The command `EXIT SINGLE USER MODE` changes the state of the cluster's data nodes from single user mode to normal mode. API nodes—such as MySQL Servers—waiting for a connection (that is, waiting for the cluster to become ready and available), are again permitted to connect. The API node denoted as the single-user node continues to run (if still connected) during and after the state change.

Example:

```
ndb_mgm> EXIT SINGLE USER MODE
```

There are two recommended ways to handle a node failure when running in single user mode:

- Method 1:
  1. Finish all single user mode transactions
  2. Issue the `EXIT SINGLE USER MODE` command
  3. Restart the cluster's data nodes
- Method 2:

Restart database nodes prior to entering single user mode.

## 17.5.7. Quick Reference: MySQL Cluster SQL Statements

This section discusses several SQL statements that can prove useful in managing and monitoring a MySQL server that is connected to a MySQL Cluster, and in some cases provide information about the cluster itself.

- `SHOW ENGINE NDB STATUS, SHOW ENGINE NDBCLUSTER STATUS`

The output of this statement contains information about the server's connection to the cluster, creation and usage of MySQL Cluster objects, and binary logging for MySQL Cluster replication.

See [Section 12.4.5.16, “SHOW ENGINE Syntax”](#), for a usage example and more detailed information.

- `SHOW ENGINES`

This statement can be used to determine whether or not clustering support is enabled in the MySQL server, and if so, whether it is active.

See [Section 12.4.5.17, “SHOW ENGINES Syntax”](#), for more detailed information.

#### Note

In MySQL 5.1 and later, this statement does not support a `LIKE` clause. However, you can use `LIKE` to filter queries against the `INFORMATION_SCHEMA.ENGINES`, as discussed in the next item.

- `SELECT * FROM INFORMATION_SCHEMA.ENGINES [WHERE ENGINE LIKE 'NDB%']`

This is the equivalent of `SHOW ENGINES`, but uses the `ENGINES` table of the `INFORMATION_SCHEMA` database (available beginning with MySQL 5.1.5). Unlike the case with the `SHOW ENGINES` statement, it is possible to filter the results using a `LIKE` clause, and to select specific columns to obtain information that may be of use in scripts. For example, the following query shows whether the server was built with `NDB` support and, if so, whether it is enabled:

```
mysql> SELECT SUPPORT FROM INFORMATION_SCHEMA.ENGINES
 -> WHERE ENGINE LIKE 'NDB%';
+-----+
| support |
+-----+
| ENABLED |
+-----+
```

See [Section 20.18, “The INFORMATION\\_SCHEMA ENGINES Table”](#), for more information.

- `SHOW VARIABLES LIKE 'NDB%'`

This statement provides a list of most server system variables relating to the `NDB` storage engine, and their values, as shown here:

```
mysql> SHOW VARIABLES LIKE 'NDB%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| ndb_autoincrement_prefetch_sz | 32 |
| ndb_cache_check_time | 0 |
| ndb_extra_logging | 0 |
| ndb_force_send | ON |
| ndb_index_stat_cache_entries | 32 |
| ndb_index_stat_enable | OFF |
| ndb_index_stat_update_freq | 20 |
| ndb_report_thresh_binlog_epoch_slip | 3 |
| ndb_report_thresh_binlog_mem_usage | 10 |
| ndb_use_copying_alter_table | OFF |
| ndb_use_exact_count | ON |
| ndb_use_transactions | ON |
+-----+-----+
```

See [Section 5.1.4, “Server System Variables”](#), for more information.

- `SELECT * FROM INFORMATION_SCHEMA.GLOBAL_VARIABLES WHERE VARIABLE_NAME LIKE 'NDB%'`

This statement is the equivalent of the `SHOW` command described in the previous item, and provides almost identical output, as shown here:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.GLOBAL_VARIABLES
 -> WHERE VARIABLE_NAME LIKE 'NDB%';
+-----+-----+
| VARIABLE_NAME | VARIABLE_VALUE |
+-----+-----+
| NDB_AUTOINCREMENT_PREFETCH_SZ | 32 |
| NDB_CACHE_CHECK_TIME | 0 |
| NDB_EXTRA_LOGGING | 0 |
| NDB_FORCE_SEND | ON |
| NDB_INDEX_STAT_CACHE_ENTRIES | 32 |
| NDB_INDEX_STAT_ENABLE | OFF |
| NDB_INDEX_STAT_UPDATE_FREQ | 20 |
| NDB_REPORT_THRESH_BINLOG_EPOCH_SLIP | 3 |
| NDB_REPORT_THRESH_BINLOG_MEM_USAGE | 10 |
| NDB_USE_COPYING_ALTER_TABLE | OFF |
| NDB_USE_EXACT_COUNT | ON |
| NDB_USE_TRANSACTIONS | ON |
+-----+-----+
```

Unlike the case with the `SHOW` command, it is possible to select individual columns. For example:

```
mysql> SELECT VARIABLE_VALUE
 -> FROM INFORMATION_SCHEMA.GLOBAL_VARIABLES
 -> WHERE VARIABLE_NAME = 'ndb_force_send';
+-----+
| VARIABLE_VALUE |
+-----+
| ON |
+-----+
```

See [Section 20.25, “The INFORMATION\\_SCHEMA GLOBAL\\_VARIABLES and SESSION\\_VARIABLES Tables”](#), and [Section 5.1.4, “Server System Variables”](#), for more information.

- SHOW STATUS LIKE 'NDB%'

This statement shows at a glance whether or not the MySQL server is acting as a cluster SQL node, and if so, it provides the MySQL server's cluster node ID, the host name and port for the cluster management server to which it is connected, and the number of data nodes in the cluster, as shown here:

```
mysql> SHOW STATUS LIKE 'NDB%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Ndb_cluster_node_id | 10
| Ndb_config_from_host | 192.168.0.103
| Ndb_config_from_port | 1186
| Ndb_number_of_data_nodes | 4
+-----+-----+
```

If the MySQL server was built with clustering support, but it is not connected to a cluster, all rows in the output of this statement contain a zero or an empty string:

```
mysql> SHOW STATUS LIKE 'NDB%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Ndb_cluster_node_id | 0
| Ndb_config_from_host | 0
| Ndb_config_from_port | 0
| Ndb_number_of_data_nodes | 0
+-----+-----+
```

See also [Section 12.4.5.37, “SHOW STATUS Syntax”](#).

- SELECT \* FROM INFORMATION\_SCHEMA.GLOBAL\_STATUS WHERE VARIABLE\_NAME LIKE 'NDB%' ;

Beginning with MySQL 5.1.12, this statement provides similar output to the `SHOW` command discussed in the previous item. However, unlike the case with `SHOW STATUS`, it is possible using the `SELECT` to extract values in SQL for use in scripts for monitoring and automation purposes.

See [Section 20.24, “The INFORMATION\\_SCHEMA GLOBAL\\_STATUS and SESSION\\_STATUS Tables”](#), for more information.

Beginning with MySQL Cluster NDB 7.1.1, you can also query the tables in the `ndbinfo` information database for real-time data about many MySQL Cluster operations. See [Section 17.5.8, “The ndbinfo MySQL Cluster Information Database”](#).

## 17.5.8. The `ndbinfo` MySQL Cluster Information Database

`ndbinfo` is a database storing containing information specific to MySQL Cluster, available beginning with MySQL Cluster NDB 7.1.1.

This database contains a number of tables, each providing a different sort of data about MySQL Cluster node status, resource usage, and operations. You can find more detailed information about each of these tables in the next several sections.

`ndbinfo` is included with MySQL Cluster support in the MySQL Server; no special compilation or configuration steps are required; the tables are created by the MySQL Server when it connects to the cluster. You can verify that `ndbinfo` support is active in a given MySQL Server instance using `SHOW PLUGINS`; if `ndbinfo` support is enabled, you should see a row containing `ndbinfo` in the `Name` column and `ACTIVE` in the `Status` column, as shown here (emphasized text):

```
mysql> SHOW PLUGINS;
+-----+-----+-----+-----+-----+
| Name | Status | Type | Library | License |
+-----+-----+-----+-----+-----+
| binlog | ACTIVE | STORAGE ENGINE | NULL | GPL |
| partition | ACTIVE | STORAGE ENGINE | NULL | GPL |
| ARCHIVE | ACTIVE | STORAGE ENGINE | NULL | GPL |
| BLACKHOLE | ACTIVE | STORAGE ENGINE | NULL | GPL |
| CSV | ACTIVE | STORAGE ENGINE | NULL | GPL |
| FEDERATED | DISABLED | STORAGE ENGINE | NULL | GPL |
| MEMORY | ACTIVE | STORAGE ENGINE | NULL | GPL |
| InnoDB | ACTIVE | STORAGE ENGINE | NULL | GPL |
| MyISAM | ACTIVE | STORAGE ENGINE | NULL | GPL |
| MRG_MYISAM | ACTIVE | STORAGE ENGINE | NULL | GPL |
| ndbcluster | ACTIVE | STORAGE ENGINE | NULL | GPL |
| ndbinfo | ACTIVE | STORAGE ENGINE | NULL | GPL |
+-----+-----+-----+-----+-----+
12 rows in set (0.00 sec)
```

You can also do this by checking the output of `SHOW ENGINES` for a line including `ndbinfo` in the `Engine` column and `YES` in

the `Support` column, as shown here (emphasized text):

Engine	Support	Comment	Transactions	XA	Savepoint
ndbcluster	YES	Clustered, fault-tolerant tables	YES	NO	NO
MRG_MYISAM	YES	Collection of identical MyISAM tables	NO	NO	NO
ndbinfo	YES	MySQL Cluster system information storage engine	NO	NO	NO
CSV	YES	CSV storage engine	NO	NO	NO
MEMORY	YES	Hash based, stored in memory, useful for temporary tables	NO	NO	NO
FEDERATED	NO	Federated MySQL storage engine	NULL	NULL	NULL
ARCHIVE	YES	Archive storage engine	NO	NO	NO
InnoDB	YES	Supports transactions, row-level locking, and foreign keys	YES	YES	YES
MyISAM	DEFAULT	Default engine as of MySQL 3.23 with great performance	NO	NO	NO
BLACKHOLE	YES	/dev/null storage engine (anything you write to it disappears)	NO	NO	NO

10 rows in set (0.00 sec)

If `ndbinfo` support is enabled, then you can access `ndbinfo` using SQL statements in `mysql` or another MySQL client. For example, you can see `ndbinfo` listed in the output of `SHOW DATABASES`, as shown here:

Database
information_schema
mysql
ndbinfo
test

4 rows in set (0.00 sec)

If the `mysqld` process was not started with the `--ndbcluster` option, `ndbinfo` is not available and is not displayed by `SHOW DATABASES`. If `mysqld` was formerly connected to a MySQL Cluster but the cluster becomes unavailable (due to events such as cluster shutdown, loss of network connectivity, and so forth), `ndbinfo` and its tables remain visible, but an attempt to access any tables (other than `blocks` or `config_params`) fails with `GOT ERROR 157 'CONNECTION TO NDB FAILED' FROM ND-BINFO`.

### Note

With the exception of the `blocks` and `config_params` tables, what we refer to as `ndbinfo` “tables” are actually views generated from internal NDB tables not visible to the MySQL Server.

All `ndbinfo` tables are read-only.

You can select the `ndbinfo` database with a `USE` statement, and then issue a `SHOW TABLES` statement to obtain a list of tables, just as for any other database, like this:

Tables_in_ndbinfo
blocks
config_params
counters
logbuffers
logspaces
memoryusage
nodes
resources
transporters

9 rows in set (0.00 sec)

### Note

In early versions of MySQL Cluster NDB 7.1, there were 10 tables in the `ndbinfo` database; however, the `pools` table was removed in MySQL Cluster NDB 7.1.3. See [Section 17.5.8.8, “The ndbinfo pools Table”](#).

You can execute `SELECT` statements against these tables, just as you would normally expect:

node_id	DATA_MEMORY	used	max
1	DATA_MEMORY	3230	6408
2	DATA_MEMORY	3230	6408
1	INDEX_MEMORY	16	12832
2	INDEX_MEMORY	16	12832

