SELECT` statements to be put into temporary tables. This helps MySQL free the table locks early and can be beneficial in cases where it takes a long time to send results to the client. The default value is 0.

- [`sql\_log\_bin`](#)

If set to 0, no logging is done to the binary log for the client. The client must have the `SUPER` privilege to set this option. The default value is 1.

- [`sql\_log\_off`](#)

If set to 1, no logging is done to the general query log for this client. The client must have the `SUPER` privilege to set this option. The default value is 0.

- [`sql\_log\_update`](#)

This variable is deprecated, and is mapped to `sql_log_bin`. It is removed in MySQL 5.5.

- [sql\\_mode](#)

<b>Command-Line Format</b>	--sql-mode=name
<b>Config-File Format</b>	sql-mode
<b>Option Sets Variable</b>	Yes, <a href="#">sql_mode</a>
<b>Variable Name</b>	<a href="#">sql_mode</a>
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
<b>Type</b>	<a href="#">set</a>
<b>Default</b>	''
<b>Valid Values</b>	ALLOW_INVALID_DATES, ANSI_QUOTES, ER-ROR_FOR_DIVISION_BY_ZERO, HIGH_NOT_PRECEDENCE, IGNORE_SPACE, NO_AUTO_CREATE_USER, NO_AUTO_VALUE_ON_ZERO, NO_BACKSLASH_ESCAPES, NO_DIR_IN_CREATE, NO_ENGINESUBSTITUTION, NO_FIELD_OPTIONS, NO_KEY_OPTIONS, NO_TABLE_OPTIONS, NO_UNSIGNED_SUBTRACTION, NO_ZERO_DATE, NO_ZERO_IN_DATE, ONLY_FULL_GROUP_BY, PAD_CHAR_TO_FULL_LENGTH, PIPES_AS_CONCAT, REAL_AS_FLOAT, STRICT_ALL_TABLES, STRICT_TRANS_TABLES

The current server SQL mode, which can be set dynamically. See [Section 5.1.7, “Server SQL Modes”](#).

- [sql\\_notes](#)

If set to 1 (the default), warnings of [Note](#) level are recorded. If set to 0, [Note](#) warnings are suppressed. [mysqldump](#) includes output to set this variable to 0 so that reloading the dump file does not produce warnings for events that do not affect the integrity of the reload operation.

- [sql\\_quote\\_show\\_create](#)

If set to 1 (the default), the server quotes identifiers for `SHOW CREATE TABLE` and `SHOW CREATE DATABASE` statements. If set to 0, quoting is disabled. This option is enabled by default so that replication works for identifiers that require quoting. See [Section 12.4.5.12, “SHOW CREATE TABLE Syntax”](#), and [Section 12.4.5.8, “SHOW CREATE DATABASE Syntax”](#).

- [sql\\_safe\\_updates](#)

If set to 1, MySQL aborts `UPDATE` or `DELETE` statements that do not use a key in the `WHERE` clause or a `LIMIT` clause. This makes it possible to catch `UPDATE` or `DELETE` statements where keys are not used properly and that would probably change or delete a large number of rows. The default value is 0.

- [sql\\_select\\_limit](#)

<b>Variable Name</b>	<a href="#">sql_select_limit</a>
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
<b>Type</b>	<a href="#">numeric</a>

The maximum number of rows to return from `SELECT` statements. The default value for a new connection is the maximum number of rows that the server permits per table, which depends on the server configuration and may be affected if the server build was configured with `--with-big-tables`. Typical default values are  $(2^{37}) - 1$  or  $(2^{64}) - 1$ . If you have changed the limit, the default value can be restored by assigning a value of `DEFAULT`.

If a `SELECT` has a `LIMIT` clause, the `LIMIT` takes precedence over the value of [sql\\_select\\_limit](#).

[sql\\_select\\_limit](#) does not apply to `SELECT` statements executed within stored routines. It also does not apply to `SELECT` statements that do not produce a result set to be returned to the client. These include `SELECT` statements in subqueries, `CREATE TABLE ... SELECT`, and `INSERT INTO ... SELECT`.

- [sql\\_warnings](#)

This variable controls whether single-row `INSERT` statements produce an information string if warnings occur. The default is 0. Set the value to 1 to produce an information string.

- `ssl_ca`

<b>Version Introduced</b>	5.1.11
<b>Command-Line Format</b>	<code>--ssl-ca=name</code>
<b>Config-File Format</b>	<code>ssl-ca</code>
<b>Option Sets Variable</b>	Yes, <code>ssl_ca</code>
<b>Variable Name</b>	<code>ssl_ca</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No
	<b>Permitted Values</b>
	Type <code>filename</code>

The path to a file with a list of trusted SSL CAs. This variable was added in MySQL 5.1.11.

- `ssl_capath`

<b>Version Introduced</b>	5.1.11
<b>Command-Line Format</b>	<code>--ssl-capath=name</code>
<b>Config-File Format</b>	<code>ssl-capath</code>
<b>Option Sets Variable</b>	Yes, <code>ssl_capath</code>
<b>Variable Name</b>	<code>ssl_capath</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No
	<b>Permitted Values</b>
	Type <code>filename</code>

The path to a directory that contains trusted SSL CA certificates in PEM format. This variable was added in MySQL 5.1.11.

- `ssl_cert`

<b>Version Introduced</b>	5.1.11
<b>Command-Line Format</b>	<code>--ssl-cert=name</code>
<b>Config-File Format</b>	<code>ssl-cert</code>
<b>Option Sets Variable</b>	Yes, <code>ssl_cert</code>
<b>Variable Name</b>	<code>ssl_cert</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No
	<b>Permitted Values</b>
	Type <code>filename</code>

The name of the SSL certificate file to use for establishing a secure connection. This variable was added in MySQL 5.1.11.

- `ssl_cipher`

<b>Version Introduced</b>	5.1.11
<b>Command-Line Format</b>	<code>--ssl-cipher=name</code>
<b>Config-File Format</b>	<code>ssl-cipher</code>
<b>Option Sets Variable</b>	Yes, <code>ssl_cipher</code>
<b>Variable Name</b>	<code>ssl_cipher</code>

<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No
	<b>Permitted Values</b>
	<b>Type</b> <code>filename</code>

A list of permissible ciphers to use for SSL encryption. This variable was added in MySQL 5.1.11.

- `ssl_key`

<b>Version Introduced</b>	5.1.11
<b>Command-Line Format</b>	<code>--ssl-key=name</code>
<b>Config-File Format</b>	<code>ssl-key</code>
<b>Option Sets Variable</b>	Yes, <code>ssl_key</code>
<b>Variable Name</b>	<code>ssl_key</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No
	<b>Permitted Values</b>
	<b>Type</b> <code>string</code>

The name of the SSL key file to use for establishing a secure connection. This variable was added in MySQL 5.1.11.

- `storage_engine`

<b>Variable Name</b>	<code>storage_engine</code>
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes

The default storage engine (table type). To set the storage engine at server startup, use the `--default-storage-engine` option. See [Section 5.1.2, “Server Command Options”](#).

- `sync_frm`

<b>Command-Line Format</b>	<code>--sync-frm</code>
<b>Config-File Format</b>	<code>sync_frm</code>
<b>Option Sets Variable</b>	Yes, <code>sync_frm</code>
<b>Variable Name</b>	<code>sync_frm</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
	<b>Type</b> <code>boolean</code>
	<b>Default</b> <code>TRUE</code>

If this variable is set to 1, when any nontemporary table is created its `.frm` file is synchronized to disk (using `fdatasync()`). This is slower but safer in case of a crash. The default is 1.

- `system_time_zone`

<b>Variable Name</b>	<code>system_time_zone</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No
	<b>Permitted Values</b>
	<b>Type</b> <code>string</code>

The server system time zone. When the server begins executing, it inherits a time zone setting from the machine defaults, possibly modified by the environment of the account used for running the server or the startup script. The value is used to set `system_time_zone`. Typically the time zone is specified by the `TZ` environment variable. It also can be specified using the `--timezone` option of the `mysqld_safe` script.

The `system_time_zone` variable differs from `time_zone`. Although they might have the same value, the latter variable is used to initialize the time zone for each client that connects. See [Section 9.6, “MySQL Server Time Zone Support”](#).

- `table_cache`

<b>Version Removed</b>	5.1.3
<b>Version Deprecated</b>	5.1.3
<b>Command-Line Format</b>	<code>--table_cache=#</code>
<b>Config-File Format</b>	<code>table_cache</code>
<b>Option Sets Variable</b>	Yes, <code>table_cache</code>
<b>Variable Name</b>	<code>table_cache</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes
<b>Deprecated</b>	5.1.3, by <code>table_open_cache</code>
<b>Permitted Values</b>	
<b>Type</b>	<code>numeric</code>
<b>Default</b>	<code>64</code>
<b>Range</b>	<code>1-524288</code>

This is the old name of `table_open_cache` before MySQL 5.1.3. From 5.1.3 on, use `table_open_cache` instead.

- `table_definition_cache`

<b>Version Introduced</b>	5.1.3
<b>Command-Line Format</b>	<code>--table_definition_cache=#</code>
<b>Config-File Format</b>	<code>table_definition_cache</code>
<b>Option Sets Variable</b>	Yes, <code>table_definition_cache</code>
<b>Variable Name</b>	<code>table_definition_cache</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes
<b>Permitted Values (&lt;= 5.1.24)</b>	
<b>Type</b>	<code>numeric</code>
<b>Default</b>	<code>128</code>
<b>Range</b>	<code>1-524288</code>
<b>Permitted Values (&gt;= 5.1.25)</b>	
<b>Type</b>	<code>numeric</code>
<b>Default</b>	<code>256</code>
<b>Range</b>	<code>256-524288</code>

The number of table definitions that can be stored in the definition cache. If you use a large number of tables, you can create a large table definition cache to speed up opening of tables. The table definition cache takes less space and does not use file descriptors, unlike the normal table cache. This variable was added in MySQL 5.1.3. The minimum and default values are 1 and 128 before MySQL 5.1.25. The minimum and default are both 256 as of MySQL 5.1.25.

- `table_lock_wait_timeout`

<b>Command-Line Format</b>	<code>--table_lock_wait_timeout=#</code>
<b>Config-File Format</b>	<code>table_lock_wait_timeout</code>
<b>Option Sets Variable</b>	Yes, <code>table_lock_wait_timeout</code>

<b>Variable Name</b>	<a href="#">table_lock_wait_timeout</a>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
<b>Permitted Values</b>		
<b>Type</b>	<a href="#">numeric</a>	
<b>Default</b>	<a href="#">50</a>	
<b>Range</b>	<a href="#">1-1073741824</a>	

This variable is unused.

- [table\\_open\\_cache](#)

<b>Version Introduced</b>	5.1.3	
<b>Command-Line Format</b>	<code>--table-open-cache=#</code>	
<b>Config-File Format</b>	<a href="#">table_open_cache</a>	
<b>Variable Name</b>	<a href="#">table_open_cache</a>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
<b>Permitted Values</b>		
<b>Type</b>	<a href="#">numeric</a>	
<b>Default</b>	<a href="#">64</a>	
<b>Range</b>	<a href="#">64-524288</a>	

The number of open tables for all threads. Increasing this value increases the number of file descriptors that `mysqld` requires. You can check whether you need to increase the table cache by checking the `Opened_tables` status variable. See [Section 5.1.6, “Server Status Variables”](#). If the value of `Opened_tables` is large and you don't do `FLUSH TABLES` often (which just forces all tables to be closed and reopened), then you should increase the value of the `table_open_cache` variable. For more information about the table cache, see [Section 7.8.2, “How MySQL Opens and Closes Tables”](#). Before MySQL 5.1.3, this variable is called `table_cache`.

- [table\\_type](#)

<b>Variable Name</b>	<a href="#">table_type</a>	
<b>Variable Scope</b>	Both	
<b>Dynamic Variable</b>	Yes	
<b>Deprecated</b>	5.2.5, by <code>storage_engine</code>	
<b>Permitted Values</b>		
<b>Type</b>	<a href="#">enumeration</a>	

This variable is a synonym for `storage_engine`. In MySQL 5.1, `storage_engine` is the preferred name; `table_type` is deprecated and is removed in MySQL 5.5.

- [thread\\_cache\\_size](#)

<b>Command-Line Format</b>	<code>--thread_cache_size=#</code>	
<b>Config-File Format</b>	<a href="#">thread_cache_size</a>	
<b>Option Sets Variable</b>	Yes, <code>thread_cache_size</code>	
<b>Variable Name</b>	<a href="#">thread_cache_size</a>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	

<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	0
<b>Range</b>	0-16384

How many threads the server should cache for reuse. When a client disconnects, the client's threads are put in the cache if there are fewer than `thread_cache_size` threads there. Requests for threads are satisfied by reusing threads taken from the cache if possible, and only when the cache is empty is a new thread created. This variable can be increased to improve performance if you have a lot of new connections. Normally, this does not provide a notable performance improvement if you have a good thread implementation. However, if your server sees hundreds of connections per second you should normally set `thread_cache_size` high enough so that most new connections use cached threads. By examining the difference between the `Connections` and `Threads_created` status variables, you can see how efficient the thread cache is. For details, see [Section 5.1.6, “Server Status Variables”](#).

- [thread\\_concurrency](#)

<b>Command-Line Format</b>	--thread_concurrency=#
<b>Config-File Format</b>	<code>thread_concurrency</code>
<b>Option Sets Variable</b>	Yes, <code>thread_concurrency</code>
<b>Variable Name</b>	<code>thread_concurrency</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	10
<b>Range</b>	1-512

This variable is specific to Solaris systems, for which `mysqld` invokes the `thr_setconcurrency()` with the variable value. This function enables applications to give the threads system a hint about the desired number of threads that should be run at the same time.

- [thread\\_handling](#)

<b>Version Introduced</b>	5.1.17
<b>Command-Line Format</b>	--thread_handling=name
<b>Config-File Format</b>	<code>thread_handling</code>
<b>Option Sets Variable</b>	Yes, <code>thread_handling</code>
<b>Variable Name</b>	<code>thread_handling</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No

The thread-handling model. The permissible values are `no-threads` (the server uses one thread) and `one-thread-per-connection` (the server uses one thread to handle each client connection). `no-threads` is useful for debugging under Linux; see [MySQL Internals: Porting](#). This variable was added in MySQL 5.1.17.

- [thread\\_stack](#)

<b>Command-Line Format</b>	--thread_stack=#
<b>Config-File Format</b>	<code>thread_stack</code>
<b>Option Sets Variable</b>	Yes, <code>thread_stack</code>
<b>Variable Name</b>	<code>thread_stack</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No

<b>Permitted Values</b>	
<b>Platform Bit Size</b>	32
<b>Type</b>	numeric
<b>Default</b>	196608
<b>Range</b>	131072-4294967295
<b>Block Size</b>	1024
<b>Permitted Values</b>	
<b>Platform Bit Size</b>	64
<b>Type</b>	numeric
<b>Default</b>	262144
<b>Range</b>	131072-18446744073709547520
<b>Block Size</b>	1024

The stack size for each thread. Many of the limits detected by the `crash-me` test are dependent on this value. See [Section 7.1.3, “The MySQL Benchmark Suite”](#). The default of 192KB (256KB for 64-bit systems) is large enough for normal operation. If the thread stack size is too small, it limits the complexity of the SQL statements that the server can handle, the recursion depth of stored procedures, and other memory-consuming actions.

- `time_format`

This variable is unused.

- `time_zone`

<b>Command-Line Format</b>	--default_time_zone=string
<b>Config-File Format</b>	default_time_zone
<b>Variable Name</b>	time_zone
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	
<b>Type</b>	string

The current time zone. This variable is used to initialize the time zone for each client that connects. By default, the initial value of this is '`SYSTEM`' (which means, “use the value of `system_time_zone`”). The value can be specified explicitly at server startup with the `--default-time-zone` option. See [Section 9.6, “MySQL Server Time Zone Support”](#).

- `timed_mutexes`

<b>Command-Line Format</b>	--timed_mutexes
<b>Config-File Format</b>	timed_mutexes
<b>Option Sets Variable</b>	Yes, <code>timed_mutexes</code>
<b>Variable Name</b>	timed_mutexes
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	
<b>Type</b>	boolean
<b>Default</b>	OFF

This variable controls whether `InnoDB` mutexes are timed. If this variable is set to 0 or `OFF` (the default), mutex timing is disabled. If the variable is set to 1 or `ON`, mutex timing is enabled. With timing enabled, the `os_wait_times` value in the output

from `SHOW ENGINE INNODB MUTEX` indicates the amount of time (in ms) spent in operating system waits. Otherwise, the value is 0.

- `timestamp = {timestamp_value | DEFAULT}`

Set the time for this client. This is used to get the original timestamp if you use the binary log to restore rows. `timestamp_value` should be a Unix epoch timestamp, not a MySQL timestamp.

`SET timestamp` affects the value returned by `NOW()` but not by `SYSDATE()`. This means that timestamp settings in the binary log have no effect on invocations of `SYSDATE()`. The server can be started with the `--sysdate-is-now` option to cause `SYSDATE()` to be an alias for `NOW()`, in which case `SET timestamp` affects both functions.

- `tmp_table_size`

<b>Command-Line Format</b>	<code>--tmp_table_size=#</code>
<b>Config-File Format</b>	<code>tmp_table_size</code>
<b>Option Sets Variable</b>	Yes, <code>tmp_table_size</code>
<b>Variable Name</b>	<code>tmp_table_size</code>
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	
<b>Type</b>	<code>numeric</code>
<b>Default</b>	<code>system dependent</code>
<b>Range</b>	<code>1024-4294967295</code>

The maximum size of internal in-memory temporary tables. (The actual limit is determined as the minimum of `tmp_table_size` and `max_heap_table_size`.) If an in-memory temporary table exceeds the limit, MySQL automatically converts it to an on-disk MyISAM table. Increase the value of `tmp_table_size` (and `max_heap_table_size` if necessary) if you do many advanced `GROUP BY` queries and you have lots of memory. This variable does not apply to user-created MEMORY tables.

You can compare the number of internal on-disk temporary tables created to the total number of internal temporary tables created by comparing the values of the `Created_tmp_disk_tables` and `Created_tmp_tables` variables.

See also Section 7.8.4, “How MySQL Uses Internal Temporary Tables”.

- `tmpdir`

<b>Command-Line Format</b>	<code>--tmpdir=name</code>
	<code>-t</code>
<b>Config-File Format</b>	<code>tmpdir</code>
<b>Option Sets Variable</b>	Yes, <code>tmpdir</code>
<b>Variable Name</b>	<code>tmpdir</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	
<b>Type</b>	<code>filename</code>

The directory used for temporary files and temporary tables. This variable can be set to a list of several paths that are used in round-robin fashion. Paths should be separated by colon characters (“:”) on Unix and semicolon characters (“;”) on Windows, NetWare, and OS/2.

The multiple-directory feature can be used to spread the load between several physical disks. If the MySQL server is acting as a replication slave, you should not set `tmpdir` to point to a directory on a memory-based file system or to a directory that is cleared when the server host restarts. A replication slave needs some of its temporary files to survive a machine restart so that it can replicate temporary tables or `LOAD DATA INFILE` operations. If files in the temporary file directory are lost when the server restarts, replication fails. You can set the slave’s temporary directory using the `slave_load_tmpdir` variable. In that case, the slave won’t use the general `tmpdir` value and you can set `tmpdir` to a nonpermanent location.

- `transaction_alloc_block_size`

<b>Command-Line Format</b>	<code>--transaction_alloc_block_size=#</code>	
<b>Config-File Format</b>	<code>transaction_alloc_block_size</code>	
<b>Option Sets Variable</b>	Yes, <code>transaction_alloc_block_size</code>	
<b>Variable Name</b>	<code>transaction_alloc_block_size</code>	
<b>Variable Scope</b>	Both	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Platform Bit Size</b>	<code>32</code>
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>8192</code>
	<b>Range</b>	<code>1024-4294967295</code>
	<b>Block Size</b>	<code>1024</code>
	<b>Permitted Values</b>	
	<b>Platform Bit Size</b>	<code>64</code>
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>8192</code>
	<b>Range</b>	<code>1024-18446744073709547520</code>
	<b>Block Size</b>	<code>1024</code>

The amount in bytes by which to increase a per-transaction memory pool which needs memory. See the description of `transaction_prealloc_size`.

- `transaction_allow_batching`

<b>Version Introduced</b>	5.1.23-ndb-6.3.7	
<b>Variable Name</b>	<code>transaction_allow_batching</code>	
<b>Variable Scope</b>	Session	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>FALSE</code>

When set to `1` or `ON`, this variable enables batching of statements within the same transaction. To use this variable, `autocommit` must first be disabled by setting it to `0` or `OFF`; otherwise, setting `transaction_allow_batching` has no effect.

This variable was added in MySQL Cluster NDB 6.3.7, and is currently supported for MySQL Cluster *only*.

- `transaction_prealloc_size`

<b>Command-Line Format</b>	<code>--transaction_prealloc_size=#</code>	
<b>Config-File Format</b>	<code>transaction_prealloc_size</code>	
<b>Option Sets Variable</b>	Yes, <code>transaction_prealloc_size</code>	
<b>Variable Name</b>	<code>transaction_prealloc_size</code>	
<b>Variable Scope</b>	Both	
<b>Dynamic Variable</b>	Yes	

<b>Permitted Values</b>	
<b>Platform Bit Size</b>	32
<b>Type</b>	numeric
<b>Default</b>	4096
<b>Range</b>	1024-4294967295
<b>Block Size</b>	1024

<b>Permitted Values</b>	
<b>Platform Bit Size</b>	64
<b>Type</b>	numeric
<b>Default</b>	4096
<b>Range</b>	1024-18446744073709547520
<b>Block Size</b>	1024

There is a per-transaction memory pool from which various transaction-related allocations take memory. The initial size of the pool in bytes is `transaction_prealloc_size`. For every allocation that cannot be satisfied from the pool because it has insufficient memory available, the pool is increased by `transaction_alloc_block_size` bytes. When the transaction ends, the pool is truncated to `transaction_prealloc_size` bytes.

By making `transaction_prealloc_size` sufficiently large to contain all statements within a single transaction, you can avoid many `malloc()` calls.

- `tx_isolation`

<b>Variable Name</b>	<code>tx_isolation</code>
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	
<b>Type</b>	<code>enumeration</code>
<b>Default</b>	<code>REPEATABLE-READ</code>
<b>Valid Values</b>	<code>READ-UNCOMMITTED, READ-COMMITTED, REPEATABLE-READ, SERIALIZABLE</code>

The default transaction isolation level. Defaults to `REPEATABLE-READ`.

This variable is set by the `SET TRANSACTION ISOLATION LEVEL` statement. See [Section 12.3.6, “SET TRANSACTION Syntax”](#). If you set `tx_isolation` directly to an isolation level name that contains a space, the name should be enclosed within quotation marks, with the space replaced by a dash. For example:

```
SET tx_isolation = 'READ-COMMITTED';
```

Any unique prefix of a valid value may be used to set the value of this variable.

- `unique_checks`

<b>Variable Name</b>	<code>unique_checks</code>
<b>Variable Scope</b>	Session
<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	
<b>Type</b>	<code>boolean</code>
<b>Default</b>	1

If set to 1 (the default), uniqueness checks for secondary indexes in [InnoDB](#) tables are performed. If set to 0, storage engines are permitted to assume that duplicate keys are not present in input data. If you know for certain that your data does not contain uniqueness violations, you can set this to 0 to speed up large table imports to [InnoDB](#).

Note that setting this variable to 0 does not *require* storage engines to ignore duplicate keys. An engine is still permitted to check for them and issue duplicate-key errors if it detects them.

- [updatable\\_views\\_with\\_limit](#)

<b>Command-Line Format</b>	--updatable_views_with_limit=#
<b>Config-File Format</b>	updatable_views_with_limit
<b>Option Sets Variable</b>	Yes, <a href="#">updatable_views_with_limit</a>
<b>Variable Name</b>	<a href="#">updatable_views_with_limit</a>
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	
<b>Type</b>	<a href="#">boolean</a>
<b>Default</b>	<a href="#">1</a>

This variable controls whether updates to a view can be made when the view does not contain all columns of the primary key defined in the underlying table, if the update statement contains a [LIMIT](#) clause. (Such updates often are generated by GUI tools.) An update is an [UPDATE](#) or [DELETE](#) statement. Primary key here means a [PRIMARY KEY](#), or a [UNIQUE](#) index in which no column can contain [NULL](#).

The variable can have two values:

- [1](#) or [YES](#): Issue a warning only (not an error message). This is the default value.
- [0](#) or [NO](#): Prohibit the update.
- [version](#)

The version number for the server.

- [version\\_comment](#)

<b>Variable Name</b>	<a href="#">version_comment</a>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	
<b>Type</b>	<a href="#">string</a>

The [configure](#) script has a [--with-comment](#) option that permits a comment to be specified when building MySQL. This variable contains the value of that comment.

- [version\\_compile\\_machine](#)

<b>Variable Name</b>	<a href="#">version_compile_machine</a>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	
<b>Type</b>	<a href="#">string</a>

The type of machine or architecture on which MySQL was built.

- [version\\_compile\\_os](#)

<b>Variable Name</b>	<a href="#">version_compile_os</a>
----------------------	------------------------------------

<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No
	<b>Permitted Values</b>
	<b>Type</b> <code>string</code>

The type of operating system on which MySQL was built.

- `wait_timeout`

<b>Command-Line Format</b>	<code>--wait_timeout=#</code>
<b>Config-File Format</b>	<code>wait_timeout</code>
<b>Option Sets Variable</b>	Yes, <code>wait_timeout</code>
<b>Variable Name</b>	<code>wait_timeout</code>
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
	<b>Type</b> <code>numeric</code>
	<b>Default</b> <code>28800</code>
	<b>Range</b> <code>1-31536000</code>
	<b>Permitted Values</b>
	<b>Type</b> <code>numeric</code>
	<b>(windows)</b>
	<b>Default</b> <code>28800</code>
	<b>Range</b> <code>1-2147483</code>

The number of seconds the server waits for activity on a noninteractive connection before closing it. This timeout applies only to TCP/IP and Unix socket file connections, not to connections made using named pipes, or shared memory.

On thread startup, the session `wait_timeout` value is initialized from the global `wait_timeout` value or from the global `interactive_timeout` value, depending on the type of client (as defined by the `CLIENT_INTERACTIVE` connect option to `mysql_real_connect()`). See also `interactive_timeout`.

- `warning_count`

The number of errors, warnings, and notes that resulted from the last statement that generated messages. This variable is read only. See [Section 12.4.5.42, “SHOW WARNINGS Syntax”](#).

## 5.1.5. Using System Variables

The MySQL server maintains many system variables that indicate how it is configured. [Section 5.1.4, “Server System Variables”](#), describes the meaning of these variables. Each system variable has a default value. System variables can be set at server startup using options on the command line or in an option file. Most of them can be changed dynamically while the server is running by means of the `SET` statement, which enables you to modify operation of the server without having to stop and restart it. You can refer to system variable values in expressions.

The server maintains two kinds of system variables. Global variables affect the overall operation of the server. Session variables affect its operation for individual client connections. A given system variable can have both a global and a session value. Global and session system variables are related as follows:

- When the server starts, it initializes all global variables to their default values. These defaults can be changed by options specified on the command line or in an option file. (See [Section 4.2.3, “Specifying Program Options”](#).)
- The server also maintains a set of session variables for each client that connects. The client's session variables are initialized at connect time using the current values of the corresponding global variables. For example, the client's SQL mode is controlled by the session `sql_mode` value, which is initialized when the client connects to the value of the global `sql_mode` value.

System variable values can be set globally at server startup by using options on the command line or in an option file. When you use a startup option to set a variable that takes a numeric value, the value can be given with a suffix of **K**, **M**, or **G** (either uppercase or lowercase) to indicate a multiplier of 1024, 1024<sup>2</sup> or 1024<sup>3</sup>; that is, units of kilobytes, megabytes, or gigabytes, respectively. Thus, the following command starts the server with a query cache size of 16 megabytes and a maximum packet size of one gigabyte:

```
mysqld --query_cache_size=16M --max_allowed_packet=1G
```

Within an option file, those variables are set like this:

```
[mysqld]
query_cache_size=16M
max_allowed_packet=1G
```

The lettercase of suffix letters does not matter; **16M** and **16m** are equivalent, as are **1G** and **1g**.

If you want to restrict the maximum value to which a system variable can be set at runtime with the **SET** statement, you can specify this maximum by using an option of the form **--maximum-var\_name=value** at server startup. For example, to prevent the value of **query\_cache\_size** from being increased to more than 32MB at runtime, use the option **--maximum-query\_cache\_size=32M**.

Many system variables are dynamic and can be changed while the server runs by using the **SET** statement. For a list, see [Section 5.1.5.2, “Dynamic System Variables”](#). To change a system variable with **SET**, refer to it as **var\_name**, optionally preceded by a modifier:

- To indicate explicitly that a variable is a global variable, precede its name by **GLOBAL** or **@@global**. The **SUPER** privilege is required to set global variables.
- To indicate explicitly that a variable is a session variable, precede its name by **SESSION**, **@@session**, or **@@**. Setting a session variable requires no special privilege, but a client can change only its own session variables, not those of any other client.
- **LOCAL** and **@@local** are synonyms for **SESSION** and **@@session**.
- If no modifier is present, **SET** changes the session variable.

A **SET** statement can contain multiple variable assignments, separated by commas. If you set several system variables, the most recent **GLOBAL** or **SESSION** modifier in the statement is used for following variables that have no modifier specified.

Examples:

```
SET sort_buffer_size=10000;
SET @@local.sort_buffer_size=10000;
SET GLOBAL sort_buffer_size=1000000, SESSION sort_buffer_size=1000000;
SET @@sort_buffer_size=1000000;
SET @@global.sort_buffer_size=1000000, @@local.sort_buffer_size=1000000;
```

The **@@var\_name** syntax for system variables is supported for compatibility with some other database systems.

If you change a session system variable, the value remains in effect until your session ends or until you change the variable to a different value. The change is not visible to other clients.

If you change a global system variable, the value is remembered and used for new connections until the server restarts. (To make a global system variable setting permanent, you should set it in an option file.) The change is visible to any client that accesses that global variable. However, the change affects the corresponding session variable only for clients that connect after the change. The global variable change does not affect the session variable for any client that is currently connected (not even that of the client that issues the **SET GLOBAL** statement).

To prevent incorrect usage, MySQL produces an error if you use **SET GLOBAL** with a variable that can only be used with **SET SESSION** or if you do not specify **GLOBAL** (or **@@global**) when setting a global variable.

To set a **SESSION** variable to the **GLOBAL** value or a **GLOBAL** value to the compiled-in MySQL default value, use the **DEFAULT** keyword. For example, the following two statements are identical in setting the session value of **max\_join\_size** to the global value:

```
SET max_join_size=DEFAULT;
SET @@session.max_join_size=@global.max_join_size;
```

Not all system variables can be set to **DEFAULT**. In such cases, use of **DEFAULT** results in an error.

You can refer to the values of specific global or session system variables in expressions by using one of the @@-modifiers. For example, you can retrieve values in a `SELECT` statement like this:

```
SELECT @@global.sql_mode, @@session.sql_mode, @@sql_mode;
```

When you refer to a system variable in an expression as `@@var_name` (that is, when you do not specify `@@global.` or `@@session.`), MySQL returns the session value if it exists and the global value otherwise. (This differs from `SET @@var_name = value`, which always refers to the session value.)

### Note

Some variables displayed by `SHOW VARIABLES` may not be available using `SELECT @@var_name` syntax; an `Unknown system variable` occurs. As a workaround in such cases, you can use `SHOW VARIABLES LIKE 'var_name'`.

Suffixes for specifying a value multiplier can be used when setting a variable at server startup, but not to set the value with `SET` at runtime. On the other hand, with `SET` you can assign a variable's value using an expression, which is not true when you set a variable at server startup. For example, the first of the following lines is legal at server startup, but the second is not:

```
shell> mysql --max_allowed_packet=16M
shell> mysql --max_allowed_packet=16*1024*1024
```

Conversely, the second of the following lines is legal at runtime, but the first is not:

```
mysql> SET GLOBAL max_allowed_packet=16M;
mysql> SET GLOBAL max_allowed_packet=16*1024*1024;
```

### Note

Some system variables can be enabled with the `SET` statement by setting them to `ON` or `1`, or disabled by setting them to `OFF` or `0`. However, to set such a variable on the command line or in an option file, you must set it to `1` or `0`; setting it to `ON` or `OFF` will not work. For example, on the command line, `--delay_key_write=1` works but `--delay_key_write=ON` does not.

To display system variable names and values, use the `SHOW VARIABLES` statement:

Variable_name	Value
auto_increment_increment	1
auto_increment_offset	1
automatic_sp_privileges	ON
back_log	50
basedir	/home/mysql/
binlog_cache_size	32768
bulk_insert_buffer_size	8388608
character_set_client	latin1
character_set_connection	latin1
character_set_database	latin1
character_set_results	latin1
character_set_server	latin1
character_set_system	utf8
character_sets_dir	/home/mysql/share/mysql/charsets/
collation_connection	latin1_swedish_ci
collation_database	latin1_swedish_ci
collation_server	latin1_swedish_ci
innodb_additional_mem_pool_size	1048576
innodb_autoextend_increment	8
innodb_buffer_pool_size	8388608
innodb_checksums	ON
innodb_commit_concurrency	0
innodb_concurrency_tickets	500
innodb_data_file_path	ibdata1:10M:autoextend
innodb_data_home_dir	
version	5.1.6-alpha-log
version_comment	Source distribution
version_compile_machine	i686
version_compile_os	suse-linux
wait_timeout	28800

With a `LIKE` clause, the statement displays only those variables that match the pattern. To obtain a specific variable name, use a `LIKE` clause as shown:

```
SHOW VARIABLES LIKE 'max_join_size';
SHOW SESSION VARIABLES LIKE 'max_join_size';
```

To get a list of variables whose name match a pattern, use the “%” wildcard character in a `LIKE` clause:

```
SHOW VARIABLES LIKE '%size%';
SHOW GLOBAL VARIABLES LIKE '%size%';
```

Wildcard characters can be used in any position within the pattern to be matched. Strictly speaking, because “\_” is a wildcard that matches any single character, you should escape it as “\\_” to match it literally. In practice, this is rarely necessary.

For `SHOW VARIABLES`, if you specify neither `GLOBAL` nor `SESSION`, MySQL returns `SESSION` values.

The reason for requiring the `GLOBAL` keyword when setting `GLOBAL`-only variables but not when retrieving them is to prevent problems in the future. If we were to remove a `SESSION` variable that has the same name as a `GLOBAL` variable, a client with the `SUPER` privilege might accidentally change the `GLOBAL` variable rather than just the `SESSION` variable for its own connection. If we add a `SESSION` variable with the same name as a `GLOBAL` variable, a client that intends to change the `GLOBAL` variable might find only its own `SESSION` variable changed.

### 5.1.5.1. Structured System Variables

A structured variable differs from a regular system variable in two respects:

- Its value is a structure with components that specify server parameters considered to be closely related.
- There might be several instances of a given type of structured variable. Each one has a different name and refers to a different resource maintained by the server.

MySQL 5.1 supports one structured variable type, which specifies parameters governing the operation of key caches. A key cache structured variable has these components:

- `key_buffer_size`
- `key_cache_block_size`
- `key_cache_division_limit`
- `key_cache_age_threshold`

This section describes the syntax for referring to structured variables. Key cache variables are used for syntax examples, but specific details about how key caches operate are found elsewhere, in [Section 7.6.1, “The MyISAM Key Cache”](#).

To refer to a component of a structured variable instance, you can use a compound name in `in-instance_name.component_name` format. Examples:

```
hot_cache.key_buffer_size
hot_cache.key_cache_block_size
cold_cache.key_cache_block_size
```

For each structured system variable, an instance with the name of `default` is always predefined. If you refer to a component of a structured variable without any instance name, the `default` instance is used. Thus, `default.key_buffer_size` and `key_buffer_size` both refer to the same system variable.

Structured variable instances and components follow these naming rules:

- For a given type of structured variable, each instance must have a name that is unique *within* variables of that type. However, instance names need not be unique *across* structured variable types. For example, each structured variable has an instance named `default`, so `default` is not unique across variable types.
- The names of the components of each structured variable type must be unique across all system variable names. If this were not true (that is, if two different types of structured variables could share component member names), it would not be clear which default structured variable to use for references to member names that are not qualified by an instance name.
- If a structured variable instance name is not legal as an unquoted identifier, refer to it as a quoted identifier using backticks. For example, `hot-cache` is not legal, but ``hot-cache`` is.
- `global`, `session`, and `local` are not legal instance names. This avoids a conflict with notation such as `@@global.var_name` for referring to nonstructured system variables.

Currently, the first two rules have no possibility of being violated because the only structured variable type is the one for key caches. These rules will assume greater significance if some other type of structured variable is created in the future.

With one exception, you can refer to structured variable components using compound names in any context where simple variable names can occur. For example, you can assign a value to a structured variable using a command-line option:

```
shell> mysqld --hot_cache.key_buffer_size=64K
```

In an option file, use this syntax:

```
[mysqld]
hot_cache.key_buffer_size=64K
```

If you start the server with this option, it creates a key cache named `hot_cache` with a size of 64KB in addition to the default key cache that has a default size of 8MB.

Suppose that you start the server as follows:

```
shell> mysqld --key_buffer_size=256K \
 --extra_cache.key_buffer_size=128K \
 --extra_cache.key_cache_block_size=2048
```

In this case, the server sets the size of the default key cache to 256KB. (You could also have written `--default.key_buffer_size=256K`.) In addition, the server creates a second key cache named `extra_cache` that has a size of 128KB, with the size of block buffers for caching table index blocks set to 2048 bytes.

The following example starts the server with three different key caches having sizes in a 3:1:1 ratio:

```
shell> mysqld --key_buffer_size=6M \
 --hot_cache.key_buffer_size=2M \
 --cold_cache.key_buffer_size=2M
```

Structured variable values may be set and retrieved at runtime as well. For example, to set a key cache named `hot_cache` to a size of 10MB, use either of these statements:

```
mysql> SET GLOBAL hot_cache.key_buffer_size = 10*1024*1024;
mysql> SET @@global.hot_cache.key_buffer_size = 10*1024*1024;
```

To retrieve the cache size, do this:

```
mysql> SELECT @@global.hot_cache.key_buffer_size;
```

However, the following statement does not work. The variable is not interpreted as a compound name, but as a simple string for a `LIKE` pattern-matching operation:

```
mysql> SHOW GLOBAL VARIABLES LIKE 'hot_cache.key_buffer_size';
```

This is the exception to being able to use structured variable names anywhere a simple variable name may occur.

### 5.1.5.2. Dynamic System Variables

Many server system variables are dynamic and can be set at runtime using `SET GLOBAL` or `SET SESSION`. You can also obtain their values using `SELECT`. See [Section 5.1.5, “Using System Variables”](#).

The following table shows the full list of all dynamic system variables. The last column indicates for each variable whether `GLOB`  
`AL` or `SESSION` (or both) apply. The table also lists session options that can be set with the `SET` statement. [Section 5.1.4, “Server System Variables”](#), discusses these options.

Variables that have a type of “string” take a string value. Variables that have a type of “numeric” take a numeric value. Variables that have a type of “boolean” can be set to 0, 1, `ON` or `OFF`. (If you set them on the command line or in an option file, use the numeric values.) Variables that are marked as “enumeration” normally should be set to one of the available values for the variable, but can also be set to the number that corresponds to the desired enumeration value. For enumerated system variables, the first enumeration value corresponds to 0. This differs from `ENUM` columns, for which the first enumeration value corresponds to 1.

**Table 5.3. Dynamic Variable Summary**

Variable Name	Variable Type	Variable Scope

## 5.1.6. Server Status Variables

The server maintains many status variables that provide information about its operation. You can view these variables and their values by using the `SHOW [GLOBAL | SESSION] STATUS` statement (see [Section 12.4.5.37, “SHOW STATUS Syntax”](#)). The optional `GLOBAL` keyword aggregates the values over all connections, and `SESSION` shows the values for the current connection.

```
mysql> SHOW GLOBAL STATUS;
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Aborted_clients | 0 |
| Aborted_connects | 0 |
| Bytes_received | 155372598 |
| Bytes_sent | 1176560426 |
...
| Connections | 30023 |
| Created_tmp_disk_tables | 0 |
| Created_tmp_files | 3 |
| Created_tmp_tables | 2 |
...
| Threads_created | 217 |
| Threads_running | 88 |
| Uptime | 1389872 |
+-----+-----+
```

The following table lists all available server status variables:

**Table 5.4. Status Variable Summary**

Many status variables are reset to 0 by the `FLUSH STATUS` statement.

The status variables have the following meanings. Variables with no version indicated were already present prior to MySQL 5.1. For information regarding their implementation history, see *MySQL 5.0 Reference Manual*.

- [`Aborted\_clients`](#)

The number of connections that were aborted because the client died without closing the connection properly. See [Section B.5.2.11, “Communication Errors and Aborted Connections”](#).

- [`Aborted\_connects`](#)

The number of failed attempts to connect to the MySQL server. See [Section B.5.2.11, “Communication Errors and Aborted Connections”](#).

- [`Binlog\_cache\_disk\_use`](#)

The number of transactions that used the temporary binary log cache but that exceeded the value of `binlog_cache_size` and used a temporary file to store statements from the transaction.

- [`Binlog\_cache\_use`](#)

The number of transactions that used the temporary binary log cache.

- [`Bytes\_received`](#)

The number of bytes received from all clients.

- [`Bytes\_sent`](#)

The number of bytes sent to all clients.

- [`Com\_xxx`](#)

The `Com_xxx` statement counter variables indicate the number of times each `xxx` statement has been executed. There is one status variable for each type of statement. For example, `Com_delete` and `Com_insert` count `DELETE` and `INSERT` statements, respectively. However, if a query result is returned from query cache, the server increments the `Qcache_hits` status variable, not `Com_select`. See [Section 7.6.3.4, “Query Cache Status and Maintenance”](#).

All of the `Com_stmt_xxx` variables are increased even if a prepared statement argument is unknown or an error occurred during execution. In other words, their values correspond to the number of requests issued, not to the number of requests successfully completed.

The `Com_stmt_xxx` status variables are as follows:

- [`Com\_stmt\_prepare`](#)
- [`Com\_stmt\_execute`](#)

- [Com\\_stmt\\_fetch](#)
- [Com\\_stmt\\_send\\_long\\_data](#)
- [Com\\_stmt\\_reset](#)
- [Com\\_stmt\\_close](#)

Those variables stand for prepared statement commands. Their names refer to the `COM_XXX` command set used in the network layer. In other words, their values increase whenever prepared statement API calls such as `mysql_stmt_prepare()`, `mysql_stmt_execute()`, and so forth are executed. However, `Com_stmt_prepare`, `Com_stmt_execute` and `Com_stmt_close` also increase for `PREPARE`, `EXECUTE`, or `DEALLOCATE PREPARE`, respectively. Additionally, the values of the older statement counter variables `Com_prepare_sql`, `Com_execute_sql`, and `Com_dealloc_sql` increase for the `PREPARE`, `EXECUTE`, and `DEALLOCATE PREPARE` statements. `Com_stmt_fetch` stands for the total number of network round-trips issued when fetching from cursors.

`Com_stmt_reprepare` indicated the number of times statements were automatically reprepared by the server after metadata changes to tables or views referred to by the statement. This variable was added in MySQL 5.1.25. A reprepare operation increments `Com_stmt_reprepare` is incremented, and also `Com_stmt_prepare`.

- [Compression](#)

Whether the client connection uses compression in the client/server protocol. Added in MySQL 5.1.2.

- [Connections](#)

The number of connection attempts (successful or not) to the MySQL server.

- [Created\\_tmp\\_disk\\_tables](#)

The number of internal on-disk temporary tables created by the server while executing statements.

If an internal temporary table is created initially as an in-memory table but becomes too large, MySQL automatically converts it to an on-disk table. The maximum size for in-memory temporary tables is the minimum of the `tmp_table_size` and `max_heap_table_size` values. If `Created_tmp_disk_tables` is large, you may want to increase the `tmp_table_size` or `max_heap_table_size` value to lessen the likelihood that internal temporary tables in memory will be converted to on-disk tables.

You can compare the number of internal on-disk temporary tables created to the total number of internal temporary tables created by comparing the values of the `Created_tmp_disk_tables` and `Created_tmp_tables` variables.

See also [Section 7.8.4, “How MySQL Uses Internal Temporary Tables”](#).

- [Created\\_tmp\\_files](#)

How many temporary files `mysqld` has created.

- [Created\\_tmp\\_tables](#)

The number of internal temporary tables created by the server while executing statements.

You can compare the number of internal on-disk temporary tables created to the total number of internal temporary tables created by comparing the values of the `Created_tmp_disk_tables` and `Created_tmp_tables` variables.

See also [Section 7.8.4, “How MySQL Uses Internal Temporary Tables”](#).

Each invocation of the `SHOW STATUS` statement uses an internal temporary table and increments the global `Created_tmp_tables` value.

- [Delayed\\_errors](#)

The number of rows written with `INSERT DELAYED` for which some error occurred (probably `duplicate key`).

- [Delayed\\_insert\\_threads](#)

The number of `INSERT DELAYED` handler threads in use.

- [Delayed\\_writes](#)

The number of `INSERT DELAYED` rows written.

- [Flush\\_commands](#)

The number of executed `FLUSH` statements.

- [Handler\\_commit](#)

The number of internal `COMMIT` statements.

- [Handler\\_delete](#)

The number of times that rows have been deleted from tables.

- [Handler\\_prepare](#)

A counter for the prepare phase of two-phase commit operations.

- [Handler\\_read\\_first](#)

The number of times the first entry in an index was read. If this value is high, it suggests that the server is doing a lot of full index scans; for example, `SELECT coll FROM foo`, assuming that `coll` is indexed.

- [Handler\\_read\\_key](#)

The number of requests to read a row based on a key. If this value is high, it is a good indication that your tables are properly indexed for your queries.

- [Handler\\_read\\_next](#)

The number of requests to read the next row in key order. This value is incremented if you are querying an index column with a range constraint or if you are doing an index scan.

- [Handler\\_read\\_prev](#)

The number of requests to read the previous row in key order. This read method is mainly used to optimize `ORDER BY ... DESC`.

- [Handler\\_read\\_rnd](#)

The number of requests to read a row based on a fixed position. This value is high if you are doing a lot of queries that require sorting of the result. You probably have a lot of queries that require MySQL to scan entire tables or you have joins that don't use keys properly.

- [Handler\\_read\\_rnd\\_next](#)

The number of requests to read the next row in the data file. This value is high if you are doing a lot of table scans. Generally this suggests that your tables are not properly indexed or that your queries are not written to take advantage of the indexes you have.

- [Handler\\_rollback](#)

The number of requests for a storage engine to perform a rollback operation.

- [Handler\\_savepoint](#)

The number of requests for a storage engine to place a savepoint.

- [Handler\\_savepoint\\_rollback](#)

The number of requests for a storage engine to roll back to a savepoint.

- [Handler\\_update](#)

The number of requests to update a row in a table.

- [Handler\\_write](#)

The number of requests to insert a row in a table.

- [Innodb\\_buffer\\_pool\\_pages\\_data](#)

The number of pages containing data (dirty or clean).

- [Innodb\\_buffer\\_pool\\_pages\\_dirty](#)  
The number of pages currently dirty.
- [Innodb\\_buffer\\_pool\\_pages\\_flushed](#)  
The number of buffer pool page-flush requests.
- [Innodb\\_buffer\\_pool\\_pages\\_free](#)  
The number of free pages.
- [Innodb\\_buffer\\_pool\\_pages\\_latched](#)

The number of latched pages in [InnoDB](#) buffer pool. These are pages currently being read or written or that cannot be flushed or removed for some other reason. Calculation of this variable is expensive, so as of MySQL 5.1.28, it is available only when the [UNIV\\_DEBUG](#) system is defined at server build time.

- [Innodb\\_buffer\\_pool\\_pages\\_misc](#)

The number of pages that are busy because they have been allocated for administrative overhead such as row locks or the adaptive hash index. This value can also be calculated as [Innodb\\_buffer\\_pool\\_pages\\_total](#) – [Innodb\\_buffer\\_pool\\_pages\\_free](#) – [Innodb\\_buffer\\_pool\\_pages\\_data](#).

- [Innodb\\_buffer\\_pool\\_pages\\_total](#)

The total size of the buffer pool, in pages.

- [Innodb\\_buffer\\_pool\\_read\\_ahead](#)

([InnoDB Plugin](#) only) The number of pages read into the [InnoDB](#) buffer pool by the read-ahead background thread.

This variable was added in MySQL 5.1.41.

- [Innodb\\_buffer\\_pool\\_read\\_ahead\\_evicted](#)

([InnoDB Plugin](#) only) The number of pages read into the [InnoDB](#) buffer pool by the read-ahead background thread that were subsequently evicted without having been accessed by queries.

This variable was added in MySQL 5.1.41.

- [Innodb\\_buffer\\_pool\\_read\\_ahead\\_rnd](#)

The number of “random” read-aheads initiated by [InnoDB](#). This happens when a query scans a large portion of a table but in random order.

For [InnoDB Plugin](#), this variable was removed in MySQL 5.1.41.

- [Innodb\\_buffer\\_pool\\_read\\_ahead\\_seq](#)

The number of sequential read-aheads initiated by [InnoDB](#). This happens when [InnoDB](#) does a sequential full table scan.

For [InnoDB Plugin](#), this variable was removed in MySQL 5.1.41.

- [Innodb\\_buffer\\_pool\\_read\\_requests](#)

The number of logical read requests [InnoDB](#) has done.

- [Innodb\\_buffer\\_pool\\_reads](#)

The number of logical reads that [InnoDB](#) could not satisfy from the buffer pool, and had to read directly from the disk.

- [Innodb\\_buffer\\_pool\\_wait\\_free](#)

Normally, writes to the [InnoDB](#) buffer pool happen in the background. However, if it is necessary to read or create a page and no clean pages are available, it is also necessary to wait for pages to be flushed first. This counter counts instances of these waits. If the buffer pool size has been set properly, this value should be small.

- [Innodb\\_buffer\\_pool\\_write\\_requests](#)

The number writes done to the [InnoDB](#) buffer pool.

- [`Innodb\_data\_fsyncs`](#)

The number of `fsync()` operations so far.

- [`Innodb\_data\_pending\_fsyncs`](#)

The current number of pending `fsync()` operations.

- [`Innodb\_data\_pending\_reads`](#)

The current number of pending reads.

- [`Innodb\_data\_pending\_writes`](#)

The current number of pending writes.

- [`Innodb\_data\_read`](#)

The amount of data read since the server was started.

- [`Innodb\_data\_reads`](#)

The total number of data reads.

- [`Innodb\_data\_writes`](#)

The total number of data writes.

- [`Innodb\_data\_written`](#)

The amount of data written so far, in bytes.

- [`Innodb dblwr\_pages\_written`](#)

The number of pages that have been written for doublewrite operations. See [Section 13.6.11.1, “InnoDB Disk I/O”](#).

- [`Innodb dblwr\_writes`](#)

The number of doublewrite operations that have been performed. See [Section 13.6.11.1, “InnoDB Disk I/O”](#).

- [`Innodb\_have\_atomic\_builtins`](#)

([InnoDB Plugin](#) only) Indicates whether the server was built with atomic instructions. This variable was added in in MySQL 5.1.38.

- [`Innodb\_log\_waits`](#)

The number of times that the log buffer was too small and a wait was required for it to be flushed before continuing.

- [`Innodb\_log\_write\_requests`](#)

The number of log write requests.

- [`Innodb\_log\_writes`](#)

The number of physical writes to the log file.

- [`Innodb\_os\_log\_fsyncs`](#)

The number of `fsync()` writes done to the log file.

- [`Innodb\_os\_log\_pending\_fsyncs`](#)

The number of pending log file `fsync()` operations.

- [`Innodb\_os\_log\_pending\_writes`](#)

The number of pending log file writes.

- [`Innodb\_os\_log\_written`](#)

The number of bytes written to the log file.

- [Innodb\\_page\\_size](#)

The compiled-in [InnoDB](#) page size (default 16KB). Many values are counted in pages; the page size enables them to be easily converted to bytes.

- [Innodb\\_pages\\_created](#)

The number of pages created.

- [Innodb\\_pages\\_read](#)

The number of pages read.

- [Innodb\\_pages\\_written](#)

The number of pages written.

- [Innodb\\_row\\_lock\\_current\\_waits](#)

The number of row locks currently being waited for.

- [Innodb\\_row\\_lock\\_time](#)

The total time spent in acquiring row locks, in milliseconds.

- [Innodb\\_row\\_lock\\_time\\_avg](#)

The average time to acquire a row lock, in milliseconds.

- [Innodb\\_row\\_lock\\_time\\_max](#)

The maximum time to acquire a row lock, in milliseconds.

- [Innodb\\_row\\_lock\\_waits](#)

The number of times a row lock had to be waited for.

- [Innodb\\_rows\\_deleted](#)

The number of rows deleted from [InnoDB](#) tables.

- [Innodb\\_rows\\_inserted](#)

The number of rows inserted into [InnoDB](#) tables.

- [Innodb\\_rows\\_read](#)

The number of rows read from [InnoDB](#) tables.

- [Innodb\\_rows\\_updated](#)

The number of rows updated in [InnoDB](#) tables.

- [Key\\_blocks\\_not\\_flushed](#)

The number of key blocks in the key cache that have changed but have not yet been flushed to disk.

- [Key\\_blocks\\_unused](#)

The number of unused blocks in the key cache. You can use this value to determine how much of the key cache is in use; see the discussion of [key\\_buffer\\_size](#) in [Section 5.1.4, “Server System Variables”](#).

- [Key\\_blocks\\_used](#)

The number of used blocks in the key cache. This value is a high-water mark that indicates the maximum number of blocks that have ever been in use at one time.

- [Key\\_read\\_requests](#)

The number of requests to read a key block from the cache.

- [Key\\_reads](#)

The number of physical reads of a key block from disk. If `Key_reads` is large, then your `key_buffer_size` value is probably too small. The cache miss rate can be calculated as `Key_reads/Key_read_requests`.

- `Key_write_requests`

The number of requests to write a key block to the cache.

- `Key_writes`

The number of physical writes of a key block to disk.

- `Last_query_cost`

The total cost of the last compiled query as computed by the query optimizer. This is useful for comparing the cost of different query plans for the same query. The default value of 0 means that no query has been compiled yet. The default value is 0. `Last_query_cost` has session scope.