```
4 rows in set (0.37 sec)
```

More complex queries are possible, as shown here:

```
mysql> SELECT SUM(used) as 'Data Memory Used, All Nodes'
 > FROM memoryusage
 > WHERE DATA_MEMORY = 'DATA_MEMORY';
+-----+
| Data Memory Used, All Nodes |
+-----+
| 6460 |
+-----+
1 row in set (0.37 sec)

mysql> SELECT SUM(max) as 'Total IndexMemory Available'
 > FROM memoryusage
 > WHERE DATA_MEMORY = 'INDEX_MEMORY';
+-----+
| Total IndexMemory Available |
+-----+
| 25664 |
+-----+
1 row in set (0.33 sec)
```

`ndbinfo` table and column names are case sensitive (as is the name of the `ndbinfo` database itself). These identifiers are in lower case. Trying to use the wrong lettercase results in an error, as shown in this example:

```
mysql> SELECT * FROM nodes;
+-----+-----+-----+-----+
| node_id | uptime | status | start_phase |
+-----+-----+-----+-----+
| 1 | 13602 | STARTED | 0 |
| 2 | 16 | STARTED | 0 |
+-----+-----+-----+-----+
2 rows in set (0.04 sec)

mysql> SELECT * FROM Nodes;
ERROR 1146 (42S02): TABLE 'NDBINFO.NODES' DOESN'T EXIST
```

### Important

Beginning with MySQL Cluster NDB 7.1.7, `mysqldump` ignores `ndbinfo` entirely, and excludes it from any output. This is true even when using the `--databases` or `--all-databases` option.

#### 17.5.8.1. The `ndbinfo blocks` Table

The `blocks` table is a static table which simply contains the names and internal IDs of all NDB kernel blocks (see [NDB Kernel Blocks](#)). It is for use by the other `ndbinfo` tables (most of which are actually views) in mapping block numbers to block names for producing human-readable output.

The following table provides information about the columns in the `blocks` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Column Name	Type	Remarks
<code>block_number</code>	integer	Block number
<code>block_name</code>	string	Block name

Although this is a static table, its content could possibly vary between different MySQL Cluster releases.

#### 17.5.8.2. The `ndbinfo config_params` Table

The `config_params` table is a static table which provides the names and internal ID numbers of all MySQL Cluster configuration parameters.

The following table provides information about the columns in the `config_params` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Column Name	Type	Remarks
<code>param_number</code>	integer	The parameter's internal ID number
<code>param_name</code>	string	The name of the parameter

Although this is a static table, its content can vary between MySQL Cluster installations, since supported parameters can vary due

to differences between software releases, cluster hardware configurations, and other factors.

### 17.5.8.3. The `ndbinfo counters` Table

The `counters` table provides running totals of events such as reads and writes for specific kernel blocks and data nodes. Counts are kept from the most recent node start or restart; a node start or restart resets all counters on that node. Not all kernel blocks have all types of counters.

The following table provides information about the columns in the `counters` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Column Name	Type	Remarks
<code>node_id</code>	integer	The data node ID
<code>block_name</code>	string	Name of the associated NDB kernel block (see <a href="#">NDB Kernel Blocks</a> ).
<code>block_instance</code>	integer	<u>REMARK</u>
<code>counter_id</code>	integer	The counter's internal ID number; normally an integer between 1 and 10, inclusive.
<code>counter_name</code>	string	The name (type) of the counter. See text for possible values.
<code>val</code>	integer	The counter's value

`counter_name` can be any one of the following: `ATTRINFO`, `TRANSACTIONS`, `COMMITS`, `READS`, `SIMPLE_READS`, `WRITES`, `ABORTS`, `TABLE_SCANS`, `RANGE_SCANS`, or `OPERATIONS`.

### 17.5.8.4. The `ndbinfo logbuffers` Table

The `logbuffer` table provides information on MySQL Cluster log buffer usage.

The following table provides information about the columns in the `logbuffers` table. For each column, the table shows the name, data type, and a brief description.

Column Name	Type	Remarks
<code>node_id</code>	integer	The ID of this data node.
<code>log_type</code>	string	Type of log; one of: <code>REDO</code> or <code>DD-UNDO</code> .
<code>log_id</code>	integer	The log ID.
<code>log_part</code>	integer	The log part number.
<code>total</code>	integer	Total space available for this log.
<code>used</code>	integer	Space used by this log.

### 17.5.8.5. The `ndbinfo logspaces` Table

This table provides information about MySQL Cluster log space usage.

The following table provides information about the columns in the `logspaces` table. For each column, the table shows the name, data type, and a brief description.

Column Name	Type	Remarks
<code>node_id</code>	integer	The ID of this data node.
<code>log_type</code>	string	Type of log; one of: <code>REDO</code> or <code>DD-UNDO</code> .
<code>log_id</code>	integer	The log ID.
<code>log_part</code>	integer	The log part number.
<code>total</code>	integer	Total space available for this log.
<code>used</code>	integer	Space used by this log.

### 17.5.8.6. The `ndbinfo memoryusage` Table

Querying this table provides information similar to that provided by the `ALL REPORT MemoryUsage` command in the `ndb_mgm` client, or logged by `ALL DUMP 1000`.

The following table provides information about the columns in the `memoryusage` table in MySQL Cluster NDB 7.1.3 and later. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Column Name	Type	Remarks
<code>node_id</code>	integer	The node ID of this data node.
<code>memory_type</code>	string	One of <code>DATA_MEMORY</code> or <code>INDEX_MEMORY</code> .
<code>used</code>	integer	Number of bytes currently used for data memory or index memory by this data node.
<code>used_pages</code>	integer	Number of pages currently used for data memory or index memory by this data node; see text.
<code>total</code>	integer	Total number of bytes of data memory or index memory available for this data node; see text.
<code>total_pages</code>	integer	Total number of memory pages available for data memory or index memory on this data node; see text.

The `total` column represents the total amount of memory in bytes available for the given resource (data memory or index memory) on a particular data node. This number should be approximately equal to the setting of the corresponding configuration parameter in the `config.ini` file.

For the `used_pages` and `total_pages` columns, resources are measured in pages, which are 32K in size for `DataMemory` and 8K for `IndexMemory`.

**MySQL Cluster NDB 7.1.2 and earlier.** The remainder of this section provides information about the `memoryusage` table as implemented prior to MySQL Cluster NDB 7.1.3. (If you are using MySQL Cluster NDB 7.1.3 or later, refer to the beginning of this section.) For each column, the table shown here provides the name, data type, and a brief description. Additional information can be found in the notes following the table.

Column Name	Type	Remarks
<code>node_id</code>	integer	The node ID of this data node.
<code>memory_type</code>	string	One of <code>DATA_MEMORY</code> or <code>INDEX_MEMORY</code>
<code>used</code>	integer	Number of memory pages used; see text.
<code>max</code>	integer	Total number of memory pages available; see text.

For the `used` and `max` columns, resources are measured in pages, which (in MySQL Cluster NDB 7.1.2 and earlier) are 16K in size for `DataMemory` and 8K for `IndexMemory`. This example shows how to use this information in obtaining totals for `DataMemory`, `IndexMemory`, or both, which you can do by summing across data nodes and table columns, like this:

```
mysql> USE ndbinfo;
Database changed
mysql> SET @IPAGE := 8 * 1024;
Query OK, 0 rows affected (0.03 sec)

mysql> SET @DPAGE := 2 * @IPAGE;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT
 -> @DPAGE * SUM(used) as 'Total DataMemory Used',
 -> @DPAGE * SUM(max) as 'Total DataMemory Available',
 -> @DPAGE * SUM(used) DIV COUNT(*) as 'Average DataMemory Used Per Node',
 -> @DPAGE * SUM(max) DIV COUNT(*) as 'Average DataMemory Available Per Node'
 -> FROM memoryusage WHERE memory_type = 'DATA_MEMORY'\G

1. row *****
 Total DataMemory Used: 106102784
 Total DataMemory Available: 209977344
 Average DataMemory Used Per Node: 53051392
 Average DataMemory Available Per Node: 104988672
1 row in set (0.34 sec)

mysql> SELECT
 -> @IPAGE * SUM(used) as 'Total IndexMemory Used',
 -> @IPAGE * SUM(max) as 'Total IndexMemory Available',
 -> @IPAGE * SUM(used) DIV COUNT(*) as 'Average IndexMemory Used Per Node',
 -> @IPAGE * SUM(max) DIV COUNT(*) as 'Average IndexMemory Available Per Node'
 -> FROM memoryusage WHERE memory_type = 'INDEX_MEMORY'\G

1. row *****
 Total IndexMemory Used: 376832
 Total IndexMemory Available: 210239488
 Average IndexMemory Used Per Node: 188416
```

```
Average IndexMemory Available Per Node: 105119744
1 row in set (0.33 sec)
```

(We use `DIV` rather than `/` in both queries so that the results in all of the output columns are integers.)

Prior to MySQL Cluster NDB 7.1.2, the `memory_type` column was named `DATA_MEMORY`. ([Bug#50926](#))

### 17.5.8.7. The `ndbinfo nodes` Table

This table contains information on the status of data nodes. For each data node that is running in the cluster, a corresponding row in this table provides the node's node ID, status, and uptime. For nodes that are starting, it also shows the current start phase.

The following table provides information about the columns in the `nodes` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Column Name	Type	Remarks
<code>node_id</code>	integer	The data node's unique node ID in the cluster.
<code>uptime</code>	integer	Time since the node was last started, in seconds.
<code>status</code>	string	Current status of the data node; see text for possible values.
<code>start_phase</code>	integer	If the data node is starting, the current start phase.

The `uptime` column shows the time in seconds that this node has been running since it was last started or restarted. This is a `BIGINT` value. This figure includes the time actually needed to start the node; in other words, this counter starts running the moment that `ndbd` or `ndbmttd` is first invoked; thus, even for a node that has not yet finished starting, `uptime` may show a non-zero value.

The `status` column shows the node's current status. This is one of: `NOTHING`, `CMVMI`, `STARTING`, `STARTED`, `SINGLEUSER`, `STOPPING_1`, `STOPPING_2`, `STOPPING_3`, or `STOPPING_4`. When the status is `STARTING`, you can see the current start phase in the `start_phase` column (see later in this section). `SINGLEUSER` is displayed in the `status` column for all data nodes when the cluster is in single user mode (see [Section 17.5.6, “MySQL Cluster Single User Mode”](#)). Seeing one of the `STOPPING` states does not necessarily mean that the node is shutting down but can mean rather that it is entering a new state; for example, if you put the cluster in single user mode, you can sometimes see data nodes report their state briefly as `STOPPING_2` before the status changes to `SINGLEUSER`.

The `start_phase` column uses the same range of values as those used in the output of the `ndb_mgm` client `node_id STATUS` command (see [Section 17.5.2, “Commands in the MySQL Cluster Management Client”](#)). If the node is not currently starting, then this column shows `0`. For a listing of MySQL Cluster start phases with descriptions, see [Section 17.5.1, “Summary of MySQL Cluster Start Phases”](#).

Nodes that are stopped are not accounted for in this table. Suppose that you have a MySQL Cluster with 2 data nodes (node IDs 1 and 2), and all nodes are running normally, then this table contains 2 rows, 1 for each data node:

```
mysql> USE ndbinfo;
Database changed
mysql> SELECT * FROM nodes;
+-----+-----+-----+-----+
| node_id | uptime | status | start_phase |
+-----+-----+-----+-----+
| 1 | 11776 | STARTED | 0 |
| 2 | 11761 | STARTED | 0 |
+-----+-----+-----+-----+
2 rows in set (0.04 sec)
```

If you shut down one of the nodes, only the node that is still running is reflected in the output of this `SELECT` statement, as shown here:

```
ndb_mgm> 2 STOP
Node 2: Node shutdown initiated
Node 2: Node shutdown completed.
Node 2 has shutdown.
```

```
mysql> SELECT * FROM nodes;
+-----+-----+-----+-----+
| node_id | uptime | status | start_phase |
+-----+-----+-----+-----+
| 1 | 11807 | STARTED | 0 |
+-----+-----+-----+-----+
1 row in set (0.02 sec)
```

### 17.5.8.8. The `ndbinfo pools` Table

## Important

This table was part of the original `ndbinfo` implementation, but was later removed (in MySQL Cluster NDB 7.1.3). The information in this section is now obsolete, and subject to removal in a future version of the documentation.

The `pools` table was originally intended to provide information about NDB memory pool usage, but was later removed.

For each column, this table shows the name, data type, and a brief description of each `ndbinfo.pools` column (as it appeared prior to MySQL Cluster NDB 7.1.3). Additional information can be found in the notes afterward.

Column Name	Type	Remarks
<code>node_id</code>	integer	The data node's node ID.
<code>block_name</code>	string	Name of the NDB kernel block using this pool.
<code>block_instance</code>	integer	Kernel block instance ID.
<code>pool_name</code>	string	The name of the pool.
<code>used</code>	integer	Amount of the pool in use.
<code>total</code>	integer	Total size of the pool.
<code>high</code>	integer	The maximum used from this pool (since the node was last started).
<code>entry_size</code>	integer	The size of each object, in bytes.
<code>param_name1</code>	string	Name of a configuration parameter associated with this pool (or <code>NULL</code> ); see text.
<code>param_name2</code>	string	Name of a configuration parameter associated with this pool (or <code>NULL</code> ); see text.
<code>param_name3</code>	string	Name of a configuration parameter associated with this pool (or <code>NULL</code> ); see text.
<code>param_name4</code>	string	Name of a configuration parameter associated with this pool (or <code>NULL</code> ); see text.

The columns `param_name1`, `param_name2`, `param_name3`, and `param_name4` contain names of configuration parameters that are associated with a given pool. If no parameters are associated with the pool, then all 4 of these columns are `NULL`. For pools that are associated with configuration parameters, these columns are not filled with non-`NULL` values in any particular order, as shown in this example:

```
mysql> SELECT
 -> DISTINCT(pool_name), block_name, param_name1, param_name2, param_name3, param_name4
 -> FROM ndbinfo.pools
 -> WHERE pool_name = 'Table';
+-----+-----+-----+-----+-----+-----+
| pool_name | block_name | param_name1 | param_name2 | param_name3 | param_name4 |
+-----+-----+-----+-----+-----+-----+
| Table | BACKUP | NULL | MaxNoOfTables | MaxNoOfOrderedIndexes | MaxNoOfUniqueHashIndexes |
| Table | SUMA | MaxNoOfTables | NULL | NULL | NULL |
+-----+-----+-----+-----+-----+-----+
2 rows in set (0.29 sec)
```

You can use a query such as the one shown here to generate a table showing the associations of pools, NDB kernel blocks, and (where applicable) configuration parameters:

```
SELECT
 DISTINCT(pool_name) as 'Pool',
 block_name as 'Block',
 IF(
 (param_name1 && param_name2 && param_name3 && param_name4) IS NULL,
 '[NONE]',
 REPLACE(
 TRIM(
 CONCAT(
 IFNULL(param_name1, ''),
 IFNULL(CONCAT(' ', param_name2), ''),
 IFNULL(CONCAT(' ', param_name3), ''),
 IFNULL(CONCAT(' ', param_name4), '')
)
), ' ', ''
)
) as 'Parameter(s)'
FROM pools ORDER BY pool_name;
```

You may also find the following stored procedure useful. It returns a list of pools associated with a given configuration parameter, along with the kernel blocks to which these pools belong. You can see here the statement used to create this stored procedure along

with sample output for some typical parameters:

```
mysql> DELIMITER |
mysql> CREATE PROCEDURE get_pools (p VARCHAR(50))
-> BEGIN
-> SELECT
-> DISTINCT(pool_name) as Pool,
-> block_name as Block
-> FROM ndbinfo.pools
-> WHERE p

### 17.5.8.9. The `ndbinfo resources` Table

This table provides information about data node resource availability and usage.

These resources are sometimes known as *super-pools*.

The following table provides information about the columns in the `resources` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Column Name	Type	Remarks
<code>node_id</code>	integer	The unique node ID of this data node.
<code>resource_name</code>	string	Name of the resource; see text.
<code>reserved</code>	integer	The amount reserved for this resource.
<code>used</code>	integer	The amount actually used by this resource.
<code>max</code>	integer	The maximum amount of this resource used, since the node was last started.

The `resource_name` can be one of `RESERVED`, `DISK_OPERATIONS`, `DISK_RECORDS`, `DATA_MEMORY`, `JOBBUFFER`, `FILE_BUFFERS`, or `TRANSPORTER_BUFFERS`.

### 17.5.8.10. The `ndbinfo transporters` Table

This table contains information about NDB transporters.

The following table provides information about the columns in the `transporters` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Column Name	Type	Remarks
<code>node_id</code>	integer	This data node's unique node ID in the cluster.
<code>remote_node_id</code>	integer	The remote data node's node ID.
<code>status</code>	string	Status of the connection.

For each running data node in the cluster, the `transporters` table displays a row showing the status of each of that node's connections with all nodes in the cluster, *including itself*. This information is shown in the table's `status` column, which can have any one of the following values: `CONNECTING`, `CONNECTED`, `DISCONNECTING`, or `DISCONNECTED`.

Connections to API and management nodes which are configured but not currently connected to the cluster are shown with status `DISCONNECTED`. Rows where the `node_id` is that of a data nodes which is not currently connected are not shown in this table. (This is similar omission of disconnected nodes in the `ndbinfo.nodes` table—see [Section 17.5.8.7, “The `ndbinfo.nodes` Table”](#), for more information).

Assume you have a 5-node cluster consisting of 2 data nodes, 2 SQL nodes, and 1 management node, as shown in the output of the `SHOW` command in the `ndb_mgm` client:

```
ndb_mgm> SHOW
Connected to Management Server at: localhost:1186
Cluster Configuration

[ndbd(NDB)] 2 node(s)
id=1 @10.100.10.1 (mysql-5.1.41 ndb-7.1.1, Nodegroup: 0, Master)
id=2 @10.100.10.2 (mysql-5.1.41 ndb-7.1.1, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)
id=10 @10.100.10.10 (mysql-5.1.41 ndb-7.1.1)

[mysqld(API)] 2 node(s)
id=20 @10.100.10.20 (mysql-5.1.41 ndb-7.1.1)
id=21 @10.100.10.21 (mysql-5.1.41 ndb-7.1.1)
```

There are 10 rows in the `transporters` table—5 for the first data node, and 5 for the second—assuming that all data nodes are running, as shown here:

```
mysql> SELECT * FROM transporters;
+-----+-----+-----+
| node_id | remote_node_id | status |
+-----+-----+-----+
| 1 | 1 | CONNECTED |
| 1 | 2 | CONNECTED |
| 1 | 10 | CONNECTED |
| 1 | 20 | CONNECTED |
| 1 | 21 | CONNECTED |
| 2 | 1 | CONNECTED |
| 2 | 2 | CONNECTED |
| 2 | 10 | CONNECTED |
| 2 | 20 | CONNECTED |
| 2 | 21 | CONNECTED |
+-----+-----+-----+
10 rows in set (0.04 sec)
```

If you shut down one of the data nodes in this cluster using the `ndb_mgm` client `STOP` command, then repeat the query, this table now shows only 5 rows—one row for each connection from the remaining data node to another node, including both itself and the data node that is currently offline, as shown here:

```
mysql> SELECT * FROM transporters;
+-----+-----+-----+
| node_id | remote_node_id | status |
+-----+-----+-----+
| 1 | 1 | CONNECTED |
| 1 | 2 | CONNECTED |
| 1 | 10 | CONNECTED |
| 1 | 20 | CONNECTED |
| 1 | 21 | CONNECTED |
+-----+-----+-----+
5 rows in set (0.02 sec)
```

## 17.5.9. MySQL Cluster Security Issues

This section discusses security considerations to take into account when setting up and running MySQL Cluster.