The `Last_query_cost` value can be computed accurately only for simple “flat” queries, not complex queries such as those with subqueries or `UNION`. For the latter, the value is set to 0.

- `Max_used_connections`

The maximum number of connections that have been in use simultaneously since the server started.

- `Not_flushed_delayed_rows`

The number of rows waiting to be written in `INSERT DELAY` queues.

- `Open_files`

The number of files that are open. This count includes regular files opened by the server. It does not include other types of files such as sockets or pipes. Also, the count does not include files that storage engines open using their own internal functions rather than asking the server level to do so.

- `Open_streams`

The number of streams that are open (used mainly for logging).

- `Open_table_definitions`

The number of cached `.frm` files. This variable was added in MySQL 5.1.3.

- `Open_tables`

The number of tables that are open.

- `Opened_files`

The number of files that have been opened with `my_open()` (a `mysys` library function). Parts of the server that open files without using this function do not increment the count. This variable was added in MySQL 5.1.21.

- `Opened_table_definitions`

The number of `.frm` files that have been cached. This variable was added in MySQL 5.1.24.

- `Opened_tables`

The number of tables that have been opened. If `Opened_tables` is big, your `table_open_cache` value is probably too small.

- `Prepared_stmt_count`

The current number of prepared statements. (The maximum number of statements is given by the `max_prepared_stmt_count` system variable.) This variable was added in MySQL 5.1.14.

- `Qcache_free_blocks`

The number of free memory blocks in the query cache.

- `Qcache_free_memory`

- The amount of free memory for the query cache.
- [Qcache\\_hits](#)  
The number of query cache hits.
- [Qcache\\_inserts](#)  
The number of queries added to the query cache.
- [Qcache\\_lowmem\\_prunes](#)  
The number of queries that were deleted from the query cache because of low memory.
- [Qcache\\_not\\_cached](#)  
The number of noncached queries (not cacheable, or not cached due to the `query_cache_type` setting).
- [Qcache\\_queries\\_in\\_cache](#)  
The number of queries registered in the query cache.
- [Qcache\\_total\\_blocks](#)  
The total number of blocks in the query cache.
- [Queries](#)  
The number of statements executed by the server. This variable includes statements executed within stored programs, unlike the [Questions](#) variable. It does not count `COM_PING` or `COM_STATISTICS` commands. This variable was added in MySQL 5.1.31.
- [Questions](#)  
The number of statements executed by the server. As of MySQL 5.1.31, this includes only statements sent to the server by clients and no longer includes statements executed within stored programs, unlike the [Queries](#) variable. This variable does not count `COM_PING`, `COM_STATISTICS`, `COM_STMT_PREPARE`, `COM_STMT_CLOSE`, or `COM_STMT_RESET` commands.
- [Rpl\\_status](#)  
The status of fail-safe replication (not implemented). This variable is unused and is removed in MySQL 5.6.
- [Select\\_full\\_join](#)  
The number of joins that perform table scans because they do not use indexes. If this value is not 0, you should carefully check the indexes of your tables.
- [Select\\_full\\_range\\_join](#)  
The number of joins that used a range search on a reference table.
- [Select\\_range](#)  
The number of joins that used ranges on the first table. This is normally not a critical issue even if the value is quite large.
- [Select\\_range\\_check](#)  
The number of joins without keys that check for key usage after each row. If this is not 0, you should carefully check the indexes of your tables.
- [Select\\_scan](#)  
The number of joins that did a full scan of the first table.
- [Slave\\_open\\_temp\\_tables](#)  
The number of temporary tables that the slave SQL thread currently has open. If the value is greater than zero, it is not safe to shut down the slave; see [Section 16.4.1.20, “Replication and Temporary Tables”](#).
- [Slave\\_retried\\_transactions](#)

The total number of times since startup that the replication slave SQL thread has retried transactions.

- `Slave_running`

This is `ON` if this server is a replication slave that is connected to a replication master, and both the I/O and SQL threads are running; otherwise, it is `OFF`.

- `Slow_launch_threads`

The number of threads that have taken more than `slow_launch_time` seconds to create.

- `Slow_queries`

The number of queries that have taken more than `long_query_time` seconds. See [Section 5.2.5, “The Slow Query Log”](#).

- `Sort_merge_passes`

The number of merge passes that the sort algorithm has had to do. If this value is large, you should consider increasing the value of the `sort_buffer_size` system variable.

- `Sort_range`

The number of sorts that were done using ranges.

- `Sort_rows`

The number of sorted rows.

- `Sort_scan`

The number of sorts that were done by scanning the table.

- `Ssl_accept_renegotiates`

The number of negotiates needed to establish the connection.

- `Ssl_accepts`

The number of accepted SSL connections.

- `Ssl_callback_cache_hits`

The number of callback cache hits.

- `Ssl_cipher`

The current SSL cipher (empty for non-SSL connections).

- `Ssl_cipher_list`

The list of possible SSL ciphers.

- `Ssl_client_connects`

The number of SSL connection attempts to an SSL-enabled master.

- `Ssl_connect_renegotiates`

The number of negotiates needed to establish the connection to an SSL-enabled master.

- `Ssl_ctx_verify_depth`

The SSL context verification depth (how many certificates in the chain are tested).

- `Ssl_ctx_verify_mode`

The SSL context verification mode.

- `Ssl_default_timeout`

The default SSL timeout.

- [`Ssl\_finished\_accepts`](#)

The number of successful SSL connections to the server.

- [`Ssl\_finished\_connects`](#)

The number of successful slave connections to an SSL-enabled master.

- [`Ssl\_session\_cache\_hits`](#)

The number of SSL session cache hits.

- [`Ssl\_session\_cache\_misses`](#)

The number of SSL session cache misses.

- [`Ssl\_session\_cache\_mode`](#)

The SSL session cache mode.

- [`Ssl\_session\_cache\_overflows`](#)

The number of SSL session cache overflows.

- [`Ssl\_session\_cache\_size`](#)

The SSL session cache size.

- [`Ssl\_session\_cache\_timeouts`](#)

The number of SSL session cache timeouts.

- [`Ssl\_sessions\_reused`](#)

How many SSL connections were reused from the cache.

- [`Ssl\_used\_session\_cache\_entries`](#)

How many SSL session cache entries were used.

- [`Ssl\_verify\_depth`](#)

The verification depth for replication SSL connections.

- [`Ssl\_verify\_mode`](#)

The verification mode for replication SSL connections.

- [`Ssl\_version`](#)

The SSL version number.

- [`Table\_locks\_immediate`](#)

The number of times that a request for a table lock could be granted immediately.

- [`Table\_locks\_waited`](#)

The number of times that a request for a table lock could not be granted immediately and a wait was needed. If this is high and you have performance problems, you should first optimize your queries, and then either split your table or tables or use replication.

- [`Tc\_log\_max\_pages\_used`](#)

For the memory-mapped implementation of the log that is used by `mysqld` when it acts as the transaction coordinator for recovery of internal XA transactions, this variable indicates the largest number of pages used for the log since the server started. If the product of `Tc_log_max_pages_used` and `Tc_log_page_size` is always significantly less than the log size, the size is larger than necessary and can be reduced. (The size is set by the `--log-tc-size` option. Currently, this variable is unused: It is unneeded for binary log-based recovery, and the memory-mapped recovery log method is not used unless the number of storage engines capable of two-phase commit is greater than one. (`InnoDB` is the only applicable engine.)

- [`Tc\_log\_page\_size`](#)

The page size used for the memory-mapped implementation of the XA recovery log. The default value is determined using `getpagesize()`. Currently, this variable is unused for the same reasons as described for `Tc_log_max_pages_used`.

- **`Tc_log_page_waits`**

For the memory-mapped implementation of the recovery log, this variable increments each time the server was not able to commit a transaction and had to wait for a free page in the log. If this value is large, you might want to increase the log size (with the `--log-tc-size` option). For binary log-based recovery, this variable increments each time the binary log cannot be closed because there are two-phase commits in progress. (The close operation waits until all such transactions are finished.)

- **`Threads_cached`**

The number of threads in the thread cache.

- **`Threads_connected`**

The number of currently open connections.

- **`Threads_created`**

The number of threads created to handle connections. If `Threads_created` is big, you may want to increase the `thread_cache_size` value. The cache miss rate can be calculated as `Threads_created/Connections`.

- **`Threads_running`**

The number of threads that are not sleeping.

- **`Uptime`**

The number of seconds that the server has been up.

- **`Uptime_since_flush_status`**

The number of seconds since the most recent `FLUSH STATUS` statement. This variable was added in 5.1.24.

## 5.1.7. Server SQL Modes

The MySQL server can operate in different SQL modes, and can apply these modes differently for different clients. This capability enables each application to tailor the server's operating mode to its own requirements.

For answers to some questions that are often asked about server SQL modes in MySQL, see [Section A.3, “MySQL 5.1 FAQ: Server SQL Mode”](#).

Modes define what SQL syntax MySQL should support and what kind of data validation checks it should perform. This makes it easier to use MySQL in different environments and to use MySQL together with other database servers.

You can set the default SQL mode by starting `mysqld` with the `--sql-mode="modes"` option, or by using `sql-mode="modes"` in `my.cnf` (Unix operating systems) or `my.ini` (Windows). `modes` is a list of different modes separated by comma (“,”) characters. The default value is empty (no modes set). The `modes` value also can be empty (`--sql-mode=""` on the command line, or `sql-mode=""` in `my.cnf` on Unix systems or in `my.ini` on Windows) if you want to clear it explicitly.

You can change the SQL mode at runtime by using a `SET [GLOBAL|SESSION] sql_mode='modes'` statement to set the `sql_mode` system value. Setting the `GLOBAL` variable requires the `SUPER` privilege and affects the operation of all clients that connect from that time on. Setting the `SESSION` variable affects only the current client. Any client can change its own session `sql_mode` value at any time.

### Important

**SQL mode and user-defined partitioning.** Changing the server SQL mode after creating and inserting data into partitioned tables can cause major changes in the behavior of such tables, and could lead to loss or corruption of data. It is strongly recommended that you never change the SQL mode once you have created tables employing user-defined partitioning.

When replicating partitioned tables, differing SQL modes on master and slave can also lead to problems. For best results, you should always use the same server SQL mode on the master and on the slave.

See [Section 18.5, “Restrictions and Limitations on Partitioning”](#), for more information.

You can retrieve the current global or session `sql_mode` value with the following statements:

```
SELECT @@GLOBAL.sql_mode;
SELECT @@SESSION.sql_mode;
```

The most important `sql_mode` values are probably these:

- [ANSI](#)

This mode changes syntax and behavior to conform more closely to standard SQL.

- [STRICT\\_TRANS\\_TABLES](#)

If a value could not be inserted as given into a transactional table, abort the statement. For a nontransactional table, abort the statement if the value occurs in a single-row statement or the first row of a multiple-row statement. More detail is given later in this section.

- [TRADITIONAL](#)

Make MySQL behave like a “traditional” SQL database system. A simple description of this mode is “give an error instead of a warning” when inserting an incorrect value into a column.

### Note

The `INSERT/UPDATE` aborts as soon as the error is noticed. This may not be what you want if you are using a non-transactional storage engine, because data changes made prior to the error may not be rolled back, resulting in a “partially done” update.

When this manual refers to “strict mode,” it means a mode where at least one of `STRICT_TRANS_TABLES` or `STRICT_ALL_TABLES` is enabled.

The following list describes all supported modes:

- [ALLOW\\_INVALID\\_DATES](#)

Don't do full checking of dates. Check only that the month is in the range from 1 to 12 and the day is in the range from 1 to 31. This is very convenient for Web applications where you obtain year, month, and day in three different fields and you want to store exactly what the user inserted (without date validation). This mode applies to `DATE` and `DATETIME` columns. It does not apply `TIMESTAMP` columns, which always require a valid date.

The server requires that month and day values be legal, and not merely in the range 1 to 12 and 1 to 31, respectively. With strict mode disabled, invalid dates such as `'2004-04-31'` are converted to `'0000-00-00'` and a warning is generated. With strict mode enabled, invalid dates generate an error. To permit such dates, enable `ALLOW_INVALID_DATES`.

- [ANSI\\_QUOTES](#)

Treat “`” as an identifier quote character (like the “`” quote character) and not as a string quote character. You can still use “`” to quote identifiers with this mode enabled. With `ANSI_QUOTES` enabled, you cannot use double quotation marks to quote literal strings, because it is interpreted as an identifier.

- [ERROR\\_FOR\\_DIVISION\\_BY\\_ZERO](#)

Produce an error in strict mode (otherwise a warning) when a division by zero (or `MOD(X, 0)`) occurs during an `INSERT` or `UPDATE`. If this mode is not enabled, MySQL instead returns `NULL` for divisions by zero. For `INSERT IGNORE` or `UPDATE IGNORE`, MySQL generates a warning for divisions by zero, but the result of the operation is `NULL`.

- [HIGH\\_NOT\\_PRECEDENCE](#)

The precedence of the `NOT` operator is such that expressions such as `NOT a BETWEEN b AND c` are parsed as `NOT (a BETWEEN b AND c)`. In some older versions of MySQL, the expression was parsed as `(NOT a) BETWEEN b AND c`. The old higher-precedence behavior can be obtained by enabling the `HIGH_NOT_PRECEDENCE` SQL mode.

```
mysql> SET sql_mode = '';
mysql> SELECT NOT 1 BETWEEN -5 AND 5;
 -> 0
mysql> SET sql_mode = 'HIGH_NOT_PRECEDENCE';
mysql> SELECT NOT 1 BETWEEN -5 AND 5;
 -> 1
```

- [IGNORE\\_SPACE](#)

Permit spaces between a function name and the “(” character. This causes built-in function names to be treated as reserved words. As a result, identifiers that are the same as function names must be quoted as described in [Section 8.2, “Schema Object Names”](#). For example, because there is a `COUNT()` function, the use of `count` as a table name in the following statement causes an error:

```
mysql> CREATE TABLE count (i INT);
ERROR 1064 (42000): You have an error in your SQL syntax
```

The table name should be quoted:

```
mysql> CREATE TABLE `count` (i INT);
Query OK, 0 rows affected (0.00 sec)
```

The `IGNORE_SPACE` SQL mode applies to built-in functions, not to user-defined functions or stored functions. It is always permissible to have spaces after a UDF or stored function name, regardless of whether `IGNORE_SPACE` is enabled.

For further discussion of `IGNORE_SPACE`, see [Section 8.2.4, “Function Name Parsing and Resolution”](#).

- [NO\\_AUTO\\_CREATE\\_USER](#)

Prevent the `GRANT` statement from automatically creating new users if it would otherwise do so, unless a nonempty password also is specified.

- [NO\\_AUTO\\_VALUE\\_ON\\_ZERO](#)

`NO_AUTO_VALUE_ON_ZERO` affects handling of `AUTO_INCREMENT` columns. Normally, you generate the next sequence number for the column by inserting either `NULL` or `0` into it. `NO_AUTO_VALUE_ON_ZERO` suppresses this behavior for `0` so that only `NULL` generates the next sequence number.

This mode can be useful if `0` has been stored in a table's `AUTO_INCREMENT` column. (Storing `0` is not a recommended practice, by the way.) For example, if you dump the table with `mysqldump` and then reload it, MySQL normally generates new sequence numbers when it encounters the `0` values, resulting in a table with contents different from the one that was dumped. Enabling `NO_AUTO_VALUE_ON_ZERO` before reloading the dump file solves this problem. `mysqldump` now automatically includes in its output a statement that enables `NO_AUTO_VALUE_ON_ZERO`, to avoid this problem.

- [NO\\_BACKSLASH\\_ESCAPES](#)

Disable the use of the backslash character (“\”) as an escape character within strings. With this mode enabled, backslash becomes an ordinary character like any other.

- [NO\\_DIR\\_IN\\_CREATE](#)

When creating a table, ignore all `INDEX DIRECTORY` and `DATA DIRECTORY` directives. This option is useful on slave replication servers.

- [NO\\_ENGINE\\_SUBSTITUTION](#)

Control automatic substitution of the default storage engine when a statement such as `CREATE TABLE` or `ALTER TABLE` specifies a storage engine that is disabled or not compiled in.

Up through MySQL 5.1.11, with `NO_ENGINE_SUBSTITUTION` disabled, the default engine is used and a warning occurs if the desired engine is known but disabled or not compiled in. If the desired engine is invalid (not a known engine name), an error occurs and the table is not created or altered.

With `NO_ENGINE_SUBSTITUTION` enabled, an error occurs and the table is not created or altered if the desired engine is unavailable for any reason (whether disabled or invalid).

As of MySQL 5.1.12, storage engines can be pluggable at runtime, so the distinction between disabled and invalid no longer applies. All unavailable engines are treated the same way:

With `NO_ENGINE_SUBSTITUTION` disabled, for `CREATE TABLE` the default engine is used and a warning occurs if the desired engine is unavailable. For `ALTER TABLE`, a warning occurs and the table is not altered.

With `NO_ENGINE_SUBSTITUTION` enabled, an error occurs and the table is not created or altered if the desired engine is unavailable.

- [NO\\_FIELD\\_OPTIONS](#)

Do not print MySQL-specific column options in the output of `SHOW CREATE TABLE`. This mode is used by `mysqldump` in

portability mode.

- [NO\\_KEY\\_OPTIONS](#)

Do not print MySQL-specific index options in the output of `SHOW CREATE TABLE`. This mode is used by `mysqldump` in portability mode.

- [NO\\_TABLE\\_OPTIONS](#)

Do not print MySQL-specific table options (such as `ENGINE`) in the output of `SHOW CREATE TABLE`. This mode is used by `mysqldump` in portability mode.

- [NO\\_UNSIGNED\\_SUBTRACTION](#)

In integer subtraction operations, do not mark the result as `UNSIGNED` if one of the operands is unsigned. In other words, *the result of a subtraction is always signed whenever this mode is in effect, even if one of the operands is unsigned*. For example, compare the type of column `c2` in table `t1` with that of column `c2` in table `t2`:

```
mysql> SET SQL_MODE='';
mysql> CREATE TABLE test (c1 BIGINT UNSIGNED NOT NULL);
mysql> CREATE TABLE t1 SELECT c1 - 1 AS c2 FROM test;
mysql> DESCRIBE t1;
+-----+-----+-----+-----+-----+
| Field | Type | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+
| c2 | bigint(21) unsigned | | | 0 | |
+-----+-----+-----+-----+-----+
mysql> SET SQL_MODE='NO_UNSIGNED_SUBTRACTION';
mysql> CREATE TABLE t2 SELECT c1 - 1 AS c2 FROM test;
mysql> DESCRIBE t2;
+-----+-----+-----+-----+-----+
| Field | Type | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+
| c2 | bigint(21) | | | 0 | |
+-----+-----+-----+-----+-----+
```

Note that this means that `BIGINT UNSIGNED` is not 100% usable in all contexts. See [Section 11.10, “Cast Functions and Operators”](#).

```
mysql> SET SQL_MODE = '';
mysql> SELECT CAST(0 AS UNSIGNED) - 1;
+-----+
| CAST(0 AS UNSIGNED) - 1 |
+-----+
| 18446744073709551615 |
+-----+
mysql> SET SQL_MODE = 'NO_UNSIGNED_SUBTRACTION';
mysql> SELECT CAST(0 AS UNSIGNED) - 1;
+-----+
| CAST(0 AS UNSIGNED) - 1 |
+-----+
| -1 |
+-----+
```

- [NO\\_ZERO\\_DATE](#)

In strict mode, do not permit '`0000-00-00`' as a valid date. You can still insert zero dates with the `IGNORE` option. When not in strict mode, the date is accepted but a warning is generated.

- [NO\\_ZERO\\_IN\\_DATE](#)

In strict mode, do not accept dates where the year part is nonzero but the month or day part is 0 (for example, '`0000-00-00`' is legal but '`2010-00-01`' and '`2010-01-00`' are not). If used with the `IGNORE` option, MySQL inserts a '`0000-00-00`' date for any such date. When not in strict mode, the date is accepted but a warning is generated.

- [ONLY\\_FULL\\_GROUP\\_BY](#)

Do not permit queries for which the `SELECT` list refers to nonaggregated columns that are not named in the `GROUP BY` clause. The following query is invalid with this mode enabled because `address` is not named in the `GROUP BY` clause:

```
SELECT name, address, MAX(age) FROM t GROUP BY name;
```

As of MySQL 5.1.11, this mode also restricts references to nonaggregated columns in the `HAVING` clause that are not named in the `GROUP BY` clause.

- [PAD\\_CHAR\\_TO\\_FULL\\_LENGTH](#)

By default, trailing spaces are trimmed from `CHAR` column values on retrieval. If `PAD_CHAR_TO_FULL_LENGTH` is enabled, trimming does not occur and retrieved `CHAR` values are padded to their full length. This mode does not apply to `VARCHAR` columns, for which trailing spaces are retained on retrieval. This mode was added in MySQL 5.1.20.

```
mysql> CREATE TABLE t1 (c1 CHAR(10));
Query OK, 0 rows affected (0.37 sec)

mysql> INSERT INTO t1 (c1) VALUES('xy');
Query OK, 1 row affected (0.01 sec)

mysql> SET sql_mode = '';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT c1, CHAR_LENGTH(c1) FROM t1;
+-----+-----+
| c1 | CHAR_LENGTH(c1) |
+-----+-----+
| xy | 2 |
+-----+-----+
1 row in set (0.00 sec)

mysql> SET sql_mode = 'PAD_CHAR_TO_FULL_LENGTH';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT c1, CHAR_LENGTH(c1) FROM t1;
+-----+-----+
| c1 | CHAR_LENGTH(c1) |
+-----+-----+
| xy | 10 |
+-----+-----+
1 row in set (0.00 sec)
```

- [PIPS\\_AS\\_CONCAT](#)

Treat `||` as a string concatenation operator (same as `CONCAT()`) rather than as a synonym for `OR`.

- [REAL\\_AS\\_FLOAT](#)

Treat `REAL` as a synonym for `FLOAT`. By default, MySQL treats `REAL` as a synonym for `DOUBLE`.

- [STRICT\\_ALL\\_TABLES](#)

Enable strict mode for all storage engines. Invalid data values are rejected. Additional detail follows.

- [STRICT\\_TRANS\\_TABLES](#)

Enable strict mode for transactional storage engines, and when possible for nontransactional storage engines. Additional details follow.

Strict mode controls how MySQL handles input values that are invalid or missing. A value can be invalid for several reasons. For example, it might have the wrong data type for the column, or it might be out of range. A value is missing when a new row to be inserted does not contain a value for a non-`NULL` column that has no explicit `DEFAULT` clause in its definition. (For a `NULL` column, `NULL` is inserted if the value is missing.)

For transactional tables, an error occurs for invalid or missing values in a statement when either of the `STRICT_ALL_TABLES` or `STRICT_TRANS_TABLES` modes are enabled. The statement is aborted and rolled back.

For nontransactional tables, the behavior is the same for either mode, if the bad value occurs in the first row to be inserted or updated. The statement is aborted and the table remains unchanged. If the statement inserts or modifies multiple rows and the bad value occurs in the second or later row, the result depends on which strict option is enabled:

- For `STRICT_ALL_TABLES`, MySQL returns an error and ignores the rest of the rows. However, in this case, the earlier rows still have been inserted or updated. This means that you might get a partial update, which might not be what you want. To avoid this, it is best to use single-row statements because these can be aborted without changing the table.
- For `STRICT_TRANS_TABLES`, MySQL converts an invalid value to the closest valid value for the column and insert the adjusted value. If a value is missing, MySQL inserts the implicit default value for the column data type. In either case, MySQL generates a warning rather than an error and continues processing the statement. Implicit defaults are described in [Section 10.1.4, “Data Type Default Values”](#).

Strict mode disallows invalid date values such as `'2004-04-31'`. It does not disallow dates with zero month or day parts such as `'2004-04-00'` or “zero” dates. To disallow these as well, enable the `NO_ZERO_IN_DATE` and `NO_ZERO_DATE` SQL modes in addition to strict mode.

If you are not using strict mode (that is, neither `STRICT_TRANS_TABLES` nor `STRICT_ALL_TABLES` is enabled), MySQL inserts adjusted values for invalid or missing values and produces warnings. In strict mode, you can produce this behavior by using `INSERT IGNORE` or `UPDATE IGNORE`. See [Section 12.4.5.42, “SHOW WARNINGS Syntax”](#).

Strict mode does not affect whether foreign key constraints are checked. `foreign_key_checks` can be used for that. (See [Section 5.1.4, “Server System Variables”](#).)

The following special modes are provided as shorthand for combinations of mode values from the preceding list.

The descriptions include all mode values that are available in the most recent version of MySQL. For older versions, a combination mode does not include individual mode values that are not available except in newer versions.

- [ANSI](#)

Equivalent to `REAL_AS_FLOAT`, `PIPES_AS_CONCAT`, `ANSI_QUOTES`, `IGNORE_SPACE`.

As of MySQL 5.1.18, `ANSI` mode also causes the server to return an error for queries where a set function `S` with an outer reference `S(outer_ref)` cannot be aggregated in the outer query against which the outer reference has been resolved. This is such a query:

```
SELECT * FROM t1 WHERE t1.a IN (SELECT MAX(t1.b) FROM t2 WHERE ...);
```

Here, `MAX(t1.b)` cannot be aggregated in the outer query because it appears in the `WHERE` clause of that query. Standard SQL requires an error in this situation. If `ANSI` mode is not enabled, the server treats `S(outer_ref)` in such queries the same way that it would interpret `S(const)`, as was always done prior to 5.1.18.

See [Section 1.8.3, “Running MySQL in ANSI Mode”](#).

- [DB2](#)

Equivalent to `PIPES_AS_CONCAT`, `ANSI_QUOTES`, `IGNORE_SPACE`, `NO_KEY_OPTIONS`, `NO_TABLE_OPTIONS`, `NO_FIELD_OPTIONS`.

- [MAXDB](#)

Equivalent to `PIPES_AS_CONCAT`, `ANSI_QUOTES`, `IGNORE_SPACE`, `NO_KEY_OPTIONS`, `NO_TABLE_OPTIONS`, `NO_FIELD_OPTIONS`, `NO_AUTO_CREATE_USER`.

- [MSSQL](#)

Equivalent to `PIPES_AS_CONCAT`, `ANSI_QUOTES`, `IGNORE_SPACE`, `NO_KEY_OPTIONS`, `NO_TABLE_OPTIONS`, `NO_FIELD_OPTIONS`.

- [MYSQL323](#)

Equivalent to `NO_FIELD_OPTIONS`, `HIGH_NOT_PRECEDENCE`.

- [MYSQL40](#)

Equivalent to `NO_FIELD_OPTIONS`, `HIGH_NOT_PRECEDENCE`.

- [ORACLE](#)

Equivalent to `PIPES_AS_CONCAT`, `ANSI_QUOTES`, `IGNORE_SPACE`, `NO_KEY_OPTIONS`, `NO_TABLE_OPTIONS`, `NO_FIELD_OPTIONS`, `NO_AUTO_CREATE_USER`.

- [POSTGRESQL](#)

Equivalent to `PIPES_AS_CONCAT`, `ANSI_QUOTES`, `IGNORE_SPACE`, `NO_KEY_OPTIONS`, `NO_TABLE_OPTIONS`, `NO_FIELD_OPTIONS`.

- [TRADITIONAL](#)

Equivalent to `STRICT_TRANS_TABLES`, `STRICT_ALL_TABLES`, `NO_ZERO_IN_DATE`, `NO_ZERO_DATE`, `ERROR_FOR_DIVISION_BY_ZERO`, `NO_AUTO_CREATE_USER`.

## 5.1.8. Server-Side Help

MySQL Server supports a `HELP` statement that returns online information from the MySQL Reference manual (see [Section 12.8.3](#),

“[HELP Syntax](#)”). The proper operation of this statement requires that the help tables in the `mysql` database be initialized with help topic information, which is done by processing the contents of the `fill_help_tables.sql` script.

If you install MySQL using a binary or source distribution on Unix, help table setup occurs when you run `mysql_install_db`. For an RPM distribution on Linux or binary distribution on Windows, help table setup occurs as part of the MySQL installation process.

If you upgrade MySQL using a binary distribution, the help tables are not upgraded automatically, but you can upgrade them manually. Locate the `fill_help_tables.sql` file in the `share` or `share/mysql` directory. Change location into that directory and process the file with the `mysql` client as follows:

```
shell> mysql -u root mysql < fill_help_tables.sql
```

You can also obtain the latest `fill_help_tables.sql` at any time to upgrade your help tables. Download the proper file for your version of MySQL from <http://dev.mysql.com/doc/index-other.html>. After downloading and uncompressing the file, process it with `mysql` as described previously.

If you are working with Bazaar and a MySQL development source tree, you will need to download the `fill_help_tables.sql` file because the tree contains only a “stub” version.

## 5.1.9. Server Response to Signals

On Unix, signals can be sent to processes. `mysqld` responds to signals sent to it as follows:

- `SIGTERM` causes the server to shut down.
- `SIGHUP` causes the server to reload the grant tables and flush the logs (like `FLUSH PRIVILEGES` and `FLUSH LOGS`). It also writes a status report to the error log that has this format:

```
Status information:
Current dir: /var/mysql/data/
Running threads: 0 Stack size: 196608
Current locks:

Key caches:
default
Buffer_size: 8388600
Block_size: 1024
Division_limit: 100
Age_limit: 300
blocks used: 0
not flushed: 0
w_requests: 0
writes: 0
r_requests: 0
reads: 0

handler status:
read_key: 0
read_next: 0
read_rnd: 0
read_first: 1
write: 0
delete: 0
update: 0

Table status:
Opened tables: 5
Open tables: 0
Open files: 7
Open streams: 0

Alarm status:
Active alarms: 1
Max used alarms: 2
Next alarm time: 67
```

On some Mac OS X 10.3 versions, `mysqld` ignores `SIGHUP` and `SIGQUIT`.

## 5.1.10. The Shutdown Process

The server shutdown process takes place as follows:

1. The shutdown process is initiated.

Server shutdown can be initiated several ways. For example, a user with the `SHUTDOWN` privilege can execute a `mysqladmin` command:

`min shutdown` command. `mysqladmin` can be used on any platform supported by MySQL. Other operating system-specific shutdown initiation methods are possible as well: The server shuts down on Unix when it receives a `SIGTERM` signal. A server running as a service on Windows shuts down when the services manager tells it to.

2. The server creates a shutdown thread if necessary.

Depending on how shutdown was initiated, the server might create a thread to handle the shutdown process. If shutdown was requested by a client, a shutdown thread is created. If shutdown is the result of receiving a `SIGTERM` signal, the signal thread might handle shutdown itself, or it might create a separate thread to do so. If the server tries to create a shutdown thread and cannot (for example, if memory is exhausted), it issues a diagnostic message that appears in the error log:

```
Error: Can't create thread to kill server
```

3. The server stops accepting new connections.

To prevent new activity from being initiated during shutdown, the server stops accepting new client connections. It does this by closing the network connections to which it normally listens for connections: the TCP/IP port, the Unix socket file, the Windows named pipe, and shared memory on Windows.

4. The server terminates current activity.

For each thread that is associated with a client connection, the connection to the client is broken and the thread is marked as killed. Threads die when they notice that they are so marked. Threads for idle connections die quickly. Threads that currently are processing statements check their state periodically and take longer to die. For additional information about thread termination, see [Section 12.4.6.4, “KILL Syntax”](#), in particular for the instructions about killed `REPAIR TABLE` or `OPTIMIZE TABLE` operations on `MyISAM` tables.

For threads that have an open transaction, the transaction is rolled back. Note that if a thread is updating a nontransactional table, an operation such as a multiple-row `UPDATE` or `INSERT` may leave the table partially updated, because the operation can terminate before completion.

If the server is a master replication server, threads associated with currently connected slaves are treated like other client threads. That is, each one is marked as killed and exits when it next checks its state.

If the server is a slave replication server, the I/O and SQL threads, if active, are stopped before client threads are marked as killed. The SQL thread is permitted to finish its current statement (to avoid causing replication problems), and then stops. If the SQL thread was in the middle of a transaction at this point, the transaction is rolled back.

5. Storage engines are shut down or closed.

At this stage, the table cache is flushed and all open tables are closed.

Each storage engine performs any actions necessary for tables that it manages. For example, `MyISAM` flushes any pending index writes for a table. `InnoDB` flushes its buffer pool to disk, unless `innodb_fast_shutdown` is 2, writes the current LSN to the tablespace, and terminates its own internal threads.

6. The server exits.

## 5.2. MySQL Server Logs

MySQL has several different logs that can help you find out what is going on inside `mysqld`.

Log Type	Information Written to Log
The error log	Problems encountered starting, running, or stopping <code>mysqld</code>
The general query log	Established client connections and statements received from clients
The binary log	All statements that change data (also used for replication)
The slow query log	All queries that took more than <code>long_query_time</code> seconds to execute or didn't use indexes

By default, all log files are created in the `mysqld` data directory. You can force `mysqld` to close and reopen the log files (or in some cases switch to a new log) by flushing the logs. Log flushing occurs when you issue a `FLUSH LOGS` statement or execute a `mysqladmin flush-logs`, `mysqladmin refresh`, `mysqldump --flush-logs`, or `mysqldump --master-data` command. See [Section 12.4.6.3, “FLUSH Syntax”](#), [Section 4.5.2, “mysqladmin — Client for Administering a MySQL Server”](#), and [Section 4.5.4, “mysqldump — A Database Backup Program”](#). In addition, the binary log is flushed when its size reaches the value of the `max_binlog_size` system variable.

If you are using MySQL replication capabilities, slave replication servers maintain additional log files called relay logs. [Chapter 16, Replication](#), discusses relay log contents and configuration.

As of MySQL 5.1.6, the server can write general query and slow query entries to log tables, log files, or both. For details, see [Section 5.2.1, “Selecting General Query and Slow Query Log Output Destinations”](#).

As of MySQL 5.1.12, additional runtime control of the general query and slow query logs is available: You can enable or disable logging, or change the name of the log file. See [Section 5.2.3, “The General Query Log”](#), and [Section 5.2.5, “The Slow Query Log”](#).

See [Section 5.3.2.1, “Administrator Guidelines for Password Security”](#), for information about keeping logs secure.

## 5.2.1. Selecting General Query and Slow Query Log Output Destinations

As of MySQL 5.1.6, the server provides flexible control over the destination for log output. Log entries can be written to log files to the `general_log` and `slow_log` tables in the `mysql` database. If logging is enabled, either or both destinations can be selected. (Before MySQL 5.1.6, the server uses only log files as the destination for general query log and slow query log entries, if those logs are enabled.)

### Note

For new installations of MySQL 5.1.6 or higher, the log tables are created during the installation procedure along with the other system tables. If you upgrade MySQL from a release older than 5.1.6 to MySQL 5.1.6 or higher, you must upgrade the system tables after upgrading to make sure that the log tables exist. See [Section 4.4.8, “mysql\\_upgrade — Check Tables for MySQL Upgrade”](#).

Currently, logging to tables incurs significantly more server overhead than logging to files. If you enable the general log or slow query log and require highest performance, you should log to files and not to tables.

**Log control at server startup.** The `--log-output` option specifies the destination for log output, if logging is enabled. This option does not in itself enable the logs. Its syntax is `--log-output[=value,...]`:

- If `--log-output` is given with a value, the value should be a comma-separated list of one or more of the words `TABLE` (log to tables), `FILE` (log to files), or `NONE` (do not log to tables or files). `NONE`, if present, takes precedence over any other specifiers.
- If `--log-output` is omitted or given without a value, the default is `FILE`. (For MySQL 5.1.6 through 5.1.20, the default logging destination is `TABLE`.)

The `general_log` system variable, if given, enables logging to the general query log for the selected log destinations. If specified at server startup, `general_log` takes an optional argument of 1 or 0 to enable or disable the log. To specify a file name other than the default for file logging, set the `general_log_file` variable. Similarly, the `slow_query_log` variable, if given, enables logging to the slow query log for the selected destinations and setting `slow_query_log_file` specifies a file name for file logging. If either log is enabled, the server opens the corresponding log file and writes startup messages to it. However, further logging of queries to the file does not occur unless the `FILE` log destination is selected. Prior to MySQL 5.1.29, the `--log` and `--log-slow-queries` options enable the general query log and slow query log. Either option may be given with a file name argument to specify a log file name to override the default.

Examples:

- To write general query log entries to the log table and the log file, use `--log-output=TABLE,FILE` to select both log destinations and the `--general_log` option to enable the general query log.
- To write general and slow query log entries only to the log tables, use `--log-output=TABLE` to select tables as the log destination and the `--general_log` and `--slow_query_log` options to enable both logs.
- To write slow query log entries only to the log file, use `--log-output=FILE` to select files as the log destination and the `--slow_query_log` option to enable the slow query log. (In this case, because the default log destination is `FILE`, you could omit the `--log-output` option.)

**Log control at runtime.** Several system variables are associated with log tables and files and enable runtime control over logging:

- The global `log_output` system variable indicates the current logging destination. It can be modified at runtime to change the destination.

- The global `general_log` and `slow_query_log` variables indicate whether the general query log and slow query log are enabled (`ON`) or disabled (`OFF`). You can set these variables at runtime to control whether the logs are enabled.
- The global `general_log_file` and `slow_query_log_file` variables indicate the names of the general query log and slow query log files. As of MySQL 5.1.29, you can set these variables at server startup or at runtime to change the names of the log files. Before MySQL 5.1.29, you can set these variables only at runtime, but the `--log` and `--log-slow-queries` options can be given with a file name argument at startup to change the log file names from their default values.
- The session `sql_log_off` variable can be set to `ON` or `OFF` to disable or enable general query logging for the current connection.

The use of tables for log output offers the following benefits:

- Log entries have a standard format. To display the current structure of the log tables, use these statements:

```
SHOW CREATE TABLE mysql.general_log;
SHOW CREATE TABLE mysql.slow_log;
```

- Log contents are accessible through SQL statements. This enables the use of queries that select only those log entries that satisfy specific criteria. For example, to select log contents associated with a particular client (which can be useful for identifying problematic queries from that client), it is easier to do this using a log table than a log file.
- Logs are accessible remotely through any client that can connect to the server and issue queries (if the client has the appropriate log table privileges). It is not necessary to log in to the server host and directly access the file system.

The log table implementation has the following characteristics:

- In general, the primary purpose of log tables is to provide an interface for users to observe the runtime execution of the server, not to interfere with its runtime execution.
- `CREATE TABLE`, `ALTER TABLE`, and `DROP TABLE` are valid operations on a log table. For `ALTER TABLE` and `DROP TABLE`, the log table cannot be in use and must be disabled, as described later.
- By default, the log tables use the `CSV` storage engine that writes data in comma-separated values format. For users who have access to the `.CSV` files that contain log table data, the files are easy to import into other programs such as spreadsheets that can process CSV input.

Beginning with MySQL 5.1.12, the log tables can be altered to use the `MyISAM` storage engine. You cannot use `ALTER TABLE` to alter a log table that is in use. The log must be disabled first. No engines other than `CSV` or `MyISAM` are legal for the log tables.

- To disable logging so that you can alter (or drop) a log table, you can use the following strategy. The example uses the general query log; the procedure for the slow query log is similar but uses the `slow_log` table and `slow_query_log` system variable.

```
SET @old_log_state = @@global.general_log;
SET GLOBAL general_log = 'OFF';
ALTER TABLE mysql.general_log ENGINE = MyISAM;
SET GLOBAL general_log = @old_log_state;
```

- `TRUNCATE TABLE` is a valid operation on a log table. It can be used to expire log entries.
- As of MySQL 5.1.13, `RENAME TABLE` is a valid operation on a log table. You can atomically rename a log table (to perform log rotation, for example) using the following strategy:

```
USE mysql;
CREATE TABLE IF NOT EXISTS general_log2 LIKE general_log;
RENAME TABLE general_log TO general_log_backup, general_log2 TO general_log;
```

- `LOCK TABLES` cannot be used on a log table.
- `INSERT`, `DELETE`, and `UPDATE` cannot be used on a log table. These operations are permitted only internally to the server itself.
- `FLUSH TABLES WITH READ LOCK` and the state of the global `read_only` system variable have no effect on log tables. The server can always write to the log tables.
- Entries written to the log tables are not written to the binary log and thus are not replicated to slave servers.

- To flush the log tables or log files, use `FLUSH TABLES` or `FLUSH LOGS`, respectively. (From MySQL 5.1.12 to 5.1.20, `FLUSH TABLES` ignores log tables and `FLUSH LOGS` flushes both the log tables and files.)
- It is not recommended to partition log tables, and doing so is not permitted beginning with MySQL 5.1.20.

## 5.2.2. The Error Log

The error log contains information indicating when `mysqld` was started and stopped and also any critical errors that occur while the server is running. If `mysqld` notices a table that needs to be automatically checked or repaired, it writes a message to the error log.

On some operating systems, the error log contains a stack trace if `mysqld` dies. The trace can be used to determine where `mysqld` died. See [MySQL Internals: Porting](#).

You can specify where `mysqld` writes the error log with the `--log-error[=file_name]` option. If the option is given with no `file_name` value, `mysqld` uses the name `host_name.err` by default. The server creates the file in the data directory unless an absolute path name is given to specify a different directory.

If you do not specify `--log-error`, or (on Windows) if you use the `--console` option, errors are written to `stderr`, the standard error output. Usually this is your terminal.

On Windows, error output is always written to the `.err` file if `--console` is not given.

In addition, on Windows, events and error messages are written to the Windows Event Log within the Application log. Entries marked as `Warning` and `Note` are written to the Event Log, but informational messages (such as information statements from individual storage engines) are not copied to the Event Log. The log entries have a source of `MySQL`. You cannot disable writing information to the Windows Event Log.

If you flush the logs using `FLUSH LOGS` or `mysqladmin flush-logs` and `mysqld` is writing the error log to a file (for example, if it was started with the `--log-error` option), the effect is version dependent:

- As of MySQL 5.1.51, the server closes and reopens the log file. To rename the file, you can do so manually before flushing. Then flushing the logs reopens a new file with the original file name. For example, you can rename the file and create a new one using the following commands:

```
shell> mv host_name.err host_name.err-old
shell> mysqladmin flush-logs
shell> mv host_name.err-old backup-directory
```

On Windows, use `rename` rather than `mv`.

- Prior to MySQL 5.1.51, the server renames the current log file with the suffix `-old`, then creates a new empty log file. Be aware that a second log-flushing operation thus causes the original error log file to be lost unless you save it under a different name. On Windows, you cannot rename the error log while the server has it open before MySQL 5.1.51. To avoid a restart, flush the logs first to cause the server to rename the original file and create a new one, then save the renamed file. That also works on Unix, or you can use the commands shown earlier.

No error log renaming occurs when the logs are flushed in any case if the server is not writing to a named file.

The `--log-warnings` option or `log_warnings` system variable can be used to control warning logging to the error log. The default value is enabled (1). Warning logging can be disabled using a value of 0. If the value is greater than 1, aborted connections are written to the error log. See [Section B.5.2.11, “Communication Errors and Aborted Connections”](#).

If you use `mysqld_safe` to start `mysqld`, `mysqld_safe` arranges for `mysqld` to write error messages to a log file or (as of MySQL 5.1.20) to `syslog`:

- Before 5.1.20, `mysqld_safe` behavior is to log to a file, using the default error log file if the `--log-error` option is not given to `mysqld_safe`. Otherwise, `mysqld_safe` uses the file name specified using `--log-error=file_name`.
- From 5.1.20 on, `mysqld_safe` has two additional error-logging options, `--syslog` and `--skip-syslog`.

In 5.1.21 and up, the default with no logging options is `--skip-syslog`, which is compatible with the default behavior of writing an error log file for releases prior to 5.1.20. To explicitly specify use of an error log file, specify `--log-error=file_name` to `mysqld_safe`, and `mysqld_safe` will arrange for `mysqld` to write messages to a log file. To use `syslog` instead, specify the `--syslog` option.

**In 5.1.20 only, the following conditions apply:** 1) The default is to use `syslog`, which is not compatible with releases prior

to 5.1.20. 2) Logging to `syslog` may fail to operate correctly in some cases; if so, use `--skip-syslog` or `--log-error`.

For logging to `syslog`, messages from `mysqld_safe` and `mysqld` are written with a tag of `mysqld_safe` and `mysqld`, respectively. As of MySQL 5.1.21, to specify a suffix for the tag, use `--syslog-tag=tag`, which modifies the tags to be `mysqld_safe-tag` and `mysqld-tag`.

If you specify `--log-error` in an option file in a section that `mysqld` reads, `mysqld_safe` also will find and use the option.

If `mysqld_safe` is used to start `mysqld` and `mysqld` dies unexpectedly, `mysqld_safe` notices that it needs to restart `mysqld` and writes a `restarted mysqld` message to the error log.

### 5.2.3. The General Query Log

The general query log is a general record of what `mysqld` is doing. The server writes information to this log when clients connect or disconnect, and it logs each SQL statement received from clients. The general query log can be very useful when you suspect an error in a client and want to know exactly what the client sent to `mysqld`.

`mysqld` writes statements to the query log in the order that it receives them, which might differ from the order in which they are executed. This logging order contrasts to the binary log, for which statements are written after they are executed but before any locks are released. (Also, the query log contains all statements, whereas the binary log does not contain statements that only select data.)

Control the general query log at server startup as follows:

- Before 5.1.6, the general query log destination is always a file. To enable the log, start `mysqld` with the `--log[=file_name]` or `-l [file_name]` option.
- As of MySQL 5.1.6, the destination can be a file or a table, or both. Start `mysqld` with the `--log[=file_name]` or `-l [file_name]` option to enable the general query log, and optionally use `--log-output` to specify the log destination (as described in [Section 5.2.1, “Selecting General Query and Slow Query Log Output Destinations”](#)).
- As of MySQL 5.1.12, as an alternative to `--log` or `-l`, use `--general_log[={0|1}]` to specify the initial general query log state. In this case, the default general query log file name is used. With no argument or an argument of 1, `--general_log` enables the log. With an argument of 0, this option disables the log.
- As of MySQL 5.1.29, use `--general_log[={0|1}]` to enable or disable the general query log, and optionally `--general_log_file=file_name` to specify a log file name. The `--log` and `-l` options are deprecated.

If you specify no name for the general query log file, the default name is `host_name.log`. The server creates the file in the data directory unless an absolute path name is given to specify a different directory.

To control the general query log at runtime, use the global `general_log` and `general_log_file` system variables. Set `general_log` to 0 (or `OFF`) to disable the log or to 1 (or `ON`) to enable it. Set `general_log_file` to specify the name of the log file. If a log file already is open, it is closed and the new file is opened.

When the general query log is enabled, the server writes output to any destinations specified by the `--log-output` option or `log_output` system variable. If you enable the log, the server opens the log file and writes startup messages to it. However, further logging of queries to the file does not occur unless the `FILE` log destination is selected. If the destination is `NONE`, no queries are written even if the general log is enabled. Setting the log file name has no effect on logging if the log destination value does not contain `FILE`.

Server restarts and log flushing do not cause a new general query log file to be generated (although flushing closes and reopens it). On Unix, you can rename the file and create a new one by using the following commands:

```
shell> mv host_name.log host_name-old.log
shell> mysqladmin flush-logs
shell> mv host_name-old.log backup-directory
```

On Windows, you cannot rename the general query log file while the server has it open before MySQL 5.1.3. You must stop the server, rename the file, and then restart the server to create a new log file.

As of MySQL 5.1.12, you can rename the general query log file at runtime by disabling the log:

```
SET GLOBAL general_log = 'OFF';
```

With the log disabled, rename the log file externally; for example, from the command line. Then enable the log again:

```
SET GLOBAL general_log = 'ON';
```

This method works on any platform and does not require a server restart.

The session `sql_log_off` variable can be set to `ON` or `OFF` to disable or enable general query logging for the current connection.

The general query log should be protected because logged statements might contain passwords. See [Section 5.3.2.1, “Administrator Guidelines for Password Security”](#).

## 5.2.4. The Binary Log

The binary log contains “events” that describe database changes such as table creation operations or changes to table data. It also contains events for statements that potentially could have made changes (for example, a `DELETE` which matched no rows), unless row-based logging is used. The binary log also contains information about how long each statement took that updated data. The binary log has two important purposes:

- For replication, the binary log is used on master replication servers as a record of the statements to be sent to slave servers. The master server sends the events contained in its binary log to its slaves, which execute those events to make the same data changes that were made on the master. See [Section 16.2, “Replication Implementation”](#).
- Certain data recovery operations require use of the binary log. After a backup has been restored, the events in the binary log that were recorded after the backup was made are re-executed. These events bring databases up to date from the point of the backup. See [Section 6.5, “Point-in-Time \(Incremental\) Recovery Using the Binary Log”](#).

Running a server with binary logging enabled makes performance slightly slower. However, the benefits of the binary log in enabling you to set up replication and for restore operations generally outweigh this minor performance decrement.

For information about server options and variables affecting the operation of binary logging, see [Section 16.1.3.4, “Binary Log Options and Variables”](#).

The binary log is not used for statements such as `SELECT` or `SHOW` that do not modify data. If you want to log all statements (for example, to identify a problem query), use the general query log. See [Section 5.2.3, “The General Query Log”](#).

The binary log should be protected because logged statements might contain passwords. See [Section 5.3.2.1, “Administrator Guidelines for Password Security”](#).

The format of the events recorded in the binary log is dependent on the binary logging format. Three format types are supported, row-based logging, statement-based logging and mixed-base logging. The binary logging format used depends on the MySQL version. For more information on logging formats, see [Section 5.2.4.1, “Binary Logging Formats”](#).

For information about the format of the binary log itself, see [http://forge.mysql.com/wiki/MySQLInternals\\_Binary\\_Log](http://forge.mysql.com/wiki/MySQLInternals_Binary_Log).

To enable the binary log, start the server with the `--log-bin[=base_name]` option. If no `base_name` value is given, the default name is the value of the `pid-file` option (which by default is the name of host machine) followed by `-bin`. If the base-name is given, the server writes the file in the data directory unless the basename is given with a leading absolute path name to specify a different directory. It is recommended that you specify a basename; see [Section B.5.8.2, “Additional Known Issues”](#), for the reason.

### Note

From MySQL 5.1.18 through 5.1.22, “mysql” was used when no `base_name` was specified. Also in these versions, a path given as part of the `--log-bin` options was treated as absolute rather than relative. The previous behaviors were restored in MySQL 5.1.23. (See [Bug#28603](#) and [Bug#28597](#).)

If you supply an extension in the log name (for example, `--log-bin=base_name.extension`), the extension is silently removed and ignored.

`mysqld` appends a numeric extension to the binary log basename to generate binary log file names. The number increases each time the server creates a new log file, thus creating an ordered series of files. The server creates a new file in the series each time it starts or flushes the logs. The server also creates a new binary log file automatically after the current log's size reaches `max_binlog_size`. A binary log file may become larger than `max_binlog_size` if you are using large transactions because a transaction is written to the file in one piece, never split between files.

To keep track of which binary log files have been used, `mysqld` also creates a binary log index file that contains the names of all used binary log files. By default, this has the same basename as the binary log file, with the extension `'.index'`. You can change the name of the binary log index file with the `--log-bin-index[=file_name]` option. You should not manually edit this file while `mysqld` is running; doing so would confuse `mysqld`.

The term “binary log file” generally denotes an individual numbered file containing database events. The term “binary log” collect-

ively denotes the set of numbered binary log files plus the index file.

The server evaluates the `--binlog-do-db` and `--binlog-ignore-db` options in the same way as it does the `--replicate-do-db` and `--replicate-ignore-db` options. For information about how this is done, see [Section 16.2.3.1, “Evaluation of Database-Level Replication and Binary Logging Options”](#).

A replication slave server by default does not write to its own binary log any data modifications that are received from the replication master. To log these modifications, start the slave with the `--log-slave-updates` option in addition to the `--log-bin` option (see [Section 16.1.3.3, “Replication Slave Options and Variables”](#)). This is done when a slave is also to act as a master to other slaves in chained replication.

You can delete all binary log files with the `RESET MASTER` statement, or a subset of them with `PURGE BINARY LOGS`. See [Section 12.4.6.6, “`RESET` Syntax”](#), and [Section 12.5.1.1, “`PURGE BINARY LOGS` Syntax”](#).

If you are using replication, you should not delete old binary log files on the master until you are sure that no slave still needs to use them. For example, if your slaves never run more than three days behind, once a day you can execute `mysqladmin flush_logs` on the master and then remove any logs that are more than three days old. You can remove the files manually, but it is preferable to use `PURGE BINARY LOGS`, which also safely updates the binary log index file for you (and which can take a date argument). See [Section 12.5.1.1, “`PURGE BINARY LOGS` Syntax”](#).

A client that has the `SUPER` privilege can disable binary logging of its own statements by using a `SET sql_log_bin=0` statement. See [Section 5.1.4, “Server System Variables”](#).

You can display the contents of binary log files with the `mysqlbinlog` utility. This can be useful when you want to reprocess statements in the log for a recovery operation. For example, you can update a MySQL server from the binary log as follows:

```
shell> mysqlbinlog log_file | mysql -h server_name
```

`mysqlbinlog` also can be used to display replication slave relay log file contents because they are written using the same format as binary log files. For more information on the `mysqlbinlog` utility and how to use it, see [Section 4.6.7, “`mysqlbinlog` — Utility for Processing Binary Log Files”](#). For more information about the binary log and recovery operations, see [Section 6.5, “Point-in-Time \(Incremental\) Recovery Using the Binary Log”](#).

Binary logging is done immediately after a statement completes but before any locks are released or any commit is done. This ensures that the log is logged in execution order.

Updates to nontransactional tables are stored in the binary log immediately after execution. In MySQL 5.1.22 and earlier versions of MySQL 5.1, an `UPDATE` statement using a stored function that modified a nontransactional table was not logged if it failed, and an `INSERT ... ON DUPLICATE KEY UPDATE` statement that encountered a duplicate key constraint—but did not actually change any data—was not logged. Beginning with MySQL 5.1.23, both of these statements are written to the binary log. ([Bug#23333](#))

Within an uncommitted transaction, all updates (`UPDATE`, `DELETE`, or `INSERT`) that change transactional tables such as `InnoDB` tables are cached until a `COMMIT` statement is received by the server. At that point, `mysqld` writes the entire transaction to the binary log before the `COMMIT` is executed.