Topics to be covered in this chapter include the following:

- MySQL Cluster and network security issues

- Configuration issues relating to running MySQL Cluster securely
- MySQL Cluster and the MySQL privilege system
- MySQL standard security procedures as applicable to MySQL Cluster

### 17.5.9.1. MySQL Cluster Security and Networking Issues

In this section, we discuss basic network security issues as they relate to MySQL Cluster. It is extremely important to remember that MySQL Cluster “out of the box” is not secure; you or your network administrator must take the proper steps to ensure that your cluster cannot be compromised over the network.

Cluster communication protocols are inherently insecure, and no encryption or similar security measures are used in communications between nodes in the cluster. Because network speed and latency have a direct impact on the cluster’s efficiency, it is also not advisable to employ SSL or other encryption to network connections between nodes, as such schemes will effectively slow communications.

It is also true that no authentication is used for controlling API node access to a MySQL Cluster. As with encryption, the overhead of imposing authentication requirements would have an adverse impact on Cluster performance.

In addition, there is no checking of the source IP address for either of the following when accessing the cluster:

- SQL or API nodes using “free slots” created by empty [`mysqld`] or [`api`] sections in the `config.ini` file

This means that, if there are any empty [`mysqld`] or [`api`] sections in the `config.ini` file, then any API nodes (including SQL nodes) that know the management server’s host name (or IP address) and port can connect to the cluster and access its data without restriction. (See [Section 17.5.9.2, “MySQL Cluster and MySQL Privileges”](#), for more information about this and related issues.)

#### Note

You can exercise some control over SQL and API node access to the cluster by specifying a `HostName` parameter for all [`mysqld`] and [`api`] sections in the `config.ini` file. However, this also means that, should you wish to connect an API node to the cluster from a previously unused host, you need to add an [`api`] section containing its host name to the `config.ini` file.

More information is available [elsewhere in this chapter](#) about the `HostName` parameter. Also see [Section 17.3.1, “Quick Test Setup of MySQL Cluster”](#), for configuration examples using `HostName` with API nodes.

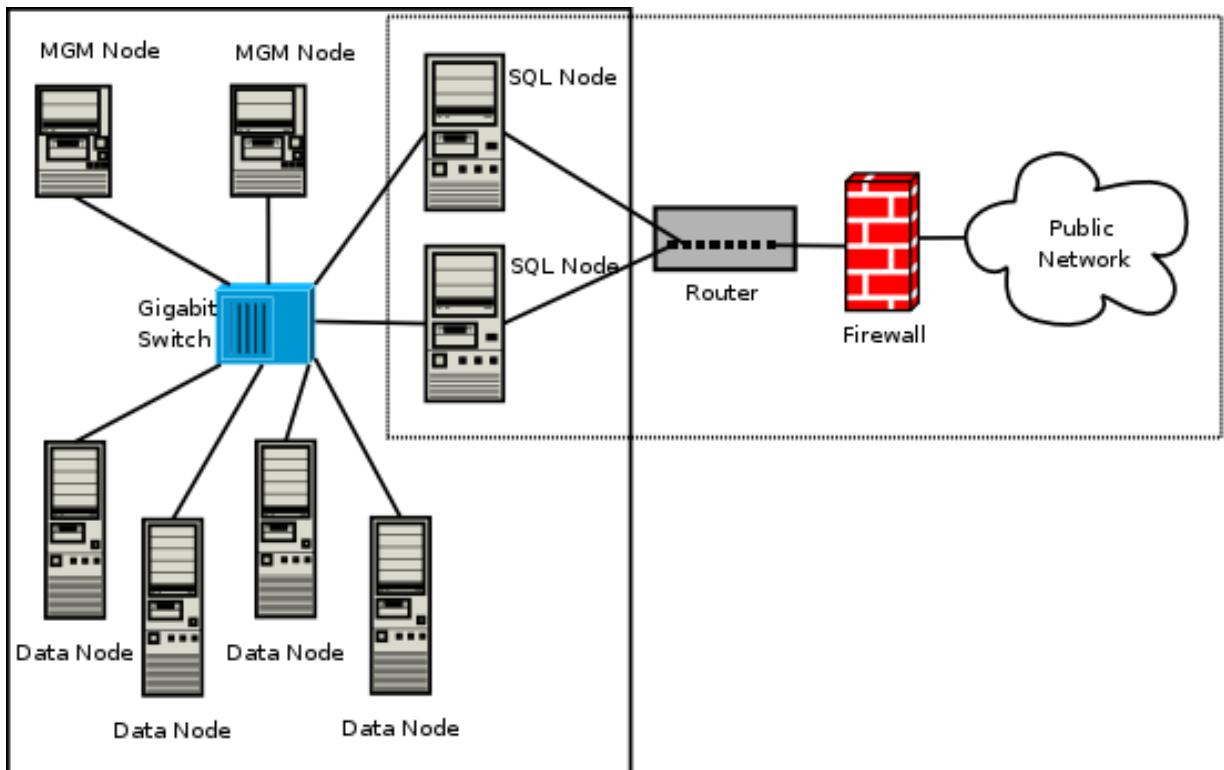

- Any `ndb_mgm` client

This means that any cluster management client that is given the management server’s host name (or IP address) and port (if not the standard port) can connect to the cluster and execute any management client command. This includes commands such as `ALL STOP` and `SHUTDOWN`.

For these reasons, it is necessary to protect the cluster on the network level. The safest network configuration for Cluster is one which isolates connections between Cluster nodes from any other network communications. This can be accomplished by any of the following methods:

1. Keeping Cluster nodes on a network that is physically separate from any public networks. This option is the most dependable; however, it is the most expensive to implement.

We show an example of a MySQL Cluster setup using such a physically segregated network here:

This setup has two networks, one private (solid box) for the Cluster management servers and data nodes, and one public (dotted box) where the SQL nodes reside. (We show the management and data nodes connected using a gigabit switch since this provides the best performance.) Both networks are protected from the outside by a hardware firewall, sometimes also known as a *network-based firewall*.

This network setup is safest because no packets can reach the cluster's management or data nodes from outside the network—and none of the cluster's internal communications can reach the outside—without going through the SQL nodes, as long as the SQL nodes do not permit any packets to be forwarded. This means, of course, that all SQL nodes must be secured against hacking attempts.

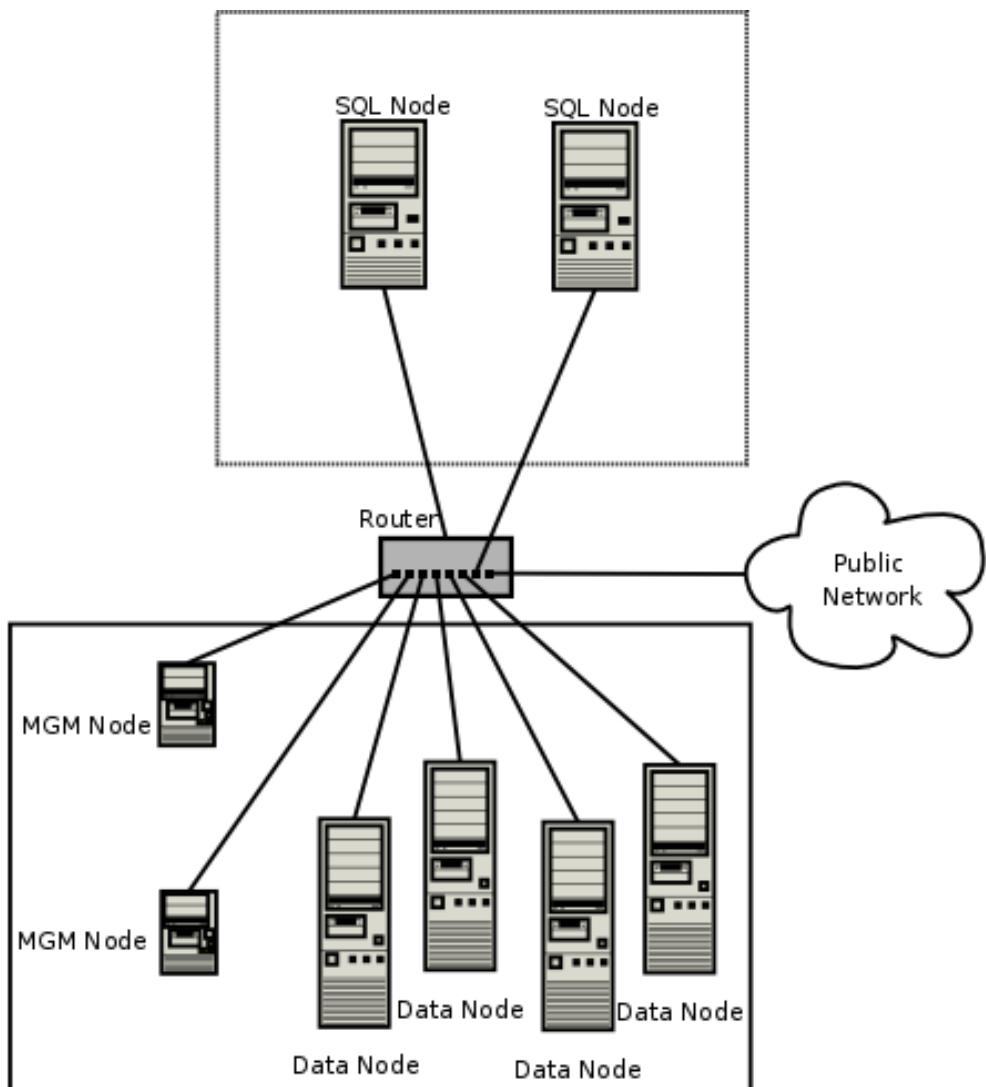

### Important

With regard to potential security vulnerabilities, an SQL node is no different from any other MySQL server. See [Section 5.3.3, “Making MySQL Secure Against Attackers”](#), for a description of techniques you can use to secure MySQL servers.

2. Using one or more software firewalls (also known as *host-based firewalls*) to control which packets pass through to the cluster from portions of the network that do not require access to it. In this type of setup, a software firewall must be installed on every host in the cluster which might otherwise be accessible from outside the local network.

The host-based option is the least expensive to implement, but relies purely on software to provide protection and so is the most difficult to keep secure.