Modifications to nontransactional tables cannot be rolled back. If a transaction that is rolled back includes modifications to nontransactional tables, the entire transaction is logged with a `ROLLBACK` statement at the end to ensure that the modifications to those tables are replicated.

When a thread that handles the transaction starts, it allocates a buffer of `binlog_cache_size` to buffer statements. If a statement is bigger than this, the thread opens a temporary file to store the transaction. The temporary file is deleted when the thread ends.

The `Binlog_cache_use` status variable shows the number of transactions that used this buffer (and possibly a temporary file) for storing statements. The `Binlog_cache_disk_use` status variable shows how many of those transactions actually had to use a temporary file. These two variables can be used for tuning `binlog_cache_size` to a large enough value that avoids the use of temporary files.

The `max_binlog_cache_size` system variable (default 4GB, which is also the maximum) can be used to restrict the total size used to cache a multiple-statement transaction. If a transaction is larger than this many bytes, it fails and rolls back. The minimum value is 4096.

If you are using the binary log and row based logging, concurrent inserts are converted to normal inserts for `CREATE ... SELECT` or `INSERT ... SELECT` statement. This is done to ensure that you can re-create an exact copy of your tables by applying the log during a backup operation. If you are using statement-based logging, the original statement is written to the log.

The binary log format has some known limitations that can affect recovery from backups. See [Section 16.4.1, “Replication Features and Issues”](#).

Binary logging for stored programs is done as described in [Section 19.7, “Binary Logging of Stored Programs”](#).

Note that the binary log format differs in MySQL 5.1 from previous versions of MySQL, due to enhancements in replication. See [Section 16.4.2, “Replication Compatibility Between MySQL Versions”](#).

Writes to the binary log file and binary log index file are handled in the same way as writes to [MyISAM](#) tables. See [Section B.5.4.3, “How MySQL Handles a Full Disk”](#).

By default, the binary log is not synchronized to disk at each write. So if the operating system or machine (not only the MySQL server) crashes, there is a chance that the last statements of the binary log are lost. To prevent this, you can make the binary log be synchronized to disk after every  $N$  writes to the binary log, with the `sync_binlog` system variable. See [Section 5.1.4, “Server System Variables”](#). 1 is the safest value for `sync_binlog`, but also the slowest. Even with `sync_binlog` set to 1, there is still the chance of an inconsistency between the table content and binary log content in case of a crash. For example, if you are using [InnoDB](#) tables and the MySQL server processes a `COMMIT` statement, it writes the whole transaction to the binary log and then commits this transaction into [InnoDB](#). If the server crashes between those two operations, the transaction is rolled back by [InnoDB](#) at restart but still exists in the binary log. To resolve this, you should set `--innodb_support_xa` to 1. Although this option is related to the support of XA transactions in InnoDB, it also ensures that the binary log and InnoDB data files are synchronized.

For this option to provide a greater degree of safety, the MySQL server should also be configured to synchronize the binary log and the [InnoDB](#) logs to disk at every transaction. The [InnoDB](#) logs are synchronized by default, and `sync_binlog=1` can be used to synchronize the binary log. The effect of this option is that at restart after a crash, after doing a rollback of transactions, the MySQL server cuts rolled back [InnoDB](#) transactions from the binary log. This ensures that the binary log reflects the exact data of [InnoDB](#) tables, and so, that the slave remains in synchrony with the master (not receiving a statement which has been rolled back).

If the MySQL server discovers at crash recovery that the binary log is shorter than it should have been, it lacks at least one successfully committed [InnoDB](#) transaction. This should not happen if `sync_binlog=1` and the disk/file system do an actual sync when they are requested to (some do not), so the server prints an error message `The binary log file_name is shorter than its expected size`. In this case, this binary log is not correct and replication should be restarted from a fresh snapshot of the master's data.

For MySQL 5.1.20 and later (and MySQL 5.0.46 and later for backward compatibility), the session values of the following system variables are written to the binary log and honored by the replication slave when parsing the binary log:

- `sql_mode` (except that the `NO_DIR_IN_CREATE` mode is not replicated; see [Section 16.4.1.32, “Replication and Variables”](#))
- `foreign_key_checks`
- `unique_checks`
- `character_set_client`
- `collation_connection`
- `collation_database`
- `collation_server`
- `sql_auto_is_null`

### 5.2.4.1. Binary Logging Formats

A number of different logging formats are used to record information in the binary log. The exact format employed depends on the version of MySQL being used. There are three logging formats:

- Replication capabilities in MySQL originally were based on propagation of SQL statements from master to slave. This is called *statement-based logging*. You can cause this format to be used by starting the server with `--binlog-format=STATEMENT`.
- In *row-based logging*, the master writes events to the binary log that indicate how individual table rows are affected. You can cause the server to use row-based logging by starting it with `--binlog-format=ROW`.
- A third option is also available: *mixed logging*. With mixed logging, statement-based logging is used by default, but the logging mode switches automatically to row-based in certain cases as described below. You can cause MySQL to use mixed logging explicitly by starting `mysqld` with the option `--binlog-format=MIXED`.

Support for row-based logging was added in MySQL 5.1.5. Mixed logging is available beginning with MySQL 5.1.8. In MySQL

5.1.12, it became the default logging mode; in 5.1.29, the default was changed back to `STATEMENT` for compatibility with MySQL 5.0.

Starting with MySQL 5.1.20, the logging format can also be set or limited by the storage engine being used. This helps to eliminate issues when replicating certain statements between a master and slave that are using different storage engines.

With statement-based replication, there may be issues with replicating nondeterministic statements. In deciding whether or not a given statement is safe for statement-based replication, MySQL determines whether it can guarantee that the statement can be replicated using statement-based logging. If MySQL cannot make this guarantee, it marks the statement as potentially unreliable and issues the warning, `STATEMENT MAY NOT BE SAFE TO LOG IN STATEMENT FORMAT`.

Prior to MySQL 5.1.36, this warning read, `STATEMENT IS NOT SAFE TO LOG IN STATEMENT FORMAT`. ([Bug#42415](#))

You can avoid these issues by using MySQL's row-based replication instead.

### 5.2.4.2. Setting The Binary Log Format

You can select the binary logging format explicitly by starting the MySQL server with `--binlog-format=type`. The supported values for `type` are:

- `STATEMENT` causes logging to be statement-based.
- `ROW` causes logging to be row-based.
- `MIXED` causes logging to use mixed format.

The default binary logging format depends on the version of MySQL you are using:

- For MySQL 5.1.11 and earlier, and for MySQL 5.1.29 and later, statement-based logging is used by default.
- For MySQL 5.1.12 through MySQL 5.1.28, mixed logging is used by default.

**Exception.** For all MySQL Cluster releases using version 6.1 or later of the `NDBCLUSTER` storage engine (even those releases based on MySQL 5.1.29 and later), the default binary log format is `MIXED`. See [Section 17.6, “MySQL Cluster Replication”](#).

The logging format also can be switched at runtime. To specify the format globally for all clients, set the global value of the `binlog_format` system variable:

```
mysql> SET GLOBAL binlog_format = 'STATEMENT';
mysql> SET GLOBAL binlog_format = 'ROW';
mysql> SET GLOBAL binlog_format = 'MIXED';
```

An individual client can control the logging format for its own statements by setting the session value of `binlog_format`:

```
mysql> SET SESSION binlog_format = 'STATEMENT';
mysql> SET SESSION binlog_format = 'ROW';
mysql> SET SESSION binlog_format = 'MIXED';
```

To change the global `binlog_format` value, you must have the `SUPER` privilege. This is also true for the session value as of MySQL 5.1.29.

In addition to switching the logging format manually, a slave server may switch the format *automatically*. This happens when the server is running in either `STATEMENT` or `MIXED` format and encounters an event in the binary log that is written in `ROW` logging format. In that case, the slave switches to row-based replication temporarily for that event, and switches back to the previous format afterward.

There are several reasons why a client might want to set binary logging on a per-session basis:

- A session that makes many small changes to the database might want to use row-based logging.
- A session that performs updates that match many rows in the `WHERE` clause might want to use statement-based logging because it will be more efficient to log a few statements than many rows.
- Some statements require a lot of execution time on the master, but result in just a few rows being modified. It might therefore be beneficial to replicate them using row-based logging.

There are exceptions when you cannot switch the replication format at runtime:

- From within a stored function or a trigger
- If the `NDBCLUSTER` storage engine is enabled
- If the session is currently in row-based replication mode and has open temporary tables

Trying to switch the format in any of these cases results in an error.

Switching the replication format at runtime is not recommended when any temporary tables exist, because temporary tables are logged only when using statement-based replication, whereas with row-based replication they are not logged. With mixed replication, temporary tables are usually logged; exceptions happen with user-defined functions (UDFs) and with the `UUID()` function.

With the binary log format set to `ROW`, many changes are written to the binary log using the row-based format. Some changes, however, still use the statement-based format. Examples include all DDL (data definition language) statements such as `CREATE TABLE`, `ALTER TABLE`, or `DROP TABLE`.

The `--binlog-row-event-max-size` option is available for servers that are capable of row-based replication. Rows are stored into the binary log in chunks having a size in bytes not exceeding the value of this option. The value must be a multiple of 256. The default value is 1024.

### Warning

When using *statement-based logging* for replication, it is possible for the data on the master and slave to become different if a statement is designed in such a way that the data modification is *nondeterministic*; that is, it is left to the will of the query optimizer. In general, this is not a good practice even outside of replication. For a detailed explanation of this issue, see [Section B.5.8.2, “Additional Known Issues”](#).

#### 5.2.4.3. Mixed Binary Logging Format

When running in `MIXED` logging format, automatic switching from statement-based to row-based logging takes place under the following conditions:

- When a DML statement updates an `NDBCLUSTER` table.
- When a function contains `UUID()`.
- Prior to MySQL 5.1.40, when two or more tables with `AUTO_INCREMENT` columns are updated. As of 5.1.40, when one or more tables with `AUTO_INCREMENT` columns are updated and a trigger or stored function is invoked. Unlike other unsafe statements, this does not generate a warning if `binlog_format = STATEMENT`.

For more information, see [Section 16.4.1.1, “Replication and AUTO\\_INCREMENT”](#).

- When any `INSERT DELAYED` is executed.
- When the body of a view requires row-based replication, the statement creating the view also uses it. For example, this occurs when the statement creating a view uses the `UUID()` function.
- When a call to a UDF is involved.
- If a statement is logged by row and the session that executed the statement has any temporary tables, logging by row is used for all subsequent statements (except for those accessing temporary tables) until all temporary tables in use by that session are dropped.

This is true whether or not any temporary tables are actually logged.

Temporary tables cannot be logged using row-based format; thus, once row-based logging is used, all subsequent statements using that table are unsafe. The server approximates this condition by treating all statements executed during the session as unsafe until the session no longer holds any temporary tables.

- Beginning with MySQL 5.1.23:
  - When `FOUND_ROWS()` or `ROW_COUNT()` is used. ([Bug#12092](#), [Bug#30244](#))
  - When `USER()`, `CURRENT_USER()`, or `CURRENT_USER` is used. ([Bug#28086](#))
- Beginning with MySQL 5.1.24, when a statement refers to one or more system variables. ([Bug#31168](#))

**Exception.** The following system variables, when used with session scope (only), do not cause the logging format to switch:

- `auto_increment_increment`
- `auto_increment_offset`
- `character_set_client`
- `character_set_connection`
- `character_set_database`
- `character_set_server`
- `collation_connection`
- `collation_database`
- `collation_server`
- `foreign_key_checks`
- `identity`
- `last_insert_id`
- `lc_time_names`
- `pseudo_thread_id`
- `sql_auto_is_null`
- `time_zone`
- `timestamp`
- `unique_checks`

For information about determining system variable scope, see [Section 5.1.5, “Using System Variables”](#).

For information about how replication treats `sql_mode`, see [Section 16.4.1.32, “Replication and Variables”](#).

- Beginning with MySQL 5.1.30, when one of the tables involved is a log table in the `mysql` database.
- Beginning with MySQL 5.1.34, when the `LOAD_FILE()` function is used. ([Bug#39701](#))

### Note

Starting with MySQL 5.1.20, a warning is generated if you try to execute a statement using statement-based logging that should be written using row-based logging. The warning is shown both in the client (in the output of `SHOW WARNINGS`) and through the `mysqld` error log. A warning is added to the `SHOW WARNINGS` table each time such a statement is executed. However, only the first statement that generated the warning for each client session is written to the error log to prevent flooding the log.

Starting with MySQL 5.1.20, in addition to the decisions above, individual engines can also determine the logging format used when information in a table is updated. The logging capabilities of an individual engine can be defined as follows:

- If an engine supports row-based logging, the engine is said to be *row-logging capable*.
- If an engine supports statement-based logging, the engine is said to be *statement-logging capable*.

A given storage engine can support either or both logging formats. The following table lists the logging formats supported by each storage engine.

Storage Engine	Row Logging Supported	Statement Logging Supported
<code>ARCHIVE</code>	Yes	Yes

Storage Engine	Row Logging Supported	Statement Logging Supported
BLACKHOLE	Yes	Yes
CSV	Yes	Yes
EXAMPLE	Yes	No
FEDERATED	Yes	Yes
HEAP	Yes	Yes
InnoDB	Yes	Yes when the transaction isolation level is <code>REPEATABLE READ</code> or <code>SERIALIZABLE</code> ; No otherwise.
MyISAM	Yes	Yes
MERGE	Yes	Yes
NDBCLUSTER	Yes	No

When determining the logging mode to be used, the capabilities of all the tables affected by the event are combined. The set of affected tables is then marked according to these rules:

- A set of tables is defined as *row-logging restricted* if the tables are row-logging capable but not statement-logging capable.
- A set of tables is defined as *statement-logging restricted* if the tables are statement-logging capable but not row-logging capable.

Once the determination of the possible logging formats required by the statement is complete it is compared to the current `binlog_format` setting. The following table is used to decide how the information is recorded in the binary log or, if appropriate, whether an error is raised. In the table, a safe operation is defined as one that is deterministic.

Several rules decide whether the statement is deterministic, as shown in the following table, where **SLR** stands for “statement-logging restricted” and **RLR** stands for “row-logging restricted”. A statement is *statement-logging restricted* if one or more of the tables it accesses is not row-logging capable. Similarly, a statement is *row-logging restricted* if any table accessed by the statement is not statement-logging capable.

Condition		Action			
Safe/un-safe	<code>binlog_format</code>	SLR	RLR	Error/Warning	Logged as
Safe	STATEMENT	Yes	Yes	ERROR: NOT LOGGABLE	
Safe	STATEMENT	Yes	No		STATEMENT
Safe	STATEMENT	No	Yes	ERROR: NOT LOGGABLE	
Safe	STATEMENT	No	No		STATEMENT
Safe	MIXED	Yes	Yes	ERROR: NOT LOGGABLE	
Safe	MIXED	Yes	No		STATEMENT
Safe	MIXED	No	Yes		ROW
Safe	MIXED	No	No		STATEMENT
Safe	ROW	Yes	Yes	ERROR: NOT LOGGABLE	
Safe	ROW	Yes	No	ERROR: NOT LOGGABLE	
Safe	ROW	No	Yes		ROW
Safe	ROW	No	No		ROW
Unsafe	STATEMENT	Yes	Yes	ERROR: NOT LOGGABLE	
Unsafe	STATEMENT	Yes	No	WARNING: UNSAFE	STATEMENT
Unsafe	STATEMENT	No	Yes	ERROR: NOT LOGGABLE	
Unsafe	STATEMENT	No	No	WARNING: UNSAFE	STATEMENT
Unsafe	MIXED	Yes	Yes	ERROR: NOT LOGGABLE	
Unsafe	MIXED	Yes	No	ERROR: NOT LOGGABLE	
Unsafe	MIXED	No	Yes		ROW

Condition				Action	
Safe/un-safe	binlog_format	SLR	RLR	Error/Warning	Logged as
Unsafe	MIXED	No	No		ROW
Unsafe	ROW	Yes	Yes	ERROR: NOT LOGGABLE	
Unsafe	ROW	Yes	No	ERROR: NOT LOGGABLE	
Unsafe	ROW	No	Yes		ROW
Unsafe	ROW	No	No		ROW

When a warning is produced by the determination, a standard MySQL warning is produced (and is available using `SHOW WARNINGS`). The information is also written to the `mysqld` error log. Only one error for each error instance per client connection is logged to prevent flooding the log. The log message includes the SQL statement that was attempted.

If a slave server was started with `--log-warnings` enabled, the slave prints messages to the error log to provide information about its status, such as the binary log and relay log coordinates where it starts its job, when it is switching to another relay log, when it reconnects after a disconnect, and so forth.

#### 5.2.4.4. Logging Format for Changes to `mysql` Database Tables

The contents of the grant tables in the `mysql` database can be modified directly (for example, with `INSERT` or `DELETE`) or indirectly (for example, with `GRANT` or `CREATE USER`). As of MySQL 5.1.17, statements that affect `mysql` database tables are written to the binary log using the following rules:

- Data manipulation statements that change data in `mysql` database tables directly are logged according to the setting of the `binlog_format` system variable. This pertains to statements such as `INSERT`, `UPDATE`, `DELETE`, `REPLACE`, `DO`, `LOAD DATA INFILE`, `SELECT`, and `TRUNCATE TABLE`.
- Statements that change the `mysql` database indirectly are logged as statements regardless of the value of `binlog_format`. This pertains to statements such as `GRANT`, `REVOKE`, `SET PASSWORD`, `RENAME USER`, `CREATE` (all forms except `CREATE TABLE ... SELECT`), `ALTER` (all forms), and `DROP` (all forms).

`CREATE TABLE ... SELECT` is a combination of data definition and data manipulation. The `CREATE TABLE` part is logged using statement format and the `SELECT` part is logged according to the value of `binlog_format`.

#### 5.2.5. The Slow Query Log

The slow query log consists of all SQL statements that took more than `long_query_time` seconds to execute and (as of MySQL 5.1.21) required at least `min_examined_row_limit` rows to be examined. The time to acquire the initial table locks is not counted as execution time. `mysqld` writes a statement to the slow query log after it has been executed and after all locks have been released, so log order might be different from execution order. The default value of `long_query_time` is 10. As of MySQL 5.1.21, the minimum value is 0, and a resolution of microseconds is supported when logging to a file. However, the microseconds part is ignored and only integer values are written when logging to tables. Prior to MySQL 5.1.21, the minimum value is 1, and the value for this variable must be an integer.

Control the slow query log at server startup as follows:

- Before 5.1.6, the slow query log destination is always a file. To enable the log, start `mysqld` with the `--log-slow-queries[=file_name]` option.
- As of MySQL 5.1.6, the destination can be a file or a table, or both. Start `mysqld` with the `--log-slow-queries[=file_name]` option to enable the slow query log, and optionally use `--log-output` to specify the log destination (as described in [Section 5.2.1, “Selecting General Query and Slow Query Log Output Destinations”](#)).
- As of MySQL 5.1.12, as an alternative to `--log-slow-queries`, use `--slow_query_log[={0|1}]` to specify the initial slow query log state. In this case, the default slow query log file name is used. With no argument or an argument of 1, `--slow_query_log` enables the log. With an argument of 0, this option disables the log.
- As of MySQL 5.1.29, use `--slow_query_log[={0|1}]` to enable or disable the slow query log, and optionally `--slow_query_log_file=file_name` to specify a log file name. The `--log-slow-queries` option is deprecated.

If you specify no name for the slow query log file, the default name is `host_name-slow.log`. The server creates the file in the data directory unless an absolute path name is given to specify a different directory.

To control the slow log at runtime, use the global `slow_query_log` and `slow_query_log_file` system variables. Set `slow_query_log` to 0 (or `OFF`) to disable the log or to 1 (or `ON`) to enable it. Set `slow_query_log_file` to specify the name of the log file. If a log file already is open, it is closed and the new file is opened.

When the slow query log is enabled, the server writes output to any destinations specified by the `--log-output` option or `log_output` system variable. If you enable the log, the server opens the log file and writes startup messages to it. However, further logging of queries to the file does not occur unless the `FILE` log destination is selected. If the destination is `NONE`, no queries are written even if the slow query log is enabled. Setting the log file name has no effect on logging if the log destination value does not contain `FILE`.

The slow query log can be used to find queries that take a long time to execute and are therefore candidates for optimization. However, examining a long slow query log can become a difficult task. To make this easier, you can process a slow query log file using the `mysqldumpslow` command to summarize the queries that appear in the log. See [Section 4.6.8, “mysqldumpslow — Summarize Slow Query Log Files”](#).

In MySQL 5.1, queries that do not use indexes are logged in the slow query log if the `--log-queries-not-using-indexes` option is specified. See [Section 5.1.2, “Server Command Options”](#).

In MySQL 5.1, the `--log-slow-admin-statements` server option enables you to request logging of slow administrative statements such as `OPTIMIZE TABLE`, `ANALYZE TABLE`, and `ALTER TABLE` to the slow query log.

Queries handled by the query cache are not added to the slow query log, nor are queries that would not benefit from the presence of an index because the table has zero rows or one row.

Prior to MySQL 5.1.45, replication slaves did not write replicated queries to the slow query log, even if the same queries were written to the slow query log on the master. ([Bug#23300](#)) In MySQL 5.1.45 and later, this behavior can be overridden using the `--log-slow-slave-statements` option.

The slow query log should be protected because logged statements might contain passwords. See [Section 5.3.2.1, “Administrator Guidelines for Password Security”](#).

## 5.2.6. Server Log Maintenance

MySQL Server can create a number of different log files to help you see what is going on. See [Section 5.2, “MySQL Server Logs”](#). However, you must clean up these files regularly to ensure that the logs do not take up too much disk space.

When using MySQL with logging enabled, you may want to back up and remove old log files from time to time and tell MySQL to start logging to new files. See [Section 6.2, “Database Backup Methods”](#).

On a Linux (Red Hat) installation, you can use the `mysql-log-rotate` script for this. If you installed MySQL from an RPM distribution, this script should have been installed automatically. You should be careful with this script if you are using the binary log for replication. You should not remove binary logs until you are certain that their contents have been processed by all slaves.

On other systems, you must install a short script yourself that you start from `cron` (or its equivalent) for handling log files.

For the binary log, you can set the `expire_logs_days` system variable to expire binary log files automatically after a given number of days (see [Section 5.1.4, “Server System Variables”](#)). If you are using replication, you should set the variable no lower than the maximum number of days your slaves might lag behind the master. To remove binary logs on demand, use the `PURGE BINARY LOGS` statement (see [Section 12.5.1.1, “PURGE BINARY LOGS Syntax”](#)).

You can force MySQL to start using new log files by flushing the logs. Log flushing occurs when you issue a `FLUSH LOGS` statement or execute a `mysqladmin flush-logs`, `mysqladmin refresh`, `mysqldump --flush-logs`, or `mysqldump --master-data` command. See [Section 12.4.6.3, “FLUSH Syntax”](#), [Section 4.5.2, “mysqladmin — Client for Administering a MySQL Server”](#), and [Section 4.5.4, “mysqldump — A Database Backup Program”](#). In addition, the binary log is flushed when its size reaches the value of the `max_binlog_size` system variable.

A log-flushing operation does the following:

- If general query logging or slow query logging to a log file is enabled, the server closes and reopens the general query log file or slow query log file.
- If binary logging is enabled, the server closes the current binary log file and opens a new log file with the next sequence number.
- If the server was started with the `--log-error` option to cause the error log to be written to a file, it renames the current log file with the suffix `-old` and creates a new empty error log file.

The server creates a new binary log file when you flush the logs. However, it just closes and reopens the general and slow query

log files. To cause new files to be created on Unix, rename the current logs before flushing them. At flush time, the server opens new logs with the original names. For example, if the general and slow query logs are named `mysql.log` and `mysql-slow.log`, you can use a series of commands like this:

```
shell> cd mysql-data-directory
shell> mv mysql.log mysql.old
shell> mv mysql-slow.log mysql-slow.old
shell> mysqladmin flush-logs
```

On Windows, use `rename` rather than `mv`.

At this point, you can make a backup of `mysql.old` and `mysql-slow.old` and then remove them from disk.

As of MySQL 5.1.12, you can rename the general query log or slow query log at runtime by disabling the log:

```
SET GLOBAL general_log = 'OFF';
SET GLOBAL slow_query_log = 'OFF';
```

With the logs disabled, rename the log files externally; for example, from the command line. Then enable the logs again:

```
SET GLOBAL general_log = 'ON';
SET GLOBAL slow_query_log = 'ON';
```

This method works on any platform and does not require a server restart.

For older versions of MySQL, you cannot rename certain log files on Windows while the server has them open. Before MySQL 5.1.3, this restriction applies to all log files. You must stop the server, rename the file, then restart the server to create a new log file. From 5.1.4 to 5.1.50, the restriction applies only to the error log file. To rename the error log file, a stop and restart can be avoided by flushing the logs to cause the server to rename the current log file with the suffix `-old` and create a new empty error log file.

## 5.3. General Security Issues

This section describes some general security issues to be aware of and what you can do to make your MySQL installation more secure against attack or misuse. For information specifically about the access control system that MySQL uses for setting up user accounts and checking database access, see [Section 5.4, “The MySQL Access Privilege System”](#).

For answers to some questions that are often asked about MySQL Server security issues, see [Section A.9, “MySQL 5.1 FAQ: Security”](#).

### 5.3.1. General Security Guidelines

Anyone using MySQL on a computer connected to the Internet should read this section to avoid the most common security mistakes.

In discussing security, we emphasize the necessity of fully protecting the entire server host (not just the MySQL server) against all types of applicable attacks: eavesdropping, altering, playback, and denial of service. We do not cover all aspects of availability and fault tolerance here.

MySQL uses security based on Access Control Lists (ACLs) for all connections, queries, and other operations that users can attempt to perform. There is also support for SSL-encrypted connections between MySQL clients and servers. Many of the concepts discussed here are not specific to MySQL at all; the same general ideas apply to almost all applications.

When running MySQL, follow these guidelines whenever possible:

- **Do not ever give anyone (except MySQL `root` accounts) access to the `user` table in the `mysql` database!** This is critical.
- Learn the MySQL access privilege system. The `GRANT` and `REVOKE` statements are used for controlling access to MySQL. Do not grant more privileges than necessary. Never grant privileges to all hosts.

Checklist:

- Try `mysql -u root`. If you are able to connect successfully to the server without being asked for a password, anyone can connect to your MySQL server as the MySQL `root` user with full privileges! Review the MySQL installation instructions, paying particular attention to the information about setting a `root` password. See [Section 2.13.2, “Securing the Initial MySQL Accounts”](#).
- Use the `SHOW GRANTS` statement to check which accounts have access to what. Then use the `REVOKE` statement to remove those privileges that are not necessary.

- Do not store any plain-text passwords in your database. If your computer becomes compromised, the intruder can take the full list of passwords and use them. Instead, use [MD5\(\)](#), [SHA1\(\)](#), or some other one-way hashing function and store the hash value.
- Do not choose passwords from dictionaries. Special programs exist to break passwords. Even passwords like “xfish98” are very bad. Much better is “duag98” which contains the same word “fish” but typed one key to the left on a standard QWERTY keyboard. Another method is to use a password that is taken from the first characters of each word in a sentence (for example, “Mary had a little lamb” results in a password of “Mhall”). The password is easy to remember and type, but difficult to guess for someone who does not know the sentence.
- Invest in a firewall. This protects you from at least 50% of all types of exploits in any software. Put MySQL behind the firewall or in a demilitarized zone (DMZ).

Checklist:

- Try to scan your ports from the Internet using a tool such as [nmap](#). MySQL uses port 3306 by default. This port should not be accessible from untrusted hosts. Another simple way to check whether or not your MySQL port is open is to try the following command from some remote machine, where `server_host` is the host name or IP number of the host on which your MySQL server runs:

```
shell> telnet server_host 3306
```

If you get a connection and some garbage characters, the port is open, and should be closed on your firewall or router, unless you really have a good reason to keep it open. If [telnet](#) hangs or the connection is refused, the port is blocked, which is how you want it to be.

- Do not trust any data entered by users of your applications. They can try to trick your code by entering special or escaped character sequences in Web forms, URLs, or whatever application you have built. Be sure that your application remains secure if a user enters something like “`; DROP DATABASE mysql;`”. This is an extreme example, but large security leaks and data loss might occur as a result of hackers using similar techniques, if you do not prepare for them.

A common mistake is to protect only string data values. Remember to check numeric data as well. If an application generates a query such as `SELECT * FROM table WHERE ID=234` when a user enters the value `234`, the user can enter the value `234 OR 1=1` to cause the application to generate the query `SELECT * FROM table WHERE ID=234 OR 1=1`. As a result, the server retrieves every row in the table. This exposes every row and causes excessive server load. The simplest way to protect from this type of attack is to use single quotation marks around the numeric constants: `SELECT * FROM table WHERE ID='234'`. If the user enters extra information, it all becomes part of the string. In a numeric context, MySQL automatically converts this string to a number and strips any trailing nonnumeric characters from it.

Sometimes people think that if a database contains only publicly available data, it need not be protected. This is incorrect. Even if it is permissible to display any row in the database, you should still protect against denial of service attacks (for example, those that are based on the technique in the preceding paragraph that causes the server to waste resources). Otherwise, your server becomes unresponsive to legitimate users.

Checklist:

- Try to enter single and double quotation marks (“`'`” and “`"`”) in all of your Web forms. If you get any kind of MySQL error, investigate the problem right away.
- Try to modify dynamic URLs by adding `%22` (“`"`”), `%23` (“`#`”), and `%27` (“`'`”) to them.
- Try to modify data types in dynamic URLs from numeric to character types using the characters shown in the previous examples. Your application should be safe against these and similar attacks.
- Try to enter characters, spaces, and special symbols rather than numbers in numeric fields. Your application should remove them before passing them to MySQL or else generate an error. Passing unchecked values to MySQL is very dangerous!
- Check the size of data before passing it to MySQL.
- Have your application connect to the database using a user name different from the one you use for administrative purposes. Do not give your applications any access privileges they do not need.
- Many application programming interfaces provide a means of escaping special characters in data values. Properly used, this prevents application users from entering values that cause the application to generate statements that have a different effect than you intend:
  - MySQL C API: Use the [mysql\\_real\\_escape\\_string\(\)](#) API call.
  - MySQL++: Use the `escape` and `quote` modifiers for query streams.

- PHP: Use the `mysql_real_escape_string()` function (available as of PHP 4.3.0, prior to that PHP version use `mysql_escape_string()`, and prior to PHP 4.0.3, use `addslashes()`). Note that only `mysql_real_escape_string()` is character set-aware; the other functions can be “bypassed” when using (invalid) multi-byte character sets. In PHP 5, you can use the `mysqli` extension, which supports the improved MySQL authentication protocol and passwords, as well as prepared statements with placeholders.
- Perl DBI: Use placeholders or the `quote()` method.
- Ruby DBI: Use placeholders or the `quote()` method.
- Java JDBC: Use a `PreparedStatement` object and placeholders.

Other programming interfaces might have similar capabilities.

- Do not transmit plain (unencrypted) data over the Internet. This information is accessible to everyone who has the time and ability to intercept it and use it for their own purposes. Instead, use an encrypted protocol such as SSL or SSH. MySQL supports internal SSL connections as of version 4.0. Another technique is to use SSH port-forwarding to create an encrypted (and compressed) tunnel for the communication.
- Learn to use the `tcpdump` and `strings` utilities. In most cases, you can check whether MySQL data streams are unencrypted by issuing a command like the following:

```
shell> tcpdump -l -i eth0 -w - src or dst port 3306 | strings
```

This works under Linux and should work with small modifications under other systems.

### Warning

If you do not see plaintext data, this does not always mean that the information actually is encrypted. If you need high security, you should consult with a security expert.

## 5.3.2. Password Security in MySQL

Passwords occur in several contexts within MySQL. The following sections provide guidelines that enable administrators and end users to keep these passwords secure and avoid exposing them. There is also a discussion of how MySQL uses password hashing internally.

### 5.3.2.1. Administrator Guidelines for Password Security

Database administrators should use the following guidelines to keep passwords secure.

MySQL stores passwords for user accounts in the `mysql.user` table. Access to this table should never be granted to any nonadministrative accounts.

Passwords can appear as plain text in SQL statements such as `CREATE USER`, `GRANT`, and `SET PASSWORD`. If these statements are logged by the MySQL server, the passwords become available to anyone with access to the logs. This applies to the general query log, the slow query log, and the binary log (see [Section 5.2, “MySQL Server Logs”](#)). To guard against unwarranted exposure to log files, they should be located in a directory that restricts access to only the server and the database administrator. If you log to tables in the `mysql` database, access to the tables should never be granted to any nonadministrative accounts.

Replication slaves store the password for the replication master in the `master.info` file. Access to this file should be restricted to the database administrator.

Database backups that include tables or log files containing passwords should be protected using a restricted access mode.

### 5.3.2.2. End-User Guidelines for Password Security

MySQL users should use the following guidelines to keep passwords secure.

When you run a client program to connect to the MySQL server, it is inadvisable to specify your password in a way that exposes it to discovery by other users. The methods you can use to specify your password when you run client programs are listed here, along with an assessment of the risks of each method. In short, the safest methods are to have the client program prompt for the password or to specify the password in a properly protected option file.

- Use a `-pyour_pass` or `--password=your_pass` option on the command line. For example:

```
shell> mysql -u francis -pfrank db_name
```

This is convenient *but insecure*, because your password becomes visible to system status programs such as `ps` that may be invoked by other users to display command lines. MySQL clients typically overwrite the command-line password argument with zeros during their initialization sequence. However, there is still a brief interval during which the value is visible. Also, on some systems this overwriting strategy is ineffective and the password remains visible to `ps`. (SystemV Unix systems and perhaps others are subject to this problem.)

If your operating environment is set up to display your current command in the title bar of your terminal window, the password remains visible as long as the command is running, even if the command has scrolled out of view in the window content area.

- Use the `-p` or `--password` option on the command line with no password value specified. In this case, the client program solicits the password interactively:

```
shell> mysql -u francis -p db_name
Enter password: *****
```

The “\*” characters indicate where you enter your password. The password is not displayed as you enter it.

It is more secure to enter your password this way than to specify it on the command line because it is not visible to other users. However, this method of entering a password is suitable only for programs that you run interactively. If you want to invoke a client from a script that runs noninteractively, there is no opportunity to enter the password from the keyboard. On some systems, you may even find that the first line of your script is read and interpreted (incorrectly) as your password.

- Store your password in an option file. For example, on Unix you can list your password in the `[client]` section of the `.my.cnf` file in your home directory:

```
[client]
password=your_pass
```

To keep the password safe, the file should not be accessible to anyone but yourself. To ensure this, set the file access mode to `400` or `600`. For example:

```
shell> chmod 600 .my.cnf
```

[Section 4.2.3.3, “Using Option Files”](#), discusses option files in more detail.

- Store your password in the `MYSQL_PWD` environment variable. See [Section 2.14, “Environment Variables”](#).

This method of specifying your MySQL password must be considered *extremely insecure* and should not be used. Some versions of `ps` include an option to display the environment of running processes. If you set `MYSQL_PWD`, your password is exposed to any other user who runs `ps`. Even on systems without such a version of `ps`, it is unwise to assume that there are no other methods by which users can examine process environments.

On Unix, the `mysql` client writes a record of executed statements to a history file (see [Section 4.5.1.3, “mysql History File”](#)). By default, this file is named `.mysql_history` and is created in your home directory. Passwords can appear as plain text in SQL statements such as `CREATE USER`, `GRANT`, and `SET PASSWORD`, so if you use these statements, they are logged in the history file. To keep this file safe, use a restrictive access mode, the same way as described earlier for the `.my.cnf` file.

If your command interpreter is configured to maintain a history, any file in which the commands are saved will contain MySQL passwords entered on the command line. For example, `bash` uses `~/.bash_history`. Any such file should have a restrictive access mode.

### 5.3.2.3. Password Hashing in MySQL

MySQL user accounts are listed in the `user` table of the `mysql` database. Each MySQL account is assigned a password, although what is stored in the `Password` column of the `user` table is not the plaintext version of the password, but a hash value computed from it. Password hash values are computed by the `PASSWORD()` function.

MySQL uses passwords in two phases of client/server communication:

- When a client attempts to connect to the server, there is an initial authentication step in which the client must present a password that has a hash value matching the hash value stored in the `user` table for the account that the client wants to use.
- After the client connects, it can (if it has sufficient privileges) set or change the password hashes for accounts listed in the `user` table. The client can do this by using the `PASSWORD()` function to generate a password hash, or by using the `GRANT` or `SET PASSWORD` statements.

In other words, the server *uses* hash values during authentication when a client first attempts to connect. The server *generates* hash values if a connected client invokes the `PASSWORD()` function or uses a `GRANT` or `SET PASSWORD` statement to set or change a password.

The password hashing mechanism was updated in MySQL 4.1 to provide better security and to reduce the risk of passwords being intercepted. However, this new mechanism is understood only by MySQL 4.1 (and newer) servers and clients, which can result in some compatibility problems. A 4.1 or newer client can connect to a pre-4.1 server, because the client understands both the old and new password hashing mechanisms. However, a pre-4.1 client that attempts to connect to a 4.1 or newer server may run into difficulties. For example, a 3.23 `mysql` client that attempts to connect to a 5.1 server may fail with the following error message:

```
shell> mysql -h localhost -u root
Client does not support authentication protocol requested
by server; consider upgrading MySQL client
```

Another common example of this phenomenon occurs for attempts to use the older PHP `mysql` extension after upgrading to MySQL 4.1 or newer. (See [Section 21.10.6, “Common Problems with MySQL and PHP”](#).)

The following discussion describes the differences between the old and new password mechanisms, and what you should do if you upgrade your server but need to maintain backward compatibility with pre-4.1 clients. Additional information can be found in [Section B.5.2.4, “Client does not support authentication protocol”](#). This information is of particular importance to PHP programmers migrating MySQL databases from version 4.0 or lower to version 4.1 or higher.

### Note

This discussion contrasts 4.1 behavior with pre-4.1 behavior, but the 4.1 behavior described here actually begins with 4.1.1. MySQL 4.1.0 is an “odd” release because it has a slightly different mechanism than that implemented in 4.1.1 and up. Differences between 4.1.0 and more recent versions are described further in MySQL 5.0 Reference Manual.

Prior to MySQL 4.1, password hashes computed by the `PASSWORD()` function are 16 bytes long. Such hashes look like this:

```
mysql> SELECT PASSWORD('mypass');
+-----+
| PASSWORD('mypass') |
+-----+
| 6f8c114b58f2ce9e |
+-----+
```

The `Password` column of the `user` table (in which these hashes are stored) also is 16 bytes long before MySQL 4.1.

As of MySQL 4.1, the `PASSWORD()` function has been modified to produce a longer 41-byte hash value:

```
mysql> SELECT PASSWORD('mypass');
+-----+
| PASSWORD('mypass') |
+-----+
| *6C8989366EAF75BB670AD8EA7A7FC1176A95CEF4 |
+-----+
```

Accordingly, the `Password` column in the `user` table also must be 41 bytes long to store these values:

- If you perform a new installation of MySQL 5.1, the `Password` column is made 41 bytes long automatically.
- Upgrading from MySQL 4.1 (4.1.1 or later in the 4.1 series) to MySQL 5.1 should not give rise to any issues in this regard because both versions use the same password hashing mechanism. If you wish to upgrade an older release of MySQL to version 5.1, you should upgrade to version 4.1 first, then upgrade the 4.1 installation to 5.1.

A widened `Password` column can store password hashes in both the old and new formats. The format of any given password hash value can be determined two ways:

- The obvious difference is the length (16 bytes versus 41 bytes).
- A second difference is that password hashes in the new format always begin with a “`*`” character, whereas passwords in the old format never do.

The longer password hash format has better cryptographic properties, and client authentication based on long hashes is more secure than that based on the older short hashes.

The differences between short and long password hashes are relevant both for how the server uses passwords during authentication and for how it generates password hashes for connected clients that perform password-changing operations.

The way in which the server uses password hashes during authentication is affected by the width of the `Password` column:

- If the column is short, only short-hash authentication is used.
- If the column is long, it can hold either short or long hashes, and the server can use either format:
  - Pre-4.1 clients can connect, although because they know only about the old hashing mechanism, they can authenticate only using accounts that have short hashes.
  - 4.1 and later clients can authenticate using accounts that have short or long hashes.

Even for short-hash accounts, the authentication process is actually a bit more secure for 4.1 and later clients than for older clients. In terms of security, the gradient from least to most secure is:

- Pre-4.1 client authenticating with short password hash
- 4.1 or later client authenticating with short password hash
- 4.1 or later client authenticating with long password hash

The way in which the server generates password hashes for connected clients is affected by the width of the `Password` column and by the `--old-passwords` option. A 4.1 or later server generates long hashes only if certain conditions are met: The `Password` column must be wide enough to hold long values and the `--old-passwords` option must not be given. These conditions apply as follows:

- The `Password` column must be wide enough to hold long hashes (41 bytes). If the column has not been updated and still has the pre-4.1 width of 16 bytes, the server notices that long hashes cannot fit into it and generates only short hashes when a client performs password-changing operations using `PASSWORD()`, `GRANT`, or `SET PASSWORD`. This is the behavior that occurs if you have upgraded to 4.1 but have not yet run the `mysql_upgrade` program to widen the `Password` column.
- If the `Password` column is wide, it can store either short or long password hashes. In this case, `PASSWORD()`, `GRANT`, and `SET PASSWORD` generate long hashes unless the server was started with the `--old-passwords` option. That option forces the server to generate short password hashes instead.

The purpose of the `--old-passwords` option is to enable you to maintain backward compatibility with pre-4.1 clients under circumstances where the server would otherwise generate long password hashes. The option doesn't affect authentication (4.1 and later clients can still use accounts that have long password hashes), but it does prevent creation of a long password hash in the `user` table as the result of a password-changing operation. Were that to occur, the account no longer could be used by pre-4.1 clients. Without the `--old-passwords` option, the following undesirable scenario is possible:

- An old client connects to an account that has a short password hash.
- The client changes its own password. Without `--old-passwords`, this results in the account having a long password hash.
- The next time the old client attempts to connect to the account, it cannot, because the account has a long password hash that requires the new hashing mechanism during authentication. (Once an account has a long password hash in the `user` table, only 4.1 and later clients can authenticate for it, because pre-4.1 clients do not understand long hashes.)

This scenario illustrates that, if you must support older pre-4.1 clients, it is dangerous to run a 4.1 or newer server without using the `--old-passwords` option. By running the server with `--old-passwords`, password-changing operations do not generate long password hashes and thus do not cause accounts to become inaccessible to older clients. (Those clients cannot inadvertently lock themselves out by changing their password and ending up with a long password hash.)

The downside of the `--old-passwords` option is that any passwords you create or change use short hashes, even for 4.1 clients. Thus, you lose the additional security provided by long password hashes. If you want to create an account that has a long hash (for example, for use by 4.1 clients), you must do so while running the server without `--old-passwords`.

The following scenarios are possible for running a 4.1 or later server:

**Scenario 1:** Short `Password` column in user table:

- Only short hashes can be stored in the `Password` column.

- The server uses only short hashes during client authentication.
- For connected clients, password hash-generating operations involving `PASSWORD()`, `GRANT`, or `SET PASSWORD` use short hashes exclusively. Any change to an account's password results in that account having a short password hash.
- The `--old-passwords` option can be used but is superfluous because with a short `Password` column, the server generates only short password hashes anyway.

**Scenario 2:** Long `Password` column; server not started with `--old-passwords` option:

- Short or long hashes can be stored in the `Password` column.
- 4.1 and later clients can authenticate using accounts that have short or long hashes.
- Pre-4.1 clients can authenticate only using accounts that have short hashes.
- For connected clients, password hash-generating operations involving `PASSWORD()`, `GRANT`, or `SET PASSWORD` use long hashes exclusively. A change to an account's password results in that account having a long password hash.

As indicated earlier, a danger in this scenario is that it is possible for accounts that have a short password hash to become inaccessible to pre-4.1 clients. A change to such an account's password made using `GRANT`, `PASSWORD()`, or `SET PASSWORD` results in the account being given a long password hash. From that point on, no pre-4.1 client can authenticate to that account until the client upgrades to 4.1.

To deal with this problem, you can change a password in a special way. For example, normally you use `SET PASSWORD` as follows to change an account password:

```
SET PASSWORD FOR 'some_user'@'some_host' = PASSWORD('mypass');
```

To change the password but create a short hash, use the `OLD_PASSWORD()` function instead:

```
SET PASSWORD FOR 'some_user'@'some_host' = OLD_PASSWORD('mypass');
```

`OLD_PASSWORD()` is useful for situations in which you explicitly want to generate a short hash.

**Scenario 3:** Long `Password` column; 4.1 or newer server started with `--old-passwords` option:

- Short or long hashes can be stored in the `Password` column.
- 4.1 and later clients can authenticate for accounts that have short or long hashes (but note that it is possible to create long hashes only when the server is started without `--old-passwords`).
- Pre-4.1 clients can authenticate only for accounts that have short hashes.
- For connected clients, password hash-generating operations involving `PASSWORD()`, `GRANT`, or `SET PASSWORD` use short hashes exclusively. Any change to an account's password results in that account having a short password hash.

In this scenario, you cannot create accounts that have long password hashes, because the `--old-passwords` option prevents generation of long hashes. Also, if you create an account with a long hash before using the `--old-passwords` option, changing the account's password while `--old-passwords` is in effect results in the account being given a short password, causing it to lose the security benefits of a longer hash.

The disadvantages for these scenarios may be summarized as follows:

In scenario 1, you cannot take advantage of longer hashes that provide more secure authentication.

In scenario 2, accounts with short hashes become inaccessible to pre-4.1 clients if you change their passwords without explicitly using `OLD_PASSWORD()`.

In scenario 3, `--old-passwords` prevents accounts with short hashes from becoming inaccessible, but password-changing operations cause accounts with long hashes to revert to short hashes, and you cannot change them back to long hashes while `--old-passwords` is in effect.

### 5.3.2.4. Implications of Password Hashing Changes in MySQL 4.1 for Application Programs

---

An upgrade to MySQL version 4.1 or later can cause compatibility issues for applications that use `PASSWORD()` to generate passwords for their own purposes. Applications really should not do this, because `PASSWORD()` should be used only to manage passwords for MySQL accounts. But some applications use `PASSWORD()` for their own purposes anyway.

If you upgrade to 4.1 or later from a pre-4.1 version of MySQL and run the server under conditions where it generates long password hashes, an application using `PASSWORD()` for its own passwords breaks. The recommended course of action in such cases is to modify the application to use another function, such as `SHA1()` or `MD5()`, to produce hashed values. If that is not possible, you can use the `OLD_PASSWORD()` function, which is provided for generating short hashes in the old format. However, you should note that `OLD_PASSWORD()` may one day no longer be supported.

If the server is running under circumstances where it generates short hashes, `OLD_PASSWORD()` is available but is equivalent to `PASSWORD()`.

PHP programmers migrating their MySQL databases from version 4.0 or lower to version 4.1 or higher should see [Section 21.10, “MySQL PHP API”](#).

### 5.3.3. Making MySQL Secure Against Attackers

When you connect to a MySQL server, you should use a password. The password is not transmitted in clear text over the connection. Password handling during the client connection sequence was upgraded in MySQL 4.1.1 to be very secure. If you are still using pre-4.1.1-style passwords, the encryption algorithm is not as strong as the newer algorithm. With some effort, a clever attacker who can sniff the traffic between the client and the server can crack the password. (See [Section 5.3.2.3, “Password Hashing in MySQL”](#), for a discussion of the different password handling methods.)

All other information is transferred as text, and can be read by anyone who is able to watch the connection. If the connection between the client and the server goes through an untrusted network, and you are concerned about this, you can use the compressed protocol to make traffic much more difficult to decipher. You can also use MySQL's internal SSL support to make the connection even more secure. See [Section 5.5.6, “Using SSL for Secure Connections”](#). Alternatively, use SSH to get an encrypted TCP/IP connection between a MySQL server and a MySQL client. You can find an Open Source SSH client at <http://www.openssh.org/>, and a commercial SSH client at <http://www.ssh.com/>.

To make a MySQL system secure, you should strongly consider the following suggestions:

- Require all MySQL accounts to have a password. A client program does not necessarily know the identity of the person running it. It is common for client/server applications that the user can specify any user name to the client program. For example, anyone can use the `mysql` program to connect as any other person simply by invoking it as `mysql -u other_user db_name` if `other_user` has no password. If all accounts have a password, connecting using another user's account becomes much more difficult.

For a discussion of methods for setting passwords, see [Section 5.5.5, “Assigning Account Passwords”](#).

- Never run the MySQL server as the Unix `root` user. This is extremely dangerous, because any user with the `FILE` privilege is able to cause the server to create files as `root` (for example, `~root/.bashrc`). To prevent this, `mysqld` refuses to run as `root` unless that is specified explicitly using the `--user=root` option.

`mysqld` can (and should) be run as an ordinary, unprivileged user instead. You can create a separate Unix account named `mysql` to make everything even more secure. Use this account only for administering MySQL. To start `mysqld` as a different Unix user, add a `user` option that specifies the user name in the `[mysqld]` group of the `my.cnf` option file where you specify server options. For example:

```
[mysqld]
user=mysql
```

This causes the server to start as the designated user whether you start it manually or by using `mysqld_safe` or `mysql.server`. For more details, see [Section 5.3.6, “How to Run MySQL as a Normal User”](#).

Running `mysqld` as a Unix user other than `root` does not mean that you need to change the `root` user name in the `user` table. *User names for MySQL accounts have nothing to do with user names for Unix accounts.*

- Do not permit the use of symlinks to tables. (This capability can be disabled with the `--skip-symbolic-links` option.) This is especially important if you run `mysqld` as `root`, because anyone that has write access to the server's data directory then could delete any file in the system! See [Section 7.9.7.2, “Using Symbolic Links for Tables on Unix”](#).
- Make sure that the only Unix user account with read or write privileges in the database directories is the account that is used for running `mysqld`.
- Do not grant the `PROCESS` or `SUPER` privilege to nonadministrative users. The output of `mysqladmin processlist` and `SHOW PROCESSLIST` shows the text of any statements currently being executed, so any user who is permitted to see the server process list might be able to see statements issued by other users such as `UPDATE user SET pass-`

---

```
word=PASSWORD('not_secure').
```

`mysqld` reserves an extra connection for users who have the `SUPER` privilege, so that a MySQL `root` user can log in and check server activity even if all normal connections are in use.

The `SUPER` privilege can be used to terminate client connections, change server operation by changing the value of system variables, and control replication servers.

- Do not grant the `FILE` privilege to nonadministrative users. Any user that has this privilege can write a file anywhere in the file system with the privileges of the `mysqld` daemon. To make this a bit safer, files generated with `SELECT ... INTO OUTFILE` do not overwrite existing files and are writable by everyone.

The `FILE` privilege may also be used to read any file that is world-readable or accessible to the Unix user that the server runs as. With this privilege, you can read any file into a database table. This could be abused, for example, by using `LOAD DATA` to load `/etc/passwd` into a table, which then can be displayed with `SELECT`.

- Stored programs and views should be written using the security guidelines discussed in [Section 19.6, “Access Control for Stored Programs and Views”](#).
- If you do not trust your DNS, you should use IP numbers rather than host names in the grant tables. In any case, you should be very careful about creating grant table entries using host name values that contain wildcards.
- If you want to restrict the number of connections permitted to a single account, you can do so by setting the `max_user_connections` variable in `mysqld`. The `GRANT` statement also supports resource control options for limiting the extent of server use permitted to an account. See [Section 12.4.1.3, “GRANT Syntax”](#).
- If the plugin directory is writable by the server, it may be possible for a user to write executable code to a file in the directory using `SELECT ... INTO DUMPFILE`. This can be prevented by making `plugin_dir` read only to the server or by setting `--secure-file-priv` to a directory where `SELECT` writes can be made safely.

### 5.3.4. Security-Related `mysqld` Options

The following `mysqld` options affect security:

**Table 5.5. Security Option/Variable Summary**

Name	Cmd-Line	Option file	System Var	Status Var	Var Scope	Dynamic
<code>allow-suspicious-udfs</code>	Yes	Yes				
<code>automat-ic_sp_privileges</code>			Yes		Global	Yes
<code>chroot</code>	Yes	Yes				
<code>des-key-file</code>	Yes	Yes				
<code>local_infile</code>			Yes		Global	Yes
<code>local-infile</code>	Yes	Yes				
<code>- Variable: loc-al_infile</code>						
<code>old-passwords</code>	Yes	Yes			Both	Yes
<code>- Variable: old_passwords</code>			Yes		Both	Yes
<code>safe-show-database</code>	Yes	Yes	Yes		Global	Yes
<code>safe-user-create</code>	Yes	Yes				
<code>secure-auth</code>	Yes	Yes			Global	Yes
<code>- Variable: se-cure_auth</code>			Yes		Global	Yes
<code>secure-file-priv</code>	Yes	Yes			Global	No
<code>- Variable: se-cure_file_priv</code>			Yes		Global	No
<code>skip-grant-tables</code>	Yes	Yes				
<code>skip-name-resolve</code>	Yes	Yes			Global	No
<code>- Variable:</code>			Yes		Global	No

Name	Cmd-Line	Option file	System Var	Status Var	Var Scope	Dynamic
skip_name_resolve						
<a href="#">skip-networking</a> - Variable: skip_networking	Yes	Yes			Global	No
			Yes		Global	No
<a href="#">skip-show-database</a> - Variable: skip_show_database	Yes	Yes			Global	No
			Yes		Global	No

- [--allow-suspicious-udfs](#)

This option controls whether user-defined functions that have only an `xxx` symbol for the main function can be loaded. By default, the option is off and only UDFs that have at least one auxiliary symbol can be loaded; this prevents attempts at loading functions from shared object files other than those containing legitimate UDFs. See [Section 22.3.2.6, “User-Defined Function Security Precautions”](#).

- [--local-infile\[={0|1}\]](#)

If you start the server with `--local-infile=0`, clients cannot use `LOCAL` in `LOAD DATA` statements. See [Section 5.3.5, “Security Issues with LOAD DATA LOCAL”](#).

- [--old-passwords](#)

Force the server to generate short (pre-4.1) password hashes for new passwords. This is useful for compatibility when the server must support older client programs. See [Section 5.3.2.3, “Password Hashing in MySQL”](#).

- [--safe-user-create](#)

If this option is enabled, a user cannot create new MySQL users by using the `GRANT` statement unless the user has the `INSERT` privilege for the `mysql.user` table or any column in the table. If you want a user to have the ability to create new users that have those privileges that the user has the right to grant, you should grant the user the following privilege:

```
GRANT INSERT(user) ON mysql.user TO 'user_name'@'host_name';
```

This ensures that the user cannot change any privilege columns directly, but has to use the `GRANT` statement to give privileges to other users.

- [--secure-auth](#)

Disallow authentication for accounts that have old (pre-4.1) passwords.

The `mysql` client also has a `--secure-auth` option, which prevents connections to a server if the server requires a password in old format for the client account.

- [--secure-file-priv=path](#)

This option limits the effect of the `LOAD_FILE()` function and the `LOAD DATA` and `SELECT ... INTO OUTFILE` statements to work only with files in the specified directory.

This option was added in MySQL 5.1.17.

- [--skip-grant-tables](#)

This option causes the server not to use the privilege system at all. This gives anyone with access to the server *unrestricted access to all databases*. You can cause a running server to start using the grant tables again by executing `mysqladmin flush-privileges` or `mysqladmin reload` command from a system shell, or by issuing a MySQL `FLUSH PRIVILEGES` statement. This option also suppresses loading of plugins and user-defined functions (UDFs).

- [--skip-merge](#)

Disable the `MERGE` storage engine. This option was added in MySQL 5.1.12 and removed in 5.1.14.

- [--skip-name-resolve](#)

Host names are not resolved. All `Host` column values in the grant tables must be IP numbers or `localhost`.

- [--skip-networking](#)

Do not permit TCP/IP connections over the network. All connections to `mysqld` must be made using Unix socket files.

- `--skip-show-database`

With this option, the `SHOW DATABASES` statement is permitted only to users who have the `SHOW DATABASES` privilege, and the statement displays all database names. Without this option, `SHOW DATABASES` is permitted to all users, but displays each database name only if the user has the `SHOW DATABASES` privilege or some privilege for the database. Note that any global privilege is a privilege for the database.

- `--ssl*`

Options that begin with `--ssl` specify whether to permit clients to connect using SSL and indicate where to find SSL keys and certificates. See [Section 5.5.6.3, “SSL Command Options”](#).

### 5.3.5. Security Issues with LOAD DATA LOCAL

The `LOAD DATA` statement can load a file that is located on the server host, or it can load a file that is located on the client host when the `LOCAL` keyword is specified.

There are two potential security issues with supporting the `LOCAL` version of `LOAD DATA` statements:

- The transfer of the file from the client host to the server host is initiated by the MySQL server. In theory, a patched server could be built that would tell the client program to transfer a file of the server's choosing rather than the file named by the client in the `LOAD DATA` statement. Such a server could access any file on the client host to which the client user has read access.
- In a Web environment where the clients are connecting from a Web server, a user could use `LOAD DATA LOCAL` to read any files that the Web server process has read access to (assuming that a user could run any command against the SQL server). In this environment, the client with respect to the MySQL server actually is the Web server, not the remote program being run by the user who connects to the Web server.

To deal with these problems, we changed how `LOAD DATA LOCAL` is handled as of MySQL 3.23.49 and MySQL 4.0.2 (4.0.13 on Windows):

- By default, all MySQL clients and libraries in binary distributions are compiled with the `--enable-local-infile` option, to be compatible with MySQL 3.23.48 and before.
- If you build MySQL from source but do not invoke `configure` with the `--enable-local-infile` option, `LOAD DATA LOCAL` cannot be used by any client unless it is written explicitly to invoke `mysql_options(..., MYSQL_OPT_LOCAL_INFILE, 0)`. See [Section 21.9.3.49, “mysql\\_options\(\)”](#).
- You can disable all `LOAD DATA LOCAL` statements from the server side by starting `mysqld` with the `-local infile=0` option.
- For the `mysql` command-line client, enable `LOAD DATA LOCAL` by specifying the `--local infile[=1]` option, or disable it with the `--local infile=0` option. For `mysqlimport`, local data file loading is off by default; enable it with the `--local` or `-L` option. In any case, successful use of a local load operation requires that the server permits it.
- If you use `LOAD DATA LOCAL` in Perl scripts or other programs that read the `[client]` group from option files, you can add the `local infile=1` option to that group. However, to keep this from causing problems for programs that do not understand `local infile`, specify it using the `loose-` prefix:

```
[client]
loose-local-infile=1
```

- If `LOAD DATA LOCAL` is disabled, either in the server or the client, a client that attempts to issue such a statement receives the following error message:

```
ERROR 1148: The used command is not allowed with this MySQL version
```

### 5.3.6. How to Run MySQL as a Normal User

On Windows, you can run the server as a Windows service using a normal user account.

On Unix, the MySQL server `mysqld` can be started and run by any user. However, you should avoid running the server as the

Unix `root` user for security reasons. To change `mysqld` to run as a normal unprivileged Unix user `user_name`, you must do the following:

1. Stop the server if it is running (use `mysqladmin shutdown`).
2. Change the database directories and files so that `user_name` has privileges to read and write files in them (you might need to do this as the Unix `root` user):

```
shell> chown -R user_name /path/to/mysql/datadir
```

If you do not do this, the server will not be able to access databases or tables when it runs as `user_name`.

If directories or files within the MySQL data directory are symbolic links, `chown -R` might not follow symbolic links for you. If it does not, you will also need to follow those links and change the directories and files they point to.

3. Start the server as user `user_name`. Another alternative is to start `mysqld` as the Unix `root` user and use the `--user=user_name` option. `mysqld` starts up, then switches to run as the Unix user `user_name` before accepting any connections.
4. To start the server as the given user automatically at system startup time, specify the user name by adding a `user` option to the `[mysqld]` group of the `/etc/my.cnf` option file or the `my.cnf` option file in the server's data directory. For example:

```
[mysqld]
user=user_name
```

If your Unix machine itself isn't secured, you should assign passwords to the MySQL `root` accounts in the grant tables. Otherwise, any user with a login account on that machine can run the `mysql` client with a `--user=root` option and perform any operation. (It is a good idea to assign passwords to MySQL accounts in any case, but especially so when other login accounts exist on the server host.) See [Section 2.13, “Post-Installation Setup and Testing”](#).

## 5.4. The MySQL Access Privilege System

The primary function of the MySQL privilege system is to authenticate a user who connects from a given host and to associate that user with privileges on a database such as `SELECT`, `INSERT`, `UPDATE`, and `DELETE`. Additional functionality includes the ability to have anonymous users and to grant privileges for MySQL-specific functions such as `LOAD DATA INFILE` and administrative operations.

There are some things that you cannot do with the MySQL privilege system:

- You cannot explicitly specify that a given user should be denied access. That is, you cannot explicitly match a user and then refuse the connection.
- You cannot specify that a user has privileges to create or drop tables in a database but not to create or drop the database itself.
- A password applies globally to an account. You cannot associate a password with a specific object such as a database, table, or routine.

The user interface to the MySQL privilege system consists of SQL statements such as `CREATE USER`, `GRANT`, and `REVOKE`. See [Section 12.4.1, “Account Management Statements”](#).

Internally, the server stores privilege information in the grant tables of the `mysql` database (that is, in the database named `mysql`). The MySQL server reads the contents of these tables into memory when it starts and bases access-control decisions on the in-memory copies of the grant tables.

The MySQL privilege system ensures that all users may perform only the operations permitted to them. As a user, when you connect to a MySQL server, your identity is determined by *the host from which you connect* and *the user name you specify*. When you issue requests after connecting, the system grants privileges according to your identity and *what you want to do*.

MySQL considers both your host name and user name in identifying you because there is no reason to assume that a given user name belongs to the same person on all hosts. For example, the user `joe` who connects from `office.example.com` need not be the same person as the user `joe` who connects from `home.example.com`. MySQL handles this by enabling you to distinguish users on different hosts that happen to have the same name: You can grant one set of privileges for connections by `joe` from `office.example.com`, and a different set of privileges for connections by `joe` from `home.example.com`. To see what privileges a given account has, use the `SHOW GRANTS` statement. For example:

```
SHOW GRANTS FOR 'joe'@'office.example.com';
SHOW GRANTS FOR 'joe'@'home.example.com';
```

MySQL access control involves two stages when you run a client program that connects to the server:

**Stage 1:** The server accepts or rejects the connection based on your identity and whether you can verify your identity by supplying the correct password.

**Stage 2:** Assuming that you can connect, the server checks each statement you issue to determine whether you have sufficient privileges to perform it. For example, if you try to select rows from a table in a database or drop a table from the database, the server verifies that you have the `SELECT` privilege for the table or the `DROP` privilege for the database.

For a more detailed description of what happens during each stage, see [Section 5.4.4, “Access Control, Stage 1: Connection Verification”](#), and [Section 5.4.5, “Access Control, Stage 2: Request Verification”](#).

If your privileges are changed (either by yourself or someone else) while you are connected, those changes do not necessarily take effect immediately for the next statement that you issue. For details about the conditions under which the server reloads the grant tables, see [Section 5.4.6, “When Privilege Changes Take Effect”](#).

For general security-related advice, see [Section 5.3, “General Security Issues”](#). For help in diagnosing privilege-related problems, see [Section 5.4.7, “Causes of Access-Denied Errors”](#).

## 5.4.1. Privileges Provided by MySQL

MySQL provides privileges that apply in different contexts and at different levels of operation:

- Administrative privileges enable users to manage operation of the MySQL server. These privileges are global because they are not specific to a particular database.
- Database privileges apply to a database and to all objects within it. These privileges can be granted for specific databases, or globally so that they apply to all databases.
- Privileges for database objects such as tables, indexes, views, and stored routines can be granted for specific objects within a database, for all objects of a given type within a database (for example, all tables in a database), or globally for all objects of a given type in all databases).

Information about account privileges is stored in the `user`, `db`, `host`, `tables_priv`, `columns_priv`, and `procs_priv` tables in the `mysql` database (see [Section 5.4.2, “Privilege System Grant Tables”](#)). The MySQL server reads the contents of these tables into memory when it starts and reloads them under the circumstances indicated in [Section 5.4.6, “When Privilege Changes Take Effect”](#). Access-control decisions are based on the in-memory copies of the grant tables.

Some releases of MySQL introduce changes to the structure of the grant tables to add new access privileges or features. Whenever you update to a new version of MySQL, you should update your grant tables to make sure that they have the current structure so that you can take advantage of any new capabilities. See [Section 4.4.8, “mysql\\_upgrade — Check Tables for MySQL Upgrade”](#).

The following table shows the privilege names used at the SQL level in the `GRANT` and `REVOKE` statements, along with the column name associated with each privilege in the grant tables and the context in which the privilege applies.

Privilege	Column	Context
<code>CREATE</code>	<code>Create_priv</code>	databases, tables, or indexes
<code>DROP</code>	<code>Drop_priv</code>	databases, tables, or views
<code>GRANT OPTION</code>	<code>Grant_priv</code>	databases, tables, or stored routines
<code>REFERENCES</code>	<code>References_priv</code>	databases or tables
<code>EVENT</code>	<code>Event_priv</code>	databases
<code>ALTER</code>	<code>Alter_priv</code>	tables
<code>DELETE</code>	<code>Delete_priv</code>	tables
<code>INDEX</code>	<code>Index_priv</code>	tables
<code>INSERT</code>	<code>Insert_priv</code>	tables or columns
<code>SELECT</code>	<code>Select_priv</code>	tables or columns
<code>UPDATE</code>	<code>Update_priv</code>	tables or columns
<code>CREATE TEMPORARY TABLES</code>	<code>Create_tmp_table_priv</code>	tables
<code>LOCK TABLES</code>	<code>Lock_tables_priv</code>	tables
<code>TRIGGER</code>	<code>Trigger_priv</code>	tables

CREATE VIEW	Create_view_priv	views
SHOW VIEW	Show_view_priv	views
ALTER ROUTINE	Alter_routine_priv	stored routines
CREATE ROUTINE	Create_routine_priv	stored routines
EXECUTE	Execute_priv	stored routines
FILE	File_priv	file access on server host
CREATE USER	Create_user_priv	server administration
PROCESS	Process_priv	server administration
RELOAD	Reload_priv	server administration
REPLICATION CLIENT	Repl_client_priv	server administration
REPLICATION SLAVE	Repl_slave_priv	server administration
SHOW DATABASES	Show_db_priv	server administration
SHUTDOWN	Shutdown_priv	server administration
SUPER	Super_priv	server administration
ALL [ PRIVILEGES ]		server administration
USAGE		server administration

The following list provides a general description of each privilege available in MySQL. Particular SQL statements might have more specific privilege requirements than indicated here. If so, the description for the statement in question provides the details.

- The `ALL` or `ALL PRIVILEGES` privilege specifier is shorthand. It stands for “all privileges available at a given privilege level” (except `GRANT OPTION`). For example, granting `ALL` at the global or table level grants all global privileges or all table-level privileges.
- The `ALTER` privilege enables use of `ALTER TABLE` to change the structure of or rename tables. (`ALTER TABLE` also requires the `INSERT` and `CREATE` privileges.)
- The `ALTER ROUTINE` privilege is needed to alter or drop stored routines (procedures and functions).
- The `CREATE` privilege enables creation of new databases and tables.
- The `CREATE ROUTINE` privilege is needed to create stored routines (procedures and functions).
- The `CREATE TEMPORARY TABLES` privilege enables the use of the keyword `TEMPORARY` in `CREATE TABLE` statements.
- The `CREATE USER` privilege enables use of `CREATE USER`, `DROP USER`, `RENAME USER`, and `REVOKE ALL PRIVILEGES`.
- The `CREATE VIEW` privilege enables use of `CREATE VIEW`.
- The `DELETE` privilege enables rows to be deleted from tables in a database.
- The `DROP` privilege enables you to drop (remove) existing databases, tables, and views. Beginning with MySQL 5.1.10, the `DROP` privilege is also required to use the statement `ALTER TABLE ... DROP PARTITION` on a partitioned table. Beginning with MySQL 5.1.16, the `DROP` privilege is required for `TRUNCATE TABLE` (before that, `TRUNCATE TABLE` requires the `DELETE` privilege). *If you grant the `DROP` privilege for the `mysql` database to a user, that user can drop the database in which the MySQL access privileges are stored.*
- The `EVENT` privilege is required to create, alter, or drop events for the Event Scheduler. This privilege was added in MySQL 5.1.6.
- The `EXECUTE` privilege is required to execute stored routines (procedures and functions).
- The `FILE` privilege gives you permission to read and write files on the server host using the `LOAD DATA INFILE` and `SELECT ... INTO OUTFILE` statements and the `LOAD_FILE()` function. A user who has the `FILE` privilege can read any file on the server host that is either world-readable or readable by the MySQL server. (This implies the user can read any file in any database directory, because the server can access any of those files.) The `FILE` privilege also enables the user to create new files in any directory where the MySQL server has write access. As a security measure, the server will not overwrite existing files.
- The `GRANT OPTION` privilege enables you to give to other users or remove from other users those privileges that you yourself possess.

- The `INDEX` privilege enables you to create or drop (remove) indexes. `INDEX` applies to existing tables. If you have the `CREATE` privilege for a table, you can include index definitions in the `CREATE TABLE` statement.
- The `INSERT` privilege enables rows to be inserted into tables in a database. `INSERT` is also required for the `ANALYZE TABLE`, `OPTIMIZE TABLE`, and `REPAIR TABLE` table-maintenance statements.
- The `LOCK TABLES` privilege enables the use of explicit `LOCK TABLES` statements to lock tables for which you have the `SELECT` privilege. This includes the use of write locks, which prevents other sessions from reading the locked table.
- The `PROCESS` privilege pertains to display of information about the threads executing within the server (that is, information about the statements being executed by sessions). The privilege enables use of `SHOW PROCESSLIST` or `mysqladmin processlist` to see threads belonging to other accounts; you can always see your own threads.
- The `REFERENCES` privilege currently is unused.
- The `RELOAD` privilege enables use of the `FLUSH` statement. It also enables `mysqladmin` commands that are equivalent to `FLUSH` operations: `flush-hosts`, `flush-logs`, `flush-privileges`, `flush-status`, `flush-tables`, `flush-threads`, `refresh`, and `reload`.

The `reload` command tells the server to reload the grant tables into memory. `flush-privileges` is a synonym for `reload`. The `refresh` command closes and reopens the log files and flushes all tables. The other `flush-xxx` commands perform functions similar to `refresh`, but are more specific and may be preferable in some instances. For example, if you want to flush just the log files, `flush-logs` is a better choice than `refresh`.

- The `REPLICATION CLIENT` privilege enables the use of `SHOW MASTER STATUS` and `SHOW SLAVE STATUS`.
- The `REPLICATION SLAVE` privilege should be granted to accounts that are used by slave servers to connect to the current server as their master. Without this privilege, the slave cannot request updates that have been made to databases on the master server.
- The `SELECT` privilege enables you to select rows from tables in a database. `SELECT` statements require the `SELECT` privilege only if they actually retrieve rows from a table. Some `SELECT` statements do not access tables and can be executed without permission for any database. For example, you can use `SELECT` as a simple calculator to evaluate expressions that make no reference to tables:

```
SELECT 1+1;
SELECT PI()*2;
```

The `SELECT` privilege is also needed for other statements that read column values. For example, `SELECT` is needed for columns referenced on the right hand side of `col_name=expr` assignment in `UPDATE` statements or for columns named in the `WHERE` clause of `DELETE` or `UPDATE` statements.

- The `SHOW DATABASES` privilege enables the account to see database names by issuing the `SHOW DATABASE` statement. Accounts that do not have this privilege see only databases for which they have some privileges, and cannot use the statement at all if the server was started with the `--skip-show-database` option. Note that *any* global privilege is a privilege for the database.
- The `SHOW VIEW` privilege enables use of `SHOW CREATE VIEW`.
- The `SHUTDOWN` privilege enables use of the `mysqladmin shutdown` command. There is no corresponding SQL statement.
- The `SUPER` privilege enables an account to use `CHANGE MASTER TO`, `KILL` or `mysqladmin kill` to kill threads belonging to other accounts (you can always kill your own threads), `PURGE BINARY LOGS`, configuration changes using `SET GLOBAL` to modify global system variables, the `mysqladmin debug` command, enabling or disabling logging, performing updates even if the `read_only` system variable is enabled, starting and stopping replication on slave servers, specification of any account in the `DEFINER` attribute of stored programs and views, and enables you to connect (once) even if the connection limit controlled by the `max_connections` system variable is reached.

To create or alter stored functions if binary logging is enabled, you may also need the `SUPER` privilege, as described in [Section 19.7, “Binary Logging of Stored Programs”](#).

- The `TRIGGER` privilege enables you to create and drop triggers. You must have this privilege for a table to create or drop triggers for that table. This privilege was added in MySQL 5.1.6. (Prior to MySQL 5.1.6, trigger operations required the `SUPER` privilege.)
- The `UPDATE` privilege enables rows to be updated in tables in a database.
- The `USAGE` privilege specifier stands for “no privileges.” It is used at the global level with `GRANT` to modify account attributes such as resource limits or SSL characteristics without affecting existing account privileges.

It is a good idea to grant to an account only those privileges that it needs. You should exercise particular caution in granting the `FILE` and administrative privileges:

- The `FILE` privilege can be abused to read into a database table any files that the MySQL server can read on the server host. This includes all world-readable files and files in the server's data directory. The table can then be accessed using `SELECT` to transfer its contents to the client host.
- The `GRANT OPTION` privilege enables users to give their privileges to other users. Two users that have different privileges and with the `GRANT OPTION` privilege are able to combine privileges.
- The `ALTER` privilege may be used to subvert the privilege system by renaming tables.
- The `SHUTDOWN` privilege can be abused to deny service to other users entirely by terminating the server.
- The `PROCESS` privilege can be used to view the plain text of currently executing statements, including statements that set or change passwords.
- The `SUPER` privilege can be used to terminate other sessions or change how the server operates.
- Privileges granted for the `mysql` database itself can be used to change passwords and other access privilege information. Passwords are stored encrypted, so a malicious user cannot simply read them to know the plain text password. However, a user with write access to the `user` table `Password` column can change an account's password, and then connect to the MySQL server using that account.

## 5.4.2. Privilege System Grant Tables

Normally, you manipulate the contents of the grant tables in the `mysql` database indirectly by using statements such as `GRANT` and `REVOKE` to set up accounts and control the privileges available to each one. See [Section 12.4.1, “Account Management Statements”](#). The discussion here describes the underlying structure of the grant tables and how the server uses their contents when interacting with clients.

Some tables in the `mysql` database do not hold grant information and are discussed elsewhere:

- The `event` table contains information about Event Scheduler events: See [Section 19.4, “Using the Event Scheduler”](#).
- The `func` table contains information about user-defined functions: See [Section 22.3, “Adding New Functions to MySQL”](#).
- The `help_xxx` tables are used for server-side help: See [Section 5.1.8, “Server-Side Help”](#).
- The `plugin` table contains information about server plugins: See [Section 12.4.3.1, “Installing and Uninstalling Plugins”](#), and [Section 22.2, “The MySQL Plugin API”](#).
- The `proc` table contains information about stored procedures and functions: See [Section 19.2, “Using Stored Routines \(Procedures and Functions\)”](#).
- The `servers` table is used by the `FEDERATED` storage engine: See [Section 13.11.2.2, “Creating a FEDERATED Table Using CREATE SERVER”](#).
- The `time_zone_xxx` tables contain time zone information: See [Section 9.6, “MySQL Server Time Zone Support”](#).
- Tables with `_log` in their name are used for logging: See [Section 5.2, “MySQL Server Logs”](#).

Each grant table contains scope columns and privilege columns:

- Scope columns determine the scope of each row (entry) in the tables; that is, the context in which the row applies. For example, a `user` table row with `Host` and `User` values of '`thomas.loc.gov`' and '`bob`' would be used for authenticating connections made to the server from the host `thomas.loc.gov` by a client that specifies a user name of `bob`. Similarly, a `db` table row with `Host`, `User`, and `Db` column values of '`thomas.loc.gov`', '`bob`' and '`reports`' would be used when `bob` connects from the host `thomas.loc.gov` to access the `reports` database. The `tables_priv` and `columns_priv` tables contain scope columns indicating tables or table/column combinations to which each row applies. The `procs_priv` scope columns indicate the stored routine to which each row applies.
- Privilege columns indicate which privileges are granted by a table row; that is, what operations can be performed. The server combines the information in the various grant tables to form a complete description of a user's privileges. [Section 5.4.5, “Access Control, Stage 2: Request Verification”](#), describes the rules that are used to do this.

The server uses the grant tables in the following manner:

- The `user` table scope columns determine whether to reject or permit incoming connections. For permitted connections, any privileges granted in the `user` table indicate the user's global (superuser) privileges. Any privilege granted in this table applies to *all* databases on the server.

#### Note

Because any global privilege is considered a privilege for all databases, any global privilege enables a user to see all database names with `SHOW DATABASES` or by examining the `SCHEMATA` table of `INFORMATION_SCHEMA`.

- The `db` table scope columns determine which users can access which databases from which hosts. The privilege columns determine which operations are permitted. A privilege granted at the database level applies to the database and to all objects in the database, such as tables and stored programs.
- The `host` table is used in conjunction with the `db` table when you want a given `db` table row to apply to several hosts. For example, if you want a user to be able to use a database from several hosts in your network, leave the `Host` value empty in the user's `db` table row, then populate the `host` table with a row for each of those hosts. This mechanism is described more detail in [Section 5.4.5, “Access Control, Stage 2: Request Verification”](#).

#### Note

The `host` table must be modified directly with statements such as `INSERT`, `UPDATE`, and `DELETE`. It is not affected by statements such as `GRANT` and `REVOKE` that modify the grant tables indirectly. Most MySQL installations need not use this table at all.

- The `tables_priv` and `columns_priv` tables are similar to the `db` table, but are more fine-grained: They apply at the table and column levels rather than at the database level. A privilege granted at the table level applies to the table and to all its columns. A privilege granted at the column level applies only to a specific column.
- The `procs_priv` table applies to stored routines. A privilege granted at the routine level applies only to a single routine.

The server uses the `user`, `db`, and `host` tables in the `mysql` database at both the first and second stages of access control (see [Section 5.4, “The MySQL Access Privilege System”](#)). The columns in the `user` and `db` tables are shown here. The `host` table is similar to the `db` table but has a specialized use as described in [Section 5.4.5, “Access Control, Stage 2: Request Verification”](#).

Table Name	<code>user</code>	<code>db</code>
<b>Scope columns</b>		
	<code>Host</code>	<code>Host</code>
	<code>User</code>	<code>Db</code>
	<code>Password</code>	<code>User</code>
<b>Privilege columns</b>		
	<code>Select_priv</code>	<code>Select_priv</code>
	<code>Insert_priv</code>	<code>Insert_priv</code>
	<code>Update_priv</code>	<code>Update_priv</code>
	<code>Delete_priv</code>	<code>Delete_priv</code>
	<code>Index_priv</code>	<code>Index_priv</code>
	<code>Alter_priv</code>	<code>Alter_priv</code>
	<code>Create_priv</code>	<code>Create_priv</code>
	<code>Drop_priv</code>	<code>Drop_priv</code>
	<code>Grant_priv</code>	<code>Grant_priv</code>
	<code>Create_view_priv</code>	<code>Create_view_priv</code>
	<code>Show_view_priv</code>	<code>Show_view_priv</code>
	<code>Create_routine_priv</code>	<code>Create_routine_priv</code>
	<code>Alter_routine_priv</code>	<code>Alter_routine_priv</code>
	<code>Execute_priv</code>	<code>Execute_priv</code>
	<code>Trigger_priv</code>	<code>Trigger_priv</code>
	<code>Event_priv</code>	<code>Event_priv</code>
	<code>Create_tmp_table_priv</code>	<code>Create_tmp_table_priv</code>
	<code>Lock_tables_priv</code>	<code>Lock_tables_priv</code>

	References_priv	References_priv
	Reload_priv	
	Shutdown_priv	
	Process_priv	
	File_priv	
	Show_db_priv	
	Super_priv	
	Repl_slave_priv	
	Repl_client_priv	
	Create_user_priv	
<b>Security columns</b>	ssl_type	
	ssl_cipher	
	x509_issuer	
	x509_subject	
<b>Resource control columns</b>	max_questions	
	max_updates	
	max_connections	
	max_user_connections	

The `Event_priv` and `Trigger_priv` columns were added in MySQL 5.1.6.

During the second stage of access control, the server performs request verification to make sure that each client has sufficient privileges for each request that it issues. In addition to the `user`, `db`, and `host` grant tables, the server may also consult the `tables_priv` and `columns_priv` tables for requests that involve tables. The latter tables provide finer privilege control at the table and column levels. They have the columns shown in the following table.

Table Name	tables_priv	columns_priv
<b>Scope columns</b>	Host	Host
	Db	Db
	User	User
	Table_name	Table_name
		Column_name
<b>Privilege columns</b>	Table_priv	Column_priv
	Column_priv	
<b>Other columns</b>	Timestamp	Timestamp
	Grantor	

The `Timestamp` and `Grantor` columns currently are unused and are discussed no further here.

For verification of requests that involve stored routines, the server may consult the `procs_priv` table, which has the columns shown in the following table.

Table Name	procs_priv
<b>Scope columns</b>	Host
	Db
	User
	Routine_name
	Routine_type
<b>Privilege columns</b>	Proc_priv
<b>Other columns</b>	Timestamp
	Grantor

The `Routine_type` column is an `ENUM` column with values of '`FUNCTION`' or '`PROCEDURE`' to indicate the type of routine the row refers to. This column enables privileges to be granted separately for a function and a procedure with the same name.

The `Timestamp` and `Grantor` columns currently are unused and are discussed no further here.

Scope columns in the grant tables contain strings. They are declared as shown here; the default value for each is the empty string.

Column Name	Type
<code>Host</code>	<code>CHAR(60)</code>
<code>User</code>	<code>CHAR(16)</code>
<code>Password</code>	<code>CHAR(41)</code>
<code>Db</code>	<code>CHAR(64)</code>
<code>Table_name</code>	<code>CHAR(64)</code>
<code>Column_name</code>	<code>CHAR(64)</code>
<code>Routine_name</code>	<code>CHAR(64)</code>

For access-checking purposes, comparisons of `User`, `Password`, `Db`, and `Table_name` values are case sensitive. Comparisons of `Host`, `Column_name`, and `Routine_name` values are not case sensitive.

In the `user`, `db`, and `host` tables, each privilege is listed in a separate column that is declared as `ENUM('N', 'Y') DEFAULT 'N'`. In other words, each privilege can be disabled or enabled, with the default being disabled.

In the `tables_priv`, `columns_priv`, and `procs_priv` tables, the privilege columns are declared as `SET` columns. Values in these columns can contain any combination of the privileges controlled by the table. Only those privileges listed in the column value are enabled.

Table Name	Column Name	Possible Set Elements
<code>tables_priv</code>	<code>Table_priv</code>	<code>'Select', 'Insert', 'Update', 'Delete', 'Create', 'Drop', 'Grant', 'References', 'Index', 'Alter', 'Create View', 'Show view', 'Trigger'</code>
<code>tables_priv</code>	<code>Column_priv</code>	<code>'Select', 'Insert', 'Update', 'References'</code>
<code>columns_priv</code>	<code>Column_priv</code>	<code>'Select', 'Insert', 'Update', 'References'</code>
<code>procs_priv</code>	<code>Proc_priv</code>	<code>'Execute', 'Alter Routine', 'Grant'</code>

Administrative privileges (such as `RELOAD` or `SHUTDOWN`) are specified only in the `user` table. Administrative operations are operations on the server itself and are not database-specific, so there is no reason to list these privileges in the other grant tables. Consequently, to determine whether you can perform an administrative operation, the server need consult only the `user` table.

The `FILE` privilege also is specified only in the `user` table. It is not an administrative privilege as such, but your ability to read or write files on the server host is independent of the database you are accessing.

The `mysqld` server reads the contents of the grant tables into memory when it starts. You can tell it to reload the tables by issuing a `FLUSH PRIVILEGES` statement or executing a `mysqladmin flush-privileges` or `mysqladmin reload` command. Changes to the grant tables take effect as indicated in [Section 5.4.6, “When Privilege Changes Take Effect”](#).

When you modify an account's privileges, it is a good idea to verify that the changes set up privileges the way you want. To check the privileges for a given account, use the `SHOW GRANTS` statement (see [Section 12.4.5.22, “SHOW GRANTS Syntax”](#)). For example, to determine the privileges that are granted to an account with user name and host name values of `bob` and `pc84.example.com`, use this statement:

```
SHOW GRANTS FOR 'bob'@'pc84.example.com';
```

### 5.4.3. Specifying Account Names

MySQL account names consist of a user name and a host name. This enables creation of accounts for users with the same name who can connect from different hosts. This section describes how to write account names, including special values and wildcard rules.

Within SQL statements such as `CREATE USER`, `GRANT`, and `SET PASSWORD`, account names are written using the following rules:

- Syntax for account names is '`user_name`'@'`host_name`'.
- An account name consisting only of a user name is equivalent to '`user_name`'@'%'. For example, '`me`' is equivalent to '`me`'@'%'.
- The user name and host name need not be quoted if they are legal as unquoted identifiers. Quotes are necessary to specify a `user_name` string containing special characters (such as "-"), or a `host_name` string containing special characters or wild-card characters (such as "%"); for example, '`test-user`'@'%.`com`'.
- Quote user names and host names as identifiers or as strings, using either backticks ("`"), single quotation marks (''), or double quotation marks ("").
- The user name and host name parts, if quoted, must be quoted separately. That is, write '`me`'@'`localhost`', not '`me@localhost`'; the latter is interpreted as '`me@localhost`'@'%'.
- A reference to the `CURRENT_USER()` (or `CURRENT_USER`) function is equivalent to specifying the current user's name and host name literally.

Account names are stored in grant tables using separate columns for the user name and host name parts:

- The `user` table contains one row for each account. The `User` and `Host` columns store the user name and host name. Another column, `Password`, stores the account password. This table also indicates which global privileges the account has.
- Other grant tables indicate privileges an account has for databases and objects within databases. These tables have `User` and `Host` columns to store the account name. Each row in these tables associates with the account in the `user` table that has the same `User` and `Host` values.

For additional detail about grant table structure, see [Section 5.4.2, “Privilege System Grant Tables”](#).

User names and host names have certain special values or wildcard conventions, as described following.

A user name is either a nonblank value that literally matches the user name for incoming connection attempts, or a blank value (empty string) that matches any user name. An account with a blank user name is an anonymous user. To specify an anonymous user in SQL statements, use a quoted empty user name part, such as '`'@'localhost`'.

The host part of an account name can take many forms, and wildcards are permitted:

- A host value can be a host name or an IP number. '`localhost`' indicates the local host. '`127.0.0.1`' indicates the loop-back interface.
- You can use the wildcard characters "%" and "\_" in host values. These have the same meaning as for pattern-matching operations performed with the `LIKE` operator. For example, a host value of '%' matches any host name, whereas a value of '%.`mysql.com`' matches any host in the `mysql.com` domain. '`192.168.1.%`' matches any host in the 192.168.1 class C network.

Because you can use IP wildcard values in host values (for example, '`192.168.1.%`' to match every host on a subnet), someone could try to exploit this capability by naming a host `192.168.1.somewhere.com`. To foil such attempts, MySQL disallows matching on host names that start with digits and a dot. Thus, if you have a host named something like `1.2.example.com`, its name never matches the host part of account names. An IP wildcard value can match only IP numbers, not host names.

- For host values specified as IP numbers, you can specify a netmask indicating how many address bits to use for the network number. The syntax is `host_ip/netmask`. For example:

```
CREATE USER 'david'@'192.58.197.0/255.255.255.0';
```

This enables `david` to connect from any client host having an IP number `client_ip` for which the following condition is true:

```
client_ip & netmask = host_ip
```

That is, for the `CREATE USER` statement just shown:

```
client_ip & 255.255.255.0 = 192.58.197.0
```

IP numbers that satisfy this condition and can connect to the MySQL server are those in the range from `192.58.197.0` to

`192.58.197.255.`

The netmask can only be used to tell the server to use 8, 16, 24, or 32 bits of the address. Examples:

- `192.0.0.0/255.0.0.0`: anything on the 192 class A network
- `192.168.0.0/255.255.0.0`: anything on the 192.168 class B network
- `192.168.1.0/255.255.255.0`: anything on the 192.168.1 class C network
- `192.168.1.1`: only this specific IP

The following netmask (28 bits) will not work:

```
192.168.0.1/255.255.255.240
```

#### 5.4.4. Access Control, Stage 1: Connection Verification

When you attempt to connect to a MySQL server, the server accepts or rejects the connection based on your identity and whether you can verify your identity by supplying the correct password. If not, the server denies access to you completely. Otherwise, the server accepts the connection, and then enters Stage 2 and waits for requests.

Your identity is based on two pieces of information:

- The client host from which you connect
- Your MySQL user name

Identity checking is performed using the three `user` table scope columns (`Host`, `User`, and `Password`). The server accepts the connection only if the `Host` and `User` columns in some `user` table row match the client host name and user name and the client supplies the password specified in that row. The rules for permissible `Host` and `User` values are given in [Section 5.4.3, “Specifying Account Names”](#).

If the `User` column value is nonblank, the user name in an incoming connection must match exactly. If the `User` value is blank, it matches any user name. If the `user` table row that matches an incoming connection has a blank user name, the user is considered to be an anonymous user with no name, not a user with the name that the client actually specified. This means that a blank user name is used for all further access checking for the duration of the connection (that is, during Stage 2).

The `Password` column can be blank. This is not a wildcard and does not mean that any password matches. It means that the user must connect without specifying a password.

Nonblank `Password` values in the `user` table represent encrypted passwords. MySQL does not store passwords in plaintext form for anyone to see. Rather, the password supplied by a user who is attempting to connect is encrypted (using the `PASSWORD()` function). The encrypted password then is used during the connection process when checking whether the password is correct. (This is done without the encrypted password ever traveling over the connection.) See [Section 5.5.1, “User Names and Passwords”](#).

From MySQL's point of view, the encrypted password is the *real* password, so you should never give anyone access to it. In particular, *do not give nonadministrative users read access to tables in the `mysql` database*.

The following table shows how various combinations of `Host` and `User` values in the `user` table apply to incoming connections.

Host Value	User Value	Permissible Connections
'thomas.loc.gov'	'fred'	fred, connecting from thomas.loc.gov
'thomas.loc.gov'	' '	Any user, connecting from thomas.loc.gov
'%'	'fred'	fred, connecting from any host
'%'	' '	Any user, connecting from any host
'%.loc.gov'	'fred'	fred, connecting from any host in the loc.gov domain
'x.y.%'	'fred'	fred, connecting from x.y.net, x.y.com, x.y.edu, and so on; this is probably not useful
'144.155.166.177'	'fred'	fred, connecting from the host with IP address 144.155.166.177
'144.155.166.%'	'fred'	fred, connecting from any host in the 144.155.166 class C subnet

'144.155.166.0/255.255.255.0'	'fred'	Same as previous example
-------------------------------	--------	--------------------------

It is possible for the client host name and user name of an incoming connection to match more than one row in the `user` table. The preceding set of examples demonstrates this: Several of the entries shown match a connection from `thomas.loc.gov` by `fred`.

When multiple matches are possible, the server must determine which of them to use. It resolves this issue as follows:

- Whenever the server reads the `user` table into memory, it sorts the rows.
- When a client attempts to connect, the server looks through the rows in sorted order.
- The server uses the first row that matches the client host name and user name.

To see how this works, suppose that the `user` table looks like this:

Host	User	...
%	root	...
%	jeffrey	...
localhost	root	...
localhost	root	...

When the server reads the table into memory, it orders the rows with the most-specific `Host` values first. Literal host names and IP numbers are the most specific. (The specificity of a literal IP number is not affected by whether it has a netmask, so `192.168.1.13` and `192.168.1.0/255.255.255.0` are considered equally specific.) The pattern '`%`' means "any host" and is least specific. Rows with the same `Host` value are ordered with the most-specific `User` values first (a blank `User` value means "any user" and is least specific). For the `user` table just shown, the result after sorting looks like this:

Host	User	...
localhost	root	...
localhost	root	...
%	jeffrey	...
%	root	...

When a client attempts to connect, the server looks through the sorted rows and uses the first match found. For a connection from `localhost` by `jeffrey`, two of the rows from the table match: the one with `Host` and `User` values of '`localhost`' and '`'`', and the one with values of '`%`' and '`jeffrey`'. The '`localhost`' row appears first in sorted order, so that is the one the server uses.

Here is another example. Suppose that the `user` table looks like this:

Host	User	...
%	jeffrey	...
thomas.loc.gov		...

The sorted table looks like this:

Host	User	...
thomas.loc.gov		...
%	jeffrey	...

A connection by `jeffrey` from `thomas.loc.gov` is matched by the first row, whereas a connection by `jeffrey` from any host is matched by the second.

### Note

It is a common misconception to think that, for a given user name, all rows that explicitly name that user are used first when the server attempts to find a match for the connection. This is not true. The preceding example illustrates this, where a connection from `thomas.loc.gov` by `jeffrey` is first matched not by the row containing '`jeffrey`' as the `User` column value, but by the row with no user name. As a result, `jeffrey` is authenticated as an anonymous user, even though he specified a user name when connecting.

If you are able to connect to the server, but your privileges are not what you expect, you probably are being authenticated as some other account. To find out what account the server used to authenticate you, use the `CURRENT_USER()` function. (See [Section 11.14, “Information Functions”](#).) It returns a value in `user_name@host_name` format that indicates the `User` and `Host` values from the matching `user` table row. Suppose that `jeffrey` connects and issues the following query:

```
mysql> SELECT CURRENT_USER();
+-----+
| CURRENT_USER() |
+-----+
| @localhost |
+-----+
```

The result shown here indicates that the matching `user` table row had a blank `User` column value. In other words, the server is treating `jeffrey` as an anonymous user.

Another way to diagnose authentication problems is to print out the `user` table and sort it by hand to see where the first match is being made.

## 5.4.5. Access Control, Stage 2: Request Verification

After you establish a connection, the server enters Stage 2 of access control. For each request that you issue through that connection, the server determines what operation you want to perform, then checks whether you have sufficient privileges to do so. This is where the privilege columns in the grant tables come into play. These privileges can come from any of the `user`, `db`, `host`, `tables_priv`, `columns_priv`, or `procs_priv` tables. (You may find it helpful to refer to [Section 5.4.2, “Privilege System Grant Tables”](#), which lists the columns present in each of the grant tables.)

The `user` table grants privileges that are assigned to you on a global basis and that apply no matter what the default database is. For example, if the `user` table grants you the `DELETE` privilege, you can delete rows from any table in any database on the server host! In other words, `user` table privileges are superuser privileges. It is wise to grant privileges in the `user` table only to super-users such as database administrators. For other users, you should leave all privileges in the `user` table set to ‘N’ and grant privileges at more specific levels only. You can grant privileges for particular databases, tables, columns, or routines.

The `db` and `host` tables grant database-specific privileges. Values in the scope columns of these tables can take the following forms:

- A blank `User` value in the `db` table matches the anonymous user. A nonblank value matches literally; there are no wildcards in user names.
- The wildcard characters “%” and “\_” can be used in the `Host` and `Db` columns of either table. These have the same meaning as for pattern-matching operations performed with the `LIKE` operator. If you want to use either character literally when granting privileges, you must escape it with a backslash. For example, to include the underscore character (“\_”) as part of a database name, specify it as “\\_” in the `GRANT` statement.
- A ‘%’ `Host` value in the `db` table means “any host.” A blank `Host` value in the `db` table means “consult the `host` table for further information” (a process that is described later in this section).
- A ‘%’ or blank `Host` value in the `host` table means “any host.”
- A ‘%’ or blank `Db` value in either table means “any database.”

The server reads the `db` and `host` tables into memory and sorts them at the same time that it reads the `user` table. The server sorts the `db` table based on the `Host`, `Db`, and `User` scope columns, and sorts the `host` table based on the `Host` and `Db` scope columns. As with the `user` table, sorting puts the most-specific values first and least-specific values last, and when the server looks for matching entries, it uses the first match that it finds.

The `tables_priv`, `columns_priv`, and `procs_priv` tables grant table-specific, column-specific, and routine-specific privileges. Values in the scope columns of these tables can take the following forms:

- The wildcard characters “%” and “\_” can be used in the `Host` column. These have the same meaning as for pattern-matching operations performed with the `LIKE` operator.
- A ‘%’ or blank `Host` value means “any host.”
- The `Db`, `Table_name`, `Column_name`, and `Routine_name` columns cannot contain wildcards or be blank.

The server sorts the `tables_priv`, `columns_priv`, and `procs_priv` tables based on the `Host`, `Db`, and `User` columns. This is similar to `db` table sorting, but simpler because only the `Host` column can contain wildcards.

The server uses the sorted tables to verify each request that it receives. For requests that require administrative privileges such as `SHUTDOWN` or `RELOAD`, the server checks only the `user` table row because that is the only table that specifies administrative privileges. The server grants access if the row permits the requested operation and denies access otherwise. For example, if you want to execute `mysqladmin shutdown` but your `user` table row doesn't grant the `SHUTDOWN` privilege to you, the server denies access without even checking the `db` or `host` tables. (They contain no `Shutdown_priv` column, so there is no need to do so.)

For database-related requests (`INSERT`, `UPDATE`, and so on), the server first checks the user's global (superuser) privileges by looking in the `user` table row. If the row permits the requested operation, access is granted. If the global privileges in the `user` table are insufficient, the server determines the user's database-specific privileges by checking the `db` and `host` tables:

1. The server looks in the `db` table for a match on the `Host`, `Db`, and `User` columns. The `Host` and `User` columns are matched to the connecting user's host name and MySQL user name. The `Db` column is matched to the database that the user wants to access. If there is no row for the `Host` and `User`, access is denied.
2. If there is a matching `db` table row and its `Host` column is not blank, that row defines the user's database-specific privileges.
3. If the matching `db` table row's `Host` column is blank, it signifies that the `host` table enumerates which hosts should be permitted access to the database. In this case, a further lookup is done in the `host` table to find a match on the `Host` and `Db` columns. If no `host` table row matches, access is denied. If there is a match, the user's database-specific privileges are computed as the intersection (*not* the union!) of the privileges in the `db` and `host` table entries; that is, the privileges that are '`Y`' in both entries. (This way you can grant general privileges in the `db` table row and then selectively restrict them on a host-by-host basis using the `host` table entries.)

After determining the database-specific privileges granted by the `db` and `host` table entries, the server adds them to the global privileges granted by the `user` table. If the result permits the requested operation, access is granted. Otherwise, the server successively checks the user's table and column privileges in the `tables_priv` and `columns_priv` tables, adds those to the user's privileges, and permits or denies access based on the result. For stored-routine operations, the server uses the `procs_priv` table rather than `tables_priv` and `columns_priv`.

Expressed in boolean terms, the preceding description of how a user's privileges are calculated may be summarized like this:

```
global privileges
OR (database privileges AND host privileges)
OR table privileges
OR column privileges
OR routine privileges
```

It may not be apparent why, if the global `user` row privileges are initially found to be insufficient for the requested operation, the server adds those privileges to the database, table, and column privileges later. The reason is that a request might require more than one type of privilege. For example, if you execute an `INSERT INTO ... SELECT` statement, you need both the `INSERT` and the `SELECT` privileges. Your privileges might be such that the `user` table row grants one privilege and the `db` table row grants the other. In this case, you have the necessary privileges to perform the request, but the server cannot tell that from either table by itself; the privileges granted by the entries in both tables must be combined.

The `host` table is not affected by the `GRANT` or `REVOKE` statements, so it is unused in most MySQL installations. If you modify it directly, you can use it for some specialized purposes, such as to maintain a list of secure servers on the local network that are granted all privileges.

You can also use the `host` table to indicate hosts that are *not* secure. Suppose that you have a machine `public.your.domain` that is located in a public area that you do not consider secure. You can enable access to all hosts on your network except that machine by using `host` table entries like this:

Host	Db	...
<code>public.your.domain</code>	<code>%</code>	... (all privileges set to 'N')
<code>%.your.domain</code>	<code>%</code>	... (all privileges set to 'Y')

## 5.4.6. When Privilege Changes Take Effect

When `mysqld` starts, it reads all grant table contents into memory. The in-memory tables become effective for access control at that point.

If you modify the grant tables indirectly using account-management statements such as `GRANT`, `REVOKE`, `SET PASSWORD`, or `RENAME USER`, the server notices these changes and loads the grant tables into memory again immediately.

If you modify the grant tables directly using statements such as `INSERT`, `UPDATE`, or `DELETE`, your changes have no effect on privilege checking until you either restart the server or tell it to reload the tables. If you change the grant tables directly but forget to reload them, your changes have *no effect* until you restart the server. This may leave you wondering why your changes seem to

make no difference!

To tell the server to reload the grant tables, perform a flush-privileges operation. This can be done by issuing a `FLUSH PRIVILEGES` statement or by executing a `mysqladmin flush-privileges` or `mysqladmin reload` command.

A grant table reload affects privileges for each existing client connection as follows:

- Table and column privilege changes take effect with the client's next request.
- Database privilege changes take effect the next time the client executes a `USE db_name` statement.

#### Note

Client applications may cache the database name; thus, this effect may not be visible to them without actually changing to a different database or flushing the privileges.

- Global privileges and passwords are unaffected for a connected client. These changes take effect only for subsequent connections.

If the server is started with the `--skip-grant-tables` option, it does not read the grant tables or implement any access control. Anyone can connect and do anything, *which is insecure*. To cause a server thus started to read the tables and enable access checking, flush the privileges.

### 5.4.7. Causes of Access-Denied Errors

If you encounter problems when you try to connect to the MySQL server, the following items describe some courses of action you can take to correct the problem.

- Make sure that the server is running. If it is not, clients cannot connect to it. For example, if an attempt to connect to the server fails with a message such as one of those following, one cause might be that the server is not running:

```
shell> mysql
ERROR 2003: Can't connect to MySQL server on 'host_name' (111)
shell> mysql
ERROR 2002: Can't connect to local MySQL server through socket
'/tmp/mysql.sock' (111)
```

- It might be that the server is running, but you are trying to connect using a TCP/IP port, named pipe, or Unix socket file different from the one on which the server is listening. To correct this when you invoke a client program, specify a `--port` option to indicate the proper port number, or a `--socket` option to indicate the proper named pipe or Unix socket file. To find out where the socket file is, you can use this command:

```
shell> netstat -ln | grep mysql
```

- Make sure that the server has not been configured to ignore network connections or (if you are attempting to connect remotely) that it has not been configured to listen only locally on its network interfaces. If the server was started with `--skip-networking`, it will not accept TCP/IP connections at all. If the server was started with `--bind-address=127.0.0.1`, it will listen for TCP/IP connections only locally on the loopback interface and will not accept remote connections.
- Check to make sure that there is no firewall blocking access to MySQL. Your firewall may be configured on the basis of the application being executed, or the port number used by MySQL for communication (3306 by default). Under Linux or Unix, check your IP tables (or similar) configuration to ensure that the port has not been blocked. Under Windows, applications such as ZoneAlarm or the Windows XP personal firewall may need to be configured not to block the MySQL port.
- The grant tables must be properly set up so that the server can use them for access control. For some distribution types (such as binary distributions on Windows, or RPM distributions on Linux), the installation process initializes the `mysql` database containing the grant tables. For distributions that do not do this, you must initialize the grant tables manually by running the `mysql_install_db` script. For details, see [Section 2.13.1, “Unix Post-Installation Procedures”](#).

To determine whether you need to initialize the grant tables, look for a `mysql` directory under the data directory. (The data directory normally is named `data` or `var` and is located under your MySQL installation directory.) Make sure that you have a file named `user.MYD` in the `mysql` database directory. If not, execute the `mysql_install_db` script. After running this script and starting the server, test the initial privileges by executing this command:

```
shell> mysql -u root test
```

The server should let you connect without error.

- After a fresh installation, you should connect to the server and set up your users and their access permissions:

```
shell> mysql -u root mysql
```

The server should let you connect because the MySQL `root` user has no password initially. That is also a security risk, so setting the password for the `root` accounts is something you should do while you're setting up your other MySQL accounts. For instructions on setting the initial passwords, see [Section 2.13.2, “Securing the Initial MySQL Accounts”](#).

- If you have updated an existing MySQL installation to a newer version, did you run the `mysql_upgrade` script? If not, do so. The structure of the grant tables changes occasionally when new capabilities are added, so after an upgrade you should always make sure that your tables have the current structure. For instructions, see [Section 4.4.8, “mysql\\_upgrade — Check Tables for MySQL Upgrade”](#).
- If a client program receives the following error message when it tries to connect, it means that the server expects passwords in a newer format than the client is capable of generating:

```
shell> mysql
Client does not support authentication protocol requested
by server; consider upgrading MySQL client
```

For information on how to deal with this, see [Section 5.3.2.3, “Password Hashing in MySQL”](#), and [Section B.5.2.4, “Client does not support authentication protocol”](#).

- Remember that client programs use connection parameters specified in option files or environment variables. If a client program seems to be sending incorrect default connection parameters when you have not specified them on the command line, check any applicable option files and your environment. For example, if you get `Access denied` when you run a client without any options, make sure that you have not specified an old password in any of your option files!

You can suppress the use of option files by a client program by invoking it with the `--no-defaults` option. For example:

```
shell> mysqladmin --no-defaults -u root version
```

The option files that clients use are listed in [Section 4.2.3.3, “Using Option Files”](#). Environment variables are listed in [Section 2.14, “Environment Variables”](#).

- If you get the following error, it means that you are using an incorrect `root` password:

```
shell> mysqladmin -u root -pxxxxx ver
Access denied for user 'root'@'localhost' (using password: YES)
```

If the preceding error occurs even when you have not specified a password, it means that you have an incorrect password listed in some option file. Try the `--no-defaults` option as described in the previous item.

For information on changing passwords, see [Section 5.5.5, “Assigning Account Passwords”](#).

If you have lost or forgotten the `root` password, see [Section B.5.4.1, “How to Reset the Root Password”](#).

- If you change a password by using `SET PASSWORD`, `INSERT`, or `UPDATE`, you must encrypt the password using the `PASSWORD()` function. If you do not use `PASSWORD()` for these statements, the password will not work. For example, the following statement assigns a password, but fails to encrypt it, so the user is not able to connect afterward:

```
SET PASSWORD FOR 'abe'@'host_name' = 'eagle';
```

Instead, set the password like this:

```
SET PASSWORD FOR 'abe'@'host_name' = PASSWORD('eagle');
```

The `PASSWORD()` function is unnecessary when you specify a password using the `CREATE USER` or `GRANT` statements or the `mysqladmin password` command. Each of those automatically uses `PASSWORD()` to encrypt the password. See [Section 5.5.5, “Assigning Account Passwords”](#), and [Section 12.4.1.1, “CREATE USER Syntax”](#).

- `localhost` is a synonym for your local host name, and is also the default host to which clients try to connect if you specify no host explicitly.

To avoid this problem on such systems, you can use a `--host=127.0.0.1` option to name the server host explicitly. This will make a TCP/IP connection to the local `mysqld` server. You can also use TCP/IP by specifying a `--host` option that uses the actual host name of the local host. In this case, the host name must be specified in a `user` table row on the server host, even though you are running the client program on the same host as the server.

- The `Access denied` error message tells you who you are trying to log in as, the client host from which you are trying to connect, and whether you were using a password. Normally, you should have one row in the `user` table that exactly matches the host name and user name that were given in the error message. For example, if you get an error message that contains `using password: NO`, it means that you tried to log in without a password.
- If you get an `Access denied` error when trying to connect to the database with `mysql -u user_name`, you may have a problem with the `user` table. Check this by executing `mysql -u root mysql` and issuing this SQL statement:

```
SELECT * FROM user;
```

The result should include a row with the `Host` and `User` columns matching your client's host name and your MySQL user name.

- If the following error occurs when you try to connect from a host other than the one on which the MySQL server is running, it means that there is no row in the `user` table with a `Host` value that matches the client host:

```
Host ... is not allowed to connect to this MySQL server
```

You can fix this by setting up an account for the combination of client host name and user name that you are using when trying to connect.

If you do not know the IP number or host name of the machine from which you are connecting, you should put a row with '`%`' as the `Host` column value in the `user` table. After trying to connect from the client machine, use a `SELECT USER()` query to see how you really did connect. Then change the '`%`' in the `user` table row to the actual host name that shows up in the log. Otherwise, your system is left insecure because it permits connections from any host for the given user name.