This type of network setup for MySQL Cluster is illustrated here:

Using this type of network setup means that there are two zones of MySQL Cluster hosts. Each cluster host must be able to communicate with all of the other machines in the cluster, but only those hosting SQL nodes (dotted box) can be permitted to have any contact with the outside, while those in the zone containing the data nodes and management nodes (solid box) must be isolated from any machines that are not part of the cluster. Applications using the cluster and user of those applications must *not* be permitted to have direct access to the management and data node hosts.

To accomplish this, you must set up software firewalls that limit the traffic to the type or types shown in the following table, according to the type of node that is running on each cluster host computer:

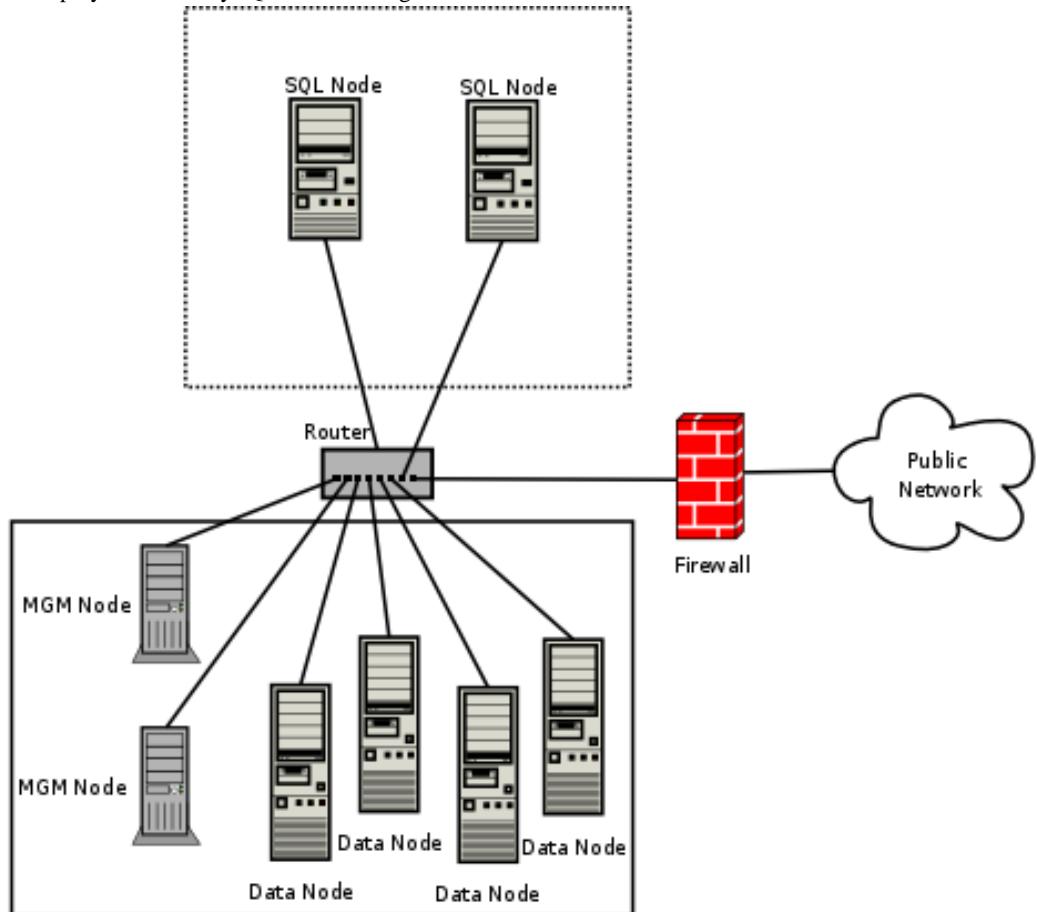

Type of Node to be Accessed	Traffic to Permit
SQL or API node	<ul style="list-style-type: none"> <li>It originates from the IP address of a management or data node (using any TCP or UDP port).</li> <li>It originates from within the network in which the cluster resides and is on the port that your application is using.</li> </ul>
Data node or Management node	<ul style="list-style-type: none"> <li>It originates from the IP address of a management or data node (using any TCP or UDP port).</li> <li>It originates from the IP address of an SQL or API node.</li> </ul>

Any traffic other than that shown in the table for a given node type should be denied.

The specifics of configuring a firewall vary from firewall application to firewall application, and are beyond the scope of this Manual. [iptables](#) is a very common and reliable firewall application, which is often used with [APF](#) as a front end to make configuration easier. You can (and should) consult the documentation for the software firewall that you employ, should you choose to implement a MySQL Cluster network setup of this type, or of a “mixed” type as discussed under the next item.

3. It is also possible to employ a combination of the first two methods, using both hardware and software to secure the cluster—that is, using both network-based and host-based firewalls. This is between the first two schemes in terms of both security level and cost. This type of network setup keeps the cluster behind the hardware firewall, but permits incoming packets to travel beyond the router connecting all cluster hosts to reach the SQL nodes.

One possible network deployment of a MySQL Cluster using hardware and software firewalls in combination is shown here:

In this case, you can set the rules in the hardware firewall to deny any external traffic except to SQL nodes and API nodes, and then permit traffic to them only on the ports required by your application.

Whatever network configuration you use, remember that your objective from the viewpoint of keeping the cluster secure remains the same—to prevent any unessential traffic from reaching the cluster while ensuring the most efficient communication between the nodes in the cluster.

Because MySQL Cluster requires large numbers of ports to be open for communications between nodes, the recommended option is to use a segregated network. This represents the simplest way to prevent unwanted traffic from reaching the cluster.

#### Note

If you wish to administer a MySQL Cluster remotely (that is, from outside the local network), the recommended way to do this is to use `ssh` or another secure login shell to access an SQL node host. From this host, you can then run the management client to access the management server safely, from within the Cluster's own local network.

Even though it is possible to do so in theory, it is *not* recommended to use `ndb_mgm` to manage a Cluster directly from outside the local network on which the Cluster is running. Since neither authentication nor encryption takes place between the management client and the management server, this represents an extremely insecure means of managing the cluster, and is almost certain to be compromised sooner or later.

### 17.5.9.2. MySQL Cluster and MySQL Privileges

In this section, we discuss how the MySQL privilege system works in relation to MySQL Cluster and the implications of this for keeping a MySQL Cluster secure.

Standard MySQL privileges apply to MySQL Cluster tables. This includes all MySQL privilege types (`SELECT` privilege, `UPDATE` privilege, `DELETE` privilege, and so on) granted on the database, table, and column level. As with any other MySQL Server, user and privilege information is stored in the `mysql` system database. The SQL statements used to grant and revoke privileges on

**NDB** tables, databases containing such tables, and columns within such tables are identical in all respects with the `GRANT` and `REVOKE` statements used in connection with database objects involving any (other) MySQL storage engine. The same thing is true with respect to the `CREATE USER` and `DROP USER` statements.

It is important to keep in mind that the MySQL grant tables use the `MyISAM` storage engine. Because of this, those tables are not duplicated or shared among MySQL servers acting as SQL nodes in a MySQL Cluster. By way of example, suppose that two SQL nodes **A** and **B** are connected to the same MySQL Cluster, which has an **NDB** table named `mytable` in a database named `mydb`, and that you execute an SQL statement on server **A** that creates a new user `jon@localhost` and grants this user the `SELECT` privilege on that table:

```
mysql> GRANT SELECT ON mydb.mytable
-> TO jon@localhost IDENTIFIED BY 'mypass';
```

This user is *not* created on server **B**. For this to take place, the statement must also be run on server **B**. Similarly, statements run on server **A** and affecting the privileges of existing users on server **A** do not affect users on server **B** unless those statements are actually run on server **B** as well.

In other words, *changes in users and their privileges do not automatically propagate between SQL nodes*. Synchronization of privileges between SQL nodes must be done either manually or by scripting an application that periodically synchronizes the privilege tables on all SQL nodes in the cluster.

Conversely, because there is no way in MySQL to deny privileges (privileges can either be revoked or not granted in the first place, but not denied as such), there is no special protection for **NDB** tables on one SQL node from users that have privileges on another SQL node. The most far-reaching example of this is the MySQL `root` account, which can perform any action on any database object. In combination with empty `[mysqld]` or `[api]` sections of the `config.ini` file, this account can be especially dangerous. To understand why, consider the following scenario:

- The `config.ini` file contains at least one empty `[mysqld]` or `[api]` section. This means that the Cluster management server performs no checking of the host from which a MySQL Server (or other API node) accesses the MySQL Cluster.
- There is no firewall, or the firewall fails to protect against access to the Cluster from hosts external to the network.
- The host name or IP address of the Cluster's management server is known or can be determined from outside the network.

If these conditions are true, then anyone, anywhere can start a MySQL Server with `--ndbcluster -ndb-connectstring=management_host` and access the Cluster. Using the MySQL `root` account, this person can then perform the following actions:

- Execute a `SHOW DATABASES` statement to obtain a list of all databases that exist in the cluster
- Execute a `SHOW TABLES FROM some_database` statement to obtain a list of all **NDB** tables in a given database
- Run any legal MySQL statements on any of those tables, such as:
  - `SELECT * FROM some_table` to read all the data from any table
  - `DELETE FROM some_table` to delete all the data from a table
  - `DESCRIBE some_table` or `SHOW CREATE TABLE some_table` to determine the table schema
  - `UPDATE some_table SET column1 = any_value1` to fill a table column with “garbage” data; this could actually cause much greater damage than simply deleting all the data

Even more insidious variations might include statements like these:

```
UPDATE some_table SET an_int_column = an_int_column + 1
```

or

```
UPDATE some_table SET a_varchar_column = REVERSE(a_varchar_column)
```

Such malicious statements are limited only by the imagination of the attacker.

The only tables that would be safe from this sort of mayhem would be those tables that were created using storage engines other than **NDB**, and so not visible to a “rogue” SQL node.

## Note

A user who can log in as `root` can also access the `INFORMATION_SCHEMA` database and its tables, and so obtain information about databases, tables, stored routines, scheduled events, and any other database objects for which metadata is stored in `INFORMATION_SCHEMA`.

It is also a very good idea to use different passwords for the `root` accounts on different cluster SQL nodes.

In sum, you cannot have a safe MySQL Cluster if it is directly accessible from outside your local network.

### Important

*Never leave the MySQL root account password empty.* This is just as true when running MySQL as a MySQL Cluster SQL node as it is when running it as a standalone (non-Cluster) MySQL Server, and should be done as part of the MySQL installation process before configuring the MySQL Server as an SQL node in a MySQL Cluster.