On Linux, another reason that this error might occur is that you are using a binary MySQL version that is compiled with a different version of the `glibc` library than the one you are using. In this case, you should either upgrade your operating system or `glibc`, or download a source distribution of MySQL version and compile it yourself. A source RPM is normally trivial to compile and install, so this is not a big problem.

- If you specify a host name when trying to connect, but get an error message where the host name is not shown or is an IP number, it means that the MySQL server got an error when trying to resolve the IP number of the client host to a name:

```
shell> mysqladmin -u root -pXXXX -h some_hostname ver
Access denied for user 'root'@'...' (using password: YES)
```

If you try to connect as `root` and get the following error, it means that you do not have a row in the `user` table with a `User` column value of '`root`' and that `mysqld` cannot resolve the host name for your client:

```
Access denied for user ''@'unknown'
```

These errors indicate a DNS problem. To fix it, execute `mysqladmin flush-hosts` to reset the internal DNS host name cache. See [Section 7.9.9, “How MySQL Uses DNS”](#).

Some permanent solutions are:

- Determine what is wrong with your DNS server and fix it.
- Specify IP numbers rather than host names in the MySQL grant tables.
- Put an entry for the client machine name in `/etc/hosts` on Unix or `\windows\hosts` on Windows.
- Start `mysqld` with the `--skip-name-resolve` option.
- Start `mysqld` with the `--skip-host-cache` option.
- On Unix, if you are running the server and the client on the same machine, connect to `localhost`. Unix connections to `localhost` use a Unix socket file rather than TCP/IP.
- On Windows, if you are running the server and the client on the same machine and the server supports named pipe connections, connect to the host name `.` (period). Connections to `.` use a named pipe rather than TCP/IP.
- If `mysql -u root test` works but `mysql -h your_hostname -u root test` results in `Access denied` (where `your_hostname` is the actual host name of the local host), you may not have the correct name for your host in the `user` table. A common problem here is that the `Host` value in the `user` table row specifies an unqualified host name, but your system's name resolution routines return a fully qualified domain name (or vice versa). For example, if you have an entry with host '`pluto`' in the `user` table, but your DNS tells MySQL that your host name is '`pluto.example.com`', the entry does not work. Try adding an entry to the `user` table that contains the IP number of your host as the `Host` column value.

(Alternatively, you could add an entry to the `user` table with a `Host` value that contains a wildcard; for example, `'pluto.%'`. However, use of `Host` values ending with “%” is *insecure* and is *not recommended*!)

- If `mysql -u user_name test` works but `mysql -u user_name other_db` does not, you have not granted access to the given user for the database named `other_db`.
- If `mysql -u user_name` works when executed on the server host, but `mysql -h host_name -u user_name` does not work when executed on a remote client host, you have not enabled access to the server for the given user name from the remote host.
- If you cannot figure out why you get `Access denied`, remove from the `user` table all entries that have `Host` values containing wildcards (entries that contain ‘%’ or ‘\_’ characters). A very common error is to insert a new entry with `Host='%`’ and `User='some_user'`, thinking that this enables you to specify `localhost` to connect from the same machine. The reason that this does not work is that the default privileges include an entry with `Host='localhost'` and `User=''`. Because that entry has a `Host` value `'localhost'` that is more specific than ‘%’, it is used in preference to the new entry when connecting from `localhost`! The correct procedure is to insert a second entry with `Host='localhost'` and `User='some_user'`, or to delete the entry with `Host='localhost'` and `User=''`. After deleting the entry, remember to issue a `FLUSH PRIVILEGES` statement to reload the grant tables. See also [Section 5.4.4, “Access Control, Stage 1: Connection Verification”](#).
- If you are able to connect to the MySQL server, but get an `Access denied` message whenever you issue a `SELECT ... INTO OUTFILE` or `LOAD DATA INFILE` statement, your entry in the `user` table does not have the `FILE` privilege enabled.
- If you change the grant tables directly (for example, by using `INSERT`, `UPDATE`, or `DELETE` statements) and your changes seem to be ignored, remember that you must execute a `FLUSH PRIVILEGES` statement or a `mysqladmin flush-privileges` command to cause the server to reload the privilege tables. Otherwise, your changes have no effect until the next time the server is restarted. Remember that after you change the `root` password with an `UPDATE` statement, you will not need to specify the new password until after you flush the privileges, because the server will not know you've changed the password yet!
- If your privileges seem to have changed in the middle of a session, it may be that a MySQL administrator has changed them. Reloading the grant tables affects new client connections, but it also affects existing connections as indicated in [Section 5.4.6, “When Privilege Changes Take Effect”](#).
- If you have access problems with a Perl, PHP, Python, or ODBC program, try to connect to the server with `mysql -u user_name db_name` or `mysql -u user_name -p your_pass db_name`. If you are able to connect using the `mysql` client, the problem lies with your program, not with the access privileges. (There is no space between `-p` and the password; you can also use the `--password=your_pass` syntax to specify the password. If you use the `-p` or `--password` option with no password value, MySQL prompts you for the password.)
- For testing purposes, start the `mysqld` server with the `--skip-grant-tables` option. Then you can change the MySQL grant tables and use the `mysqlaccess` script to check whether your modifications have the desired effect. When you are satisfied with your changes, execute `mysqladmin flush-privileges` to tell the `mysqld` server to reload the privileges. This enables you to begin using the new grant table contents without stopping and restarting the server.
- If you get the following error, you may have a problem with the `db` or `host` table:  

`Access to database denied`

If the entry selected from the `db` table has an empty value in the `Host` column, make sure that there are one or more corresponding entries in the `host` table specifying which hosts the `db` table entry applies to. This problem occurs infrequently because the `host` table is rarely used.

- If everything else fails, start the `mysqld` server with a debugging option (for example, `--debug=d,general,query`). This prints host and user information about attempted connections, as well as information about each command issued. See [MySQL Internals: Porting](#).
- If you have any other problems with the MySQL grant tables and feel you must post the problem to the mailing list, always provide a dump of the MySQL grant tables. You can dump the tables with the `mysqldump mysql` command. To file a bug report, see the instructions at [Section 1.7, “How to Report Bugs or Problems”](#). In some cases, you may need to restart `mysqld` with `--skip-grant-tables` to run `mysqldump`.

## 5.5. MySQL User Account Management

This section describes how to set up accounts for clients of your MySQL server. It discusses the following topics:

- The meaning of account names and passwords as used in MySQL and how that compares to names and passwords used by your operating system
- How to set up new accounts and remove existing accounts
- How to change passwords
- Guidelines for using passwords securely
- How to use secure connections with SSL

See also [Section 12.4.1, “Account Management Statements”](#), which describes the syntax and use for all user-management SQL statements.

### 5.5.1. User Names and Passwords

A MySQL account is defined in terms of a user name and the client host or hosts from which the user can connect to the server. The account also has a password. There are several distinctions between the way user names and passwords are used by MySQL and the way they are used by your operating system:

- User names, as used by MySQL for authentication purposes, have nothing to do with user names (login names) as used by Windows or Unix. On Unix, most MySQL clients by default try to log in using the current Unix user name as the MySQL user name, but that is for convenience only. The default can be overridden easily, because client programs permit any user name to be specified with a `--user` option. Because this means that anyone can attempt to connect to the server using any user name, you cannot make a database secure in any way unless all MySQL accounts have passwords. Anyone who specifies a user name for an account that has no password is able to connect successfully to the server.
- MySQL user names can be up to 16 characters long. Operating system user names, because they are completely unrelated to MySQL user names, may be of a different maximum length. For example, Unix user names typically are limited to eight characters.

#### Warning

The limit on MySQL user name length is hard-coded in the MySQL servers and clients, and trying to circumvent it by modifying the definitions of the tables in the `mysql` database *does not work*.

You should never alter any of the tables in the `mysql` database in any manner whatsoever except by means of the procedure that is described in [Section 4.4.8, “mysql\\_upgrade — Check Tables for MySQL Upgrade”](#). Attempting to redefine MySQL’s system tables in any other fashion results in undefined (and unsupported!) behavior.

- It is best to use only ASCII characters for user names and passwords.
- MySQL passwords have nothing to do with passwords for logging in to your operating system. There is no necessary connection between the password you use to log in to a Windows or Unix machine and the password you use to access the MySQL server on that machine.
- MySQL encrypts passwords using its own algorithm. This encryption is the same as that implemented by the `PASSWORD()` SQL function but differs from that used during the Unix login process. Unix password encryption is the same as that implemented by the `ENCRYPT()` SQL function. See the descriptions of the `PASSWORD()` and `ENCRYPT()` functions in [Section 11.13, “Encryption and Compression Functions”](#).

From version 4.1 on, MySQL employs a stronger authentication method that has better password protection during the connection process than in earlier versions. It is secure even if TCP/IP packets are sniffed or the `mysql` database is captured. (In earlier versions, even though passwords are stored in encrypted form in the `user` table, knowledge of the encrypted password value could be used to connect to the MySQL server.) [Section 5.3.2.3, “Password Hashing in MySQL”](#), discusses password encryption further.

When you install MySQL, the grant tables are populated with an initial set of accounts. These accounts have names and access privileges that are described in [Section 2.13.2, “Securing the Initial MySQL Accounts”](#), which also discusses how to assign passwords to them. Thereafter, you normally set up, modify, and remove MySQL accounts using statements such as `GRANT` and `REVOKE`. See [Section 12.4.1, “Account Management Statements”](#).

When you connect to a MySQL server with a command-line client, you should specify the user name and password for the account that you want to use:

```
shell> mysql --user=monty --password=password db_name
```

If you prefer short options, the command looks like this:

```
shell> mysql -u monty -ppassword db_name
```

There must be *no space* between the `-p` option and the following password value.

If you omit the `password` value following the `--password` or `-p` option on the command line, the client prompts for one.

Specifying a password on the command line should be considered insecure. See [Section 5.3.2.2, “End-User Guidelines for Password Security”](#). You can use an option file to avoid giving the password on the command line.

For additional information about specifying user names, passwords, and other connection parameters, see [Section 4.2.2, “Connecting to the MySQL Server”](#).

## 5.5.2. Adding User Accounts

You can create MySQL accounts in two ways:

- By using statements intended for creating accounts, such as `CREATE USER` or `GRANT`. These statements cause the server to make appropriate modifications to the grant tables.
- By manipulating the MySQL grant tables directly with statements such as `INSERT`, `UPDATE`, or `DELETE`.

The preferred method is to use account-creation statements because they are more concise and less error-prone than manipulating the grant tables directly. `CREATE USER` and `GRANT` are described in [Section 12.4.1, “Account Management Statements”](#).

Another option for creating accounts is to use one of several available third-party programs that offer capabilities for MySQL account administration. `phpMyAdmin` is one such program.

The following examples show how to use the `mysql` client program to set up new accounts. These examples assume that privileges have been set up according to the defaults described in [Section 2.13.2, “Securing the Initial MySQL Accounts”](#). This means that to make changes, you must connect to the MySQL server as the MySQL `root` user, and the `root` account must have the `INSERT` privilege for the `mysql` database and the `RELOAD` administrative privilege.

As noted in the examples where appropriate, some of the statements will fail if the server's SQL mode has been set to enable certain restrictions. In particular, strict mode (`STRICT_TRANS_TABLES`, `STRICT_ALL_TABLES`) and `NO_AUTO_CREATE_USER` will prevent the server from accepting some of the statements. Workarounds are indicated for these cases. For more information about SQL modes and their effect on grant table manipulation, see [Section 5.1.7, “Server SQL Modes”](#), and [Section 12.4.1.3, “GRANT Syntax”](#).

First, use the `mysql` program to connect to the server as the MySQL `root` user:

```
shell> mysql --user=root mysql
```

If you have assigned a password to the `root` account, you'll also need to supply a `--password` or `-p` option, both for this `mysql` command and for those later in this section.

After connecting to the server as `root`, you can add new accounts. The following statements use `GRANT` to set up four new accounts:

```
mysql> CREATE USER 'monty'@'localhost' IDENTIFIED BY 'some_pass';
mysql> GRANT ALL PRIVILEGES ON *.* TO 'monty'@'localhost'
 > WITH GRANT OPTION;
mysql> CREATE USER 'monty'@'%'
 IDENTIFIED BY 'some_pass';
mysql> GRANT ALL PRIVILEGES ON *.* TO 'monty'@'%'
 > WITH GRANT OPTION;
mysql> CREATE USER 'admin'@'localhost';
mysql> GRANT RELOAD,PROCESS ON *.* TO 'admin'@'localhost';
mysql> CREATE USER 'dummy'@'localhost';
```

The accounts created by these statements have the following properties:

- Two of the accounts have a user name of `monty` and a password of `some_pass`. Both accounts are superuser accounts with full privileges to do anything. The `'monty'@'localhost'` account can be used only when connecting from the local host. The `'monty'@'%'` account uses the `'%'` wildcard for the host part, so it can be used to connect from any host.

It is necessary to have both accounts for `monty` to be able to connect from anywhere as `monty`. Without the `localhost` account, the anonymous-user account for `localhost` that is created by `mysql_install_db` would take precedence when

`monty` connects from the local host. As a result, `monty` would be treated as an anonymous user. The reason for this is that the anonymous-user account has a more specific `Host` column value than the '`monty'@'%'` account and thus comes earlier in the `user` table sort order. (`user` table sorting is discussed in [Section 5.4.4, “Access Control, Stage 1: Connection Verification”](#).)

- The '`admin`'@'`localhost`' account has no password. This account can be used only by `admin` to connect from the local host. It is granted the `RELOAD` and `PROCESS` administrative privileges. These privileges enable the `admin` user to execute the `mysqladmin reload`, `mysqladmin refresh`, and `mysqladmin flush-xxx` commands, as well as `mysqladmin processlist`. No privileges are granted for accessing any databases. You could add such privileges later by issuing other `GRANT` statements.
  - The '`dummy`'@'`localhost`' account has no password. This account can be used only to connect from the local host. No privileges are granted. It is assumed that you will grant specific privileges to the account later.

The statements that create accounts with no password will fail if the `NO_AUTO_CREATE_USER` SQL mode is enabled. To deal with this, use an `IDENTIFIED BY` clause that specifies a nonempty password.

To check the privileges for an account, use `SHOW GRANTS`:

```
mysql> SHOW GRANTS FOR 'admin'@'localhost';
+-----+-----+
| Grants for admin@localhost | |
+-----+-----+
| GRANT RELOAD, PROCESS ON *.* TO 'admin'@'localhost' | |
+-----+-----+
```

As an alternative to `CREATE USER` and `GRANT`, you can create the same accounts directly by issuing `INSERT` statements and then telling the server to reload the grant tables using `FLUSH PRIVILEGES`:

```
shell> mysql --user=root mysql
mysql> INSERT INTO user
-> VALUES('localhost','monty',PASSWORD('some_pass')),
-> 'Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y');
mysql> INSERT INTO user
-> VALUES('%','monty',PASSWORD('some_pass')),
-> 'Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y',
-> 'Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y',
-> 'Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y');
mysql> INSERT INTO user SET Host='localhost',User='admin',
-> Reload_priv='Y', Process_priv='Y';
mysql> INSERT INTO user (Host,User,Password)
-> VALUES('localhost','dummy','');
mysql> FLUSH PRIVILEGES;
```

When you create accounts with `INSERT`, it is necessary to use `FLUSH PRIVILEGES` to tell the server to reload the grant tables. Otherwise, the changes go unnoticed until you restart the server. With `CREATE USER, FLUSH PRIVILEGES` is unnecessary.

The reason for using the `PASSWORD()` function with `INSERT` is to encrypt the password. The `CREATE USER` statement encrypts the password for you, so `PASSWORD()` is unnecessary.

The '`Y`' values enable privileges for the accounts. Depending on your MySQL version, you may have to use a different number of '`Y`' values in the first two `INSERT` statements. The `INSERT` statement for the `admin` account employs the more readable extended `INSERT` syntax using `SET`.

In the `INSERT` statement for the `dummy` account, only the `Host`, `User`, and `Password` columns in the `user` table row are assigned values. None of the privilege columns are set explicitly, so MySQL assigns them all the default value of '`N`'. This is equivalent to what `CREATE USER` does.

If strict SQL mode is enabled, all columns that have no default value must have a value specified. In this case, `INSERT` statements must explicitly specify values for the `ssl_cipher`, `x509_issuer`, and `x509_subject` columns.

To set up a superuser account, it is necessary only to create a `user` table entry with the privilege columns set to '`Y`'. The `user` table privileges are global, so no entries in any of the other grant tables are needed.

The next examples create three accounts and give them access to specific databases. Each of them has a user name of `custom` and password of `obscure`.

To create the accounts with `CREATE USER` and `GRANT`, use the following statements:

```
shell> mysql --user=root mysql
mysql> CREATE USER 'custom'@'localhost' IDENTIFIED BY 'obscure';
```

```
--> ON bankaccount.*
--> TO 'custom'@'localhost';
mysql> CREATE USER 'custom'@'host47.example.com' IDENTIFIED BY 'obscure';
mysql> GRANT SELECT,INSERT,UPDATE,DELETE,CREATE,DROP
```

```

-> ON expenses.* ;
-> TO 'custom'@'host47.example.com';
mysql> CREATE USER 'custom'@'server.domain' IDENTIFIED BY 'obscure';
mysql> GRANT SELECT,INSERT,UPDATE,DELETE,CREATE,DROP
-> ON customer.* ;
-> TO 'custom'@'server.domain';

```

The three accounts can be used as follows:

- The first account can access the `bankaccount` database, but only from the local host.
- The second account can access the `expenses` database, but only from the host `host47.example.com`.
- The third account can access the `customer` database, but only from the host `server.domain`.

To set up the `custom` accounts without `GRANT`, use `INSERT` statements as follows to modify the grant tables directly:

```

shell> mysql --user=root mysql
mysql> INSERT INTO user (Host,User,Password)
-> VALUES('localhost','custom',PASSWORD('obscure'));
mysql> INSERT INTO user (Host,User,Password)
-> VALUES('host47.example.com','custom',PASSWORD('obscure'));
mysql> INSERT INTO user (Host,User,Password)
-> VALUES('server.domain','custom',PASSWORD('obscure'));
mysql> INSERT INTO db
-> (Host,Db,User,Select_priv,Insert_priv,
-> Update_priv,Delete_priv,Create_priv,Drop_priv)
-> VALUES('localhost','bankaccount','custom',
-> 'Y','Y','Y','Y','Y','Y');
mysql> INSERT INTO db
-> (Host,Db,User,Select_priv,Insert_priv,
-> Update_priv,Delete_priv,Create_priv,Drop_priv)
-> VALUES('host47.example.com','expenses','custom',
-> 'Y','Y','Y','Y','Y','Y');
mysql> INSERT INTO db
-> (Host,Db,User,Select_priv,Insert_priv,
-> Update_priv,Delete_priv,Create_priv,Drop_priv)
-> VALUES('server.domain','customer','custom',
-> 'Y','Y','Y','Y','Y','Y');
mysql> FLUSH PRIVILEGES;

```

The first three `INSERT` statements add `user` table entries that permit the user `custom` to connect from the various hosts with the given password, but grant no global privileges (all privileges are set to the default value of '`N`'). The next three `INSERT` statements add `db` table entries that grant privileges to `custom` for the `bankaccount`, `expenses`, and `customer` databases, but only when accessed from the proper hosts. As usual when you modify the grant tables directly, you must tell the server to reload them with `FLUSH PRIVILEGES` so that the privilege changes take effect.

To create a user who has access from all machines in a given domain (for example, `mydomain.com`), you can use the “`%`” wild-card character in the host part of the account name:

```
mysql> CREATE USER 'myname'@'%.mydomain.com' IDENTIFIED BY 'mypass';
```

To do the same thing by modifying the grant tables directly, do this:

```

mysql> INSERT INTO user (Host,User,Password,...)
-> VALUES('%.mydomain.com','myname',PASSWORD('mypass'),...);
mysql> FLUSH PRIVILEGES;

```

### 5.5.3. Removing User Accounts

To remove an account, use the `DROP USER` statement, which is described in [Section 12.4.1.2, “DROP USER Syntax”](#).

### 5.5.4. Setting Account Resource Limits

One means of limiting use of MySQL server resources is to set the global `max_user_connections` system variable to a nonzero value. This limits the number of simultaneous connections that can be made by any given account, but places no limits on what a client can do once connected. In addition, setting `max_user_connections` does not enable management of individual accounts. Both types of control are of interest to many MySQL administrators, particularly those working for Internet Service Providers.

In MySQL 5.1, you can limit use of the following server resources for individual accounts:

- The number of queries that an account can issue per hour

- The number of updates that an account can issue per hour
- The number of times an account can connect to the server per hour
- The number of simultaneous connections to the server by an account

Any statement that a client can issue counts against the query limit (unless its results are served from the query cache). Only statements that modify databases or tables count against the update limit.

An “account” in this context corresponds to a row in the `mysql.user` table. That is, a connection is assessed against the `User` and `Host` values in the `user` table row that applies to the connection. For example, an account `'usera'@'%example.com'` corresponds to a row in the `user` table that has `User` and `Host` values of `usera` and `%example.com`, to permit `usera` to connect from any host in the `example.com` domain. In this case, the server applies resource limits in this row collectively to all connections by `usera` from any host in the `example.com` domain because all such connections use the same account.

Before MySQL 5.0.3, an “account” was assessed against the actual host from which a user connects. This older method accounting may be selected by starting the server with the `--old-style-user-limits` option. In this case, if `usera` connects simultaneously from `host1.example.com` and `host2.example.com`, the server applies the account resource limits separately to each connection. If `usera` connects again from `host1.example.com`, the server applies the limits for that connection together with the existing connection from that host.

To set resource limits for an account, use the `GRANT` statement (see [Section 12.4.1.3, “GRANT Syntax”](#)). Provide a `WITH` clause that names each resource to be limited. The default value for each limit is zero (no limit). For example, to create a new account that can access the `customer` database, but only in a limited fashion, issue these statements:

```
mysql> CREATE USER 'francis'@'localhost' IDENTIFIED BY 'frank';
mysql> GRANT ALL ON customer.* TO 'francis'@'localhost'
 -> WITH MAX_QUERIES_PER_HOUR 20
 -> MAX_UPDATES_PER_HOUR 10
 -> MAX_CONNECTIONS_PER_HOUR 5
 -> MAX_USER_CONNECTIONS 2;
```

The limit types need not all be named in the `WITH` clause, but those named can be present in any order. The value for each per-hour limit should be an integer representing a count per hour. For `MAX_USER_CONNECTIONS`, the limit is an integer representing the maximum number of simultaneous connections by the account. If this limit is set to zero, the global `max_user_connections` system variable value determines the number of simultaneous connections. If `max_user_connections` is also zero, there is no limit for the account.

To modify existing limits for an account, use a `GRANT USAGE` statement at the global level (`ON *.*`). The following statement changes the query limit for `francis` to 100:

```
mysql> GRANT USAGE ON *.* TO 'francis'@'localhost'
 -> WITH MAX_QUERIES_PER_HOUR 100;
```

The statement modifies only the limit value specified and leaves the account otherwise unchanged.

To remove a limit, set its value to zero. For example, to remove the limit on how many times per hour `francis` can connect, use this statement:

```
mysql> GRANT USAGE ON *.* TO 'francis'@'localhost'
 -> WITH MAX_CONNECTIONS_PER_HOUR 0;
```

As mentioned previously, the simultaneous-connection limit for an account is determined from the `MAX_USER_CONNECTIONS` limit and the `max_user_connections` system variable. Suppose that the global `max_user_connections` value is 10 and three accounts have resource limits specified with `GRANT`:

```
GRANT ... TO 'user1'@'localhost' WITH MAX_USER_CONNECTIONS 0;
GRANT ... TO 'user2'@'localhost' WITH MAX_USER_CONNECTIONS 5;
GRANT ... TO 'user3'@'localhost' WITH MAX_USER_CONNECTIONS 20;
```

`user1` has a connection limit of 10 (the global `max_user_connections` value) because it has a zero `MAX_USER_CONNECTIONS` limit. `user2` and `user3` have connection limits of 5 and 20, respectively, because they have nonzero `MAX_USER_CONNECTIONS` limits.

The server stores resource limits for an account in the `user` table row corresponding to the account. The `max_questions`, `max_updates`, and `max_connections` columns store the per-hour limits, and the `max_user_connections` column stores the `MAX_USER_CONNECTIONS` limit. (See [Section 5.4.2, “Privilege System Grant Tables”](#).) If your `user` table does not have these columns, it must be upgraded; see [Section 4.4.8, “mysql\\_upgrade — Check Tables for MySQL Upgrade”](#).

Resource-use counting takes place when any account has a nonzero limit placed on its use of any of the resources.

As the server runs, it counts the number of times each account uses resources. If an account reaches its limit on number of connections within the last hour, further connections for the account are rejected until that hour is up. Similarly, if the account reaches its limit on the number of queries or updates, further queries or updates are rejected until the hour is up. In all such cases, an appropriate error message is issued.

Resource counting is done per account, not per client. For example, if your account has a query limit of 50, you cannot increase your limit to 100 by making two simultaneous client connections to the server. Queries issued on both connections are counted together.

The current per-hour resource-use counts can be reset globally for all accounts, or individually for a given account:

- To reset the current counts to zero for all accounts, issue a `FLUSH USER_RESOURCES` statement. The counts also can be reset by reloading the grant tables (for example, with a `FLUSH PRIVILEGES` statement or a `mysqladmin reload` command).
- The counts for an individual account can be set to zero by re-granting it any of its limits. To do this, use `GRANT USAGE` as described earlier and specify a limit value equal to the value that the account currently has.

Counter resets do not affect the `MAX_USER_CONNECTIONS` limit.

All counts begin at zero when the server starts; counts are not carried over through a restart.

For the `MAX_USER_CONNECTIONS` limit, an edge case can occur if the account currently has open the maximum number of connections permitted to it: A disconnect followed quickly by a connect can result in an error (`ER_TOO_MANY_USER_CONNECTIONS` or `ER_USER_LIMIT_REACHED`) if the server has not fully processed the disconnect by the time the connect occurs. When the server finishes disconnect processing, another connection will once more be permitted.

## 5.5.5. Assigning Account Passwords

To assign a password when you create a new account with `CREATE USER`, include an `IDENTIFIED BY` clause:

```
mysql> CREATE USER 'jeffrey'@'localhost' IDENTIFIED BY 'biscuit';
```

To assign or change a password for an existing account, one way is to issue a `SET PASSWORD` statement:

```
mysql> SET PASSWORD FOR 'jeffrey'@'localhost' = PASSWORD('biscuit');
```

Only users such as `root` that have update access to the `mysql` database can change the password for other users. If you are not connected as an anonymous user, you can change your own password by omitting the `FOR` clause:

```
mysql> SET PASSWORD = PASSWORD('biscuit');
```

You can also use a `GRANT USAGE` statement at the global level (`ON *.*`) to assign a password to an account without affecting the account's current privileges:

```
mysql> GRANT USAGE ON *.* TO 'jeffrey'@'localhost' IDENTIFIED BY 'biscuit';
```

Passwords can be assigned from the command line by using the `mysqladmin` command:

```
shell> mysqladmin -u user_name -h host_name password "newpwd"
```

The account for which this command resets the password is the one with a `user` table row that matches `user_name` in the `User` column and the client host *from which you connect* in the `Host` column.

Although it is generally preferable to assign passwords using one of the preceding methods, you can also do so by modifying the `user` table directly:

- To establish a password when creating a new account, provide a value for the `Password` column:

```
shell> mysql -u root mysql
mysql> INSERT INTO user (Host,User,Password)
 -> VALUES('localhost','jeffrey',PASSWORD('biscuit'));
mysql> FLUSH PRIVILEGES;
```

- To change the password for an existing account, use `UPDATE` to set the `Password` column value:

```
shell> mysql -u root mysql
mysql> UPDATE user SET Password = PASSWORD('bagel')
 -> WHERE Host = 'localhost' AND User = 'francis';
mysql> FLUSH PRIVILEGES;
```

When you assign passwords using `CREATE USER` or `GRANT` with an `IDENTIFIED BY` clause or with the `mysqladmin password` command, they take care of encrypting the password for you.

When you assign an account a nonempty password using `SET PASSWORD`, `INSERT`, or `UPDATE`, you must use the `PASSWORD()` function to encrypt the password. `PASSWORD()` is necessary because the `user` table stores passwords in encrypted form, not as plaintext. If you forget that fact, you are likely to set passwords like this:

```
shell> mysql -u root mysql
mysql> INSERT INTO user (Host,User,Password)
 -> VALUES('localhost','jeffrey','biscuit');
mysql> FLUSH PRIVILEGES;
```

The result is that the literal value '`biscuit`' is stored as the password in the `user` table, not the encrypted value. When `jeffrey` attempts to connect to the server using this password, the value is encrypted and compared to the value stored in the `user` table. However, the stored value is the literal string '`biscuit`', so the comparison fails and the server rejects the connection:

```
shell> mysql -u jeffrey -pbiscuit test
Access denied
```

#### Note

`PASSWORD()` encryption differs from Unix password encryption. See [Section 5.5.1, “User Names and Passwords”](#).

## 5.5.6. Using SSL for Secure Connections

MySQL supports secure (encrypted) connections between MySQL clients and the server using the Secure Sockets Layer (SSL) protocol. This section discusses how to use SSL connections. For information on how to require users to use SSL connections, see the discussion of the `REQUIRE` clause of the `GRANT` statement in [Section 12.4.1.3, “GRANT Syntax”](#).

The standard configuration of MySQL is intended to be as fast as possible, so encrypted connections are not used by default. Doing so would make the client/server protocol much slower. Encrypting data is a CPU-intensive operation that requires the computer to do additional work and can delay other MySQL tasks. For applications that require the security provided by encrypted connections, the extra computation is warranted.

MySQL enables encryption on a per-connection basis. You can choose a normal unencrypted connection or a secure encrypted SSL connection according the requirements of individual applications.

Secure connections are based on the OpenSSL API and are available through the MySQL C API. Replication uses the C API, so secure connections can be used between master and slave servers.

Another way to connect securely is from within an SSH connection to the MySQL server host. For an example, see [Section 5.5.7, “Connecting to MySQL Remotely from Windows with SSH”](#).

### 5.5.6.1. Basic SSL Concepts

To understand how MySQL uses SSL, it is necessary to explain some basic SSL and X509 concepts. People who are familiar with these can skip this part of the discussion.

By default, MySQL uses unencrypted connections between the client and the server. This means that someone with access to the network could watch all your traffic and look at the data being sent or received. They could even change the data while it is in transit between client and server. To improve security a little, you can compress client/server traffic by using the `--compress` option when invoking client programs. However, this does not foil a determined attacker.

When you need to move information over a network in a secure fashion, an unencrypted connection is unacceptable. Encryption is the way to make any kind of data unreadable. In fact, today's practice requires many additional security elements from encryption algorithms. They should resist many kind of known attacks such as changing the order of encrypted messages or replaying data twice.

SSL is a protocol that uses different encryption algorithms to ensure that data received over a public network can be trusted. It has mechanisms to detect any data change, loss, or replay. SSL also incorporates algorithms that provide identity verification using the X509 standard.

X509 makes it possible to identify someone on the Internet. It is most commonly used in e-commerce applications. In basic terms,

there should be some company called a “Certificate Authority” (or CA) that assigns electronic certificates to anyone who needs them. Certificates rely on asymmetric encryption algorithms that have two encryption keys (a public key and a secret key). A certificate owner can show the certificate to another party as proof of identity. A certificate consists of its owner's public key. Any data encrypted with this public key can be decrypted only using the corresponding secret key, which is held by the owner of the certificate.

If you need more information about SSL, X509, or encryption, use your favorite Internet search engine to search for the keywords in which you are interested.

### 5.5.6.2. Using SSL Connections

To use SSL connections between the MySQL server and client programs, your system must support either OpenSSL or yaSSL and your version of MySQL must be built with SSL support.

To make it easier to use secure connections, MySQL is bundled with yaSSL. (MySQL and yaSSL employ the same licensing model, whereas OpenSSL uses an Apache-style license.) yaSSL support initially was available only for a few platforms, but now it is available on all MySQL platforms supported by Oracle Corporation.

To get secure connections to work with MySQL and SSL, you must do the following:

1. If you are not using a binary (precompiled) version of MySQL that has been built with SSL support, and you are going to use OpenSSL rather than the bundled yaSSL library, install OpenSSL if it has not already been installed. We have tested MySQL with OpenSSL 0.9.6. To obtain OpenSSL, visit <http://www.openssl.org>.

Building MySQL using OpenSSL requires a shared OpenSSL library, otherwise linker errors occur. Alternatively, build MySQL using yaSSL.

2. If you are not using a binary (precompiled) version of MySQL that has been built with SSL support, configure a MySQL source distribution to use SSL. When you configure MySQL, invoke the `configure` script like this:

```
shell> ./configure --with-ssl
```

That configures the distribution to use the bundled yaSSL library. To use OpenSSL instead, specify the `--with-ssl` option with the path to the directory where the OpenSSL header files and libraries are located:

```
shell> ./configure --with-ssl=path
```

#### Note

On some platforms the full determination of the You may also need to explicitly add the SSL library and header directories. You can do this by setting the `LDFLAGS`, `CFLAGS`, `CPPFLAGS` and `CXXFLAGS` with the full directories. For example:

```
shell> LDFLAGS="-L/usr/local/ssl/lib" CFLAGS="-I/usr/local/ssl/include" \
CPPFLAGS="-I/usr/local/ssl/include" CXXFLAGS="-I/usr/local/ssl/include" \
configure --with-ssl=/usr/local/ssl
```

Before MySQL 5.1.11, you must use the appropriate option to select the SSL library that you want to use.

For yaSSL:

```
shell> ./configure --with-yassl
```

For OpenSSL:

```
shell> ./configure --with-openssl
```

Note that yaSSL support on Unix platforms requires that either `/dev/urandom` or `/dev/random` be available to retrieve true random numbers. For additional information (especially regarding yaSSL on Solaris versions prior to 2.8 and HP-UX), see [Bug#13164](#).

3. Make sure that the `user` in the `mysql` database includes the SSL-related columns (beginning with `ssl_` and `x509_`). If your `user` table does not have these columns, it must be upgraded; see [Section 4.4.8, “mysql\\_upgrade — Check Tables for MySQL Upgrade”](#).
4. To check whether a server binary is compiled with SSL support, invoke it with the `--ssl` option. An error will occur if the server does not support SSL:

```
shell> mysqld --ssl --help
060525 14:18:52 [ERROR] mysqld: unknown option '--ssl'
```

To check whether a running `mysqld` server supports SSL, examine the value of the `have_ssl` system variable (if you have no `have_ssl` variable, check for `have_openssl`):

```
mysql> SHOW VARIABLES LIKE 'have_ssl';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| have_ssl | YES |
+-----+-----+
```

If the value is `YES`, the server supports SSL connections. If the value is `DISABLED`, the server supports SSL connections but was not started with the appropriate `--ssl-xxx` options (described later in this section).

To enable SSL connections, the proper SSL-related options must be used (see [Section 5.5.6.3, “SSL Command Options”](#)).

To start the MySQL server so that it permits clients to connect using SSL, use the options that identify the key and certificate files the server needs when establishing a secure connection:

```
shell> mysqld --ssl-ca=ca-cert.pem \
--ssl-cert=server-cert.pem \
--ssl-key=server-key.pem
```

- `--ssl-ca` identifies the Certificate Authority (CA) certificate.
- `--ssl-cert` identifies the server public key. This can be sent to the client and authenticated against the CA certificate that it has.
- `--ssl-key` identifies the server private key.

To establish a secure connection to a MySQL server with SSL support, the options that a client must specify depend on the SSL requirements of the user account that the client uses. (See the discussion of the `REQUIRE` clause in [Section 12.4.1.3, “GRANT Syntax”](#).)

If the account has no special SSL requirements or was created using a `GRANT` statement that includes the `REQUIRE SSL` option, a client can connect securely by using just the `--ssl-ca` option:

```
shell> mysql --ssl-ca=ca-cert.pem
```

To require that a client certificate also be specified, create the account using the `REQUIRE X509` option. Then the client must also specify the proper client key and certificate files or the server will reject the connection:

```
shell> mysql --ssl-ca=ca-cert.pem \
--ssl-cert=client-cert.pem \
--ssl-key=client-key.pem
```

In other words, the options are similar to those used for the server. Note that the Certificate Authority certificate has to be the same.

A client can determine whether the current connection with the server uses SSL by checking the value of the `Ssl_cipher` status variable. The value of `Ssl_cipher` is nonempty if SSL is used, and empty otherwise. For example:

```
mysql> SHOW STATUS LIKE 'Ssl_cipher';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Ssl_cipher | DHE-RSA-AES256-SHA |
+-----+-----+
```

For the `mysql` client, you can use the `STATUS` or `\s` command and check the `SSL` line:

```
mysql> \s
...
SSL: Not in use
...
```

Or:

```
mysql> \s
```

```
...
SSL: Cipher in use is DHE-RSA-AES256-SHA
...
```

To establish a secure connection from within an application program, use the `mysql_ssl_set()` C API function to set the appropriate certificate options before calling `mysql_real_connect()`. See [Section 21.9.3.67, “mysql\\_ssl\\_set\(\)”](#). After the connection is established, you can use `mysql_get_ssl_cipher()` to determine whether SSL is in use. A non-`NULL` return value indicates a secure connection and names the SSL cipher used for encryption. A `NULL` return value indicates that SSL is not being used. See [Section 21.9.3.33, “mysql\\_get\\_ssl\\_cipher\(\)”](#).

### 5.5.6.3. SSL Command Options

The following list describes options that are used for specifying the use of SSL, certificate files, and key files. They can be given on the command line or in an option file. These options are not available unless MySQL has been built with SSL support. See [Section 5.5.6.2, “Using SSL Connections”](#). (There are also `--master-ssl*` options that can be used for setting up a secure connection from a slave replication server to a master server; see [Section 16.1.3, “Replication and Binary Logging Options and Variables”](#).)

**Table 5.6. SSL Option/Variable Summary**

Name	Cmd-Line	Option file	System Var	Status Var	Var Scope	Dynamic
<code>have_openssl</code>			Yes		Global	No
<code>have_ssl</code>			Yes		Global	No
<code>skip-ssl</code>	Yes	Yes				
<code>ssl</code>	Yes	Yes				
<code>ssl-ca</code>	Yes	Yes			Global	No
<code>- Variable: ssl_ca</code>			Yes		Global	No
<code>ssl-capath</code>	Yes	Yes			Global	No
<code>- Variable: ssl_capath</code>			Yes		Global	No
<code>ssl-cert</code>	Yes	Yes			Global	No
<code>- Variable: ssl_cert</code>			Yes		Global	No
<code>ssl-cipher</code>	Yes	Yes			Global	No
<code>- Variable: ssl_cipher</code>			Yes		Global	No
<code>ssl-key</code>	Yes	Yes			Global	No
<code>- Variable: ssl_key</code>			Yes		Global	No
<code>ssl-verify-server-cert</code>	Yes	Yes				

- `--ssl`

For the server, this option specifies that the server permits SSL connections. For a client program, it permits the client to connect to the server using SSL. This option is not sufficient in itself to cause an SSL connection to be used. You must also specify the `--ssl-ca` option, and possibly the `--ssl-cert` and `--ssl-key` options.

This option is more often used in its opposite form to override any other SSL options and indicate that SSL should *not* be used. To do this, specify the option as `--skip-ssl` or `--ssl=0`.

Note that use of `--ssl` does not *require* an SSL connection. For example, if the server or client is compiled without SSL support, a normal unencrypted connection is used.

The secure way to require use of an SSL connection is to create an account on the server that includes a `REQUIRE SSL` clause in the `GRANT` statement. Then use that account to connect to the server, where both the server and the client have SSL support enabled.

The `REQUIRE` clause permits other SSL-related restrictions as well. The description of `REQUIRE` in [Section 12.4.1.3, “GRANT Syntax”](#), provides additional detail about which SSL command options may or must be specified by clients that connect using accounts that are created using the various `REQUIRE` options.

- `--ssl-ca=file_name`

The path to a file that contains a list of trusted SSL CAs.

- `--ssl-capath=directory_name`

The path to a directory that contains trusted SSL CA certificates in PEM format.

- `--ssl-cert=file_name`

The name of the SSL certificate file to use for establishing a secure connection.

- `--ssl-cipher=cipher_list`

A list of permissible ciphers to use for SSL encryption. For greatest portability, `cipher_list` should be a list of one or more cipher names, separated by colons. Examples:

```
--ssl-cipher=AES128-SHA
--ssl-cipher=DHE-RSA-AES256-SHA:AES128-SHA
```

This format is understood both by OpenSSL and yaSSL. OpenSSL supports a more flexible syntax for specifying ciphers, as described in the OpenSSL documentation at <http://www.openssl.org/docs/apps/ciphers.html>. However, this extended syntax will fail if used with a MySQL installation compiled against yaSSL.

If no cipher in the list is supported, SSL connections will not work.

- `--ssl-key=file_name`

The name of the SSL key file to use for establishing a secure connection.

- `--ssl-verify-server-cert`

This option is available for client programs only, not the server. It causes the server's Common Name value in the certificate that the server sends to the client to be verified against the host name that the client uses for connecting to the server, and the connection is rejected if there is a mismatch. This feature can be used to prevent man-in-the-middle attacks. Verification is disabled by default. This option was added in MySQL 5.1.11.

As of MySQL 5.1.18, if you use SSL when establishing a client connection, you can tell the client not to authenticate the server certificate by specifying neither `--ssl-ca` nor `--ssl-capath`. The server still verifies the client according to any applicable requirements established using `GRANT` statements for the client, and it still uses any `--ssl-ca/-ssl-capath` values that were passed to server at startup time.

#### 5.5.6.4. Setting Up SSL Certificates for MySQL

This section demonstrates how to set up SSL certificate and key files for use by MySQL servers and clients. The first example shows a simplified procedure such as you might use from the command line. The second shows a script that contains more detail. The first two examples are intended for use on Unix and both use the `openssl` command that is part of OpenSSL. The third example describes how to set up SSL files on Windows.

Following the third example, instructions are given for using the files to test SSL connections. You can also use the files as described in [Section 5.5.6.2, “Using SSL Connections”](#).

##### Example 1: Creating SSL files from the command line on Unix

The following example shows a set of commands to create MySQL server and client certificate and key files. You will need to respond to several prompts by the `openssl` commands. For testing, you can press Enter to all prompts. For production use, you should provide nonempty responses.

```
Create clean environment
shell> rm -rf newcerts
shell> mkdir newcerts && cd newcerts

Create CA certificate
shell> openssl genrsa 2048 > ca-key.pem
shell> openssl req -new -x509 -nodes -days 1000 \
 -key ca-key.pem > ca-cert.pem

Create server certificate
shell> openssl req -newkey rsa:2048 -days 1000 \
 -nodes -keyout server-key.pem > server-req.pem
shell> openssl x509 -req -in server-req.pem -days 1000 \
 -CA ca-cert.pem -CAkey ca-key.pem -set_serial 01 > server-cert.pem

Create client certificate
shell> openssl req -newkey rsa:2048 -days 1000 \
 -nodes -keyout client-key.pem > client-req.pem
shell> openssl x509 -req -in client-req.pem -days 1000 \
 -CA ca-cert.pem -CAkey ca-key.pem -set_serial 01 > client-cert.pem
```

**Example 2: Creating SSL files using a script on Unix**

Here is an example script that shows how to set up SSL certificates for MySQL:

```
DIR=`pwd`/openssl
PRIV=$DIR/private

mkdir $DIR $PRIV $DIR/newcerts
cp /usr/share/ssl/openssl.cnf $DIR
replace ./demoCA $DIR -- $DIR/openssl.cnf

Create necessary files: $database, $serial and $new_certs_dir
directory (optional)

touch $DIR/index.txt
echo "01" > $DIR/serial

#
Generation of Certificate Authority(CA)
#

openssl req -new -x509 -keyout $PRIV/cakey.pem -out $DIR/ca-cert.pem \
 -days 3600 -config $DIR/openssl.cnf

Sample output:
Using configuration from /home/monty/openssl/openssl.cnf
Generating a 1024 bit RSA private key
.....+++++
.....+++++
writing new private key to '/home/monty/openssl/private/cakey.pem'
Enter PEM pass phrase:
Verifying password - Enter PEM pass phrase:

### Example 3: Creating SSL files on Windows

Download OpenSSL for Windows. An overview of available packages can be seen here: <http://www.slproweb.com/products/Win32OpenSSL.html>

Choose of the following packages, depending on your architecture (32-bit or 64-bit):

- Win32 OpenSSL v0.9.8l Light, available at: [http://www.slproweb.com/download/Win32OpenSSL\\_Light-0\\_9\\_8l.exe](http://www.slproweb.com/download/Win32OpenSSL_Light-0_9_8l.exe)
- Win64 OpenSSL v0.9.8l Light, available at: [http://www.slproweb.com/download/Win64OpenSSL\\_Light-0\\_9\\_8l.exe](http://www.slproweb.com/download/Win64OpenSSL_Light-0_9_8l.exe)

if a message occurs during setup indicating '*...critical component is missing: Microsoft Visual C++ 2008 Redistributables*', cancel the setup and download one of the following packages as well, again depending on your architecture (32-bit or 64-bit):

- Visual C++ 2008 Redistributables (x86), available at: <http://www.microsoft.com/downloads/details.aspx?FamilyID=9b2da534-3e03-4391-8a4d-074b9f2bc1bf>
- Visual C++ 2008 Redistributables (x64), available at: <http://www.microsoft.com/downloads/details.aspx?familyid=BD2A6171-E2D6-4230-B809-9A8D7548C1B6>

After installing the additional package, restart the OpenSSL setup.

During installation, leave the default `C:\OpenSSL` as the install path, and also leave the default option '`Copy OpenSSL DLL files to the Windows system directory`' selected.

When the installation has finished, add `C:\OpenSSL\bin` to the Windows System Path variable of your server:

1. On the Windows desktop, right-click the My Computer icon, and select Properties.
2. Next select the Advanced tab from the SYSTEM PROPERTIES menu that appears, and click the ENVIRONMENT VARIABLES button.
3. Under **SYSTEM VARIABLES**, select Path, and then click the EDIT button. The EDIT SYSTEM VARIABLE dialogue should appear.
4. Add '`;C:\OpenSSL\bin`' to the end (notice the semicolon).
5. Press OK 3 times.
6. Check that OpenSSL was correctly integrated into the Path variable by opening a new command console ([Start>Run>cmd.exe](#)) and verifying that OpenSSL is available:

```
Microsoft Windows [Version ...]
Copyright (c) 2006 Microsoft Corporation. All rights reserved.

C:\Windows\system32>cd \
C:\>openssl
OpenSSL> exit <<< If you see the OpenSSL prompt, installation was successful.