You should never convert the system tables in the `mysql` database to use the `NDB` storage engine. There are a number of reasons why you should not do this, but the most important reason is this: *Many of the SQL statements that affect `mysql` tables storing information about user privileges, stored routines, scheduled events, and other database objects cease to function if these tables are changed to use any storage engine other than MyISAM.* This is a consequence of various MySQL Server internals which are not expected to change in the foreseeable future.

If you need to synchronize `mysql` system tables between SQL nodes, you can use standard MySQL replication to do so, or employ a script to copy table entries between the MySQL servers.

**Summary.** The two most important points to remember regarding the MySQL privilege system with regard to MySQL Cluster are:

1. Users and privileges established on one SQL node do not automatically exist or take effect on other SQL nodes in the cluster.

Conversely, removing a user or privilege on one SQL node in the cluster does not remove the user or privilege from any other SQL nodes.

2. Once a MySQL user is granted privileges on an `NDB` table from one SQL node in a MySQL Cluster, that user can “see” any data in that table regardless of the SQL node from which the data originated.

### 17.5.9.3. MySQL Cluster and MySQL Security Procedures

In this section, we discuss MySQL standard security procedures as they apply to running MySQL Cluster.

In general, any standard procedure for running MySQL securely also applies to running a MySQL Server as part of a MySQL Cluster. First and foremost, you should always run a MySQL Server as the `mysql` system user; this is no different from running MySQL in a standard (non-Cluster) environment. The `mysql` system account should be uniquely and clearly defined. Fortunately, this is the default behavior for a new MySQL installation. You can verify that the `mysqld` process is running as the system user `mysql` by using the system command such as the one shown here:

```
shell> ps aux | grep mysql
root 10467 0.0 0.1 3616 1380 pts/3 S 11:53 0:00 \
/bin/sh ./mysqld_safe --ndbcluster --ndb-connectstring=localhost:1186
mysql 10512 0.2 2.5 58528 26636 pts/3 Sl 11:53 0:00 \
/usr/local/mysql/libexec/mysqld --basedir=/usr/local/mysql \
--datadir=/usr/local/mysql/var --user=mysql --ndbcluster \
--ndb-connectstring=localhost:1186 --pid-file=/usr/local/mysql/var/mothra.pid \
--log-error=/usr/local/mysql/var/mothra.err
jon 10579 0.0 0.0 2736 688 pts/0 S+ 11:54 0:00 grep mysql
```

If the `mysqld` process is running as any other user than `mysql`, you should immediately shut it down and restart it as the `mysql` user. If this user does not exist on the system, the `mysql` user account should be created, and this user should be part of the `mysql` user group; in this case, you should also make sure that the MySQL `DataDir` on this system is owned by the `mysql` user, and that the SQL node's `my.cnf` file includes `user=mysql` in the `[mysqld]` section. Alternatively, you can start the server with `-user=mysql` on the command line, but it is preferable to use the `my.cnf` option, since you might forget to use the command-line option and so have `mysqld` running as another user unintentionally. The `mysqld_safe` startup script forces MySQL to run as the `mysql` user.

### Important

Never run `mysqld` as the system root user. Doing so means that potentially any file on the system can be read by MySQL, and thus—should MySQL be compromised—by an attacker.

As mentioned in the previous section (see [Section 17.5.9.2, “MySQL Cluster and MySQL Privileges”](#)), you should always set a root password for the MySQL Server as soon as you have it running. You should also delete the anonymous user account that is installed by default. You can accomplish these tasks using the following statements:

```
shell> mysql -u root
mysql> UPDATE mysql.user
-> SET Password=PASSWORD('secure_password')
-> WHERE User='root';

mysql> DELETE FROM mysql.user
-> WHERE User='';
```

```
mysql> FLUSH PRIVILEGES;
```

Be very careful when executing the `DELETE` statement not to omit the `WHERE` clause, or you risk deleting *all* MySQL users. Be sure to run the `FLUSH PRIVILEGES` statement as soon as you have modified the `mysql.user` table, so that the changes take immediate effect. Without `FLUSH PRIVILEGES`, the changes do not take effect until the next time that the server is restarted.

#### Note

Many of the MySQL Cluster utilities such as `ndb_show_tables`, `ndb_desc`, and `ndb_select_all` also work without authentication and can reveal table names, schemas, and data. By default these are installed on Unix-style systems with the permissions `wxr-xr-x` (755), which means they can be executed by any user that can access the `mysql/bin` directory.

See [Section 17.4, “MySQL Cluster Programs”](#), for more information about these utilities.

## 17.5.10. MySQL Cluster Disk Data Tables

Beginning with MySQL 5.1.6, it is possible to store the nonindexed columns of `NDB` tables on disk, rather than in RAM as with previous versions of MySQL Cluster.

As part of implementing MySQL Cluster Disk Data work, a number of improvements were made in MySQL Cluster for the efficient handling of very large amounts (terabytes) of data during node recovery and restart. These include a “no-steal” algorithm for synchronising a starting node with very large data sets. For more information, see the paper [Recovery Principles of MySQL Cluster 5.1](#), by MySQL Cluster developers Mikael Ronström and Jonas Oreland.

MySQL Cluster Disk Data performance can be influenced by a number of configuration parameters. For information about these parameters and their effects, see [MySQL Cluster Disk Data configuration parameters](#) and [MySQL Cluster Disk Data storage and GCP STOP errors](#)

The performance of a MySQL Cluster that uses Disk Data storage can also be greatly improved by separating data node file systems from undo log files and tablespace data files, which can be done using symbolic links. For more information, see [Section 17.5.10.2, “Using Symbolic Links with Disk Data Objects”](#).

### 17.5.10.1. MySQL Cluster Disk Data Objects

MySQL Cluster Disk Data storage is implemented using a number of *Disk Data objects*. These include the following:

- *Tablespaces* act as containers for other Disk Data objects.
- *Undo log files* undo information required for rolling back transactions.
- One or more undo log files are assigned to a *log file group*, which is then assigned to a tablespace.
- *Data files* store Disk Data table data. A data file is assigned directly to a tablespace.

Undo log files and data files are actual files in the filesystem of each data node; by default they are placed in `ndb_node_id_fs` in the `DataDir` specified in the MySQL Cluster `config.ini` file, and where `node_id` is the data node's node ID. It is possible to place these elsewhere by specifying either an absolute or relative path as part of the filename when creating the undo log or data file. Statements that create these files are shown later in this section.

MySQL Cluster tablespaces and log file groups are not implemented as files.

#### Important

Although not all Disk Data objects are implemented as files, they all share the same namespace. This means that *each Disk Data object* must be uniquely named (and not merely each Disk Data object of a given type). For example, you cannot have a tablespace and a log file group both named `dd1`.

Assuming that you have already set up a MySQL Cluster with all nodes (including management and SQL nodes) running MySQL 5.1.6 or newer, the basic steps for creating a Cluster table on disk are as follows:

1. Create a log file group, and assign one or more undo log files to it (an undo log file is also sometimes referred to as an *undofile*).

#### Note

In MySQL 5.1 and later, undo log files are necessary only for Disk Data tables. They are no longer used for `NDB-`

- `CLUSTER` tables that are stored only in memory.
2. Create a tablespace; assign the log file group, as well as one or more data files, to the tablespace.
  3. Create a Disk Data table that uses this tablespace for data storage.

Each of these tasks can be accomplished using SQL statements in the `mysql` client or other MySQL client application, as shown in the example that follows.

1. We create a log file group named `lg_1` using `CREATE LOGFILE GROUP`. This log file group is to be made up of two undo log files, which we name `undo_1.log` and `undo_2.log`, whose initial sizes are 16 MB and 12 MB, respectively. (The default initial size for an undo log file is 128 MB.) Optionally, you can also specify a size for the log file group's undo buffer, or permit it to assume the default value of 8 MB. In this example, we set the UNDO buffer's size at 2 MB. A log file group must be created with an undo log file; so we add `undo_1.log` to `lg_1` in this `CREATE LOGFILE GROUP` statement:

```
CREATE LOGFILE GROUP lg_1
 ADD UNDOFILE 'undo_1.log'
 INITIAL_SIZE 16M
 UNDO_BUFFER_SIZE 2M
 ENGINE NDBCLUSTER;
```

To add `undo_2.log` to the log file group, use the following `ALTER LOGFILE GROUP` statement:

```
ALTER LOGFILE GROUP lg_1
 ADD UNDOFILE 'undo_2.log'
 INITIAL_SIZE 12M
 ENGINE NDBCLUSTER;
```

Some items of note:

- The `.log` file extension used here is not required. We use it merely to make the log files easily recognisable.
- Every `CREATE LOGFILE GROUP` and `ALTER LOGFILE GROUP` statement must include an `ENGINE` clause. In MySQL 5.1 (including MySQL Cluster NDB 6.X and 7.X through 7.1), the permitted values for this clause are `NDB-CLUSTER` and `NDB`.

## Important

In MySQL 5.1.8 and later, there can exist only one log file group in the same MySQL Cluster at any given time.

- When you add an undo log file to a log file group using `ADD UNDOFILE 'filename'`, a file with the name `filename` is created in the `ndb_node_id_fs` directory within the `DataDir` of each data node in the cluster, where `node_id` is the node ID of the data node. Each undo log file is of the size specified in the SQL statement. For example, if a MySQL Cluster has 4 data nodes, then the `ALTER LOGFILE GROUP` statement just shown creates 4 undo log files, 1 each on in the data directory of each of the 4 data nodes; each of these files is named `undo_2.log` and each file is 12 MB in size.
- `UNDO_BUFFER_SIZE` is limited by the amount of system memory available.
- For more information about the `CREATE LOGFILE GROUP` statement, see [Section 12.1.14, “CREATE LOGFILE GROUP Syntax”](#). For more information about `ALTER LOGFILE GROUP`, see [Section 12.1.3, “ALTER LOGFILE GROUP Syntax”](#).

2. Now we can create a tablespace, which contains files to be used by MySQL Cluster Disk Data tables for storing their data. A tablespace is also associated with a particular log file group. When creating a new tablespace, you must specify the log file group which it is to use for undo logging; you must also specify a data file. You can add more data files to the tablespace after the tablespace is created; it is also possible to drop data files from a tablespace (an example of dropping data files is provided later in this section).

Assume that we wish to create a tablespace named `ts_1` which uses `lg_1` as its log file group. This tablespace is to contain two data files named `data_1.dat` and `data_2.dat`, whose initial sizes are 32 MB and 48 MB, respectively. (The default value for `INITIAL_SIZE` is 128 MB.) We can do this using two SQL statements, as shown here:

```
CREATE TABLESPACE ts_1
 ADD DATAFILE 'data_1.dat'
 USE LOGFILE GROUP lg_1
 INITIAL_SIZE 32M
 ENGINE NDBCLUSTER;

ALTER TABLESPACE ts_1
```

```
ADD DATAFILE 'data_2.dat'
INITIAL_SIZE 48M
ENGINE NDBCLUSTER;
```

The `CREATE TABLESPACE` statement creates a tablespace `ts_1` with the data file `data_1.dat`, and associates `ts_1` with log file group `lg_1`. The `ALTER TABLESPACE` adds the second data file (`data_2.dat`).

Some items of note:

- As is the case with the `.log` file extension used in this example for undo log files, there is no special significance for the `.dat` file extension; it is used merely for easy recognition of data files.
- When you add a data file to a tablespace using `ADD DATAFILE 'filename'`, a file with the name `filename` is created in the `ndb_node_id_fs` directory within the `DataDir` of each data node in the cluster, where `node_id` is the node ID of the data node. Each undo log file is of the size specified in the SQL statement. For example, if a MySQL Cluster has 4 data nodes, then the `ALTER TABLESPACE` statement just shown creates 4 undo log files, 1 each on in the data directory of each of the 4 data nodes; each of these files is named `data_2.dat` and each file is 48 MB in size.
- All `CREATE TABLESPACE` and `ALTER TABLESPACE` statements must contain an `ENGINE` clause; only tables using the same storage engine as the tablespace can be created in the tablespace. In MySQL 5.1 (including MySQL Cluster NDB 6.X and 7.X through 7.1), the only permitted values for this clause are `NDBCLUSTER` and `NDB`.
- For more information about the `CREATE TABLESPACE` and `ALTER TABLESPACE` statements, see [Section 12.1.18, “CREATE TABLESPACE Syntax”](#), and [Section 12.1.8, “ALTER TABLESPACE Syntax”](#).

3.

Now it is possible to create a table whose nonindexed columns are stored on disk in the tablespace `ts_1`:

```
CREATE TABLE dt_1 (
 member_id INT UNSIGNED NOT NULL AUTO_INCREMENT PRIMARY KEY,
 last_name VARCHAR(50) NOT NULL,
 first_name VARCHAR(50) NOT NULL,
 dob DATE NOT NULL,
 joined DATE NOT NULL,
 INDEX(last_name, first_name)
)
TABLESPACE ts_1 STORAGE DISK
ENGINE NDBCLUSTER;
```

The `TABLESPACE ... STORAGE DISK` option tells the `NDBCLUSTER` storage engine to use tablespace `ts_1` for disk data storage.

### Note

Beginning with MySQL Cluster NDB 6.2.5 and MySQL Cluster NDB 6.3.2, it is also possible to specify whether an individual column is stored on disk or in memory by using a `STORAGE` clause as part of the column's definition in a `CREATE TABLE` or `ALTER TABLE` statement. `STORAGE DISK` causes the column to be stored on disk, and `STORAGE MEMORY` causes in-memory storage to be used. See [Section 12.1.17, “CREATE TABLE Syntax”](#), for more information.

Once table `ts_1` has been created as shown, you can perform `INSERT`, `SELECT`, `UPDATE`, and `DELETE` statements on it just as you would with any other MySQL table.

For table `dt_1` as it has been defined here, only the `dob` and `joined` columns are stored on disk. This is because there are indexes on the `id`, `last_name`, and `first_name` columns, and so data belonging to these columns is stored in RAM. In MySQL 5.1 (including MySQL Cluster NDB 6.X and 7.X through 7.1), only nonindexed columns can be held on disk; indexes and indexed column data continue to be stored in memory. This tradeoff between the use of indexes and conservation of RAM is something you must keep in mind as you design Disk Data tables.

**Performance note.** The performance of a cluster using Disk Data storage is greatly improved if Disk Data files are kept on a separate physical disk from the data node file system. This must be done for each data node in the cluster to derive any noticeable benefit.

You may use absolute and relative file system paths with `ADD UNDOFILE` and `ADD DATAFILE`. Relative paths are calculated relative to the data node's data directory. You may also use symbolic links; see [Section 17.5.10.2, “Using Symbolic Links with Disk Data Objects”](#), for more information and examples.

A log file group, a tablespace, and any Disk Data tables using these must be created in a particular order. The same is true for dropping any of these objects:

- A log file group cannot be dropped as long as any tablespaces are using it.
- A tablespace cannot be dropped as long as it contains any data files.
- You cannot drop any data files from a tablespace as long as there remain any tables which are using the tablespace.
- Beginning with MySQL 5.1.12, it is no longer possible to drop files created in association with a different tablespace than the one with which the files were created. ([Bug#20053](#))

For example, to drop all the objects created so far in this section, you would use the following statements:

```
mysql> DROP TABLE dt_1;
mysql> ALTER TABLESPACE ts_1
 -> DROP DATAFILE 'data_2.dat'
 -> ENGINE NDBCLUSTER;
mysql> ALTER TABLESPACE ts_1
 -> DROP DATAFILE 'data_1.dat'
 -> ENGINE NDBCLUSTER;
mysql> DROP TABLESPACE ts_1
 -> ENGINE NDBCLUSTER;
mysql> DROP LOGFILE GROUP lg_1
 -> ENGINE NDBCLUSTER;
```

These statements must be performed in the order shown, except that the two `ALTER TABLESPACE ... DROP DATAFILE` statements may be executed in either order.

You can obtain information about data files used by Disk Data tables by querying the `FILES` table in the `INFORMATION_SCHEMA` database. An extra “`NULL` row” was added to this table in MySQL 5.1.14 for providing additional information about undo log files. For more information and examples of use, see [Section 20.21, “The INFORMATION\\_SCHEMA FILES Table”](#).

Beginning with MySQL Cluster NDB 6.3.27 and MySQL Cluster NDB 7.0.8, it is also possible to view information about allocated and free disk space for each Disk Data table or table partition using the `ndb_desc` utility. For more information, see [Section 17.4.9, “ndb\\_desc — Describe NDB Tables”](#).

### 17.5.10.2. Using Symbolic Links with Disk Data Objects

The performance of a MySQL Cluster that uses Disk Data storage can be greatly improved by separating data node file systems from undo log files and tablespace data files and placing these on different disks. Previous to MySQL Cluster NDB 6.2.17, MySQL Cluster NDB 6.3.22, and MySQL Cluster NDB 6.4.3, there was no direct support for this in MySQL Cluster, but it was possible to achieve this separation using symbolic links as described in this section.

Beginning with MySQL Cluster NDB 6.2.17, MySQL Cluster NDB 6.3.22, and MySQL Cluster NDB 6.4.3, the data node configuration parameters `FileSystemPathDD`, `FileSystemPathDataFiles`, and `FileSystemPathUndoFiles` make the use of symbolic links for this purpose unnecessary. For information about these parameters, see [Disk Data filesystem parameters](#).

Each data node in the cluster creates a file system in the directory named `ndb_node_id_fs` under the data node's `DataDir` as defined in the `config.ini` file. In this example, we assume that each data node host has 3 disks, aliased as `/data0`, `/data1`, and `/data2`, and that the cluster's `config.ini` includes the following:

```
[ndbd_default]
DataDir= /data0
```

Our objective is to place all Disk Data log files in `/data1`, and all Disk Data data files in `/data2`, on each data node host.

#### Note

In this example, we assume that the cluster's data node hosts are all using Linux operating systems. For other platforms, you may need to substitute your operating system's commands for those shown here.

To accomplish this, perform the following steps:

- Under the data node file system create symbolic links pointing to the other drives:

```
shell> cd /data0/ndb_2_fs
shell> ls
D1 D10 D11 D2 D8 D9 LCP
shell> ln -s /data0 dnlogs
shell> ln -s /data1 dndata
```

You should now have two symbolic links:

```
shell> ls -l --hide=D*
lrwxrwxrwx 1 user group 30 2007-03-19 13:58 dndata -> /data1
lrwxrwxrwx 1 user group 30 2007-03-19 13:59 dnlogs -> /data2
```

We show this only for the data node with node ID 2; however, you must do this for *each* data node.

- Now, in the `mysql` client, create a log file group and tablespace using the symbolic links, as shown here:

```
mysql> CREATE LOGFILE GROUP lg1
 -> ADD UNDOFILE 'dnlogs/undo1.log'
 -> INITIAL_SIZE 150M
 -> UNDO_BUFFER_SIZE = 1M
 -> ENGINE=NDBCLUSTER;

mysql> CREATE TABLESPACE ts1
 -> ADD DATAFILE 'dndata/data1.log'
 -> USE LOGFILE GROUP lg1
 -> INITIAL_SIZE 1G
 -> ENGINE=NDBCLUSTER;
```

Verify that the files were created and placed correctly as shown here:

```
shell> cd /data1
shell> ls -l
total 2099304
-rw-rw-r-- 1 user group 157286400 2007-03-19 14:02 undo1.dat

shell> cd /data2
shell> ls -l
total 2099304
-rw-rw-r-- 1 user group 1073741824 2007-03-19 14:02 data1.dat
```

- If you are running multiple data nodes on one host, you must take care to avoid having them try to use the same space for Disk Data files. You can make this easier by creating a symbolic link in each data node filesystem. Suppose you are using `/data0` for both data node filesystems, but you wish to have the Disk Data files for both nodes on `/data1`. In this case, you can do something similar to what is shown here:

```
shell> cd /data0
shell> ln -s /data1/dn2 ndb_2_fs/dd
shell> ln -s /data1/dn3 ndb_3_fs/dd
shell> ls -l --hide=D* ndb_2_fs
lrwxrwxrwx 1 user group 30 2007-03-19 14:22 dd -> /data1/dn2
shell> ls -l --hide=D* ndb_3_fs
lrwxrwxrwx 1 user group 30 2007-03-19 14:22 dd -> /data1/dn3
```

Now you can create a logfile group and tablespace using the symbolic link, like this:

```
mysql> CREATE LOGFILE GROUP lg1
 -> ADD UNDOFILE 'dd/undo1.log'
 -> INITIAL_SIZE 150M
 -> UNDO_BUFFER_SIZE = 1M
 -> ENGINE=NDBCLUSTER;

mysql> CREATE TABLESPACE ts1
 -> ADD DATAFILE 'dd/data1.log'
 -> USE LOGFILE GROUP lg1
 -> INITIAL_SIZE 1G
 -> ENGINE=NDBCLUSTER;
```

Verify that the files were created and placed correctly as shown here:

```
shell> cd /data1
shell> ls
dn2 dn3
shell> ls dn2
undo1.log data1.log
shell> ls dn3
undo1.log data1.log
```

### 17.5.10.3. MySQL Cluster Disk Data Storage Requirements

The following items apply to Disk Data storage requirements:

- Variable-length columns of Disk Data tables take up a fixed amount of space. For each row, this is equal to the space required to store the largest possible value for that column.