C:\>
```

Depending on your version of Windows, the preceding instructions might be slightly different.

After OpenSSL has been installed, use the instructions from Example 1 (shown earlier in this section), with the following changes:

- Change the follow Unix commands:

```
Create clean environment
shell> rm -rf newcerts
shell> mkdir newcerts && cd newcerts
```

On Windows, use these commands instead:

```
Create clean environment
shell> md c:\newcerts
shell> cd c:\newcerts
```

- When a '\ ' character is shown at the end of a command line, this '\ ' character must be removed and the command lines entered all on a single line.
- For references to `my.cnf` option files, substitute `my.ini` instead.

### Testing SSL connections

To test SSL connections, start the server as follows, where `$DIR` is the path name to the directory where the sample `my.cnf` option file is located:

```
shell> mysqld --defaults-file=$DIR/my.cnf &
```

Then invoke a client program using the same option file:

```
shell> mysql --defaults-file=$DIR/my.cnf
```

If you have a MySQL source distribution, you can also test your setup by modifying the preceding `my.cnf` file to refer to the demonstration certificate and key files in the `mysql-test/std_data` directory of the distribution.

## 5.5.7. Connecting to MySQL Remotely from Windows with SSH

This section describes how to get a secure connection to a remote MySQL server with SSH. The information was provided by David Carlson <[dcarlson@mplcomm.com](mailto:dcarlson@mplcomm.com)>.

1. Install an SSH client on your Windows machine. As a user, the best nonfree one I have found is from `SecureCRT` from <http://www.vandyke.com/>. Another option is `f-secure` from <http://www.f-secure.com/>. You can also find some free ones on Google at <http://directory.google.com/Top/Computers/Internet/Protocols/SSH/Clients/Windows/>.
2. Start your Windows SSH client. Set `Host_Name = yourmysqlserver_URL_or_IP`. Set `userid=your_userid` to log in to your server. This `userid` value might not be the same as the user name of your MySQL account.
3. Set up port forwarding. Either do a remote forward (Set `local_port: 3306,remote_host: yourmysqlserver-name_or_ip,remote_port: 3306`) or a local forward (Set `port: 3306,host: localhost,remote_port: 3306`).
4. Save everything, otherwise you will have to redo it the next time.
5. Log in to your server with the SSH session you just created.
6. On your Windows machine, start some ODBC application (such as Access).
7. Create a new file in Windows and link to MySQL using the ODBC driver the same way you normally do, except type in `localhost` for the MySQL host server, not `yourmysqlservername`.

At this point, you should have an ODBC connection to MySQL, encrypted using SSH.

## 5.5.8. Auditing MySQL Account Activity

Applications can use the following guidelines to perform auditing that ties database activity to MySQL accounts.

MySQL accounts correspond to rows in the `mysql.user` table. When a client connects successfully, the server authenticates the client to a particular row in this table. The `User` and `Host` column values in this row uniquely identify the account and correspond to the '`user_name'@'host_name'`' format in which account names are written in SQL statements.

The account used to authenticate a client determines which privileges the client has. Normally, the `CURRENT_USER()` function can be invoked to determine which account this is for the client user. Its value is constructed from the `User` and `Host` columns of the `user` table row for the account.

However, there are circumstances under which the `CURRENT_USER()` value corresponds not to the client user but to a different account. This occurs in contexts when privilege checking is not based the client's account:

- Stored routines (procedures and functions) defined with the `SQL SECURITY DEFINER` characteristic
- Views defined with the `SQL SECURITY DEFINER` characteristic (as of MySQL 5.1.12)
- Triggers and events

In those contexts, privilege checking is done against the `DEFINER` account and `CURRENT_USER()` refers to that account, not to the account for the client who invoked the stored routine or view or who caused the trigger to activate. To determine the invoking user, you can call the `USER()` function, which returns a value indicating the actual user name provided by the client and the host from which the client connected. However, this value does not necessarily correspond directly to an account in the `user` table, because the `USER()` value never contains wildcards, whereas account values (as returned by `CURRENT_USER()`) may contain user name and host name wildcards.

For example, a blank user name matches any user, so an account of '`'@'localhost'`' enables clients to connect as an anonymous user from the local host with any user name. If this case, if a client connects as `user1` from the local host, `USER()` and `CURRENT_USER()` return different values:

```
mysql> SELECT USER(), CURRENT_USER();
+-----+-----+
| USER() | CURRENT_USER() |
+-----+-----+
| user1@localhost | @localhost |
+-----+-----+
```

The host name part of an account can contain wildcards, too. If the host name contains a '%' or '\_' pattern character or uses netmask notation, the account can be used for clients connecting from multiple hosts and the `CURRENT_USER()` value will not indicate which one. For example, the account '`user2'@'%example.com'`' can be used by `user2` to connect from any host in the `example.com` domain. If `user2` connects from `remote.example.com`, `USER()` and `CURRENT_USER()` return different values:

```
mysql> SELECT USER(), CURRENT_USER();
+-----+-----+
| USER() | CURRENT_USER() |
+-----+-----+
| user2@remote.example.com | user2@%example.com |
+-----+-----+
```

If an application must invoke `USER()` for user auditing (for example, if it does auditing from within triggers) but must also be able to associate the `USER()` value with an account in the `user` table, it is necessary to avoid accounts that contain wildcards in the `User` or `Host` column. Specifically, do not permit `User` to be empty (which creates an anonymous-user account), and do not permit pattern characters or netmask notation in `Host` values. All accounts must have a nonempty `User` value and literal `Host` value.

With respect to the previous examples, the '`'@'localhost'`' and '`'user2'@'%example.com'`' accounts should be changed not to use wildcards:

```
RENAME USER ''@'localhost' TO 'user1'@'localhost';
RENAME USER 'user2'@'%example.com' TO 'user2'@'remote.example.com';
```

If `user2` must be able to connect from several hosts in the `example.com` domain, there should be a separate account for each host.

To extract the user name or host name part from a `CURRENT_USER()` or `USER()` value, use the `SUBSTRING()` function:

```
mysql> SELECT SUBSTRING_INDEX(CURRENT_USER(),'@',1);
+-----+
| SUBSTRING_INDEX(CURRENT_USER(),'@',1) |
+-----+
| user1 |
+-----+

mysql> SELECT SUBSTRING_INDEX(CURRENT_USER(),'@',-1);
+-----+
| SUBSTRING_INDEX(CURRENT_USER(),'@',-1) |
+-----+
| localhost |
+-----+
```

## 5.6. Running Multiple MySQL Servers on the Same Machine

In some cases, you might want to run multiple `mysqld` servers on the same machine. You might want to test a new MySQL release while leaving your existing production setup undisturbed. Or you might want to give different users access to different `mysqld` servers that they manage themselves. (For example, you might be an Internet Service Provider that wants to provide independent MySQL installations for different customers.)

To run multiple servers on a single machine, each server must have unique values for several operating parameters. These can be set on the command line or in option files. See [Section 4.2.3, “Specifying Program Options”](#).

At least the following options must be different for each server:

- `--port=port_num`

`--port` controls the port number for TCP/IP connections. (Alternatively, if the host has multiple network addresses, you can use `--bind-address` to cause different servers to listen to different interfaces.)

- `--socket=path`

`--socket` controls the Unix socket file path on Unix and the name of the named pipe on Windows. On Windows, it is necessary to specify distinct pipe names only for those servers that support named-pipe connections.

- `--shared-memory-base-name=name`

This option currently is used only on Windows. It designates the shared-memory name used by a Windows server to permit clients to connect using shared memory. It is necessary to specify distinct shared-memory names only for those servers that support shared-memory connections.

- `--pid-file=file_name`

This option is used only on Unix. It indicates the path name of the file in which the server writes its process ID.

If you use the following log file options, they must be different for each server:

- `--general_log` or `--log[=file_name]`
- `--log-bin[=file_name]`
- `--slow_query_log` or `--log-slow-queries[=file_name]`
- `--log-error[=file_name]`

[Section 5.2.6, “Server Log Maintenance”](#), discusses the log file options further.

For better performance, you can specify the following options differently for each server, to spread the load between several physical disks:

- `--tmpdir=path`

Having different temporary directories also makes it easier to determine which MySQL server created any given temporary file.

With very limited exceptions, each server should use a different data directory, which is specified using the `--datadir=path` option.

### Warning

Normally, you should never have two servers that update data in the same databases. This may lead to unpleasant surprises if your operating system does not support fault-free system locking. If (despite this warning) you run multiple servers using the same data directory and they have logging enabled, you must use the appropriate options to specify log file names that are unique to each server. Otherwise, the servers try to log to the same files. Please note that this kind of setup only works with `MyISAM` and `MERGE` tables, and not with any of the other storage engines.

The warning against sharing a data directory among servers also applies in an NFS environment. Permitting multiple MySQL servers to access a common data directory over NFS is a *very bad idea*.

- The primary problem is that NFS is the speed bottleneck. It is not meant for such use.
- Another risk with NFS is that you must devise a way to ensure that two or more servers do not interfere with each other. Usually NFS file locking is handled by the `lockd` daemon, but at the moment there is no platform that performs locking 100% reliably in every situation.

Make it easy for yourself: Forget about sharing a data directory among servers over NFS. A better solution is to have one computer that contains several CPUs and use an operating system that handles threads efficiently.

If you have multiple MySQL installations in different locations, you can specify the base installation directory for each server with the `--basedir=path` option to cause each server to use a different data directory, log files, and PID file. (The defaults for all these values are determined relative to the base directory). In that case, the only other options you need to specify are the `-socket` and `--port` options. Suppose that you install different versions of MySQL using `tar` file binary distributions. These install in different locations, so you can start the server for each installation using the command `bin/mysqld_safe` under its corresponding base directory. `mysqld_safe` determines the proper `--basedir` option to pass to `mysqld`, and you need specify only the `--socket` and `--port` options to `mysqld_safe`.

As discussed in the following sections, it is possible to start additional servers by setting environment variables or by specifying appropriate command-line options. However, if you need to run multiple servers on a more permanent basis, it is more convenient to use option files to specify for each server those option values that must be unique to it. The `--defaults-file` option is useful for this purpose.

## 5.6.1. Running Multiple Servers on Windows

You can run multiple servers on Windows by starting them manually from the command line, each with appropriate operating parameters. On Windows NT-based systems, you also have the option of installing several servers as Windows services and running them that way. General instructions for running MySQL servers from the command line or as services are given in [Section 2.4, “Installing MySQL on Microsoft Windows”](#). This section describes how to make sure that you start each server with different values for those startup options that must be unique per server, such as the data directory. These options are described in [Section 5.6, “Running Multiple MySQL Servers on the Same Machine”](#).

### 5.6.1.1. Starting Multiple Windows Servers at the Command Line

To start multiple servers manually from the command line, you can specify the appropriate options on the command line or in an option file. It is more convenient to place the options in an option file, but it is necessary to make sure that each server gets its own set of options. To do this, create an option file for each server and tell the server the file name with a `--defaults-file` option when you run it.

Suppose that you want to run `mysqld` on port 3307 with a data directory of `C:\mydata1`, and `mysqld-debug` on port 3308 with a data directory of `C:\mydata2`. (To do this, make sure that before you start the servers, each data directory exists and has its own copy of the `mysql` database that contains the grant tables.) Then create two option files. For example, create one file named `C:\my-opt1.cnf` that looks like this:

```
[mysqld]
datadir = C:/mydata1
port = 3307
```

Create a second file named `C:\my-opt2.cnf` that looks like this:

```
[mysqld]
datadir = C:/mydata2
port = 3308
```

Then start each server with its own option file:

```
C:\> C:\mysql\bin\mysqld --defaults-file=C:\my-opt1.cnf
C:\> C:\mysql\bin\mysqld-debug --defaults-file=C:\my-opt2.cnf
```

On NT, each server starts in the foreground (no new prompt appears until the server exits later), so you will need to issue those two commands in separate console windows.

To shut down the servers, you must connect to each using the appropriate port number:

```
C:\> C:\mysql\bin\mysqladmin --port=3307 shutdown
C:\> C:\mysql\bin\mysqladmin --port=3308 shutdown
```

Servers configured as just described permit clients to connect over TCP/IP. If your version of Windows supports named pipes and you also want to permit named-pipe connections, use the `mysqld-nt` (MySQL 5.1.20 and earlier), `mysqld` (MySQL 5.1.21 and later) or `mysqld-debug` server and specify options that enable the named pipe and specify its name. Each server that supports named-pipe connections must use a unique pipe name. For example, the `C:\my-opt1.cnf` file might be written like this:

```
[mysqld]
datadir = C:/mydata1
port = 3307
enable-named-pipe
socket = mypipe1
```

Then start the server this way:

```
C:\> C:\mysql\bin\mysqld --defaults-file=C:\my-optsl.cnf
```

Modify `C:\my-opt2.cnf` similarly for use by the second server.

A similar procedure applies for servers that you want to support shared-memory connections. Enable such connections with the `--shared-memory` option and specify a unique shared-memory name for each server with the `--shared-memory-base-name` option.

### 5.6.1.2. Starting Multiple Windows Servers as Services

On NT-based systems, a MySQL server can run as a Windows service. The procedures for installing, controlling, and removing a single MySQL service are described in [Section 2.4.5.7, “Starting MySQL Server as a Microsoft Windows Service”](#).

You can also install multiple MySQL servers as services. In this case, you must make sure that each server uses a different service name in addition to all the other parameters that must be unique for each server.

For the following instructions, assume that you want to run the `mysqld` server from two different versions of MySQL that are installed at `C:\mysql-5.0.19` and `C:\mysql-5.1.52`, respectively. (This might be the case if you are running 5.0.19 as your production server, but also want to conduct tests using 5.1.52.)

The following principles apply when installing a MySQL service with the `--install` or `--install-manual` option:

- If you specify no service name, the server uses the default service name of `MySQL` and the server reads options from the `[mysqld]` group in the standard option files.
- If you specify a service name after the `--install` option, the server ignores the `[mysqld]` option group and instead reads options from the group that has the same name as the service. The server reads options from the standard option files.
- If you specify a `--defaults-file` option after the service name, the server ignores the standard option files and reads options only from the `[mysqld]` group of the named file.

#### Note

In MySQL 5.1, all servers read the `[mysqld]` group if they read the standard option files, whether installed using the default service name (`MySQL`) or another service name. This enables you to use the `[mysqld]` group for options that should be used by all MySQL services, and an option group named after each service for use by the server installed with that service name.

Based on the preceding information, you have several ways to set up multiple services. The following instructions describe some examples. Before trying any of them, be sure that you shut down and remove any existing MySQL services first.

- **Approach 1:** Specify the options for all services in one of the standard option files. To do this, use a different service name for each server. Suppose that you want to run the 5.0.19 `mysqld` using the service name `mysqld1` and the 5.1.52 `mysqld` using the service name `mysqld2`. In this case, you can use the `[mysqld1]` group for 5.0.19 and the `[mysqld2]` group for 5.1.52. For example, you can set up `C:\my.cnf` like this:

```
options for mysqld1 service
[mysqld1]
basedir = C:/mysql-5.0.19
port = 3307
enable-named-pipe
socket = mypipe1

options for mysqld2 service
[mysqld2]
basedir = C:/mysql-5.1.52
port = 3308
enable-named-pipe
socket = mypipe2
```

Install the services as follows, using the full server path names to ensure that Windows registers the correct executable program for each service:

```
C:\> C:\mysql-5.0.19\bin\mysqld --install mysqld1
C:\> C:\mysql-5.1.52\bin\mysqld --install mysqld2
```

To start the services, use the services manager, or use `NET START` with the appropriate service names:

```
C:\> NET START mysqld1
C:\> NET START mysqld2
```

To stop the services, use the services manager, or use `NET STOP` with the appropriate service names:

```
C:\> NET STOP mysqld1
C:\> NET STOP mysqld2
```

- **Approach 2:** Specify options for each server in separate files and use `--defaults-file` when you install the services to tell each server what file to use. In this case, each file should list options using a `[mysqld]` group.

With this approach, to specify options for the 5.0.19 `mysqld-nt`, create a file `C:\my-opt1.cnf` that looks like this:

```
[mysqld]
basedir = C:/mysql-5.0.19
port = 3307
enable-named-pipe
socket = mypipe1
```

For the 5.1.52 `mysqld`, create a file `C:\my-opt2.cnf` that looks like this:

```
[mysqld]
basedir = C:/mysql-5.1.52
port = 3308
enable-named-pipe
socket = mypipe2
```

Install the services as follows (enter each command on a single line):

```
C:\> C:\mysql-5.0.19\bin\mysqld --install mysqld1
--defaults-file=C:\my-opt1.cnf
C:\> C:\mysql-5.1.52\bin\mysqld --install mysqld2
--defaults-file=C:\my-opt2.cnf
```

To use a `--defaults-file` option when you install a MySQL server as a service, you must precede the option with the service name.

After installing the services, start and stop them the same way as in the preceding example.

To remove multiple services, use `mysqld --remove` for each one, specifying a service name following the `--remove` option. If the service name is the default (`MySQL`), you can omit it.

## 5.6.2. Running Multiple Servers on Unix

The easiest way to run multiple servers on Unix is to compile them with different TCP/IP ports and Unix socket files so that each one is listening on different network interfaces. Compiling in different base directories for each installation also results automatically in a separate, compiled-in data directory, log file, and PID file location for each server.

Assume that an existing 5.0.19 server is configured for the default TCP/IP port number (3306) and Unix socket file (`/tmp/mysql.sock`). To configure a new 5.1.52 server to have different operating parameters, use a `configure` command something like this:

```
shell> ./configure --with-tcp-port=port_number \
--with-unix-socket-path=file_name \
--prefix=/usr/local/mysql-5.1.52
```

Here, `port_number` and `file_name` must be different from the default TCP/IP port number and Unix socket file path name, and the `--prefix` value should specify an installation directory different from the one under which the existing MySQL installation is located.

If you have a MySQL server listening on a given port number, you can use the following command to find out what operating parameters it is using for several important configurable variables, including the base directory and Unix socket file name:

```
shell> mysqladmin --host=host_name --port=port_number variables
```

With the information displayed by that command, you can tell what option values *not* to use when configuring an additional server.

Note that if you specify `localhost` as a host name, `mysqladmin` defaults to using a Unix socket file connection rather than TCP/IP. You can explicitly specify the connection protocol to use by using the `--protocol={TCP|SOCKET|PIPE|MEMORY}`

option.

You don't have to compile a new MySQL server just to start with a different Unix socket file and TCP/IP port number. It is also possible to use the same server binary and start each invocation of it with different parameter values at runtime. One way to do so is by using command-line options:

```
shell> mysqld_safe --socket=file_name --port=port_number
```

To start a second server, provide different `--socket` and `--port` option values, and pass a `--datadir=path` option to `mysqld_safe` so that the server uses a different data directory.

Another way to achieve a similar effect is to use environment variables to set the Unix socket file name and TCP/IP port number:

```
shell> MYSQL_UNIX_PORT=/tmp/mysqld-new.sock
shell> MYSQL_TCP_PORT=3307
shell> export MYSQL_UNIX_PORT MYSQL_TCP_PORT
shell> mysql_install_db --user=mysql
shell> mysqld_safe --datadir=/path/to/datadir &
```

This is a quick way of starting a second server to use for testing. The nice thing about this method is that the environment variable settings apply to any client programs that you invoke from the same shell. Thus, connections for those clients are automatically directed to the second server.

[Section 2.14, “Environment Variables”](#), includes a list of other environment variables you can use to affect `mysqld`.

For automatic server execution, the startup script that is executed at boot time should execute the following command once for each server with an appropriate option file path for each command:

```
shell> mysqld_safe --defaults-file=file_name
```

Each option file should contain option values specific to a given server.

On Unix, the `mysqld_multi` script is another way to start multiple servers. See [Section 4.3.4, “mysqld\\_multi — Manage Multiple MySQL Servers”](#).

### 5.6.3. Using Client Programs in a Multiple-Server Environment

To connect with a client program to a MySQL server that is listening to different network interfaces from those compiled into your client, you can use one of the following methods:

- Start the client with `--host=host_name --port=port_number` to connect using TCP/IP to a remote server, with `--host=127.0.0.1 --port=port_number` to connect using TCP/IP to a local server, or with `--host=localhost --socket=file_name` to connect to a local server using a Unix socket file or a Windows named pipe.
- Start the client with `--protocol=TCP` to connect using TCP/IP, `--protocol=SOCKET` to connect using a Unix socket file, `--protocol=PIPE` to connect using a named pipe, or `--protocol=MEMORY` to connect using shared memory. For TCP/IP connections, you may also need to specify `--host` and `--port` options. For the other types of connections, you may need to specify a `--socket` option to specify a Unix socket file or Windows named-pipe name, or a `--shared-memory-base-name` option to specify the shared-memory name. Shared-memory connections are supported only on Windows.
- On Unix, set the `MYSQL_UNIX_PORT` and `MYSQL_TCP_PORT` environment variables to point to the Unix socket file and TCP/IP port number before you start your clients. If you normally use a specific socket file or port number, you can place commands to set these environment variables in your `.login` file so that they apply each time you log in. See [Section 2.14, “Environment Variables”](#).
- Specify the default Unix socket file and TCP/IP port number in the `[client]` group of an option file. For example, you can use `C:\my.cnf` on Windows, or the `.my.cnf` file in your home directory on Unix. See [Section 4.2.3.3, “Using Option Files”](#).
- In a C program, you can specify the socket file or port number arguments in the `mysql_real_connect()` call. You can also have the program read option files by calling `mysql_options()`. See [Section 21.9.3, “C API Function Descriptions”](#).
- If you are using the Perl `DBD::mysql` module, you can read options from MySQL option files. For example:

```
$dsn = "DBI:mysql:test;mysql_read_default_group=client";
 . "mysql_read_default_file=/usr/local/mysql/data/my.cnf";
$dh = DBI->connect($dsn, $user, $password);
```

See [Section 21.11, “MySQL Perl API”](#).

Other programming interfaces may provide similar capabilities for reading option files.

---

# Chapter 6. Backup and Recovery

It is important to back up your databases so that you can recover your data and be up and running again in case problems occur, such as system crashes, hardware failures, or users deleting data by mistake. Backups are also essential as a safeguard before upgrading a MySQL installation, and they can be used to transfer a MySQL installation to another system or to set up replication slave servers.

MySQL offers a variety of backup strategies from which you can choose the methods that best suit the requirements for your installation. This chapter discusses several backup and recovery topics with which you should be familiar:

- Types of backups: Logical versus physical, full versus incremental, and so forth
- Methods for creating backups
- Recovery methods, including point-in-time recovery
- Backup scheduling, compression, and encryption
- Table maintenance, to enable recovery of corrupt tables

## Additional Resources

Resources related to backup or to maintaining data availability include the following:

- A forum dedicated to backup issues is available at <http://forums.mysql.com/list.php?93>.
- Details for `mysqldump`, `mysqlhotcopy`, and other MySQL backup programs can be found in [Chapter 4, MySQL Programs](#).
- The syntax of the SQL statements described here is given in [Chapter 12, SQL Statement Syntax](#).
- For additional information about InnoDB backup procedures, see [Section 13.6.6, “Backing Up and Recovering an InnoDB Database”](#).
- Replication enables you to maintain identical data on multiple servers. This has several benefits, such as enabling client query load to be distributed over servers, availability of data even if a given server is taken offline or fails, and the ability to make backups with no impact on the master by using a slave server. See [Chapter 16, Replication](#).
- MySQL Cluster provides a high-availability, high-redundancy version of MySQL adapted for the distributed computing environment. See [Chapter 17, MySQL Cluster NDB 6.X/7.X](#). For information specifically about MySQL Cluster backup, see [Section 17.5.3, “Online Backup of MySQL Cluster”](#).
- Distributed Replicated Block Device (DRBD) is another high-availability solution. It works by replicating a block device from a primary server to a secondary server at the block level. See [Chapter 14, High Availability and Scalability](#)

## 6.1. Backup and Recovery Types

This section describes the characteristics of different types of backups.

### Logical Versus Physical (Raw) Backups

Logical backups save information represented as logical database structure (`CREATE DATABASE`, `CREATE TABLE` statements) and content (`INSERT` statements or delimited-text files). Physical backups consist of raw copies of the directories and files that store database contents.

Logical backup methods have these characteristics:

- The backup is done by querying the MySQL server to obtain database structure and content information.
- Backup is slower than physical methods because the server must access database information and convert it to logical format. If the output is written on the client side, the server must also send it to the backup program.
- Output is larger than for physical backup, particularly when saved in text format.
- Backup and restore granularity is available at the server level (all databases), database level (all tables in a particular database), or table level. This is true regardless of storage engine.

- The backup does not include log or configuration files, or other database-related files that are not part of databases.
- Backups stored in logical format are machine independent and highly portable.
- Logical backups are performed with the MySQL server running. The server is not taken offline.
- Logical backup tools include the `mysqldump` program and the `SELECT ... INTO OUTFILE` statement. These work for any storage engine, even `MEMORY`.
- To restore logical backups, SQL-format dump files can be processed using the `mysql` client. To load delimited-text files, use the `LOAD DATA INFILE` statement or the `mysqlimport` client.

Physical backup methods have these characteristics:

- The backup consists of exact copies of database directories and files. Typically this is a copy of all or part of the MySQL data directory. Data from `MEMORY` tables cannot be backed up this way because their contents are not stored on disk.
- Physical backup methods are faster than logical because they involve only file copying without conversion.
- Output is more compact than for logical backup.
- Backup and restore granularity ranges from the level of the entire data directory down to the level of individual files. This may or may not provide for table-level granularity, depending on storage engine. (Each `MyISAM` table corresponds uniquely to a set of files, but an `InnoDB` table shares file storage with other `InnoDB` tables.)
- In addition to databases, the backup can include any related files such as log or configuration files.
- Backups are portable only to other machines that have identical or similar hardware characteristics.
- Backups can be performed while the MySQL server is not running. If the server is running, it is necessary to perform appropriate locking so that the server does not change database contents during the backup.
- Physical backup tools include file system-level commands (such as `cp`, `scp`, `tar`, `rsync`), `mysqlhotcopy` for `MyISAM` tables, `ibbackup` for `InnoDB` tables, or `START BACKUP` for `NDB` tables.
- For restore, files copied at the file system level or with `mysqlhotcopy` can be copied back to their original locations with file system commands; `ibbackup` restores `InnoDB` tables, and `ndb_restore` restores `NDB` tables.

### Online Versus Offline Backups

Online backups take place while the MySQL server is running so that the database information can be obtained from the server. Offline backups take place while the server is stopped. This distinction can also be described as “hot” versus “cold” backups; a “warm” backup is one where the server remains running but locked against modifying data while you access database files externally.

Online backup methods have these characteristics:

- The backup is less intrusive to other clients, which can connect to the MySQL server during the backup and may be able to access data depending on what operations they need to perform.
- Care must be taken to impose appropriate locking so that data modifications do not take place that would compromise backup integrity.

Offline backup methods have these characteristics:

- Clients can be affected adversely because the server is unavailable during backup.
- The backup procedure is simpler because there is no possibility of interference from client activity.

A similar distinction between online and offline applies for recovery operations, and similar characteristics apply. However, it is more likely that clients will be affected for online recovery than for online backup because recovery requires stronger locking. During backup, clients might be able to read data while it is being backed up. Recovery modifies data and does not just read it, so clients must be prevented from accessing data while it is being restored.

### Local Versus Remote Backups

---

A local backup is performed on the same host where the MySQL server runs, whereas a remote backup is done from a different host. For some types of backups, the backup can be initiated from a remote host even if the output is written locally on the server host.

- `mysqldump` can connect to local or remote servers. For SQL output (`CREATE` and `INSERT` statements), local or remote dumps can be done and generate output on the client. For delimited-text output (with the `--tab` option), data files are created on the server host.
- `mysqlhotcopy` performs only local backups: It connects to the server to lock it against data modifications and then copies local table files.
- `SELECT ... INTO OUTFILE` can be initiated from a local or remote client host, but the output file is created on the server host.
- Physical backup methods typically are initiated locally on the MySQL server host so that the server can be taken offline, although the destination for copied files might be remote.

### Snapshot Backups

Some file system implementations enable “snapshots” to be taken. These provide logical copies of the file system at a given point in time, without requiring a physical copy of the entire file system. (For example, the implementation may use copy-on-write techniques so that only parts of the file system modified after the snapshot time need be copied.) MySQL itself does not provide the capability for taking file system snapshots. It is available through third-party solutions such as Veritas, LVM, or ZFS.

### Full Versus Incremental Backups

A full backup includes all data managed by a MySQL server at a given point in time. An incremental backup consists of the changes made to the data during a given time span (from one point in time to another). MySQL has different ways to perform full backups, such as those described earlier in this section. Incremental backups are made possible by enabling the server's binary log, which the server uses to record data changes.

### Full Versus Point-in-Time (Incremental) Recovery

A full recovery restores all data from a full backup. This restores the server instance to the state that it had when the backup was made. If that state is not sufficiently current, a full recovery can be followed by recovery of incremental backups made since the full backup, to bring the server to a more up-to-date state.

Incremental recovery is recovery of changes made during a given time span. This is also called point-in-time recovery because it makes a server's state current up to a given time. Point-in-time recovery is based on the binary log and typically follows a full recovery from the backup files that restores the server to its state when the backup was made. Then the data changes written in the binary log files are applied as incremental recovery to redo data modifications and bring the server up to the desired point in time.

### Table Maintenance

Data integrity can be compromised if tables become corrupt. MySQL provides programs for checking `MyISAM` tables and repairing them should problems be found. See [Section 6.6, “MyISAM Table Maintenance and Crash Recovery”](#).

### Backup Scheduling, Compression, and Encryption

Backup scheduling is valuable for automating backup procedures. Compression of backup output reduces space requirements, and encryption of the output provides better security against unauthorized access of backed-up data. MySQL itself does not provide these capabilities. `ibbackup` can compress `InnoDB` backups, and compression or encryption of backup output can be achieved using file system utilities. Other third-party solutions may be available.

## 6.2. Database Backup Methods

This section summarizes some general methods for making backups.

### Making Backups by Copying Table Files

For storage engines that represent each table using its own files, tables can be backed up by copying those files. For example, `MyISAM` tables are stored as files, so it is easy to do a backup by copying files (`*.frm`, `*.MYD`, and `*.MYI` files). To get a consistent backup, stop the server or do a `LOCK TABLES` on the relevant tables followed by `FLUSH TABLES` for the tables. See [Section 12.3.5, “LOCK TABLES and UNLOCK TABLES Syntax”](#), and [Section 12.4.6.3, “FLUSH Syntax”](#). You need only a read lock; this enables other clients to continue to query the tables while you are making a copy of the files in the database directory. The `FLUSH TABLES` statement is needed to ensure that the all active index pages are written to disk before you start the backup.

You can also create a binary backup simply by copying all table files, as long as the server isn't updating anything. The `mysql-`

`hotcopy` script uses this method. (But note that table file copying methods do not work if your database contains `InnoDB` tables. `mysqlhotcopy` does not work for `InnoDB` tables because `InnoDB` does not necessarily store table contents in database directories. Also, even if the server is not actively updating data, `InnoDB` may still have modified data cached in memory and not flushed to disk.)

### Making Delimited-Text File Backups

To create a text file containing a table's data, you can use `SELECT * INTO OUTFILE 'file_name' FROM tbl_name`. The file is created on the MySQL server host, not the client host. For this statement, the output file cannot already exist because permitting files to be overwritten constitutes a security risk. See [Section 12.2.8, “SELECT Syntax”](#). This method works for any kind of data file, but saves only table data, not the table structure.

Another way to create text data files (along with files containing `CREATE TABLE` statements for the backed up tables) is to use `mysqldump` with the `--tab` option. See [Section 6.4.3, “Dumping Data in Delimited-Text Format with mysqldump”](#).

To reload a delimited-text data file, use `LOAD DATA INFILE` or `mysqlimport`.

### Making Backups with mysqldump or mysqlhotcopy

The `mysqldump` program and the `mysqlhotcopy` script can make backups. `mysqldump` is more general because it can back up all kinds of tables. `mysqlhotcopy` works only with some storage engines. (See [Section 6.4, “Using mysqldump for Backups”](#), and [Section 4.6.9, “mysqlhotcopy — A Database Backup Program”](#).)

For `InnoDB` tables, it is possible to perform an online backup that takes no locks on tables using the `--single-transaction` option to `mysqldump`. See [Section 6.3.1, “Establishing a Backup Policy”](#).

### Making Incremental Backups by Enabling the Binary Log

MySQL supports incremental backups: You must start the server with the `--log-bin` option to enable binary logging; see [Section 5.2.4, “The Binary Log”](#). The binary log files provide you with the information you need to replicate changes to the database that are made subsequent to the point at which you performed a backup. At the moment you want to make an incremental backup (containing all changes that happened since the last full or incremental backup), you should rotate the binary log by using `FLUSH LOGS`. This done, you need to copy to the backup location all binary logs which range from the one of the moment of the last full or incremental backup to the last but one. These binary logs are the incremental backup; at restore time, you apply them as explained in [Section 6.5, “Point-in-Time \(Incremental\) Recovery Using the Binary Log”](#). The next time you do a full backup, you should also rotate the binary log using `FLUSH LOGS`, `mysqldump --flush-logs`, or `mysqlhotcopy --flushlog`. See [Section 4.5.4, “mysqldump — A Database Backup Program”](#), and [Section 4.6.9, “mysqlhotcopy — A Database Backup Program”](#).

### Making Backups Using Replication Slaves

If you have performance problems with your master server while making backups, one strategy that can help is to set up replication and perform backups on the slave rather than on the master. See [Section 16.3.1, “Using Replication for Backups”](#).

If you are backing up a slave replication server, you should back up its `master.info` and `relay-log.info` files when you back up the slave's databases, regardless of the backup method you choose. These information files are always needed to resume replication after you restore the slave's data. If your slave is replicating `LOAD DATA INFILE` statements, you should also back up any `SQL_LOAD-*` files that exist in the directory that the slave uses for this purpose. The slave needs these files to resume replication of any interrupted `LOAD DATA INFILE` operations. The location of this directory is the value of the `-slave-load-tmpdir` option. If the server was not started with that option, the directory location is the value of the `tmpdir` system variable.

### Recovering Corrupt Tables

If you have to restore `MyISAM` tables that have become corrupt, try to recover them using `REPAIR TABLE` or `myisamchk -r` first. That should work in 99.9% of all cases. If `myisamchk` fails, see [Section 6.6, “MyISAM Table Maintenance and Crash Recovery”](#).

### Making Backups Using a File System Snapshot

If you are using a Veritas file system, you can make a backup like this:

1. From a client program, execute `FLUSH TABLES WITH READ LOCK`.
2. From another shell, execute `mount vxfs snapshot`.
3. From the first client, execute `UNLOCK TABLES`.
4. Copy files from the snapshot.
5. Unmount the snapshot.

Similar snapshot capabilities may be available in other file systems, such as LVM or ZFS.

## 6.3. Example Backup and Recovery Strategy

This section discusses a procedure for performing backups that enables you to recover data after several types of crashes:

- Operating system crash
- Power failure
- File system crash
- Hardware problem (hard drive, motherboard, and so forth)

The example commands do not include options such as `--user` and `--password` for the `mysqldump` and `mysql` client programs. You should include such options as necessary to enable client programs to connect to the MySQL server.

Assume that data is stored in the `InnoDB` storage engine, which has support for transactions and automatic crash recovery. Assume also that the MySQL server is under load at the time of the crash. If it were not, no recovery would ever be needed.

For cases of operating system crashes or power failures, we can assume that MySQL's disk data is available after a restart. The `InnoDB` data files might not contain consistent data due to the crash, but `InnoDB` reads its logs and finds in them the list of pending committed and noncommitted transactions that have not been flushed to the data files. `InnoDB` automatically rolls back those transactions that were not committed, and flushes to its data files those that were committed. Information about this recovery process is conveyed to the user through the MySQL error log. The following is an example log excerpt:

```
InnoDB: Database was not shut down normally.
InnoDB: Starting recovery from log files...
InnoDB: Starting log scan based on checkpoint at
InnoDB: log sequence number 0 13674004
InnoDB: Doing recovery: scanned up to log sequence number 0 13739520
InnoDB: Doing recovery: scanned up to log sequence number 0 13805056
InnoDB: Doing recovery: scanned up to log sequence number 0 13870592
InnoDB: Doing recovery: scanned up to log sequence number 0 13936128
...
InnoDB: Doing recovery: scanned up to log sequence number 0 20555264
InnoDB: Doing recovery: scanned up to log sequence number 0 20620800
InnoDB: Doing recovery: scanned up to log sequence number 0 20664692
InnoDB: 1 uncommitted transaction(s) which must be rolled back
InnoDB: Starting rollback of uncommitted transactions
InnoDB: Rolling back trx no 16745
InnoDB: Rolling back of trx no 16745 completed
InnoDB: Rollback of uncommitted transactions completed
InnoDB: Starting an apply batch of log records to the database...
InnoDB: Apply batch completed
InnoDB: Started
mysqld: ready for connections
```

For the cases of file system crashes or hardware problems, we can assume that the MySQL disk data is *not* available after a restart. This means that MySQL fails to start successfully because some blocks of disk data are no longer readable. In this case, it is necessary to reformat the disk, install a new one, or otherwise correct the underlying problem. Then it is necessary to recover our MySQL data from backups, which means that backups must already have been made. To make sure that is the case, design and implement a backup policy.

### 6.3.1. Establishing a Backup Policy

To be useful, backups must be scheduled regularly. A full backup (a snapshot of the data at a point in time) can be done in MySQL with several tools. For example, `InnoDB Hot Backup` provides online nonblocking physical backup of the `InnoDB` data files, and `mysqldump` provides online logical backup. This discussion uses `mysqldump`.

Assume that we make a full backup of all our `InnoDB` tables in all databases using the following command on Sunday at 1 p.m., when load is low:

```
shell> mysqldump --single-transaction --all-databases > backup_sunday_1_PM.sql
```

The resulting `.sql` file produced by `mysqldump` contains a set of SQL `INSERT` statements that can be used to reload the dumped tables at a later time.

This backup operation acquires a global read lock on all tables at the beginning of the dump (using `FLUSH TABLES WITH READ LOCK`). As soon as this lock has been acquired, the binary log coordinates are read and the lock is released. If long updating statements are running when the `FLUSH` statement is issued, the backup operation may stall until those statements finish. After that, the dump becomes lock-free and does not disturb reads and writes on the tables.

It was assumed earlier that the tables to back up are `InnoDB` tables, so `--single-transaction` uses a consistent read and guarantees that data seen by `mysqldump` does not change. (Changes made by other clients to `InnoDB` tables are not seen by the `mysqldump` process.) If the backup operation includes nontransactional tables, consistency requires that they do not change during the backup. For example, for the `MyISAM` tables in the `mysql` database, there must be no administrative changes to MySQL accounts during the backup.

Full backups are necessary, but it is not always convenient to create them. They produce large backup files and take time to generate. They are not optimal in the sense that each successive full backup includes all data, even that part that has not changed since the previous full backup. It is more efficient to make an initial full backup, and then to make incremental backups. The incremental backups are smaller and take less time to produce. The tradeoff is that, at recovery time, you cannot restore your data just by re-loading the full backup. You must also process the incremental backups to recover the incremental changes.

To make incremental backups, we need to save the incremental changes. In MySQL, these changes are represented in the binary log, so the MySQL server should always be started with the `--log-bin` option to enable that log. With binary logging enabled, the server writes each data change into a file while it updates data. Looking at the data directory of a MySQL server that was started with the `--log-bin` option and that has been running for some days, we find these MySQL binary log files:

```
-rw-rw---- 1 guilhem guilhem 1277324 Nov 10 23:59 gbichot2-bin.000001
-rw-rw---- 1 guilhem guilhem 4 Nov 10 23:59 gbichot2-bin.000002
-rw-rw---- 1 guilhem guilhem 79 Nov 11 11:06 gbichot2-bin.000003
-rw-rw---- 1 guilhem guilhem 508 Nov 11 11:08 gbichot2-bin.000004
-rw-rw---- 1 guilhem guilhem 220047446 Nov 12 16:47 gbichot2-bin.000005
-rw-rw---- 1 guilhem guilhem 998412 Nov 14 10:08 gbichot2-bin.000006
-rw-rw---- 1 guilhem guilhem 361 Nov 14 10:07 gbichot2-bin.index
```

Each time it restarts, the MySQL server creates a new binary log file using the next number in the sequence. While the server is running, you can also tell it to close the current binary log file and begin a new one manually by issuing a `FLUSH LOGS` SQL statement or with a `mysqladmin flush-logs` command. `mysqldump` also has an option to flush the logs. The `.index` file in the data directory contains the list of all MySQL binary logs in the directory.

The MySQL binary logs are important for recovery because they form the set of incremental backups. If you make sure to flush the logs when you make your full backup, the binary log files created afterward contain all the data changes made since the backup. Let's modify the previous `mysqldump` command a bit so that it flushes the MySQL binary logs at the moment of the full backup, and so that the dump file contains the name of the new current binary log:

```
shell> mysqldump --single-transaction --flush-logs --master-data=2 \
 --all-databases > backup_sunday_1_PM.sql
```

After executing this command, the data directory contains a new binary log file, `gbichot2-bin.000007`, because the `--flush-logs` option causes the server to flush its logs. The `--master-data` option causes `mysqldump` to write binary log information to its output, so the resulting `.sql` dump file includes these lines:

```
-- Position to start replication or point-in-time recovery from
-- CHANGE MASTER TO MASTER_LOG_FILE='gbichot2-bin.000007',MASTER_LOG_POS=4;
```

Because the `mysqldump` command made a full backup, those lines mean two things:

- The dump file contains all changes made before any changes written to the `gbichot2-bin.000007` binary log file or newer.
- All data changes logged after the backup are not present in the dump file, but are present in the `gbichot2-bin.000007` binary log file or newer.

On Monday at 1 p.m., we can create an incremental backup by flushing the logs to begin a new binary log file. For example, executing a `mysqladmin flush-logs` command creates `gbichot2-bin.000008`. All changes between the Sunday 1 p.m. full backup and Monday 1 p.m. will be in the `gbichot2-bin.000007` file. This incremental backup is important, so it is a good idea to copy it to a safe place. (For example, back it up on tape or DVD, or copy it to another machine.) On Tuesday at 1 p.m., execute another `mysqladmin flush-logs` command. All changes between Monday 1 p.m. and Tuesday 1 p.m. will be in the `gbichot2-bin.000008` file (which also should be copied somewhere safe).

The MySQL binary logs take up disk space. To free up space, purge them from time to time. One way to do this is by deleting the binary logs that are no longer needed, such as when we make a full backup:

```
shell> mysqldump --single-transaction --flush-logs --master-data=2 \
 --all-databases --delete-master-logs > backup_sunday_1_PM.sql
```

### Note

Deleting the MySQL binary logs with `mysqldump --delete-master-logs` can be dangerous if your server is

a replication master server, because slave servers might not yet fully have processed the contents of the binary log. The description for the `PURGE BINARY LOGS` statement explains what should be verified before deleting the MySQL binary logs. See [Section 12.5.1.1, “PURGE BINARY LOGS Syntax”](#).

### 6.3.2. Using Backups for Recovery

Now, suppose that we have a catastrophic crash on Wednesday at 8 a.m. that requires recovery from backups. To recover, first we restore the last full backup we have (the one from Sunday 1 p.m.). The full backup file is just a set of SQL statements, so restoring it is very easy:

```
shell> mysql < backup_sunday_1_PM.sql
```

At this point, the data is restored to its state as of Sunday 1 p.m.. To restore the changes made since then, we must use the incremental backups; that is, the `gbichot2-bin.000007` and `gbichot2-bin.000008` binary log files. Fetch the files if necessary from where they were backed up, and then process their contents like this:

```
shell> mysqlbinlog gbichot2-bin.000007 gbichot2-bin.000008 | mysql
```

We now have recovered the data to its state as of Tuesday 1 p.m., but still are missing the changes from that date to the date of the crash. To not lose them, we would have needed to have the MySQL server store its MySQL binary logs into a safe location (RAID disks, SAN, ...) different from the place where it stores its data files, so that these logs were not on the destroyed disk. (That is, we can start the server with a `--log-bin` option that specifies a location on a different physical device from the one on which the data directory resides. That way, the logs are safe even if the device containing the directory is lost.) If we had done this, we would have the `gbichot2-bin.000009` file (and any subsequent files) at hand, and we could apply them using `mysqlbinlog` and `mysql` to restore the most recent data changes with no loss up to the moment of the crash:

```
shell> mysqlbinlog gbichot2-bin.000009 ... | mysql
```

For more information about using `mysqlbinlog` to process binary log files, see [Section 6.5, “Point-in-Time \(Incremental\) Recovery Using the Binary Log”](#).

### 6.3.3. Backup Strategy Summary

In case of an operating system crash or power failure, `InnoDB` itself does all the job of recovering data. But to make sure that you can sleep well, observe the following guidelines:

- Always run the MySQL server with the `--log-bin` option, or even `--log-bin=log_name`, where the log file name is located on some safe media different from the drive on which the data directory is located. If you have such safe media, this technique can also be good for disk load balancing (which results in a performance improvement).
- Make periodic full backups, using the `mysqldump` command shown earlier in [Section 6.3.1, “Establishing a Backup Policy”](#), that makes an online, nonblocking backup.
- Make periodic incremental backups by flushing the logs with `FLUSH LOGS` or `mysqladmin flush-logs`.

## 6.4. Using `mysqldump` for Backups

This section describes how to use `mysqldump` to produce dump files, and how to reload dump files. A dump file can be used in several ways:

- As a backup to enable data recovery in case of data loss.
- As a source of data for setting up replication slaves.
- As a source of data for experimentation:
  - To make a copy of a database that you can use without changing the original data.
  - To test potential upgrade incompatibilities.

`mysqldump` produces two types of output, depending on whether the `--tab` option is given:

- Without `--tab`, `mysqldump` writes SQL statements to the standard output. This output consists of `CREATE` statements to create dumped objects (databases, tables, stored routines, and so forth), and `INSERT` statements to load data into tables. The

output can be saved in a file and reloaded later using `mysql` to recreate the dumped objects. Options are available to modify the format of the SQL statements, and to control which objects are dumped.

- With `--tab`, `mysqldump` produces two output files for each dumped table. The server writes one file as tab-delimited text, one line per table row. This file is named `tbl_name.txt` in the output directory. The server also sends a `CREATE TABLE` statement for the table to `mysqldump`, which writes it as a file named `tbl_name.sql` in the output directory.

## 6.4.1. Dumping Data in SQL Format with `mysqldump`

This section describes how to use `mysqldump` to create SQL-format dump files. For information about reloading such dump files, see [Section 6.4.2, “Reloading SQL-Format Backups”](#).

By default, `mysqldump` writes information as SQL statements to the standard output. You can save the output in a file:

```
shell> mysqldump [arguments] > file_name
```

To dump all databases, invoke `mysqldump` with the `--all-databases` option:

```
shell> mysqldump --all-databases > dump.sql
```

To dump only specific databases, name them on the command line and use the `--databases` option:

```
shell> mysqldump --databases db1 db2 db3 > dump.sql
```

The `--databases` option causes all names on the command line to be treated as database names. Without this option, `mysqldump` treats the first name as a database name and those following as table names.

With `--all-databases` or `--databases`, `mysqldump` writes `CREATE DATABASE` and `USE` statements prior to the dump output for each database. This ensures that when the dump file is reloaded, it creates each database if it does not exist and makes it the default database so database contents are loaded into the same database from which they came. If you want to cause the dump file to force a drop of each database before recreating it, use the `--add-drop-database` option as well. In this case, `mysqldump` writes a `DROP DATABASE` statement preceding each `CREATE DATABASE` statement.

To dump a single database, name it on the command line:

```
shell> mysqldump --databases test > dump.sql
```

In the single-database case, it is permissible to omit the `--databases` option:

```
shell> mysqldump test > dump.sql
```

The difference between the two preceding commands is that without `--databases`, the dump output contains no `CREATE DATABASE` or `USE` statements. This has several implications:

- When you reload the dump file, you must specify a default database name so that the server knows which database to reload.
- For reloading, you can specify a database name different from the original name, which enables you to reload the data into a different database.
- If the database to be reloaded does not exist, you must create it first.
- Because the output will contain no `CREATE DATABASE` statement, the `--add-drop-database` option has no effect. If you use it, it produces no `DROP DATABASE` statement.

To dump only specific tables from a database, name them on the command line following the database name:

```
shell> mysqldump test t1 t3 t7 > dump.sql
```

## 6.4.2. Reloading SQL-Format Backups

To reload a dump file written by `mysqldump` that consists of SQL statements, use it as input to the `mysql` client. If the dump file was created by `mysqldump` with the `--all-databases` or `--databases` option, it contains `CREATE DATABASE` and `USE` statements and it is not necessary to specify a default database into which to load the data:

```
shell> mysql < dump.sql
```

Alternatively, from within `mysql`, use a `source` command:

```
mysql> source dump.sql
```

If the file is a single-database dump not containing `CREATE DATABASE` and `USE` statements, create the database first (if necessary):

```
shell> mysqladmin create db1
```

Then specify the database name when you load the dump file:

```
shell> mysql db1 < dump.sql
```

Alternatively, from within `mysql`, create the database, select it as the default database, and load the dump file:

```
mysql> CREATE DATABASE IF NOT EXISTS db1;
mysql> USE db1;
mysql> source dump.sql
```

### 6.4.3. Dumping Data in Delimited-Text Format with `mysqldump`

This section describes how to use `mysqldump` to create delimited-text dump files. For information about reloading such dump files, see [Section 6.4.4, “Reloading Delimited-Text Format Backups”](#).

If you invoke `mysqldump` with the `--tab=dir_name` option, it uses `dir_name` as the output directory and dumps tables individually in that directory using two files for each table. The table name is the basename for these files. For a table named `t1`, the files are named `t1.sql` and `t1.txt`. The `.sql` file contains a `CREATE TABLE` statement for the table. The `.txt` file contains the table data, one line per table row.

The following command dumps the contents of the `db1` database to files in the `/tmp` database:

```
shell> mysqldump --tab=/tmp db1
```

The `.txt` files containing table data are written by the server, so they are owned by the system account used for running the server. The server uses `SELECT ... INTO OUTFILE` to write the files, so you must have the `FILE` privilege to perform this operation, and an error occurs if a given `.txt` file already exists.

The server sends the `CREATE` definitions for dumped tables to `mysqldump`, which writes them to `.sql` files. These files therefore are owned by the user who executes `mysqldump`.

It is best that `--tab` be used only for dumping a local server. If you use it with a remote server, the `--tab` directory must exist on both the local and remote hosts, and the `.txt` files will be written by the server in the remote directory (on the server host), whereas the `.sql` files will be written by `mysqldump` in the local directory (on the client host).

For `mysqldump --tab`, the server by default writes table data to `.txt` files one line per row with tabs between column values, no quotation marks around column values, and newline as the line terminator. (These are the same defaults as for `SELECT ... INTO OUTFILE`.)

To enable data files to be written using a different format, `mysqldump` supports these options:

- `--fields-terminated-by=str`

The string for separating column values (default: tab).

- `--fields-enclosed-by=char`

The character within which to enclose column values (default: no character).

- `--fields-optionally-enclosed-by=char`

The character within which to enclose non-numeric column values (default: no character).

- `--fields-escaped-by=char`

The character for escaping special characters (default: no escaping).

- `--lines-terminated-by=str`

The line-termination string (default: newline).

Depending on the value you specify for any of these options, it might be necessary on the command line to quote or escape the value appropriately for your command interpreter. Alternatively, specify the value using hex notation. Suppose that you want `mysqldump` to quote column values within double quotation marks. To do so, specify double quote as the value for the `--fields-enclosed-by` option. But this character is often special to command interpreters and must be treated specially. For example, on Unix, you can quote the double quote like this:

```
--fields-enclosed-by= '"'
```

On any platform, you can specify the value in hex:

```
--fields-enclosed-by=0x22
```

It is common to use several of the data-formatting options together. For example, to dump tables in comma-separated values format with lines terminated by carriage-return/newline pairs (`\r\n`), use this command (enter it on a single line):

```
shell> mysqldump --tab=/tmp --fields-terminated-by=,
--fields-enclosed-by='"' --lines-terminated-by=0xd0a db1
```

Should you use any of the data-formatting options to dump table data, you will need to specify the same format when you reload data files later, to ensure proper interpretation of the file contents.

#### 6.4.4. Reloading Delimited-Text Format Backups

For backups produced with `mysqldump --tab`, each table is represented in the output directory by an `.sql` file containing the `CREATE TABLE` statement for the table, and a `.txt` file containing the table data. To reload a table, first change location into the output directory. Then process the `.sql` file with `mysql` to create an empty table and process the `.txt` file to load the data into the table:

```
shell> mysql db1 < t1.sql
shell> mysqlimport db1 t1.txt
```

An alternative to using `mysqlimport` to load the data file is to use the `LOAD DATA INFILE` statement from within the `mysql` client:

```
mysql> USE db1;
mysql> LOAD DATA INFILE 't1.txt' INTO TABLE t1;
```

If you used any data-formatting options with `mysqldump` when you initially dumped the table, you must use the same options with `mysqlimport` or `LOAD DATA INFILE` to ensure proper interpretation of the data file contents:

```
shell> mysqlimport --fields-terminated-by=,
--fields-enclosed-by='"' --lines-terminated-by=0xd0a db1 t1.txt
```

Or:

```
mysql> USE db1;
mysql> LOAD DATA INFILE 't1.txt' INTO TABLE t1
 -> FIELDS TERMINATED BY ',' FIELDS ENCLOSED BY ''
 -> LINES TERMINATED BY '\r\n';
```

#### 6.4.5. `mysqldump` Tips

This section surveys techniques that enable you to use `mysqldump` to solve specific problems:

- How to make a copy a database
- How to copy a database from one server to another
- How to dump stored programs (stored procedures and functions, triggers, and events)
- How to dump definitions and data separately

##### 6.4.5.1. Making a Copy of a Database

---

```
shell> mysqldump db1 > dump.sql
shell> mysqladmin create db2
shell> mysql db2 < dump.sql
```

Do not use `--databases` on the `mysqldump` command line because that causes `USE db1` to be included in the dump file, which overrides the effect of naming `db2` on the `mysql` command line.

#### 6.4.5.2. Copy a Database from one Server to Another

On Server 1:

```
shell> mysqldump --databases db1 > dump.sql
```

Copy the dump file from Server 1 to Server 2.

On Server 2:

```
shell> mysql < dump.sql
```

Use of `--databases` with the `mysqldump` command line causes the dump file to include `CREATE DATABASE` and `USE` statements that create the database if it does exist and make it the default database for the reloaded data.

Alternatively, you can omit `--databases` from the `mysqldump` command. Then you will need to create the database on Server 2 (if necessary) and specify it as the default database when you reload the dump file.

On Server 1:

```
shell> mysqldump db1 > dump.sql
```

On Server 2:

```
shell> mysqladmin create db1
shell> mysql db1 < dump.sql
```

You can specify a different database name in this case, so omitting `--databases` from the `mysqldump` command enables you to dump data from one database and load it into another.

#### 6.4.5.3. Dumping Stored Programs

Several options control how `mysqldump` handles stored programs (stored procedures and functions, triggers, and events):

- `--events`: Dump Event Scheduler events
- `--routines`: Dump stored procedures and functions
- `--triggers`: Dump triggers for tables

The `--triggers` option is enabled by default so that when tables are dumped, they are accompanied by any triggers they have. The other options are disabled by default and must be specified explicitly to dump the corresponding objects. To disable any of these options explicitly, use its skip form: `--skip-events`, `--skip-routines`, or `--skip-triggers`.

#### 6.4.5.4. Dumping Table Definitions and Content Separately

The `--no-data` option tells `mysqldump` not to dump table data, resulting in the dump file containing only statements to create the tables. Conversely, the `--no-create-info` option tells `mysqldump` to suppress `CREATE` statements from the output, so that the dump file contains only table data.

For example, to dump table definitions and data separately for the `test` database, use these commands:

```
shell> mysqldump --no-data test > dump-defs.sql
shell> mysqldump --no-create-info test > dump-data.sql
```

For a definition-only dump, add the `--routines` and `--events` options to also include stored routine and event definitions:

```
shell> mysqldump --no-data --routines --events test > dump-defs.sql
```

#### 6.4.5.5. Using `mysqldump` to Test for Upgrade Incompatibilities

When contemplating a MySQL upgrade, it is prudent to install the newer version separately from your current production version. Then you can dump the database and database object definitions from the production server and load them into the new server to verify that they are handled properly. (This is also useful for testing downgrades.)

On the production server:

```
shell> mysqldump --all-databases --no-data --routines --events > dump-defs.sql
```

On the upgraded server:

```
shell> mysql < dump-defs.sql
```

Because the dump file does not contain table data, it can be processed quickly. This enables you to spot potential incompatibilities without waiting for lengthy data-loading operations. Look for warnings or errors while the dump file is being processed.

After you have verified that the definitions are handled properly, dump the data and try to load it into the upgraded server.

On the production server:

```
shell> mysqldump --all-databases --no-create-info > dump-data.sql
```

On the upgraded server:

```
shell> mysql < dump-data.sql
```

Now check the table contents and run some test queries.

## 6.5. Point-in-Time (Incremental) Recovery Using the Binary Log

Point-in-time recovery refers to recovery of data changes made since a given point in time. Typically, this type of recovery is performed after restoring a full backup that brings the server to its state as of the time the backup was made. (The full backup can be made in several ways, such as those listed in [Section 6.2, “Database Backup Methods”](#).) Point-in-time recovery then brings the server up to date incrementally from the time of the full backup to a more recent time.

Point-in-time recovery is based on these principles:

- The source of information for point-in-time recovery is the set of incremental backups represented by the binary log files generated subsequent to the full backup operation. Therefore, the server must be started with the `--log-bin` option to enable binary logging (see [Section 5.2.4, “The Binary Log”](#)).

To restore data from the binary log, you must know the name and location of the current binary log files. By default, the server creates binary log files in the data directory, but a path name can be specified with the `--log-bin` option to place the files in a different location. [Section 5.2.4, “The Binary Log”](#).

To see a listing of all binary log files, use this statement:

```
mysql> SHOW BINARY LOGS;
```

To determine the name of the current binary log file, issue the following statement:

```
mysql> SHOW MASTER STATUS;
```

- The `mysqlbinlog` utility converts the events in the binary log files from binary format to text so that they can be executed or viewed. `mysqlbinlog` has options for selecting sections of the binary log based on event times or position of events within the log. See [Section 4.6.7, “mysqlbinlog — Utility for Processing Binary Log Files”](#).
- Executing events from the binary log causes the data modifications they represent to be redone. This enables recovery of data changes for a given span of time. To execute events from the binary log, process `mysqlbinlog` output using the `mysql` client:

```
shell> mysqlbinlog binlog_files | mysql -u root -p
```

- Viewing log contents can be useful when you need to determine event times or positions to select partial log contents prior to executing events. To view events from the log, send `mysqlbinlog` output into a paging program:

```
shell> mysqlbinlog binlog_files | more
```

Alternatively, save the output in a file and view the file in a text editor:

```
shell> mysqlbinlog binlog_files > tmpfile
shell> ... edit tmpfile ...
```

- Saving the output in a file is useful as a preliminary to executing the log contents with certain events removed, such as an accidental `DROP DATABASE`. You can delete from the file any statements not to be executed before executing its contents. After editing the file, execute the contents as follows:

```
shell> mysql -u root -p < tmpfile
```

If you have more than one binary log to execute on the MySQL server, the safe method is to process them all using a single connection to the server. Here is an example that demonstrates what may be *unsafe*:

```
shell> mysqlbinlog binlog.000001 | mysql -u root -p # DANGER!!
shell> mysqlbinlog binlog.000002 | mysql -u root -p # DANGER!!
```

Processing binary logs this way using different connections to the server causes problems if the first log file contains a `CREATE TEMPORARY TABLE` statement and the second log contains a statement that uses the temporary table. When the first `mysql` process terminates, the server drops the temporary table. When the second `mysql` process attempts to use the table, the server reports “unknown table.”

To avoid problems like this, use a *single* connection to execute the contents of all binary logs that you want to process. Here is one way to do so:

```
shell> mysqlbinlog binlog.000001 binlog.000002 | mysql -u root -p
```

Another approach is to write all the logs to a single file and then process the file:

```
shell> mysqlbinlog binlog.000001 > /tmp/statements.sql
shell> mysqlbinlog binlog.000002 >> /tmp/statements.sql
shell> mysql -u root -p -e "source /tmp/statements.sql"
```

## 6.5.1. Point-in-Time Recovery Using Event Times

To indicate the start and end times for recovery, specify the `--start-datetime` and `--stop-datetime` options for `mysqlbinlog`, in `DATETIME` format. As an example, suppose that exactly at 10:00 a.m. on April 20, 2005 an SQL statement was executed that deleted a large table. To restore the table and data, you could restore the previous night's backup, and then execute the following command:

```
shell> mysqlbinlog --stop-datetime="2005-04-20 9:59:59" \
 /var/log/mysql/bin.123456 | mysql -u root -p
```

This command recovers all of the data up until the date and time given by the `--stop-datetime` option. If you did not detect the erroneous SQL statement that was entered until hours later, you will probably also want to recover the activity that occurred afterward. Based on this, you could run `mysqlbinlog` again with a start date and time, like so:

```
shell> mysqlbinlog --start-datetime="2005-04-20 10:01:00" \
 /var/log/mysql/bin.123456 | mysql -u root -p
```

In this command, the SQL statements logged from 10:01 a.m. on will be re-executed. The combination of restoring of the previous night's dump file and the two `mysqlbinlog` commands restores everything up until one second before 10:00 a.m. and everything from 10:01 a.m. on.

To use this method of point-in-time recovery, you should examine the log to be sure of the exact times to specify for the commands. To display the log file contents without executing them, use this command:

```
shell> mysqlbinlog /var/log/mysql/bin.123456 > /tmp/mysql_restore.sql
```

Then open the `/tmp/mysql_restore.sql` file with a text editor to examine it.

Excluding specific changes by specifying times for `mysqlbinlog` does not work well if multiple statements executed at the same time as the one to be excluded.

## 6.5.2. Point-in-Time Recovery Using Event Positions

Instead of specifying dates and times, the `--start-position` and `--stop-position` options for `mysqlbinlog` can be used for specifying log positions. They work the same as the start and stop date options, except that you specify log position numbers rather than dates. Using positions may enable you to be more precise about which part of the log to recover, especially if many transactions occurred around the same time as a damaging SQL statement. To determine the position numbers, run `mysqlbinlog` for a range of times near the time when the unwanted transaction was executed, but redirect the results to a text file for examination. This can be done like so:

```
shell> mysqlbinlog --start-datetime="2005-04-20 9:55:00" \
 --stop-datetime="2005-04-20 10:05:00" \
 /var/log/mysql/bin.123456 > /tmp/mysql_restore.sql
```

This command creates a small text file in the `/tmp` directory that contains the SQL statements around the time that the deleterious SQL statement was executed. Open this file with a text editor and look for the statement that you do not want to repeat. Determine the positions in the binary log for stopping and resuming the recovery and make note of them. Positions are labeled as `log_pos` followed by a number. After restoring the previous backup file, use the position numbers to process the binary log file. For example, you would use commands something like these:

```
shell> mysqlbinlog --stop-position=368312 /var/log/mysql/bin.123456 \
 | mysql -u root -p
shell> mysqlbinlog --start-position=368315 /var/log/mysql/bin.123456 \
 | mysql -u root -p
```

The first command recovers all the transactions up until the stop position given. The second command recovers all transactions from the starting position given until the end of the binary log. Because the output of `mysqlbinlog` includes `SET TIMESTAMP` statements before each SQL statement recorded, the recovered data and related MySQL logs will reflect the original times at which the transactions were executed.

## 6.6. MyISAM Table Maintenance and Crash Recovery

This section discusses how to use `myisamchk` to check or repair MyISAM tables (tables that have `.MYD` and `.MYI` files for storing data and indexes). For general `myisamchk` background, see [Section 4.6.3, “`myisamchk` — MyISAM Table-Maintenance Utility”](#). Other table-repair information can be found at [Section 2.12.4, “Rebuilding or Repairing Tables or Indexes”](#).

You can use `myisamchk` to check, repair, or optimize database tables. The following sections describe how to perform these operations and how to set up a table maintenance schedule. For information about using `myisamchk` to get information about your tables, see [Section 4.6.3.5, “Obtaining Table Information with `myisamchk`”](#).

Even though table repair with `myisamchk` is quite secure, it is always a good idea to make a backup *before* doing a repair or any maintenance operation that could make a lot of changes to a table.

`myisamchk` operations that affect indexes can cause `FULLTEXT` indexes to be rebuilt with full-text parameters that are incompatible with the values used by the MySQL server. To avoid this problem, follow the guidelines in [Section 4.6.3.1, “`myisamchk` General Options”](#).

MyISAM table maintenance can also be done using the SQL statements that perform operations similar to what `myisamchk` can do:

- To check MyISAM tables, use `CHECK TABLE`.
- To repair MyISAM tables, use `REPAIR TABLE`.
- To optimize MyISAM tables, use `OPTIMIZE TABLE`.
- To analyze MyISAM tables, use `ANALYZE TABLE`.

For additional information about these statements, see [Section 12.4.2, “Table Maintenance Statements”](#).

These statements can be used directly or by means of the `mysqlcheck` client program. One advantage of these statements over `myisamchk` is that the server does all the work. With `myisamchk`, you must make sure that the server does not use the tables at the same time so that there is no unwanted interaction between `myisamchk` and the server.

### 6.6.1. Using `myisamchk` for Crash Recovery

This section describes how to check for and deal with data corruption in MySQL databases. If your tables become corrupted frequently, you should try to find the reason why. See [Section B.5.4.2, “What to Do If MySQL Keeps Crashing”](#).

For an explanation of how MyISAM tables can become corrupted, see [Section 13.5.4, “MyISAM Table Problems”](#).

If you run `mysqld` with external locking disabled (which is the default), you cannot reliably use `myisamchk` to check a table when `mysqld` is using the same table. If you can be certain that no one will access the tables through `mysqld` while you run `myisamchk`, you only have to execute `mysqladmin flush-tables` before you start checking the tables. If you cannot guarantee this, you must stop `mysqld` while you check the tables. If you run `myisamchk` to check tables that `mysqld` is updating at the same time, you may get a warning that a table is corrupt even when it is not.

If the server is run with external locking enabled, you can use `myisamchk` to check tables at any time. In this case, if the server tries to update a table that `myisamchk` is using, the server will wait for `myisamchk` to finish before it continues.

If you use `myisamchk` to repair or optimize tables, you *must* always ensure that the `mysqld` server is not using the table (this also applies if external locking is disabled). If you do not stop `mysqld`, you should at least do a `mysqladmin flush-tables` before you run `myisamchk`. Your tables *may become corrupted* if the server and `myisamchk` access the tables simultaneously.

When performing crash recovery, it is important to understand that each MyISAM table `tbl_name` in a database corresponds to the three files in the database directory shown in the following table.

File	Purpose
<code>tbl_name.frm</code>	Definition (format) file
<code>tbl_name.MYD</code>	Data file
<code>tbl_name.MYI</code>	Index file

Each of these three file types is subject to corruption in various ways, but problems occur most often in data files and index files.

`myisamchk` works by creating a copy of the `.MYD` data file row by row. It ends the repair stage by removing the old `.MYD` file and renaming the new file to the original file name. If you use `--quick`, `myisamchk` does not create a temporary `.MYD` file, but instead assumes that the `.MYD` file is correct and generates only a new index file without touching the `.MYD` file. This is safe, because `myisamchk` automatically detects whether the `.MYD` file is corrupt and aborts the repair if it is. You can also specify the `--quick` option twice to `myisamchk`. In this case, `myisamchk` does not abort on some errors (such as duplicate-key errors) but instead tries to resolve them by modifying the `.MYD` file. Normally the use of two `--quick` options is useful only if you have too little free disk space to perform a normal repair. In this case, you should at least make a backup of the table before running `myisamchk`.

## 6.6.2. How to Check MyISAM Tables for Errors

To check a MyISAM table, use the following commands:

- `myisamchk tbl_name`

This finds 99.99% of all errors. What it cannot find is corruption that involves *only* the data file (which is very unusual). If you want to check a table, you should normally run `myisamchk` without options or with the `-s` (silent) option.

- `myisamchk -m tbl_name`

This finds 99.999% of all errors. It first checks all index entries for errors and then reads through all rows. It calculates a checksum for all key values in the rows and verifies that the checksum matches the checksum for the keys in the index tree.

- `myisamchk -e tbl_name`

This does a complete and thorough check of all data (`-e` means “extended check”). It does a check-read of every key for each row to verify that they indeed point to the correct row. This may take a long time for a large table that has many indexes. Normally, `myisamchk` stops after the first error it finds. If you want to obtain more information, you can add the `-v` (verbose) option. This causes `myisamchk` to keep going, up through a maximum of 20 errors.

- `myisamchk -e -i tbl_name`

This is like the previous command, but the `-i` option tells `myisamchk` to print additional statistical information.

In most cases, a simple `myisamchk` command with no arguments other than the table name is sufficient to check a table.

## 6.6.3. How to Repair MyISAM Tables

The discussion in this section describes how to use `myisamchk` on MyISAM tables (extensions `.MYI` and `.MYD`).

You can also use the `CHECK TABLE` and `REPAIR TABLE` statements to check and repair MyISAM tables. See [Section 12.4.2.3, “CHECK TABLE Syntax”](#), and [Section 12.4.2.6, “REPAIR TABLE Syntax”](#).

Symptoms of corrupted tables include queries that abort unexpectedly and observable errors such as these:

- `tbl_name.frm` is locked against change
- Can't find file `tbl_name.MYI` (Errcode: `nnn`)
- Unexpected end of file
- Record file is crashed
- Got error `nnn` from table handler

To get more information about the error, run `perror nnn`, where `nnn` is the error number. The following example shows how to use `perror` to find the meanings for the most common error numbers that indicate a problem with a table:

```
shell> perror 126 127 132 134 135 136 141 144 145
MySQL error code 126 = Index file is crashed
MySQL error code 127 = Record-file is crashed
MySQL error code 132 = Old database file
MySQL error code 134 = Record was already deleted (or record file crashed)
MySQL error code 135 = No more room in record file
MySQL error code 136 = No more room in index file
MySQL error code 141 = Duplicate unique key or constraint on write or update
MySQL error code 144 = Table is crashed and last repair failed
MySQL error code 145 = Table was marked as crashed and should be repaired
```

Note that error 135 (no more room in record file) and error 136 (no more room in index file) are not errors that can be fixed by a simple repair. In this case, you must use `ALTER TABLE` to increase the `MAX_ROWS` and `AVG_ROW_LENGTH` table option values:

```
ALTER TABLE tbl_name MAX_ROWS=xxx AVG_ROW_LENGTH=yyy;
```

If you do not know the current table option values, use `SHOW CREATE TABLE`.

For the other errors, you must repair your tables. `myisamchk` can usually detect and fix most problems that occur.

The repair process involves up to four stages, described here. Before you begin, you should change location to the database directory and check the permissions of the table files. On Unix, make sure that they are readable by the user that `mysqld` runs as (and to you, because you need to access the files you are checking). If it turns out you need to modify files, they must also be writable by you.

This section is for the cases where a table check fails (such as those described in [Section 6.6.2, “How to Check MyISAM Tables for Errors”](#)), or you want to use the extended features that `myisamchk` provides.

The `myisamchk` options used for table maintenance with are described in [Section 4.6.3, “myisamchk — MyISAM Table-Maintenance Utility”](#). `myisamchk` also has variables that you can set to control memory allocation that may improve performance. See [Section 4.6.3.6, “myisamchk Memory Usage”](#).

If you are going to repair a table from the command line, you must first stop the `mysqld` server. Note that when you do `mysql -admin shutdown` on a remote server, the `mysqld` server is still available for a while after `mysqladmin` returns, until all statement-processing has stopped and all index changes have been flushed to disk.

### Stage 1: Checking your tables

Run `myisamchk * .MYI` or `myisamchk -e * .MYI` if you have more time. Use the `-s` (silent) option to suppress unnecessary information.

If the `mysqld` server is stopped, you should use the `--update-state` option to tell `myisamchk` to mark the table as “checked.”

You have to repair only those tables for which `myisamchk` announces an error. For such tables, proceed to Stage 2.

If you get unexpected errors when checking (such as `out of memory` errors), or if `myisamchk` crashes, go to Stage 3.

### Stage 2: Easy safe repair

First, try `myisamchk -r -q tbl_name` (`-r -q` means “quick recovery mode”). This attempts to repair the index file without touching the data file. If the data file contains everything that it should and the delete links point at the correct locations within the data file, this should work, and the table is fixed. Start repairing the next table. Otherwise, use the following procedure:

1. Make a backup of the data file before continuing.
2. Use `myisamchk -r tbl_name` (-r means “recovery mode”). This removes incorrect rows and deleted rows from the data file and reconstructs the index file.
3. If the preceding step fails, use `myisamchk --safe-recover tbl_name`. Safe recovery mode uses an old recovery method that handles a few cases that regular recovery mode does not (but is slower).

### Note

If you want a repair operation to go much faster, you should set the values of the `sort_buffer_size` and `key_buffer_size` variables each to about 25% of your available memory when running `myisamchk`.

If you get unexpected errors when repairing (such as `out of memory` errors), or if `myisamchk` crashes, go to Stage 3.

### Stage 3: Difficult repair

You should reach this stage only if the first 16KB block in the index file is destroyed or contains incorrect information, or if the index file is missing. In this case, it is necessary to create a new index file. Do so as follows:

1. Move the data file to a safe place.
2. Use the table description file to create new (empty) data and index files:

```
shell> mysql db_name
mysql> SET autocommit=1;
mysql> TRUNCATE TABLE tbl_name;
mysql> quit
```

3. Copy the old data file back onto the newly created data file. (Do not just move the old file back onto the new file. You want to retain a copy in case something goes wrong.)

### Important

If you are using replication, you should stop it prior to performing the above procedure, since it involves file system operations, and these are not logged by MySQL.

Go back to Stage 2. `myisamchk -r -q` should work. (This should not be an endless loop.)

You can also use the `REPAIR TABLE tbl_name USE_FRM` SQL statement, which performs the whole procedure automatically. There is also no possibility of unwanted interaction between a utility and the server, because the server does all the work when you use `REPAIR TABLE`. See [Section 12.4.2.6, “REPAIR TABLE Syntax”](#).

### Stage 4: Very difficult repair

You should reach this stage only if the `.frm` description file has also crashed. That should never happen, because the description file is not changed after the table is created:

1. Restore the description file from a backup and go back to Stage 3. You can also restore the index file and go back to Stage 2. In the latter case, you should start with `myisamchk -r`.
2. If you do not have a backup but know exactly how the table was created, create a copy of the table in another database. Remove the new data file, and then move the `.frm` description and `.MYI` index files from the other database to your crashed database. This gives you new description and index files, but leaves the `.MYD` data file alone. Go back to Stage 2 and attempt to reconstruct the index file.

## 6.6.4. MyISAM Table Optimization

To coalesce fragmented rows and eliminate wasted space that results from deleting or updating rows, run `myisamchk` in recovery mode:

```
shell> myisamchk -r tbl_name
```

You can optimize a table in the same way by using the `OPTIMIZE TABLE` SQL statement. `OPTIMIZE TABLE` does a table repair and a key analysis, and also sorts the index tree so that key lookups are faster. There is also no possibility of unwanted interaction between a utility and the server, because the server does all the work when you use `OPTIMIZE TABLE`. See [Section 12.4.2.5, “Optimizing Tables”](#).

“`OPTIMIZE TABLE` Syntax”.

`myisamchk` has a number of other options that you can use to improve the performance of a table:

- `--analyze` or `-a`: Perform key distribution analysis. This improves join performance by enabling the join optimizer to better choose the order in which to join the tables and which indexes it should use.
- `--sort-index` or `-S`: Sort the index blocks. This optimizes seeks and makes table scans that use indexes faster.
- `--sort-records=index_num` or `-R index_num`: Sort data rows according to a given index. This makes your data much more localized and may speed up range-based `SELECT` and `ORDER BY` operations that use this index.

For a full description of all available options, see [Section 4.6.3, “`myisamchk` — MyISAM Table-Maintenance Utility”](#).

## 6.6.5. Setting Up a MyISAM Table Maintenance Schedule

It is a good idea to perform table checks on a regular basis rather than waiting for problems to occur. One way to check and repair MyISAM tables is with the `CHECK TABLE` and `REPAIR TABLE` statements. See [Section 12.4.2, “Table Maintenance Statements”](#).

Another way to check tables is to use `myisamchk`. For maintenance purposes, you can use `myisamchk -s`. The `-s` option (short for `--silent`) causes `myisamchk` to run in silent mode, printing messages only when errors occur.

It is also a good idea to enable automatic MyISAM table checking. For example, whenever the machine has done a restart in the middle of an update, you usually need to check each table that could have been affected before it is used further. (These are “expected crashed tables.”) To cause the server to check MyISAM tables automatically, start it with the `--myisam-recover` option. See [Section 5.1.2, “Server Command Options”](#).

You should also check your tables regularly during normal system operation. For example, you can run a `cron` job to check important tables once a week, using a line like this in a `crontab` file:

```
35 0 * * 0 /path/to/myisamchk --fast --silent /path/to/datadir/*/*.MYI
```

This prints out information about crashed tables so that you can examine and repair them as necessary.

To start with, execute `myisamchk -s` each night on all tables that have been updated during the last 24 hours. As you see that problems occur infrequently, you can back off the checking frequency to once a week or so.

Normally, MySQL tables need little maintenance. If you are performing many updates to MyISAM tables with dynamic-sized rows (tables with `VARCHAR`, `BLOB`, or `TEXT` columns) or have tables with many deleted rows you may want to defragment/reclaim space from the tables from time to time. You can do this by using `OPTIMIZE TABLE` on the tables in question. Alternatively, if you can stop the `mysqld` server for a while, change location into the data directory and use this command while the server is stopped:

```
shell> myisamchk -r -s --sort-index --sort_buffer_size=16M /*/*.MYI
```

---

# Chapter 7. Optimization

This chapter explains different ways to optimize MySQL and provides examples. Optimization is a complex task because ultimately it requires understanding of the entire system to be optimized. Although it may be possible to perform some local optimizations with little knowledge of your system or application, the more optimal you want your system to become, the more you must know about it.

## 7.1. Optimization Overview

The most important factor in making a system fast is its basic design. You must also know what kinds of processing your system is doing, and what its bottlenecks are. In most cases, system bottlenecks arise from these sources:

- Disk seeks. It takes time for the disk to find a piece of data. With modern disks, the mean time for this is usually lower than 10ms, so we can in theory do about 100 seeks a second. This time improves slowly with new disks and is very hard to optimize for a single table. The way to optimize seek time is to distribute the data onto more than one disk.
- Disk reading and writing. When the disk is at the correct position, we need to read the data. With modern disks, one disk delivers at least 10–20MB/s throughput. This is easier to optimize than seeks because you can read in parallel from multiple disks.
- CPU cycles. When we have the data in main memory, we need to process it to get our result. Having small tables compared to the amount of memory is the most common limiting factor. But with small tables, speed is usually not the problem.
- Memory bandwidth. When the CPU needs more data than can fit in the CPU cache, main memory bandwidth becomes a bottleneck. This is an uncommon bottleneck for most systems, but one to be aware of.

### 7.1.1. MySQL Design Limitations and Tradeoffs

When using the [MyISAM](#) storage engine, MySQL uses extremely fast table locking that permits multiple readers or a single writer. The biggest problem with this storage engine occurs when you have a steady stream of mixed updates and slow selects on a single table. If this is a problem for certain tables, you can use another storage engine for them. See [Chapter 13, “Storage Engines”](#).

MySQL can work with both transactional and nontransactional tables. To make it easier to work smoothly with nontransactional tables (which cannot roll back if something goes wrong), MySQL has the following rules. Note that these rules apply *only* when not running in strict SQL mode or if you use the `IGNORE` specifier for `INSERT` or `UPDATE`.

- All columns have default values.
- If you insert an inappropriate or out-of-range value into a column, MySQL sets the column to the “best possible value” instead of reporting an error. For numeric values, this is 0, the smallest possible value or the largest possible value. For strings, this is either the empty string or as much of the string as can be stored in the column.
- All calculated expressions return a value that can be used instead of signaling an error condition. For example, 1/0 returns `NULL`.

To change the preceding behaviors, you can enable stricter data handling by setting the server SQL mode appropriately. For more information about data handling, see [Section 1.8.6, “How MySQL Deals with Constraints”](#), [Section 5.1.7, “Server SQL Modes”](#), and [Section 12.2.5, “`INSERT` Syntax”](#).

### 7.1.2. Designing Applications for Portability

Because all SQL servers implement different parts of standard SQL, it takes work to write portable database applications. It is very easy to achieve portability for very simple selects and inserts, but becomes more difficult the more capabilities you require. If you want an application that is fast with many database systems, it becomes even more difficult.

All database systems have some weak points. That is, they have different design compromises that lead to different behavior.

To make a complex application portable, you need to determine which SQL servers it must work with, and then determine what features those servers support. You can use the MySQL `crash-me` program to find functions, types, and limits that you can use with a selection of database servers. `crash-me` does not check for every possible feature, but it is still reasonably comprehensive, performing about 450 tests. An example of the type of information `crash-me` can provide is that you should not use column names that are longer than 18 characters if you want to be able to use Informix or DB2.

The `crash-me` program and the MySQL benchmarks are all very database independent. By taking a look at how they are written, you can get a feeling for what you must do to make your own applications database independent. The programs can be found in the

`sql-bench` directory of MySQL source distributions. They are written in Perl and use the DBI database interface. Use of DBI in itself solves part of the portability problem because it provides database-independent access methods. See [Section 7.1.3, “The MySQL Benchmark Suite”](#).

If you strive for database independence, you need to get a good feeling for each SQL server's bottlenecks. For example, MySQL is very fast in retrieving and updating rows for `MyISAM` tables, but has a problem in mixing slow readers and writers on the same table. Transactional database systems in general are not very good at generating summary tables from log tables, because in this case row locking is almost useless.

To make your application *really* database independent, you should define an easily extendable interface through which you manipulate your data. For example, C++ is available on most systems, so it makes sense to use a C++ class-based interface to the databases.

If you use some feature that is specific to a given database system (such as the `REPLACE` statement, which is specific to MySQL), you should implement the same feature for other SQL servers by coding an alternative method. Although the alternative might be slower, it enables the other servers to perform the same tasks.

With MySQL, you can use the `/* ! */` syntax to add MySQL-specific keywords to a statement. The code inside `/* */` is treated as a comment (and ignored) by most other SQL servers. For information about writing comments, see [Section 8.6, “Comment Syntax”](#).

If high performance is more important than exactness, as for some Web applications, it is possible to create an application layer that caches all results to give you even higher performance. By letting old results expire after a while, you can keep the cache reasonably fresh. This provides a method to handle high load spikes, in which case you can dynamically increase the cache size and set the expiration timeout higher until things get back to normal.

In this case, the table creation information should contain information about the initial cache size and how often the table should normally be refreshed.

An attractive alternative to implementing an application cache is to use the MySQL query cache. By enabling the query cache, the server handles the details of determining whether a query result can be reused. This simplifies your application. See [Section 7.6.3, “The MySQL Query Cache”](#).

### 7.1.3. The MySQL Benchmark Suite

This benchmark suite is meant to tell any user what operations a given SQL implementation performs well or poorly. You can get a good idea for how the benchmarks work by looking at the code and results in the `sql-bench` directory in any MySQL source distribution.

Note that this benchmark is single-threaded, so it measures the minimum time for the operations performed. We plan to add multi-threaded tests to the benchmark suite in the future.

To use the benchmark suite, the following requirements must be satisfied:

- The benchmark suite is provided with MySQL source distributions. You can either download a released distribution from <http://dev.mysql.com/downloads/>, or use the current development source tree. (See [Section 2.3.4, “Installing from the Development Source Tree”](#).)
- The benchmark scripts are written in Perl and use the Perl DBI module to access database servers, so DBI must be installed. You also need the server-specific DBD drivers for each of the servers you want to test. For example, to test MySQL, PostgreSQL, and DB2, you must have the `DBD::mysql`, `DBD::Pg`, and `DBD::DB2` modules installed. See [Section 2.15, “Perl Installation Notes”](#).

After you obtain a MySQL source distribution, you can find the benchmark suite located in its `sql-bench` directory. To run the benchmark tests, build MySQL, and then change location into the `sql-bench` directory and execute the `run-all-tests` script:

```
shell> cd sql-bench
shell> perl run-all-tests --server=server_name
```

`server_name` should be the name of one of the supported servers. To get a list of all options and supported servers, invoke this command:

```
shell> perl run-all-tests --help
```

The `crash-me` script also is located in the `sql-bench` directory. `crash-me` tries to determine what features a database system supports and what its capabilities and limitations are by actually running queries. For example, it determines:

- What data types are supported
- How many indexes are supported
- What functions are supported
- How big a query can be
- How big a `VARCHAR` column can be

For more information about benchmark results, visit <http://www.mysql.com/why-mysql/benchmarks/>.

## 7.1.4. Using Your Own Benchmarks

You should definitely benchmark your application and database to find out where the bottlenecks are. After fixing one bottleneck (or by replacing it with a “dummy” module), you can proceed to identify the next bottleneck. Even if the overall performance for your application currently is acceptable, you should at least make a plan for each bottleneck and decide how to solve it if someday you really need the extra performance.

For examples of portable benchmark programs, look at those in the MySQL benchmark suite. See [Section 7.1.3, “The MySQL Benchmark Suite”](#). You can take any program from this suite and modify it for your own needs. By doing this, you can try different solutions to your problem and test which really is fastest for you.

Another free benchmark suite is the Open Source Database Benchmark, available at <http://osdb.sourceforge.net/>.

It is very common for a problem to occur only when the system is very heavily loaded. We have had many customers who contact us when they have a (tested) system in production and have encountered load problems. In most cases, performance problems turn out to be due to issues of basic database design (for example, table scans are not good under high load) or problems with the operating system or libraries. Most of the time, these problems would be much easier to fix if the systems were not already in production.

To avoid problems like this, you should put some effort into benchmarking your whole application under the worst possible load:

- The `mysqlslap` program can be helpful for simulating a high load produced by multiple clients issuing queries simultaneously. See [Section 4.5.7, “mysqlslap — Load Emulation Client”](#).
- You can also try Super Smack, available at <http://jeremy.zawodny.com/mysql/super-smack/>.

As suggested by the names of these programs, they can bring a system to its knees, so make sure to use them only on your development systems.

## 7.2. Obtaining Query Execution Plan Information

### 7.2.1. Optimizing Queries with `EXPLAIN`

The `EXPLAIN` statement can be used either as a synonym for `DESCRIBE` or as a way to obtain information about how MySQL executes a `SELECT` statement:

- `EXPLAIN tbl_name` is synonymous with `DESCRIBE tbl_name` or `SHOW COLUMNS FROM tbl_name`:

```
EXPLAIN tbl_name
```

- When you precede a `SELECT` statement with the keyword `EXPLAIN`, MySQL displays information from the optimizer about the query execution plan. That is, MySQL explains how it would process the `SELECT`, including information about how tables are joined and in which order:

```
EXPLAIN [EXTENDED | PARTITIONS] SELECT select_options
```

- `EXPLAIN PARTITIONS` is available beginning with MySQL 5.1.5. It is useful only when examining queries involving partitioned tables. For details, see [Section 18.3.4, “Obtaining Information About Partitions”](#).

This section describes the second use of `EXPLAIN` for obtaining query execution plan information. See also [Section 12.8.2, “EXPLAIN Syntax”](#). For a description of the `DESCRIBE` and `SHOW COLUMNS` statements, see [Section 12.8.1, “DESCRIBE Syntax”](#), and [Section 12.4.5.6, “SHOW COLUMNS Syntax”](#).

With the help of `EXPLAIN`, you can see where you should add indexes to tables to get a faster `SELECT` that uses indexes to find rows. You can also use `EXPLAIN` to check whether the optimizer joins the tables in an optimal order. To give a hint to the optimizer to use a join order corresponding to the order in which the tables are named in the `SELECT` statement, begin the statement with `SELECT STRAIGHT_JOIN` rather than just `SELECT`. (See [Section 12.2.8, “`SELECT` Syntax”](#).)

If you have a problem with indexes not being used when you believe that they should be, you should run `ANALYZE TABLE` to update table statistics such as cardinality of keys, that can affect the choices the optimizer makes. See [Section 12.4.2.1, “`ANALYZE TABLE` Syntax”](#).

## 7.2.2. `EXPLAIN` Output Format

`EXPLAIN` returns a row of information for each table used in the `SELECT` statement. The tables are listed in the output in the order that MySQL would read them while processing the query. MySQL resolves all joins using a nested-loop join method. This means that MySQL reads a row from the first table, and then finds a matching row in the second table, the third table, and so on. When all tables are processed, MySQL outputs the selected columns and backtracks through the table list until a table is found for which there are more matching rows. The next row is read from this table and the process continues with the next table.

When the `EXTENDED` keyword is used, `EXPLAIN` produces extra information that can be viewed by issuing a `SHOW WARNINGS` statement following the `EXPLAIN` statement. This information displays how the optimizer qualifies table and column names in the `SELECT` statement, what the `SELECT` looks like after the application of rewriting and optimization rules, and possibly other notes about the optimization process. `EXPLAIN EXTENDED` also displays the `filtered` column as of MySQL 5.1.12.

### Note

You cannot use the `EXTENDED` and `PARTITIONS` keywords together in the same `EXPLAIN` statement.

Each output row from `EXPLAIN` provides information about one table, and each row contains the following columns:

- `id`

The `SELECT` identifier. This is the sequential number of the `SELECT` within the query.

- `select_type`

The type of `SELECT`, which can be any of those shown in the following table.

<code>SIMPLE</code>	Simple <code>SELECT</code> (not using <code>UNION</code> or subqueries)
<code>PRIMARY</code>	Outermost <code>SELECT</code>
<code>UNION</code>	Second or later <code>SELECT</code> statement in a <code>UNION</code>
<code>DEPENDENT UNION</code>	Second or later <code>SELECT</code> statement in a <code>UNION</code> , dependent on outer query
<code>UNION RESULT</code>	Result of a <code>UNION</code> .
<code>SUBQUERY</code>	First <code>SELECT</code> in subquery
<code>DEPENDENT SUBQUERY</code>	First <code>SELECT</code> in subquery, dependent on outer query
<code>DERIVED</code>	Derived table <code>SELECT</code> (subquery in <code>FROM</code> clause)
<code>UNCACHEABLE SUBQUERY</code>	A subquery for which the result cannot be cached and must be re-evaluated for each row of the outer query
<code>UNCACHEABLE UNION</code>	The second or later select in a <code>UNION</code> that belongs to an uncacheable subquery (see <a href="#">UNCACHEABLE SUBQUERY</a> )

`DEPENDENT` typically signifies the use of a correlated subquery. See [Section 12.2.9.7, “Correlated Subqueries”](#).

`DEPENDENT SUBQUERY` evaluation differs from `UNCACHEABLE SUBQUERY` evaluation. For `DEPENDENT SUBQUERY`, the subquery is re-evaluated only once for each set of different values of the variables from its outer context. For `UNCACHEABLE SUBQUERY`, the subquery is re-evaluated for each row of the outer context. Cacheability of subqueries is subject to the restrictions detailed in [Section 7.6.3.1, “How the Query Cache Operates”](#). For example, referring to user variables makes a subquery uncacheable.

- `table`

The table to which the row of output refers.

- `type`

The join type. The different join types are listed here, ordered from the best type to the worst:

- `system`

The table has only one row (= system table). This is a special case of the `const` join type.

- `const`

The table has at most one matching row, which is read at the start of the query. Because there is only one row, values from the column in this row can be regarded as constants by the rest of the optimizer. `const` tables are very fast because they are read only once.

`const` is used when you compare all parts of a `PRIMARY KEY` or `UNIQUE` index to constant values. In the following queries, `tbl_name` can be used as a `const` table:

```
SELECT * FROM tbl_name WHERE primary_key=1;
SELECT * FROM tbl_name
 WHERE primary_key_part1=1 AND primary_key_part2=2;
```

- `eq_ref`

One row is read from this table for each combination of rows from the previous tables. Other than the `system` and `const` types, this is the best possible join type. It is used when all parts of an index are used by the join and the index is a `PRIMARY KEY` or `UNIQUE NOT NULL` index.

`eq_ref` can be used for indexed columns that are compared using the `=` operator. The comparison value can be a constant or an expression that uses columns from tables that are read before this table. In the following examples, MySQL can use an `eq_ref` join to process `ref_table`:

```
SELECT * FROM ref_table,other_table
 WHERE ref_table.key_column=other_table.column;
SELECT * FROM ref_table,other_table
 WHERE ref_table.key_column_part1=other_table.column
 AND ref_table.key_column_part2=1;
```

- `ref`

All rows with matching index values are read from this table for each combination of rows from the previous tables. `ref` is used if the join uses only a leftmost prefix of the key or if the key is not a `PRIMARY KEY` or `UNIQUE` index (in other words, if the join cannot select a single row based on the key value). If the key that is used matches only a few rows, this is a good join type.

`ref` can be used for indexed columns that are compared using the `=` or `<=>` operator. In the following examples, MySQL can use a `ref` join to process `ref_table`:

```
SELECT * FROM ref_table WHERE key_column=expr;
SELECT * FROM ref_table,other_table
 WHERE ref_table.key_column=other_table.column;
SELECT * FROM ref_table,other_table
 WHERE ref_table.key_column_part1=other_table.column
 AND ref_table.key_column_part2=1;
```

- `fulltext`

The join is performed using a `FULLTEXT` index.

- `ref_or_null`

This join type is like `ref`, but with the addition that MySQL does an extra search for rows that contain `NULL` values. This join type optimization is used most often in resolving subqueries. In the following examples, MySQL can use a `ref_or_null` join to process `ref_table`:

```
SELECT * FROM ref_table
 WHERE key_column=expr OR key_column IS NULL;
```

See Section 7.3.1.6, “`IS NULL` Optimization”.

- `index_merge`

This join type indicates that the Index Merge optimization is used. In this case, the `key` column in the output row contains a list of indexes used, and `key_len` contains a list of the longest key parts for the indexes used. For more information, see

Section 7.3.1.4, “Index Merge Optimization”.

- `unique_subquery`

This type replaces `ref` for some `IN` subqueries of the following form:

```
value IN (SELECT primary_key FROM single_table WHERE some_expr)
```

`unique_subquery` is just an index lookup function that replaces the subquery completely for better efficiency.

- `index_subquery`

This join type is similar to `unique_subquery`. It replaces `IN` subqueries, but it works for nonunique indexes in subqueries of the following form:

```
value IN (SELECT key_column FROM single_table WHERE some_expr)
```

- `range`

Only rows that are in a given range are retrieved, using an index to select the rows. The `key` column in the output row indicates which index is used. The `key_len` contains the longest key part that was used. The `ref` column is `NULL` for this type.

`range` can be used when a key column is compared to a constant using any of the `=`, `<>`, `>`, `>=`, `<`, `<=`, `IS NULL`, `<=>`, `BETWEEN`, or `IN( )` operators:

```
SELECT * FROM tbl_name
WHERE key_column = 10;

SELECT * FROM tbl_name
WHERE key_column BETWEEN 10 and 20;

SELECT * FROM tbl_name
WHERE key_column IN (10,20,30);

SELECT * FROM tbl_name
WHERE key_part1= 10 AND key_part2 IN (10,20,30);
```

- `index`

This join type is the same as `ALL`, except that only the index tree is scanned. This usually is faster than `ALL` because the index file usually is smaller than the data file.

MySQL can use this join type when the query uses only columns that are part of a single index.

- `ALL`

A full table scan is done for each combination of rows from the previous tables. This is normally not good if the table is the first table not marked `const`, and usually very bad in all other cases. Normally, you can avoid `ALL` by adding indexes that enable row retrieval from the table based on constant values or column values from earlier tables.

- `possible_keys`

The `possible_keys` column indicates which indexes MySQL can choose from use to find the rows in this table. Note that this column is totally independent of the order of the tables as displayed in the output from `EXPLAIN`. That means that some of the keys in `possible_keys` might not be usable in practice with the generated table order.

If this column is `NULL`, there are no relevant indexes. In this case, you may be able to improve the performance of your query by examining the `WHERE` clause to check whether it refers to some column or columns that would be suitable for indexing. If so, create an appropriate index and check the query with `EXPLAIN` again. See Section 12.1.7, “ALTER TABLE Syntax”.

To see what indexes a table has, use `SHOW INDEX FROM tbl_name`.

- `key`

The `key` column indicates the key (index) that MySQL actually decided to use. If MySQL decides to use one of the `possible_keys` indexes to look up rows, that index is listed as the key value.

It is possible that `key` will name an index that is not present in the `possible_keys` value. This can happen if none of the `possible_keys` indexes are suitable for looking up rows, but all the columns selected by the query are columns of some other index. That is, the named index covers the selected columns, so although it is not used to determine which rows to retrieve, an index scan is more efficient than a data row scan.

For [InnoDB](#), a secondary index might cover the selected columns even if the query also selects the primary key because [InnoDB](#) stores the primary key value with each secondary index. If `key` is `NULL`, MySQL found no index to use for executing the query more efficiently.

To force MySQL to use or ignore an index listed in the `possible_keys` column, use `FORCE INDEX`, `USE INDEX`, or `IGNORE INDEX` in your query. See [Section 12.2.8.2, “Index Hint Syntax”](#).

For [MyISAM](#) tables, running `ANALYZE TABLE` helps the optimizer choose better indexes. For [MyISAM](#) tables, `myisamchk --analyze` does the same. See [Section 12.4.2.1, “ANALYZE TABLE Syntax”](#), and [Section 6.6, “MyISAM Table Maintenance and Crash Recovery”](#).

- [key\\_len](#)

The `key_len` column indicates the length of the key that MySQL decided to use. The length is `NULL` if the `key` column says `NULL`. Note that the value of `key_len` enables you to determine how many parts of a multiple-part key MySQL actually uses.

- [ref](#)

The `ref` column shows which columns or constants are compared to the index named in the `key` column to select rows from the table.

- [rows](#)

The `rows` column indicates the number of rows MySQL believes it must examine to execute the query.

For [InnoDB](#) tables, this number is an estimate, and may not always be exact.

- [filtered](#)

The `filtered` column indicates an estimated percentage of table rows that will be filtered by the table condition. That is, `rows` shows the estimated number of rows examined and `rows × filtered / 100` shows the number of rows that will be joined with previous tables. This column is displayed if you use `EXPLAIN EXTENDED`. (New in MySQL 5.1.12)

- [Extra](#)

This column contains additional information about how MySQL resolves the query. The following list explains the values that can appear in this column. If you want to make your queries as fast as possible, you should look out for `Extra` values of [Using filesort](#) and [Using temporary](#).

- [const row not found](#)

For a query such as `SELECT ... FROM tbl_name`, the table was empty.

- [Distinct](#)

MySQL is looking for distinct values, so it stops searching for more rows for the current row combination after it has found the first matching row.

- [Full scan on NULL key](#)

This occurs for subquery optimization as a fallback strategy when the optimizer cannot use an index-lookup access method.

- [Impossible HAVING](#)

The `HAVING` clause is always false and cannot select any rows.

- [Impossible WHERE](#)

The `WHERE` clause is always false and cannot select any rows.

- [Impossible WHERE noticed after reading const tables](#)

MySQL has read all `const` (and `system`) tables and notice that the `WHERE` clause is always false.

- [No matching min/max row](#)

No row satisfies the condition for a query such as `SELECT MIN(...) FROM ... WHERE condition`.

- [no matching row in const table](#)

For a query with a join, there was an empty table or a table with no rows satisfying a unique index condition.

- [No tables used](#)

The query has no `FROM` clause, or has a `FROM DUAL` clause.

- [Not exists](#)

MySQL was able to do a `LEFT JOIN` optimization on the query and does not examine more rows in this table for the previous row combination after it finds one row that matches the `LEFT JOIN` criteria. Here is an example of the type of query that can be optimized this way:

```
SELECT * FROM t1 LEFT JOIN t2 ON t1.id=t2.id
WHERE t2.id IS NULL;
```

Assume that `t2.id` is defined as `NOT NULL`. In this case, MySQL scans `t1` and looks up the rows in `t2` using the values of `t1.id`. If MySQL finds a matching row in `t2`, it knows that `t2.id` can never be `NULL`, and does not scan through the rest of the rows in `t2` that have the same `id` value. In other words, for each row in `t1`, MySQL needs to do only a single lookup in `t2`, regardless of how many rows actually match in `t2`.

- [Range checked for each record \(index map: N\)](#)

MySQL found no good index to use, but found that some of indexes might be used after column values from preceding tables are known. For each row combination in the preceding tables, MySQL checks whether it is possible to use a `range` or `index_merge` access method to retrieve rows. This is not very fast, but is faster than performing a join with no index at all. The applicability criteria are as described in [Section 7.3.1.3, “Range Optimization”](#), and [Section 7.3.1.4, “Index Merge Optimization”](#), with the exception that all column values for the preceding table are known and considered to be constants.

Indexes are numbered beginning with 1, in the same order as shown by `SHOW INDEX` for the table. The index map value `N` is a bitmask value that indicates which indexes are candidates. For example, a value of `0x19` (binary 11001) means that indexes 1, 4, and 5 will be considered.

- [Scanned N databases](#)

This indicates how many directory scans the server performs when processing a query for `INFORMATION_SCHEMA` tables, as described in [Section 7.3.3, “INFORMATION\\_SCHEMA Optimization”](#). The value of `N` can be 0, 1, or `all`.

- [Select tables optimized away](#)

The query contained only aggregate functions (`MIN()`, `MAX()`) that were all resolved using an index, or `COUNT(*)` for `MyISAM`, and no `GROUP BY` clause. The optimizer determined that only one row should be returned.

- [Skip\\_open\\_table, Open\\_frm\\_only, Open\\_trigger\\_only, Open\\_full\\_table](#)

These values indicate file-opening optimizations that apply to queries for `INFORMATION_SCHEMA` tables, as described in [Section 7.3.3, “INFORMATION\\_SCHEMA Optimization”](#).

- [Skip\\_open\\_table](#): Table files do not need to be opened. The information has already become available within the query by scanning the database directory.
- [Open\\_frm\\_only](#): Only the table's `.frm` file need be opened.
- [Open\\_trigger\\_only](#): Only the table's `.TRG` file need be opened.
- [Open\\_full\\_table](#): The unoptimized information lookup. The `.frm`, `.MYD`, and `.MYI` files must be opened.

- [unique row not found](#)

For a query such as `SELECT ... FROM tbl_name`, no rows satisfy the condition for a `UNIQUE` index or `PRIMARY KEY` on the table.

- [Using filesort](#)

MySQL must do an extra pass to find out how to retrieve the rows in sorted order. The sort is done by going through all rows according to the join type and storing the sort key and pointer to the row for all rows that match the `WHERE` clause. The keys then are sorted and the rows are retrieved in sorted order. See [Section 7.3.1.11, “ORDER BY Optimization”](#).

- [Using index](#)

The column information is retrieved from the table using only information in the index tree without having to do an additional seek to read the actual row. This strategy can be used when the query uses only columns that are part of a single in-

dex.

For **InnoDB** tables that have a user-defined clustered index, that index can be used even when **Using index** is absent from the **Extra** column. This is the case if **type** is **index** and **key** is **PRIMARY**.

- **Using index for group-by**

Similar to the **Using index** table access method, **Using index for group-by** indicates that MySQL found an index that can be used to retrieve all columns of a **GROUP BY** or **DISTINCT** query without any extra disk access to the actual table. Additionally, the index is used in the most efficient way so that for each group, only a few index entries are read. For details, see [Section 7.3.1.12, “GROUP BY Optimization”](#).

- **Using join buffer**

Tables from earlier joins are read in portions into the join buffer, and then their rows are used from the buffer to perform the join with the current table.

- **Using sort\_union(...), Using union(...), Using intersect(...)**

These indicate how index scans are merged for the **index\_merge** join type. See [Section 7.3.1.4, “Index Merge Optimization”](#).

- **Using temporary**

To resolve the query, MySQL needs to create a temporary table to hold the result. This typically happens if the query contains **GROUP BY** and **ORDER BY** clauses that list columns differently.

- **Using where**

A **WHERE** clause is used to restrict which rows to match against the next table or send to the client. Unless you specifically intend to fetch or examine all rows from the table, you may have something wrong in your query if the **Extra** value is not **Using where** and the table join type is **ALL** or **index**.

- **Using where with pushed condition**

This item applies to **NDBCLUSTER** tables *only*. It means that MySQL Cluster is using the Condition Pushdown optimization to improve the efficiency of a direct comparison between a nonindexed column and a constant. In such cases, the condition is “pushed down” to the cluster’s data nodes and is evaluated on all data nodes simultaneously. This eliminates the need to send nonmatching rows over the network, and can speed up such queries by a factor of 5 to 10 times over cases where Condition Pushdown could be but is not used. For more information, see [Section 7.3.1.5, “Condition Pushdown Optimization”](#).

You can get a good indication of how good a join is by taking the product of the values in the **rows** column of the **EXPLAIN** output. This should tell you roughly how many rows MySQL must examine to execute the query. If you restrict queries with the **max\_join\_size** system variable, this row product also is used to determine which multiple-table **SELECT** statements to execute and which to abort. See [Section 7.9.3, “Tuning Server Parameters”](#).

The following example shows how a multiple-table join can be optimized progressively based on the information provided by **EXPLAIN**.

Suppose that you have the **SELECT** statement shown here and that you plan to examine it using **EXPLAIN**:

```
EXPLAIN SELECT tt.TicketNumber, tt.TimeIn,
 tt.ProjectReference, tt.EstimatedShipDate,
 tt.ActualShipDate, tt.ClientID,
 tt.ServiceCodes, tt.RepetitiveID,
 tt.CurrentProcess, tt.CurrentDPPerson,
 tt.RecordVolume, tt.DPPrinted, et.COUNTRY,
 et_1.COUNTRY, do.CUSTNAME
 FROM tt, et, et AS et_1, do
 WHERE tt.SubmitTime IS NULL
 AND tt.ActualPC = et.EMPLOYID
 AND tt.AssignedPC = et_1.EMPLOYID
 AND tt.ClientID = do.CUSTNMBR;
```

For this example, make the following assumptions:

- The columns being compared have been declared as follows.

Table	Column	Data Type
-------	--------	-----------

tt	ActualPC	CHAR(10)
tt	AssignedPC	CHAR(10)
tt	ClientID	CHAR(10)
et	EMPLOYID	CHAR(15)
do	CUSTNMBR	CHAR(15)

- The tables have the following indexes.

Table	Index
tt	ActualPC
tt	AssignedPC
tt	ClientID
et	EMPLOYID (primary key)
do	CUSTNMBR (primary key)

- The `tt.ActualPC` values are not evenly distributed.

Initially, before any optimizations have been performed, the `EXPLAIN` statement produces the following information:

```
table type possible_keys key key_len ref rows Extra
et ALL PRIMARY NULL NULL NULL 74
do ALL PRIMARY NULL NULL NULL 2135
et_1 ALL PRIMARY NULL NULL NULL 74
tt ALL AssignedPC, NULL NULL NULL 3872
 ClientID,
 ActualPC
Range checked for each record (index map: 0x23)
```

Because `type` is `ALL` for each table, this output indicates that MySQL is generating a Cartesian product of all the tables; that is, every combination of rows. This takes quite a long time, because the product of the number of rows in each table must be examined. For the case at hand, this product is  $74 \times 2135 \times 74 \times 3872 = 45,268,558,720$  rows. If the tables were bigger, you can only imagine how long it would take.

One problem here is that MySQL can use indexes on columns more efficiently if they are declared as the same type and size. In this context, `VARCHAR` and `CHAR` are considered the same if they are declared as the same size. `tt.ActualPC` is declared as `CHAR(10)` and `et.EMPLOYID` is `CHAR(15)`, so there is a length mismatch.

To fix this disparity between column lengths, use `ALTER TABLE` to lengthen `ActualPC` from 10 characters to 15 characters:

```
mysql> ALTER TABLE tt MODIFY ActualPC VARCHAR(15);
```

Now `tt.ActualPC` and `et.EMPLOYID` are both `VARCHAR(15)`. Executing the `EXPLAIN` statement again produces this result:

```
table type possible_keys key key_len ref rows Extra
tt ALL AssignedPC, NULL NULL NULL 3872 Using
 ClientID,
 ActualPC
do ALL PRIMARY NULL NULL NULL 2135
 Range checked for each record (index map: 0x1)
et_1 ALL PRIMARY NULL NULL NULL 74
 Range checked for each record (index map: 0x1)
et eq_ref PRIMARY PRIMARY 15 tt.ActualPC 1
```

This is not perfect, but is much better: The product of the `rows` values is less by a factor of 74. This version executes in a couple of seconds.

A second alteration can be made to eliminate the column length mismatches for the `tt.AssignedPC = et_1.EMPLOYID` and `tt.ClientID = do.CUSTNMBR` comparisons:

```
mysql> ALTER TABLE tt MODIFY AssignedPC VARCHAR(15),
-> MODIFY ClientID VARCHAR(15);
```

After that modification, `EXPLAIN` produces the output shown here:

table	type	possible_keys	key	key_len	ref	rows	Extra
et	ALL	PRIMARY	NULL	NULL	NULL	74	
tt	ref	AssignedPC, ClientID, ActualPC	ActualPC	15	et.EMPLOYID	52	Using where
et_1	eq_ref	PRIMARY	PRIMARY	15	tt.AssignedPC	1	
do	eq_ref	PRIMARY	PRIMARY	15	tt.ClientID	1	

At this point, the query is optimized almost as well as possible. The remaining problem is that, by default, MySQL assumes that values in the `tt.ActualPC` column are evenly distributed, and that is not the case for the `tt` table. Fortunately, it is easy to tell MySQL to analyze the key distribution:

```
mysql> ANALYZE TABLE tt;
```

With the additional index information, the join is perfect and `EXPLAIN` produces this result:

table	type	possible_keys	key	key_len	ref	rows	Extra
tt	ALL	AssignedPC, ClientID, ActualPC	NULL	NULL	NULL	3872	Using where
et	eq_ref	PRIMARY	PRIMARY	15	tt.ActualPC	1	
et_1	eq_ref	PRIMARY	PRIMARY	15	tt.AssignedPC	1	
do	eq_ref	PRIMARY	PRIMARY	15	tt.ClientID	1	

Note that the `rows` column in the output from `EXPLAIN` is an educated guess from the MySQL join optimizer. You should check whether the numbers are even close to the truth by comparing the `rows` product with the actual number of rows that the query returns. If the numbers are quite different, you might get better performance by using `STRAIGHT_JOIN` in your `SELECT` statement and trying to list the tables in a different order in the `FROM` clause.

It is possible in some cases to execute statements that modify data when `EXPLAIN SELECT` is used with a subquery; for more information, see [Section 12.2.9.8, “Subqueries in the FROM Clause”](#).

## 7.2.3. Estimating Query Performance

In most cases, you can estimate query performance by counting disk seeks. For small tables, you can usually find a row in one disk seek (because the index is probably cached). For bigger tables, you can estimate that, using B-tree indexes, you need this many seeks to find a row: `log(row_count) / log(index_block_length / 3 * 2 / (index_length + data_pointer_length)) + 1`.

In MySQL, an index block is usually 1,024 bytes and the data pointer is usually four bytes. For a 500,000-row table with a key value length of three bytes (the size of `MEDIUMINT`), the formula indicates `log(500,000)/log(1024/3*2/(3+4)) + 1 = 4` seeks.

This index would require storage of about  $500,000 * 7 * 3/2 = 5.2\text{MB}$  (assuming a typical index buffer fill ratio of 2/3), so you probably have much of the index in memory and so need only one or two calls to read data to find the row.

For writes, however, you need four seek requests to find where to place a new index value and normally two seeks to update the index and write the row.

Note that the preceding discussion does not mean that your application performance slowly degenerates by  $\log N$ . As long as everything is cached by the OS or the MySQL server, things become only marginally slower as the table gets bigger. After the data gets too big to be cached, things start to go much slower until your applications are bound only by disk seeks (which increase by  $\log N$ ). To avoid this, increase the key cache size as the data grows. For `MyISAM` tables, the key cache size is controlled by the `key_buffer_size` system variable. See [Section 7.9.3, “Tuning Server Parameters”](#).

## 7.3. Optimizing SQL Statements

### 7.3.1. Optimizing `SELECT` Statements

First, one factor affects all statements: The more complex your permissions setup, the more overhead you have. Using simpler permissions when you issue `GRANT` statements enables MySQL to reduce permission-checking overhead when clients execute statements. For example, if you do not grant any table-level or column-level privileges, the server need not ever check the contents of the `tables_priv` and `columns_priv` tables. Similarly, if you place no resource limits on any accounts, the server does not have to perform resource counting. If you have a very high statement-processing load, it may be worth the time to use a simplified grant structure to reduce permission-checking overhead.

If your problem is with a specific MySQL expression or function, you can perform a timing test by invoking the `BENCHMARK()` function using the `mysql` client program. Its syntax is `BENCHMARK(loop_count,expression)`. The return value is always zero, but `mysql` prints a line displaying approximately how long the statement took to execute. For example:

```
mysql> SELECT BENCHMARK(1000000,1+1);
```

```
+-----+
| BENCHMARK(1000000,1+1) |
+-----+
| 0 |
+-----+
1 row in set (0.32 sec)
```

This result was obtained on a Pentium II 400MHz system. It shows that MySQL can execute 1,000,000 simple addition expressions in 0.32 seconds on that system.

All MySQL functions should be highly optimized, but there may be some exceptions. `BENCHMARK()` is an excellent tool for finding out if some function is a problem for your queries.

### 7.3.1.1. Speed of `SELECT` Statements

In general, when you want to make a slow `SELECT ... WHERE` query faster, the first thing to check is whether you can add an index. All references between different tables should usually be done with indexes. You can use the `EXPLAIN` statement to determine which indexes are used for a `SELECT`. See [Section 7.2.1, “Optimizing Queries with EXPLAIN”](#), and [Section 7.5.3, “How MySQL Uses Indexes”](#).

Some general tips for speeding up queries on `MyISAM` tables:

- To help MySQL better optimize queries, use `ANALYZE TABLE` or run `myisamchk --analyze` on a table after it has been loaded with data. This updates a value for each index part that indicates the average number of rows that have the same value. (For unique indexes, this is always 1.) MySQL uses this to decide which index to choose when you join two tables based on a nonconstant expression. You can check the result from the table analysis by using `SHOW INDEX FROM tbl_name` and examining the `Cardinality` value. `myisamchk --description --verbose` shows index distribution information.
- To sort an index and data according to an index, use `myisamchk --sort-index --sort-records=1` (assuming that you want to sort on index 1). This is a good way to make queries faster if you have a unique index from which you want to read all rows in order according to the index. The first time you sort a large table this way, it may take a long time.

### 7.3.1.2. `WHERE` Clause Optimization

This section discusses optimizations that can be made for processing `WHERE` clauses. The examples use `SELECT` statements, but the same optimizations apply for `WHERE` clauses in `DELETE` and `UPDATE` statements.

Work on the MySQL optimizer is ongoing, so this section is incomplete. MySQL performs a great many optimizations, not all of which are documented here.

Some of the optimizations performed by MySQL follow:

- Removal of unnecessary parentheses:

```
((a AND b) AND c OR (((a AND b) AND (c AND d))))
-> (a AND b AND c) OR (a AND b AND c AND d)
```

- Constant folding:

```
(a<b AND b=c) AND a=5
-> b>5 AND b=c AND a=5
```

- Constant condition removal (needed because of constant folding):

```
(B>=5 AND B=5) OR (B=6 AND 5=5) OR (B=7 AND 5=6)
-> B=5 OR B=6
```

- Constant expressions used by indexes are evaluated only once.
- `COUNT(*)` on a single table without a `WHERE` is retrieved directly from the table information for `MyISAM` and `MEMORY` tables. This is also done for any `NOT NULL` expression when used with only one table.
- Early detection of invalid constant expressions. MySQL quickly detects that some `SELECT` statements are impossible and returns no rows.
- `HAVING` is merged with `WHERE` if you do not use `GROUP BY` or aggregate functions (`COUNT()`, `MIN()`, and so on).
- For each table in a join, a simpler `WHERE` is constructed to get a fast `WHERE` evaluation for the table and also to skip rows as soon as possible.

- All constant tables are read first before any other tables in the query. A constant table is any of the following:
  - An empty table or a table with one row.
  - A table that is used with a `WHERE` clause on a `PRIMARY KEY` or a `UNIQUE` index, where all index parts are compared to constant expressions and are defined as `NOT NULL`.

All of the following tables are used as constant tables:

```
SELECT * FROM t WHERE primary_key=1;
SELECT * FROM t1,t2
 WHERE t1.primary_key=1 AND t2.primary_key=t1.id;
```

- The best join combination for joining the tables is found by trying all possibilities. If all columns in `ORDER BY` and `GROUP BY` clauses come from the same table, that table is preferred first when joining.
- If there is an `ORDER BY` clause and a different `GROUP BY` clause, or if the `ORDER BY` or `GROUP BY` contains columns from tables other than the first table in the join queue, a temporary table is created.
- If you use the `SQL_SMALL_RESULT` option, MySQL uses an in-memory temporary table.
- Each table index is queried, and the best index is used unless the optimizer believes that it is more efficient to use a table scan. At one time, a scan was used based on whether the best index spanned more than 30% of the table, but a fixed percentage no longer determines the choice between using an index or a scan. The optimizer now is more complex and bases its estimate on additional factors such as table size, number of rows, and I/O block size.
- In some cases, MySQL can read rows from the index without even consulting the data file. If all columns used from the index are numeric, only the index tree is used to resolve the query.
- Before each row is output, those that do not match the `HAVING` clause are skipped.

Some examples of queries that are very fast:

```
SELECT COUNT(*) FROM tbl_name;
SELECT MIN(key_part1),MAX(key_part1) FROM tbl_name;
SELECT MAX(key_part2) FROM tbl_name
 WHERE key_part1=constant;
SELECT ... FROM tbl_name
 ORDER BY key_part1,key_part2,... LIMIT 10;
SELECT ... FROM tbl_name
 ORDER BY key_part1 DESC, key_part2 DESC, ... LIMIT 10;
```

MySQL resolves the following queries using only the index tree, assuming that the indexed columns are numeric:

```
SELECT key_part1,key_part2 FROM tbl_name WHERE key_part1=val;
SELECT COUNT(*) FROM tbl_name
 WHERE key_part1=val1 AND key_part2=val2;
SELECT key_part2 FROM tbl_name GROUP BY key_part1;
```

The following queries use indexing to retrieve the rows in sorted order without a separate sorting pass:

```
SELECT ... FROM tbl_name
 ORDER BY key_part1,key_part2,... ;
SELECT ... FROM tbl_name
 ORDER BY key_part1 DESC, key_part2 DESC, ... ;
```

### 7.3.1.3. Range Optimization

The `range` access method uses a single index to retrieve a subset of table rows that are contained within one or several index value intervals. It can be used for a single-part or multiple-part index. The following sections give a detailed description of how intervals are extracted from the `WHERE` clause.

#### 7.3.1.3.1. The Range Access Method for Single-Part Indexes

For a single-part index, index value intervals can be conveniently represented by corresponding conditions in the `WHERE` clause, so we speak of *range conditions* rather than “intervals.”

The definition of a range condition for a single-part index is as follows:

- For both **BTREE** and **HASH** indexes, comparison of a key part with a constant value is a range condition when using the `=`, `<=`, `IN( )`, `IS NULL`, or `IS NOT NULL` operators.
- Additionally, for **BTREE** indexes, comparison of a key part with a constant value is a range condition when using the `>`, `<`, `>=`, `<=`, `BETWEEN`, `!=`, or `<>` operators, or `LIKE` comparisons if the argument to `LIKE` is a constant string that does not start with a wildcard character.
- For all types of indexes, multiple range conditions combined with `OR` or `AND` form a range condition.

“Constant value” in the preceding descriptions means one of the following:

- A constant from the query string
- A column of a `const` or `system` table from the same join
- The result of an uncorrelated subquery
- Any expression composed entirely from subexpressions of the preceding types

Here are some examples of queries with range conditions in the `WHERE` clause:

```
SELECT * FROM t1
 WHERE key_col > 1
 AND key_col < 10;

SELECT * FROM t1
 WHERE key_col = 1
 OR key_col IN (15,18,20);

SELECT * FROM t1
 WHERE key_col LIKE 'ab%'
 OR key_col BETWEEN 'bar' AND 'foo';
```

Note that some nonconstant values may be converted to constants during the constant propagation phase.

MySQL tries to extract range conditions from the `WHERE` clause for each of the possible indexes. During the extraction process, conditions that cannot be used for constructing the range condition are dropped, conditions that produce overlapping ranges are combined, and conditions that produce empty ranges are removed.

Consider the following statement, where `key1` is an indexed column and `nonkey` is not indexed:

```
SELECT * FROM t1 WHERE
 (key1 < 'abc' AND (key1 LIKE 'abcde%' OR key1 LIKE '%b')) OR
 (key1 < 'bar' AND nonkey = 4) OR
 (key1 < 'uux' AND key1 > 'z');
```

The extraction process for key `key1` is as follows:

1. Start with original `WHERE` clause:

```
(key1 < 'abc' AND (key1 LIKE 'abcde%' OR key1 LIKE '%b')) OR
(key1 < 'bar' AND nonkey = 4) OR
(key1 < 'uux' AND key1 > 'z')
```

2. Remove `nonkey = 4` and `key1 LIKE '%b'` because they cannot be used for a range scan. The correct way to remove them is to replace them with `TRUE`, so that we do not miss any matching rows when doing the range scan. Having replaced them with `TRUE`, we get:

```
(key1 < 'abc' AND (key1 LIKE 'abcde%' OR TRUE)) OR
(key1 < 'bar' AND TRUE) OR
(key1 < 'uux' AND key1 > 'z')
```

3. Collapse conditions that are always true or false:

- `(key1 LIKE 'abcde%' OR TRUE)` is always true
- `(key1 < 'uux' AND key1 > 'z')` is always false

Replacing these conditions with constants, we get:

```
(key1 < 'abc' AND TRUE) OR (key1 < 'bar' AND TRUE) OR (FALSE)
```

Removing unnecessary `TRUE` and `FALSE` constants, we obtain:

```
(key1 < 'abc') OR (key1 < 'bar')
```

4. Combining overlapping intervals into one yields the final condition to be used for the range scan:

```
(key1 < 'bar')
```

In general (and as demonstrated by the preceding example), the condition used for a range scan is less restrictive than the `WHERE` clause. MySQL performs an additional check to filter out rows that satisfy the range condition but not the full `WHERE` clause.

The range condition extraction algorithm can handle nested `AND/OR` constructs of arbitrary depth, and its output does not depend on the order in which conditions appear in `WHERE` clause.

Currently, MySQL does not support merging multiple ranges for the `range` access method for spatial indexes. To work around this limitation, you can use a `UNION` with identical `SELECT` statements, except that you put each spatial predicate in a different `SELECT`.

### 7.3.1.3.2. The Range Access Method for Multiple-Part Indexes

Range conditions on a multiple-part index are an extension of range conditions for a single-part index. A range condition on a multiple-part index restricts index rows to lie within one or several key tuple intervals. Key tuple intervals are defined over a set of key tuples, using ordering from the index.

For example, consider a multiple-part index defined as `key1(key_part1, key_part2, key_part3)`, and the following set of key tuples listed in key order:

<code>key_part1</code>	<code>key_part2</code>	<code>key_part3</code>
NULL	1	'abc'
NULL	1	'xyz'
NULL	2	'foo'
1	1	'abc'
1	1	'xyz'
1	2	'abc'
2	1	'aaa'

The condition `key_part1 = 1` defines this interval:

```
(1,-inf,-inf) <= (key_part1,key_part2,key_part3) < (1,+inf,+inf)
```

The interval covers the 4th, 5th, and 6th tuples in the preceding data set and can be used by the range access method.

By contrast, the condition `key_part3 = 'abc'` does not define a single interval and cannot be used by the range access method.

The following descriptions indicate how range conditions work for multiple-part indexes in greater detail.

- For `HASH` indexes, each interval containing identical values can be used. This means that the interval can be produced only for conditions in the following form:

```
key_part1 cmp const1
AND key_part2 cmp const2
AND ...
AND key_partN cmp constN;
```

Here, `const1, const2, ...` are constants, `cmp` is one of the `=`, `<=`, or `IS NULL` comparison operators, and the conditions cover all index parts. (That is, there are `N` conditions, one for each part of an `N`-part index.) For example, the following is a range condition for a three-part `HASH` index:

```
key_part1 = 1 AND key_part2 IS NULL AND key_part3 = 'foo'
```

For the definition of what is considered to be a constant, see [Section 7.3.1.3.1, “The Range Access Method for Single-Part Indexes”](#).

- For a `BTREE` index, an interval might be usable for conditions combined with `AND`, where each condition compares a key part with a constant value using `=`, `<=`, `IS NULL`, `>`, `<`, `>=`, `<=`, `!=`, `<>`, `BETWEEN`, or `LIKE 'pattern'` (where `'pattern'` does not start with a wildcard). An interval can be used as long as it is possible to determine a single key tuple containing all rows that match the condition (or two intervals if `<>` or `!=` is used). For example, for this condition:

```
key_part1 = 'foo' AND key_part2 >= 10 AND key_part3 > 10
```

The single interval is:

```
('foo',10,10) < (key_part1,key_part2,key_part3) < ('foo',+inf,+inf)
```

It is possible that the created interval contains more rows than the initial condition. For example, the preceding interval includes the value `('foo', 11, 0)`, which does not satisfy the original condition.

- If conditions that cover sets of rows contained within intervals are combined with `OR`, they form a condition that covers a set of rows contained within the union of their intervals. If the conditions are combined with `AND`, they form a condition that covers a set of rows contained within the intersection of their intervals. For example, for this condition on a two-part index:

```
(key_part1 = 1 AND key_part2 < 2) OR (key_part1 > 5)
```

The intervals are:

```
(1,-inf) < (key_part1,key_part2) < (1,2)
(5,-inf) < (key_part1,key_part2)
```

In this example, the interval on the first line uses one key part for the left bound and two key parts for the right bound. The interval on the second line uses only one key part. The `key_len` column in the `EXPLAIN` output indicates the maximum length of the key prefix used.

In some cases, `key_len` may indicate that a key part was used, but that might be not what you would expect. Suppose that `key_part1` and `key_part2` can be `NULL`. Then the `key_len` column displays two key part lengths for the following condition:

```
key_part1 >= 1 AND key_part2 < 2
```

But, in fact, the condition is converted to this:

```
key_part1 >= 1 AND key_part2 IS NOT NULL
```

Section 7.3.1.3.1, “The Range Access Method for Single-Part Indexes”, describes how optimizations are performed to combine or eliminate intervals for range conditions on a single-part index. Analogous steps are performed for range conditions on multiple-part indexes.

#### 7.3.1.4. Index Merge Optimization

The `Index Merge` method is used to retrieve rows with several `range` scans and to merge their results into one. The merge can produce unions, intersections, or unions-of-intersections of its underlying scans. This access method merges index scans from a single table; it does not merge scans across multiple tables.

In `EXPLAIN` output, the Index Merge method appears as `index_merge` in the `type` column. In this case, the `key` column contains a list of indexes used, and `key_len` contains a list of the longest key parts for those indexes.

Examples:

```
SELECT * FROM tbl_name WHERE key1 = 10 OR key2 = 20;
SELECT * FROM tbl_name
 WHERE (key1 = 10 OR key2 = 20) AND non_key=30;
SELECT * FROM t1, t2
 WHERE (t1.key1 IN (1,2) OR t1.key2 LIKE 'value%')
 AND t2.key1=t1.some_col;
SELECT * FROM t1, t2
 WHERE t1.key1=1
 AND (t2.key1=t1.some_col OR t2.key2=t1.some_col2);
```

The Index Merge method has several access algorithms (seen in the `Extra` field of `EXPLAIN` output):

- Using `intersect(...)`
- Using `union(...)`
- Using `sort_union(...)`

The following sections describe these methods in greater detail.

### Note

The Index Merge optimization algorithm has the following known deficiencies:

- If a range scan is possible on some key, the optimizer will not consider using Index Merge Union or Index Merge Sort-Union algorithms. For example, consider this query:

```
SELECT * FROM t1 WHERE (goodkey1 < 10 OR goodkey2 < 20) AND badkey < 30;
```

For this query, two plans are possible:

- An Index Merge scan using the `(goodkey1 < 10 OR goodkey2 < 20)` condition.
- A range scan using the `badkey < 30` condition.

However, the optimizer considers only the second plan.

- If your query has a complex `WHERE` clause with deep `AND/OR` nesting and MySQL doesn't choose the optimal plan, try distributing terms using the following identity laws:

```
(x AND y) OR z = (x OR z) AND (y OR z)
(x OR y) AND z = (x AND z) OR (y AND z)
```

- Index Merge is not applicable to full-text indexes. We plan to extend it to cover these in a future MySQL release.

The choice between different possible variants of the Index Merge access method and other access methods is based on cost estimates of various available options.

#### 7.3.1.4.1. The Index Merge Intersection Access Algorithm

This access algorithm can be employed when a `WHERE` clause was converted to several range conditions on different keys combined with `AND`, and each condition is one of the following:

- In this form, where the index has exactly `N` parts (that is, all index parts are covered):

```
key_part1=const1 AND key_part2=const2 ... AND key_partN=constN
```

- Any range condition over a primary key of an `InnoDB` table.

Examples:

```
SELECT * FROM innodb_table WHERE primary_key < 10 AND key_col1=20;
SELECT * FROM tbl_name
WHERE (key1_part1=1 AND key1_part2=2) AND key2=2;
```

The Index Merge intersection algorithm performs simultaneous scans on all used indexes and produces the intersection of row sequences that it receives from the merged index scans.

If all columns used in the query are covered by the used indexes, full table rows are not retrieved (`EXPLAIN` output contains `Using index` in `Extra` field in this case). Here is an example of such a query:

```
SELECT COUNT(*) FROM t1 WHERE key1=1 AND key2=1;
```

If the used indexes don't cover all columns used in the query, full rows are retrieved only when the range conditions for all used keys are satisfied.

If one of the merged conditions is a condition over a primary key of an [InnoDB](#) table, it is not used for row retrieval, but is used to filter out rows retrieved using other conditions.

#### 7.3.1.4.2. The Index Merge Union Access Algorithm

The applicability criteria for this algorithm are similar to those for the Index Merge method intersection algorithm. The algorithm can be employed when the table's [WHERE](#) clause was converted to several range conditions on different keys combined with [OR](#), and each condition is one of the following:

- In this form, where the index has exactly  $N$  parts (that is, all index parts are covered):

```
key_part1=const1 AND key_part2=const2 ... AND key_partN=constN
```

- Any range condition over a primary key of an [InnoDB](#) table.
- A condition for which the Index Merge method intersection algorithm is applicable.

Examples:

```
SELECT * FROM t1 WHERE key1=1 OR key2=2 OR key3=3;
SELECT * FROM innodb_table WHERE (key1=1 AND key2=2) OR
 (key3='foo' AND key4='bar') AND key5=5;
```

#### 7.3.1.4.3. The Index Merge Sort-Union Access Algorithm

This access algorithm is employed when the [WHERE](#) clause was converted to several range conditions combined by [OR](#), but for which the Index Merge method union algorithm is not applicable.

Examples:

```
SELECT * FROM tbl_name WHERE key_col1 < 10 OR key_col2 < 20;
SELECT * FROM tbl_name
 WHERE (key_col1 > 10 OR key_col2 = 20) AND nonkey_col=30;
```

The difference between the sort-union algorithm and the union algorithm is that the sort-union algorithm must first fetch row IDs for all rows and sort them before returning any rows.

#### 7.3.1.5. Condition Pushdown Optimization

This optimization improves the efficiency of direct comparisons between a nonindexed column and a constant. In such cases, the condition is “pushed down” to the storage engine for evaluation. This optimization can be used only by the [NDBCLUSTER](#) storage engine.

For MySQL Cluster, this optimization can eliminate the need to send nonmatching rows over the network between the cluster's data nodes and the MySQL Server that issued the query, and can speed up queries where it is used by a factor of 5 to 10 times over cases where condition pushdown could be but is not used.

Suppose that a MySQL Cluster table is defined as follows:

```
CREATE TABLE t1 (
 a INT,
 b INT,
 KEY(a)
) ENGINE=NDBCLUSTER;
```

Condition pushdown can be used with queries such as the one shown here, which includes a comparison between a nonindexed column and a constant:

```
SELECT a, b FROM t1 WHERE b = 10;
```

The use of condition pushdown can be seen in the output of [EXPLAIN](#):

```
mysql> EXPLAIN SELECT a,b FROM t1 WHERE b = 10\G
***** 1. row *****
 id: 1
 select_type: SIMPLE
 table: t1
 type: ALL
possible_keys: NULL
```

```

key: NULL
key_len: NULL
ref: NULL
rows: 10
Extra: Using where with pushed condition

```

However, condition pushdown *cannot* be used with either of these two queries:

```

SELECT a,b FROM t1 WHERE a = 10;
SELECT a,b FROM t1 WHERE b + 1 = 10;

```

Condition pushdown is not applicable to the first query because an index exists on column `a`. (An index access method would be more efficient and so would be chosen in preference to condition pushdown.) Condition pushdown cannot be employed for the second query because the comparison involving the nonindexed column `b` is indirect. (However, condition pushdown could be applied if you were to reduce `b + 1 = 10` to `b = 9` in the `WHERE` clause.)

Condition pushdown may also be employed when an indexed column is compared with a constant using a `>` or `<` operator:

```

mysql> EXPLAIN SELECT a, b FROM t1 WHERE a < 2\G
***** 1. row *****
 id: 1
 select_type: SIMPLE
 table: t1
 type: range
possible_keys: a
 key: a
 key_len: 5
 ref: NULL
 rows: 2
 Extra: Using where with pushed condition

```

Other supported comparisons for condition pushdown include the following:

- `column [NOT] LIKE pattern`

`pattern` must be a string literal containing the pattern to be matched; for syntax, see [Section 11.5.1, “String Comparison Functions”](#).

- `column IS [NOT] NULL`
- `column IN (value_list)`

Each item in the `value_list` must be a constant, literal value.

- `column BETWEEN constant1 AND constant2`

`constant1` and `constant2` must each be a constant, literal value.

In all of the cases in the preceding list, it is possible for the condition to be converted into the form of one or more direct comparisons between a column and a constant.

Condition pushdown is disabled by default. To enable it at server startup, set the `engine_condition_pushdown` system variable. For example, in a `my.cnf` file, use these lines:

```

[mysqld]
engine_condition_pushdown=1

```

At runtime, enable condition pushdown with either of the following statements:

```

SET engine_condition_pushdown=ON;

```

```

SET engine_condition_pushdown=1;

```

**Limitations.** Condition pushdown is subject to the following limitations:

- Condition pushdown is supported only by the `NDBCLUSTER` storage engine.
- Columns may be compared with constants only; however, this includes expressions which evaluate to constant values.
- Columns used in comparisons cannot be of any of the `BLOB` or `TEXT` types.
- A string value to be compared with a column must use the same collation as the column.

- Joins are not directly supported; conditions involving multiple tables are pushed separately where possible. Use `EXPLAIN EXTENDED` to determine which conditions are actually pushed down.

### 7.3.1.6. `IS NULL` Optimization

MySQL can perform the same optimization on `col_name IS NULL` that it can use for `col_name = constant_value`. For example, MySQL can use indexes and ranges to search for `NULL` with `IS NULL`.

Examples:

```
SELECT * FROM tbl_name WHERE key_col IS NULL;
SELECT * FROM tbl_name WHERE key_col <=> NULL;
SELECT * FROM tbl_name
 WHERE key_col=const1 OR key_col=const2 OR key_col IS NULL;
```

If a `WHERE` clause includes a `col_name IS NULL` condition for a column that is declared as `NOT NULL`, that expression is optimized away. This optimization does not occur in cases when the column might produce `NULL` anyway; for example, if it comes from a table on the right side of a `LEFT JOIN`.

MySQL can also optimize the combination `col_name = expr OR col_name IS NULL`, a form that is common in resolved subqueries. `EXPLAIN` shows `ref_or_null` when this optimization is used.

This optimization can handle one `IS NULL` for any key part.

Some examples of queries that are optimized, assuming that there is an index on columns `a` and `b` of table `t2`:

```
SELECT * FROM t1 WHERE t1.a=expr OR t1.a IS NULL;
SELECT * FROM t1, t2 WHERE t1.a=t2.a OR t2.a IS NULL;
SELECT * FROM t1, t2
 WHERE (t1.a=t2.a OR t2.a IS NULL) AND t2.b=t1.b;
SELECT * FROM t1, t2
 WHERE t1.a=t2.a AND (t2.b=t1.b OR t2.b IS NULL);
SELECT * FROM t1, t2
 WHERE (t1.a=t2.a AND t2.a IS NULL AND ...)
 OR (t1.a=t2.a AND t2.a IS NULL AND ...);
```

`ref_or_null` works by first doing a read on the reference key, and then a separate search for rows with a `NULL` key value.

Note that the optimization can handle only one `IS NULL` level. In the following query, MySQL uses key lookups only on the expression `(t1.a=t2.a AND t2.a IS NULL)` and is not able to use the key part on `b`:

```
SELECT * FROM t1, t2
 WHERE (t1.a=t2.a AND t2.a IS NULL)
 OR (t1.b=t2.b AND t2.b IS NULL);
```

### 7.3.1.7. `LEFT JOIN` and `RIGHT JOIN` Optimization

MySQL implements an `A LEFT JOIN B join_condition` as follows:

- Table `B` is set to depend on table `A` and all tables on which `A` depends.
- Table `A` is set to depend on all tables (except `B`) that are used in the `LEFT JOIN` condition.
- The `LEFT JOIN` condition is used to decide how to retrieve rows from table `B`. (In other words, any condition in the `WHERE` clause is not used.)
- All standard join optimizations are performed, with the exception that a table is always read after all tables on which it depends. If there is a circular dependence, MySQL issues an error.
- All standard `WHERE` optimizations are performed.
- If there is a row in `A` that matches the `WHERE` clause, but there is no row in `B` that matches the `ON` condition, an extra `B` row is generated with all columns set to `NULL`.
- If you use `LEFT JOIN` to find rows that do not exist in some table and you have the following test: `col_name IS NULL` in the `WHERE` part, where `col_name` is a column that is declared as `NOT NULL`, MySQL stops searching for more rows (for a

particular key combination) after it has found one row that matches the `LEFT JOIN` condition.

The implementation of `RIGHT JOIN` is analogous to that of `LEFT JOIN` with the roles of the tables reversed.

The join optimizer calculates the order in which tables should be joined. The table read order forced by `LEFT JOIN` or `STRAIGHT_JOIN` helps the join optimizer do its work much more quickly, because there are fewer table permutations to check. Note that this means that if you do a query of the following type, MySQL does a full scan on `b` because the `LEFT JOIN` forces it to be read before `d`:

```
SELECT *
 FROM a JOIN b LEFT JOIN c ON (c.key=a.key)
 LEFT JOIN d ON (d.key=a.key)
 WHERE b.key=d.key;
```

The fix in this case is reverse the order in which `a` and `b` are listed in the `FROM` clause:

```
SELECT *
 FROM b JOIN a LEFT JOIN c ON (c.key=a.key)
 LEFT JOIN d ON (d.key=a.key)
 WHERE b.key=d.key;
```

For a `LEFT JOIN`, if the `WHERE` condition is always false for the generated `NULL` row, the `LEFT JOIN` is changed to a normal join. For example, the `WHERE` clause would be false in the following query if `t2.column1` were `NULL`:

```
SELECT * FROM t1 LEFT JOIN t2 ON (column1) WHERE t2.column2=5;
```

Therefore, it is safe to convert the query to a normal join:

```
SELECT * FROM t1, t2 WHERE t2.column2=5 AND t1.column1=t2.column1;
```

This can be made faster because MySQL can use table `t2` before table `t1` if doing so would result in a better query plan. To provide a hint about the table join order, use `STRAIGHT_JOIN`. (See Section 12.2.8, “[SELECT Syntax](#)”.)

### 7.3.1.8. Nested-Loop Join Algorithms

MySQL executes joins between tables using a nested-loop algorithm or variations on it.

#### Nested-Loop Join Algorithm

A simple nested-loop join (NLJ) algorithm reads rows from the first table in a loop one at a time, passing each row to a nested loop that processes the next table in the join. This process is repeated as many times as there remain tables to be joined.

Assume that a join between three tables `t1`, `t2`, and `t3` is to be executed using the following join types:

Table	Join Type
t1	range
t2	ref
t3	ALL

If a simple NLJ algorithm is used, the join would be processed like this:

```
for each row in t1 matching range {
 for each row in t2 matching reference key {
 for each row in t3 {
 if row satisfies join conditions,
 send to client
 }
 }
}
```

Because the NLJ algorithm passes rows one at a time from outer loops to inner loops, tables processed in the inner loops typically are read many times.

#### Block Nested-Loop Join Algorithm

A Block Nested-Loop (BNL) Join algorithm uses buffering of rows read in outer loops to reduce the number of times that tables in inner loops must be read. For example, if 10 rows are read into a buffer and the buffer is passed to the next inner loop, each row read in the inner loop can be compared against all 10 rows in the buffer. The reduces the number of times the inner table must be read by an order of magnitude.

MySQL uses join buffering under these conditions:

- The `join_buffer_size` system variable determines the size of each join buffer.
- Join buffering can be used when the join is of type `ALL` or `index` (in other words, when no possible keys can be used, and a full scan is done, of either the data or index rows, respectively), or `range`.
- One buffer is allocated for each join that can be buffered, so a given query might be processed using multiple join buffers.
- A join buffer is never allocated for the first nonconst table, even if it would be of type `ALL` or `index`.
- A join buffer is allocated prior to executing the join and freed after the query is done.
- Only columns of interest to the join are stored in the join buffer, not whole rows.

For the example join described previously for the NLJ algorithm (without buffering), the join would be done as follow using join buffering:

```

for each row in t1 matching range {
 for each row in t2 matching reference key {
 store used columns from t1, t2 in join buffer
 if buffer is full {
 for each row in t3 {
 for each t1, t2 combination in join buffer {
 if row satisfies join conditions,
 send to client
 }
 }
 empty buffer
 }
 }
}

if buffer is not empty {
 for each row in t3 {
 for each t1, t2 combination in join buffer {
 if row satisfies join conditions,
 send to client
 }
 }
}

```

If `S` is the size of each stored `t1, t2` combination in the join buffer and `C` is the number of combinations in the buffer, the number of times table `t3` is scanned is:

```
(S * C)/join_buffer_size + 1
```

One implication is that the number of `t3` scans decreases as the value of `join_buffer_size` increases, up to the point when `join_buffer_size` is large enough to hold all previous row combinations. At that point, there is no speed to be gained by making it larger.

### 7.3.1.9. Nested Join Optimization

The syntax for expressing joins permits nested joins. The following discussion refers to the join syntax described in Section 12.2.8.1, “JOIN Syntax”.

The syntax of `table_factor` is extended in comparison with the SQL Standard. The latter accepts only `table_reference`, not a list of them inside a pair of parentheses. This is a conservative extension if we consider each comma in a list of `table_reference` items as equivalent to an inner join. For example:

```
SELECT * FROM t1 LEFT JOIN (t2, t3, t4)
 ON (t2.a=t1.a AND t3.b=t1.b AND t4.c=t1.c)
```

is equivalent to:

```
SELECT * FROM t1 LEFT JOIN (t2 CROSS JOIN t3 CROSS JOIN t4)
 ON (t2.a=t1.a AND t3.b=t1.b AND t4.c=t1.c)
```

In MySQL, `CROSS JOIN` is a syntactic equivalent to `INNER JOIN` (they can replace each other). In standard SQL, they are not equivalent. `INNER JOIN` is used with an `ON` clause; `CROSS JOIN` is used otherwise.

In general, parentheses can be ignored in join expressions containing only inner join operations. After removing parentheses and grouping operations to the left, the join expression:

```
t1 LEFT JOIN (t2 LEFT JOIN t3 ON t2.b=t3.b OR t2.b IS NULL)
 ON t1.a=t2.a
```

transforms into the expression:

```
(t1 LEFT JOIN t2 ON t1.a=t2.a) LEFT JOIN t3
 ON t2.b=t3.b OR t2.b IS NULL
```

Yet, the two expressions are not equivalent. To see this, suppose that the tables **t1**, **t2**, and **t3** have the following state:

- Table **t1** contains rows **(1)**, **(2)**
- Table **t2** contains row **(1, 101)**
- Table **t3** contains row **(101)**

In this case, the first expression returns a result set including the rows **(1, 1, 101, 101)**, **(2, NULL, NULL, NULL)**, whereas the second expression returns the rows **(1, 1, 101, 101)**, **(2, NULL, NULL, 101)**:

```
mysql> SELECT *
-> FROM t1
-> LEFT JOIN
-> (t2 LEFT JOIN t3 ON t2.b=t3.b OR t2.b IS NULL)
-> ON t1.a=t2.a;
+-----+-----+-----+
| a | a | b | b |
+-----+-----+-----+
| 1 | 1 | 101 | 101 |
| 2 | NULL | NULL | NULL |
+-----+-----+-----+
mysql> SELECT *
-> FROM (t1 LEFT JOIN t2 ON t1.a=t2.a)
-> LEFT JOIN t3
-> ON t2.b=t3.b OR t2.b IS NULL;
+-----+-----+-----+
| a | a | b | b |
+-----+-----+-----+
| 1 | 1 | 101 | 101 |
| 2 | NULL | NULL | 101 |
+-----+-----+-----+
```

In the following example, an outer join operation is used together with an inner join operation:

```
t1 LEFT JOIN (t2, t3) ON t1.a=t2.a
```

That expression cannot be transformed into the following expression:

```
t1 LEFT JOIN t2 ON t1.a=t2.a, t3.
```

For the given table states, the two expressions return different sets of rows:

```
mysql> SELECT *
-> FROM t1 LEFT JOIN (t2, t3) ON t1.a=t2.a;
+-----+-----+-----+
| a | a | b | b |
+-----+-----+-----+
| 1 | 1 | 101 | 101 |
| 2 | NULL | NULL | NULL |
+-----+-----+-----+
mysql> SELECT *
-> FROM t1 LEFT JOIN t2 ON t1.a=t2.a, t3;
+-----+-----+-----+
| a | a | b | b |
+-----+-----+-----+
| 1 | 1 | 101 | 101 |
| 2 | NULL | NULL | 101 |
+-----+-----+-----+
```

Therefore, if we omit parentheses in a join expression with outer join operators, we might change the result set for the original expression.

More exactly, we cannot ignore parentheses in the right operand of the left outer join operation and in the left operand of a right join operation. In other words, we cannot ignore parentheses for the inner table expressions of outer join operations. Parentheses for the other operand (operand for the outer table) can be ignored.

The following expression:

```
(t1,t2) LEFT JOIN t3 ON P(t2.b,t3.b)
```

is equivalent to this expression:

```
t1, t2 LEFT JOIN t3 ON P(t2.b,t3.b)
```

for any tables `t1, t2, t3` and any condition `P` over attributes `t2.b` and `t3.b`.

Whenever the order of execution of the join operations in a join expression (`join_table`) is not from left to right, we talk about nested joins. Consider the following queries:

```
SELECT * FROM t1 LEFT JOIN (t2 LEFT JOIN t3 ON t2.b=t3.b) ON t1.a=t2.a
WHERE t1.a > 1

SELECT * FROM t1 LEFT JOIN (t2, t3) ON t1.a=t2.a
WHERE (t2.b=t3.b OR t2.b IS NULL) AND t1.a > 1
```

Those queries are considered to contain these nested joins:

```
t2 LEFT JOIN t3 ON t2.b=t3.b
t2, t3
```

The nested join is formed in the first query with a left join operation, whereas in the second query it is formed with an inner join operation.

In the first query, the parentheses can be omitted: The grammatical structure of the join expression will dictate the same order of execution for join operations. For the second query, the parentheses cannot be omitted, although the join expression here can be interpreted unambiguously without them. (In our extended syntax the parentheses in `(t2, t3)` of the second query are required, although theoretically the query could be parsed without them: We still would have unambiguous syntactical structure for the query because `LEFT JOIN` and `ON` would play the role of the left and right delimiters for the expression `(t2, t3)`.)

The preceding examples demonstrate these points:

- For join expressions involving only inner joins (and not outer joins), parentheses can be removed. You can remove parentheses and evaluate left to right (or, in fact, you can evaluate the tables in any order).
- The same is not true, in general, for outer joins or for outer joins mixed with inner joins. Removal of parentheses may change the result.

Queries with nested outer joins are executed in the same pipeline manner as queries with inner joins. More exactly, a variation of the nested-loop join algorithm is exploited. Recall by what algorithmic schema the nested-loop join executes a query. Suppose that we have a join query over 3 tables `T1, T2, T3` of the form:

```
SELECT * FROM T1 INNER JOIN T2 ON P1(T1,T2)
 INNER JOIN T3 ON P2(T2,T3)
WHERE P(T1,T2,T3).
```

Here, `P1(T1, T2)` and `P2(T3, T3)` are some join conditions (on expressions), whereas `P(t1, t2, t3)` is a condition over columns of tables `T1, T2, T3`.

The nested-loop join algorithm would execute this query in the following manner:

```
FOR each row t1 in T1 {
 FOR each row t2 in T2 such that P1(t1,t2) {
 FOR each row t3 in T3 such that P2(t2,t3) {
 IF P(t1,t2,t3) {
 t:=t1||t2||t3; OUTPUT t;
 }
 }
 }
}
```

The notation `t1 || t2 || t3` means “a row constructed by concatenating the columns of rows `t1, t2`, and `t3`.” In some of the following examples, `NULL` where a row name appears means that `NULL` is used for each column of that row. For example, `t1 || t2 || NULL` means “a row constructed by concatenating the columns of rows `t1` and `t2`, and `NULL` for each column of `t3`.”

Now let's consider a query with nested outer joins:

```
SELECT * FROM T1 LEFT JOIN
 (T2 LEFT JOIN T3 ON P2(T2,T3))
 ON P1(T1,T2)
WHERE P(T1,T2,T3).
```

For this query, we modify the nested-loop pattern to get:

```

FOR each row t1 in T1 {
 BOOL f1:=FALSE;
 FOR each row t2 in T2 such that P1(t1,t2) {
 BOOL f2:=FALSE;
 FOR each row t3 in T3 such that P2(t2,t3) {
 IF P(t1,t2,t3) {
 t:=t1||t2||t3; OUTPUT t;
 }
 f2=TRUE;
 f1=TRUE;
 }
 IF (!f2) {
 IF P(t1,t2,NULL) {
 t:=t1||t2||NULL; OUTPUT t;
 }
 f1=TRUE;
 }
 }
 IF (!f1) {
 IF P(t1,NULL,NULL) {
 t:=t1||NULL||NULL; OUTPUT t;
 }
 }
}

```

In general, for any nested loop for the first inner table in an outer join operation, a flag is introduced that is turned off before the loop and is checked after the loop. The flag is turned on when for the current row from the outer table a match from the table representing the inner operand is found. If at the end of the loop cycle the flag is still off, no match has been found for the current row of the outer table. In this case, the row is complemented by `NULL` values for the columns of the inner tables. The result row is passed to the final check for the output or into the next nested loop, but only if the row satisfies the join condition of all embedded outer joins.

In our example, the outer join table expressed by the following expression is embedded:

```
(T2 LEFT JOIN T3 ON P2(T2,T3))
```

Note that for the query with inner joins, the optimizer could choose a different order of nested loops, such as this one:

```

FOR each row t3 in T3 {
 FOR each row t2 in T2 such that P2(t2,t3) {
 FOR each row t1 in T1 such that P1(t1,t2) {
 IF P(t1,t2,t3) {
 t:=t1||t2||t3; OUTPUT t;
 }
 }
 }
}

```

For the queries with outer joins, the optimizer can choose only such an order where loops for outer tables precede loops for inner tables. Thus, for our query with outer joins, only one nesting order is possible. For the following query, the optimizer will evaluate two different nestings:

```
SELECT * T1 LEFT JOIN (T2,T3) ON P1(T1,T2) AND P2(T1,T3)
WHERE P(T1,T2,T3)
```

The nestings are these:

```

FOR each row t1 in T1 {
 BOOL f1:=FALSE;
 FOR each row t2 in T2 such that P1(t1,t2) {
 FOR each row t3 in T3 such that P2(t1,t3) {
 IF P(t1,t2,t3) {
 t:=t1||t2||t3; OUTPUT t;
 }
 f1:=TRUE
 }
 IF (!f1) {
 IF P(t1,NULL,NULL) {
 t:=t1||NULL||NULL; OUTPUT t;
 }
 }
 }
}

```

and:

```

FOR each row t1 in T1 {
 BOOL f1:=FALSE;
 FOR each row t3 in T3 such that P2(t1,t3) {
 FOR each row t2 in T2 such that P1(t1,t2) {
 IF P(t1,t2,t3) {

```

```

 t:=t1||t2||t3; OUTPUT t;
 }
 f1:=TRUE
}
IF (!f1) {
 IF P(t1,NULL,NULL) {
 t:=t1||NULL||NULL; OUTPUT t;
 }
}

```

In both nestings,  $T_1$  must be processed in the outer loop because it is used in an outer join.  $T_2$  and  $T_3$  are used in an inner join, so that join must be processed in the inner loop. However, because the join is an inner join,  $T_2$  and  $T_3$  can be processed in either order.

When discussing the nested-loop algorithm for inner joins, we omitted some details whose impact on the performance of query execution may be huge. We did not mention so-called “pushed-down” conditions. Suppose that our `WHERE` condition  $P(T_1, T_2, T_3)$  can be represented by a conjunctive formula:

```
P(T1,T2,T3) = C1(T1) AND C2(T2) AND C3(T3).
```

In this case, MySQL actually uses the following nested-loop schema for the execution of the query with inner joins:

```

FOR each row t1 in T1 such that C1(t1) {
 FOR each row t2 in T2 such that P1(t1,t2) AND C2(t2) {
 FOR each row t3 in T3 such that P2(t2,t3) AND C3(t3) {
 IF P(t1,t2,t3) {
 t:=t1||t2||t3; OUTPUT t;
 }
 }
 }
}

```

You see that each of the conjuncts  $C_1(T_1)$ ,  $C_2(T_2)$ ,  $C_3(T_3)$  are pushed out of the most inner loop to the most outer loop where it can be evaluated. If  $C_1(T_1)$  is a very restrictive condition, this condition pushdown may greatly reduce the number of rows from table  $T_1$  passed to the inner loops. As a result, the execution time for the query may improve immensely.

For a query with outer joins, the `WHERE` condition is to be checked only after it has been found that the current row from the outer table has a match in the inner tables. Thus, the optimization of pushing conditions out of the inner nested loops cannot be applied directly to queries with outer joins. Here we have to introduce conditional pushed-down predicates guarded by the flags that are turned on when a match has been encountered.

For our example with outer joins with:

```
P(T1,T2,T3)=C1(T1) AND C2(T2) AND C3(T3)
```

the nested-loop schema using guarded pushed-down conditions looks like this:

```

FOR each row t1 in T1 such that C1(t1) {
 BOOL f1:=FALSE;
 FOR each row t2 in T2
 such that P1(t1,t2) AND (f1?C2(t2):TRUE) {
 BOOL f2:=FALSE;
 FOR each row t3 in T3
 such that P2(t2,t3) AND (f1&&f2?C3(t3):TRUE) {
 IF (f1&&f2?TRUE:(C2(t2) AND C3(t3))) {
 t:=t1||t2||t3; OUTPUT t;
 }
 f2=TRUE;
 f1=TRUE;
 }
 IF (!f2) {
 IF (f1?TRUE:C2(t2) && P(t1,t2,NULL)) {
 t:=t1||t2||NULL; OUTPUT t;
 }
 f1=TRUE;
 }
 IF (!f1 && P(t1,NULL,NULL)) {
 t:=t1||NULL||NULL; OUTPUT t;
 }
 }
 }
}

```

In general, pushed-down predicates can be extracted from join conditions such as  $P_1(T_1, T_2)$  and  $P(T_2, T_3)$ . In this case, a pushed-down predicate is guarded also by a flag that prevents checking the predicate for the `NULL`-complemented row generated by the corresponding outer join operation.

Note that access by key from one inner table to another in the same nested join is prohibited if it is induced by a predicate from the

`WHERE` condition. (We could use conditional key access in this case, but this technique is not employed yet in MySQL 5.1.)

### 7.3.1.10. Outer Join Simplification

Table expressions in the `FROM` clause of a query are simplified in many cases.

At the parser stage, queries with right outer joins operations are converted to equivalent queries containing only left join operations. In the general case, the conversion is performed according to the following rule:

```
(T1, ...) RIGHT JOIN (T2,...) ON P(T1,...,T2,...) =
(T2, ...) LEFT JOIN (T1,...) ON P(T1,...,T2,...)
```

All inner join expressions of the form `T1 INNER JOIN T2 ON P(T1,T2)` are replaced by the list `T1, T2, P(T1,T2)` being joined as a conjunct to the `WHERE` condition (or to the join condition of the embedding join, if there is any).

When the optimizer evaluates plans for join queries with outer join operation, it takes into consideration only the plans where, for each such operation, the outer tables are accessed before the inner tables. The optimizer options are limited because only such plans enables us to execute queries with outer joins operations by the nested loop schema.

Suppose that we have a query of the form:

```
SELECT * T1 LEFT JOIN T2 ON P1(T1,T2)
WHERE P(T1,T2) AND R(T2)
```

with `R(T2)` narrowing greatly the number of matching rows from table `T2`. If we executed the query as it is, the optimizer would have no other choice besides to access table `T1` before table `T2` that may lead to a very inefficient execution plan.

Fortunately, MySQL converts such a query into a query without an outer join operation if the `WHERE` condition is null-rejected. A condition is called null-rejected for an outer join operation if it evaluates to `FALSE` or to `UNKNOWN` for any `NULL`-complemented row built for the operation.

Thus, for this outer join:

```
T1 LEFT JOIN T2 ON T1.A=T2.A
```

Conditions such as these are null-rejected:

```
T2.B IS NOT NULL,
T2.B > 3,
T2.C <= T1.C,
T2.B < 2 OR T2.C > 1
```

Conditions such as these are not null-rejected:

```
T2.B IS NULL,
T1.B < 3 OR T2.B IS NOT NULL,
T1.B < 3 OR T2.B > 3
```

The general rules for checking whether a condition is null-rejected for an outer join operation are simple. A condition is null-rejected in the following cases:

- If it is of the form `A IS NOT NULL`, where `A` is an attribute of any of the inner tables
- If it is a predicate containing a reference to an inner table that evaluates to `UNKNOWN` when one of its arguments is `NULL`
- If it is a conjunction containing a null-rejected condition as a conjunct
- If it is a disjunction of null-rejected conditions

A condition can be null-rejected for one outer join operation in a query and not null-rejected for another. In the query:

```
SELECT * FROM T1 LEFT JOIN T2 ON T2.A=T1.A
 LEFT JOIN T3 ON T3.B=T1.B
WHERE T3.C > 0
```

the `WHERE` condition is null-rejected for the second outer join operation but is not null-rejected for the first one.

If the `WHERE` condition is null-rejected for an outer join operation in a query, the outer join operation is replaced by an inner join operation.

For example, the preceding query is replaced with the query:

```
SELECT * FROM T1 LEFT JOIN T2 ON T2.A=T1.A
 INNER JOIN T3 ON T3.B=T1.B
 WHERE T3.C > 0
```

For the original query, the optimizer would evaluate plans compatible with only one access order **T1 , T2 , T3**. For the replacing query, it additionally considers the access sequence **T3 , T1 , T2**.

A conversion of one outer join operation may trigger a conversion of another. Thus, the query:

```
SELECT * FROM T1 LEFT JOIN T2 ON T2.A=T1.A
 LEFT JOIN T3 ON T3.B=T2.B
 WHERE T3.C > 0
```

will be first converted to the query:

```
SELECT * FROM T1 LEFT JOIN T2 ON T2.A=T1.A
 INNER JOIN T3 ON T3.B=T2.B
 WHERE T3.C > 0
```

which is equivalent to the query:

```
SELECT * FROM (T1 LEFT JOIN T2 ON T2.A=T1.A), T3
 WHERE T3.C > 0 AND T3.B=T2.B
```

Now the remaining outer join operation can be replaced by an inner join, too, because the condition **T3 .B=T2 .B** is null-rejected and we get a query without outer joins at all:

```
SELECT * FROM (T1 INNER JOIN T2 ON T2.A=T1.A), T3
 WHERE T3.C > 0 AND T3.B=T2.B
```

Sometimes we succeed in replacing an embedded outer join operation, but cannot convert the embedding outer join. The following query:

```
SELECT * FROM T1 LEFT JOIN
 (T2 LEFT JOIN T3 ON T3.B=T2.B)
 ON T2.A=T1.A
 WHERE T3.C > 0
```

is converted to:

```
SELECT * FROM T1 LEFT JOIN
 (T2 INNER JOIN T3 ON T3.B=T2.B)
 ON T2.A=T1.A
 WHERE T3.C > 0,
```

That can be rewritten only to the form still containing the embedding outer join operation:

```
SELECT * FROM T1 LEFT JOIN
 (T2,T3)
 ON (T2.A=T1.A AND T3.B=T2.B)
 WHERE T3.C > 0.
```

When trying to convert an embedded outer join operation in a query, we must take into account the join condition for the embedding outer join together with the **WHERE** condition. In the query:

```
SELECT * FROM T1 LEFT JOIN
 (T2 LEFT JOIN T3 ON T3.B=T2.B)
 ON T2.A=T1.A AND T3.C=T1.C
 WHERE T3.D > 0 OR T1.D > 0
```

the **WHERE** condition is not null-rejected for the embedded outer join, but the join condition of the embedding outer join **T2 .A=T1 .A AND T3 .C=T1 .C** is null-rejected. So the query can be converted to:

```
SELECT * FROM T1 LEFT JOIN
 (T2, T3)
 ON T2.A=T1.A AND T3.C=T1.C AND T3.B=T2.B
 WHERE T3.D > 0 OR T1.D > 0
```

### 7.3.1.11. ORDER BY Optimization

In some cases, MySQL can use an index to satisfy an `ORDER BY` clause without doing any extra sorting.

The index can also be used even if the `ORDER BY` does not match the index exactly, as long as all of the unused portions of the index and all the extra `ORDER BY` columns are constants in the `WHERE` clause. The following queries use the index to resolve the `ORDER BY` part:

```
SELECT * FROM t1
 ORDER BY key_part1,key_part2,... ;

SELECT * FROM t1
 WHERE key_part1=constant
 ORDER BY key_part2;

SELECT * FROM t1
 ORDER BY key_part1 DESC, key_part2 DESC;

SELECT * FROM t1
 WHERE key_part1=1
 ORDER BY key_part1 DESC, key_part2 DESC;
```

In some cases, MySQL *cannot* use indexes to resolve the `ORDER BY`, although it still uses indexes to find the rows that match the `WHERE` clause. These cases include the following:

- You use `ORDER BY` on different keys:

```
SELECT * FROM t1 ORDER BY key1, key2;
```

- You use `ORDER BY` on nonconsecutive parts of a key:

```
SELECT * FROM t1 WHERE key2=constant ORDER BY key_part2;
```

- You mix `ASC` and `DESC`:

```
SELECT * FROM t1 ORDER BY key_part1 DESC, key_part2 ASC;
```

- The key used to fetch the rows is not the same as the one used in the `ORDER BY`:

```
SELECT * FROM t1 WHERE key2=constant ORDER BY key1;
```

- You use `ORDER BY` with an expression that includes terms other than the key column name:

```
SELECT * FROM t1 ORDER BY ABS(key);
SELECT * FROM t1 ORDER BY -key;
```

- You are joining many tables, and the columns in the `ORDER BY` are not all from the first nonconstant table that is used to retrieve rows. (This is the first table in the `EXPLAIN` output that does not have a `const` join type.)
- You have different `ORDER BY` and `GROUP BY` expressions.
- You index only a prefix of a column named in the `ORDER BY` clause. In this case, the index cannot be used to fully resolve the sort order. For example, if you have a `CHAR(20)` column, but index only the first 10 bytes, the index cannot distinguish values past the 10th byte and a `filesort` will be needed.
- The type of table index used does not store rows in order. For example, this is true for a `HASH` index in a `MEMORY` table.

Availability of an index for sorting may be affected by the use of column aliases. Suppose that the column `t1.a` is indexed. In this statement, the name of the column in the select list is `a`. It refers to `t1.a`, so for the reference to `a` in the `ORDER BY`, the index can be used:

```
SELECT a FROM t1 ORDER BY a;
```

In this statement, the name of the column in the select list is also `a`, but it is the alias name. It refers to `ABS(a)`, so for the reference to `a` in the `ORDER BY`, the index cannot be used:

```
SELECT ABS(a) AS a FROM t1 ORDER BY a;
```

In the following statement, the `ORDER BY` refers to a name that is not the name of a column in the select list. But there is a column in `t1` named `a`, so the `ORDER BY` uses that, and the index can be used. (The resulting sort order may be completely different from the order for `ABS(a)`, of course.)

```
SELECT ABS(a) AS b FROM t1 ORDER BY a;
```

By default, MySQL sorts all `GROUP BY col1, col2, ...` queries as if you specified `ORDER BY col1, col2, ...` in the query as well. If you include an `ORDER BY` clause explicitly that contains the same column list, MySQL optimizes it away without any speed penalty, although the sorting still occurs. If a query includes `GROUP BY` but you want to avoid the overhead of sorting the result, you can suppress sorting by specifying `ORDER BY NULL`. For example:

```
INSERT INTO foo
SELECT a, COUNT(*) FROM bar GROUP BY a ORDER BY NULL;
```

With `EXPLAIN SELECT ... ORDER BY`, you can check whether MySQL can use indexes to resolve the query. It cannot if you see `Using filesort` in the `Extra` column. See [Section 7.2.1, “Optimizing Queries with EXPLAIN”](#).

MySQL has two `filesort` algorithms for sorting and retrieving results. The original method uses only the `ORDER BY` columns. The modified method uses not just the `ORDER BY` columns, but all the columns used in the query.

The optimizer selects which `filesort` algorithm to use. It normally uses the modified algorithm except when `BLOB` or `TEXT` columns are involved, in which case it uses the original algorithm.

The original `filesort` algorithm works as follows:

1. Read all rows according to key or by table scanning. Rows that do not match the `WHERE` clause are skipped.
2. For each row, store a pair of values in a buffer (the sort key and the row pointer). The size of the buffer is the value of the `sort_buffer_size` system variable.
3. When the buffer gets full, run a qsort (quicksort) on it and store the result in a temporary file. Save a pointer to the sorted block. (If all pairs fit into the sort buffer, no temporary file is created.)
4. Repeat the preceding steps until all rows have been read.
5. Do a multi-merge of up to `MERGEBUFF` (7) regions to one block in another temporary file. Repeat until all blocks from the first file are in the second file.
6. Repeat the following until there are fewer than `MERGEBUFF2` (15) blocks left.
7. On the last multi-merge, only the pointer to the row (the last part of the sort key) is written to a result file.
8. Read the rows in sorted order by using the row pointers in the result file. To optimize this, we read in a big block of row pointers, sort them, and use them to read the rows in sorted order into a row buffer. The size of the buffer is the value of the `read_rnd_buffer_size` system variable. The code for this step is in the `sql/records.cc` source file.

One problem with this approach is that it reads rows twice: One time when evaluating the `WHERE` clause, and again after sorting the pair values. And even if the rows were accessed successively the first time (for example, if a table scan is done), the second time they are accessed randomly. (The sort keys are ordered, but the row positions are not.)

The modified `filesort` algorithm incorporates an optimization such that it records not only the sort key value and row position, but also the columns required for the query. This avoids reading the rows twice. The modified `filesort` algorithm works like this:

1. Read the rows that match the `WHERE` clause.
2. For each row, record a tuple of values consisting of the sort key value and row position, and also the columns required for the query.
3. Sort the tuples by sort key value
4. Retrieve the rows in sorted order, but read the required columns directly from the sorted tuples rather than by accessing the table a second time.

Using the modified `filesort` algorithm, the tuples are longer than the pairs used in the original method, and fewer of them fit in the sort buffer (the size of which is given by `sort_buffer_size`). As a result, it is possible for the extra I/O to make the modified approach slower, not faster. To avoid a slowdown, the optimization is used only if the total size of the extra columns in the sort tuple does not exceed the value of the `max_length_for_sort_data` system variable. (A symptom of setting the value of this variable too high is that you should see high disk activity and low CPU activity.)

For slow queries for which `filesort` is not used, you might try lowering `max_length_for_sort_data` to a value that is

appropriate to trigger a `filesort`.

If you want to increase `ORDER BY` speed, check whether you can get MySQL to use indexes rather than an extra sorting phase. If this is not possible, you can try the following strategies:

- Increase the size of the `sort_buffer_size` variable.
- Increase the size of the `read_rnd_buffer_size` variable.
- Use less RAM per row by declaring columns only as large as they need to be to hold the values stored in them. For example, `CHAR(16)` is better than `CHAR(200)` if values never exceed 16 characters.
- Change `tmpdir` to point to a dedicated file system with large amounts of free space. Also, this option accepts several paths that are used in round-robin fashion, so you can use this feature to spread the load across several directories. Paths should be separated by colon characters (“`:`”) on Unix and semicolon characters (“`;`”) on Windows, NetWare, and OS/2. The paths should be for directories in file systems that are located on different *physical* disks, not different partitions on the same disk.

### 7.3.1.12. GROUP BY Optimization

The most general way to satisfy a `GROUP BY` clause is to scan the whole table and create a new temporary table where all rows from each group are consecutive, and then use this temporary table to discover groups and apply aggregate functions (if any). In some cases, MySQL is able to do much better than that and to avoid creation of temporary tables by using index access.

The most important preconditions for using indexes for `GROUP BY` are that all `GROUP BY` columns reference attributes from the same index, and that the index stores its keys in order (for example, this is a `BTREE` index and not a `HASH` index). Whether use of temporary tables can be replaced by index access also depends on which parts of an index are used in a query, the conditions specified for these parts, and the selected aggregate functions.

There are two ways to execute a `GROUP BY` query through index access, as detailed in the following sections. In the first method, the grouping operation is applied together with all range predicates (if any). The second method first performs a range scan, and then groups the resulting tuples.