For general information about calculating these values, see [Section 10.5, “Data Type Storage Requirements”](#).

You can obtain an estimate of the amount of space available in data files and undo log files by querying the `INFORMATION_SCHEMA.FILES` table. For more information and examples, see [Section 20.21, “The INFORMATION\\_SCHEMA.FILES Table”](#).

### Note

The `OPTIMIZE TABLE` statement does not have any effect on Disk Data tables.

- In a Disk Data table, the first 256 bytes of a `TEXT` or `BLOB` column are stored in memory; only the remainder is stored on disk.
- Each row in a Disk Data table uses 8 bytes in memory to point to the data stored on disk. This means that, in some cases, converting an in-memory column to the disk-based format can actually result in greater memory usage. For example, converting a `CHAR(4)` column from memory-based to disk-based format increases the amount of `DataMemory` used per row from 4 to 8 bytes.

### Important

Starting the cluster with the `--initial` option does *not* remove Disk Data files. You must remove these manually prior to performing an initial restart of the cluster.

## 17.5.11. Adding MySQL Cluster Data Nodes Online

This section describes how to add MySQL Cluster data nodes “online”—that is, without needing to shut down the cluster completely and restart it as part of the process. This capability is available in MySQL Cluster NDB 7.0 (beginning with MySQL Cluster NDB 6.4.0) and later MySQL Cluster release series.

### Important

Currently, you must add new data nodes to a MySQL Cluster as part of a new node group. In addition, it is not possible to change the number of replicas (or the number of nodes per node group) online.

### 17.5.11.1. Adding MySQL Cluster Data Nodes Online: General Issues

This section provides general information about the behavior of and current limitations in adding MySQL Cluster nodes online.

**Redistribution of Data.** The ability to add new nodes online includes a means to reorganize `NDBCLUSTER` table data and indexes so that they are distributed across all data nodes, including the new ones. Table reorganization of both in-memory and Disk Data tables is supported. This redistribution does not currently include unique indexes (only ordered indexes are redistributed) or `BLOB` table data, but we are working to add redistribution of these in the near future. The redistribution for `NDBCLUSTER` tables already existing before the new data nodes were added is not automatic, but can be accomplished using simple SQL statements in `mysql` or another MySQL client application. However, all data and indexes added to tables created after a new node group has been added are distributed automatically among all cluster data nodes, including those added as part of the new node group.

**Partial starts.** It is possible to add a new node group without all of the new data nodes being started. It is also possible to add a new node group to a degraded cluster—that is, a cluster that is only partially started, or where one or more data nodes are not running. In the latter case, the cluster must have enough nodes running to be viable before the new node group can be added.

**Effects on ongoing operations.** Normal DML operations using MySQL Cluster data are not prevented by the creation or addition of a new node group, or by table reorganization. However, it is not possible to perform DDL concurrently with table reorganization—that is, no other DDL statements can be issued while an `ALTER TABLE ... REORGANIZE PARTITION` statement is executing. In addition, during the execution of `ALTER TABLE ... REORGANIZE PARTITION` (or the execution of any other DDL statement), it is not possible to restart cluster data nodes.

**Failure handling.** Failures of data nodes during node group creation and table reorganization are handled as shown in the following table:

Failure occurs during:	Failure occurs in:		
	“Old” data nodes	“New” data nodes	System
Node group creation	<ul style="list-style-type: none"> <li>• <b>If a node other than the master fails:</b> The creation of the node group is always rolled forward.</li> </ul>	<ul style="list-style-type: none"> <li>• <b>If a node other than the master fails:</b> The creation of the node group is always rolled forward.</li> </ul>	<ul style="list-style-type: none"> <li>• <b>If the execution of CREATE NODEGROUP has reached the internal commit point:</b> When restarted, the cluster includes the new</li> </ul>

Failure occurs during:	Failure occurs in:		
	“Old” data nodes	“New” data nodes	System
	<ul style="list-style-type: none"> <li>• <b>If the master fails:</b> <ul style="list-style-type: none"> <li>• <b>If the internal commit point has been reached:</b> The creation of the node group is rolled forward.</li> <li>• <b>If the internal commit point has not yet been reached.</b> The creation of the node group is rolled back</li> </ul> </li> </ul>	<ul style="list-style-type: none"> <li>• <b>If the master fails:</b> <ul style="list-style-type: none"> <li>• <b>If the internal commit point has been reached:</b> The creation of the node group is rolled forward.</li> <li>• <b>If the internal commit point has not yet been reached.</b> The creation of the node group is rolled back</li> </ul> </li> </ul>	node group. Otherwise it without. <ul style="list-style-type: none"> <li>• <b>If the execution of <code>CREATE NODEGROUP</code> has not yet reached the internal commit point:</b> When restarted, the cluster does not include the new node group.</li> </ul>
Table reorganization	<ul style="list-style-type: none"> <li>• <b>If a node other than the master fails:</b> The table reorganization is always rolled forward.</li> <li>• <b>If the master fails:</b> <ul style="list-style-type: none"> <li>• <b>If the internal commit point has been reached:</b> The table reorganization is rolled forward.</li> <li>• <b>If the internal commit point has not yet been reached.</b> The table reorganization is rolled back.</li> </ul> </li> </ul>	<ul style="list-style-type: none"> <li>• <b>If a node other than the master fails:</b> The table reorganization is always rolled forward.</li> <li>• <b>If the master fails:</b> <ul style="list-style-type: none"> <li>• <b>If the internal commit point has been reached:</b> The table reorganization is rolled forward.</li> <li>• <b>If the internal commit point has not yet been reached.</b> The table reorganization is rolled back.</li> </ul> </li> </ul>	<ul style="list-style-type: none"> <li>• <b>If the execution of an <code>ALTER ONLINE TABLE table REORGANIZE PARTITION</code> statement has reached the internal commit point:</b> When the cluster is restarted, the data and indexes belonging to <code>table</code> are distributed using the “new” data nodes.</li> <li>• <b>If the execution of an <code>ALTER ONLINE TABLE table REORGANIZE PARTITION</code> statement has not yet reached the internal commit point:</b> When the cluster is restarted, the data and indexes belonging to <code>table</code> are distributed using only the “old” data nodes.</li> </ul>

**Dropping node groups.** The `ndb_mgm` client supports a `DROP NODEGROUP` command, but it is possible to drop a node group only when no data nodes in the node group contain any data. Since there is currently no way to “empty” a specific data node or node group, this command works only the following two cases:

1. After issuing `CREATE NODEGROUP` in the `ndb_mgm` client, but before issuing any `ALTER ONLINE TABLE ... REORGANIZE PARTITION` statements in the `mysql` client.
2. After dropping all `NDBCLUSTER` tables using `DROP TABLE`.

`TRUNCATE TABLE` does not work for this purpose because the data nodes continue to store the table definitions.

### 17.5.11.2. Adding MySQL Cluster Data Nodes Online: Basic procedure

In this section, we list the basic steps required to add new data nodes to a MySQL Cluster. For a detailed example, see Section 17.5.11.3, “Adding MySQL Cluster Data Nodes Online: Detailed Example”.

#### Note

Beginning with MySQL Cluster NDB 7.0.4, this procedure applies whether you are using `ndbd` or `ndbmtd` binaries for the data node processes. Previously, this did not work with multi-threaded data nodes. ([Bug#43108](#))

Assuming that you already have a running MySQL Cluster, adding data nodes online requires the following steps:

1. Edit the cluster configuration `config.ini` file, adding new `[ndbd]` sections corresponding to the nodes to be added. In the case where the cluster uses multiple management servers, these changes need to be made to all `config.ini` files used by the management servers.

You must be careful that node IDs for any new data nodes added in the `config.ini` file do not overlap node IDs used by existing nodes. In the event that you have API nodes using dynamically allocated node IDs and these IDs match node IDs that you want to use for new data nodes, it is possible to force any such API nodes to “migrate”, as described later in this procedure.

2. Perform a rolling restart of all MySQL Cluster management servers.

### **Important**

All management servers must be restarted with the `--reload` or `--initial` option to force the reading of the new configuration.

3. Perform a rolling restart of all existing MySQL Cluster data nodes. It is not necessary (or usually even desirable) to use `--initial` when restarting the existing data nodes.

If you are using API nodes with dynamically allocated IDs matching any node IDs that you wish to assign to new data nodes, you must restart all API nodes (including SQL nodes) before restarting any of the data nodes processes in this step. This causes any API nodes with node IDs that were previously not explicitly assigned to relinquish those node IDs and acquire new ones.

4. Perform a rolling restart of any SQL or API nodes connected to the MySQL Cluster.
5. Perform an initial start of the new data nodes.

### **Note**

The new data nodes may be started in any order, and can also be started concurrently, as long as they are started after the rolling restarts of all existing nodes have been completed and before proceeding to the next step.

6. Execute one or more `CREATE NODEGROUP` commands in the MySQL Cluster management client to create the new node group or node groups to which the new data nodes will belong.
7. Redistribute the cluster's data among all data nodes (including the new ones) by issuing an `ALTER ONLINE TABLE ... REORGANIZE PARTITION` statement in the `mysql` client for each `NDBCLUSTER` table.

### **Note**

This needs to be done only for tables already existing at the time the new node group is added. Data in tables created after the new node group is added is distributed automatically; however, data added to any given table `tbl` that existed before the new nodes were added is not distributed using the new nodes until that table has been reorganized using `ALTER ONLINE TABLE tbl REORGANIZE PARTITION`.

8. Reclaim the space freed on the “old” nodes by issuing, for each `NDBCLUSTER` table, an `OPTIMIZE TABLE` statement in the `mysql` client.

### **Note**

Previously, when adding multiple new node groups to a MySQL Cluster, it was necessary to add only the nodes to be assigned to a given new node group, create that node group using `CREATE NODEGROUP`, then repeat this process for each new node group to be added to the cluster. Beginning with MySQL Cluster NDB 7.0.16 and MySQL Cluster 7.1.5, this issue is resolved; you can add the nodes desired, then issue several `CREATE NODEGROUP` commands in succession to add the new node groups to the cluster. ([Bug#54497](#))

## 17.5.11.3. Adding MySQL Cluster Data Nodes Online: Detailed Example

In this section we provide a detailed example illustrating how to add new MySQL Cluster data nodes online, starting with a MySQL Cluster having 2 data nodes in a single node group and concluding with a cluster having 4 data nodes in 2 node groups.

**Starting configuration.** For purposes of illustration, we assume a minimal configuration, and that the cluster uses a `config.ini` file containing only the following information:

```
[ndbd default]
DataMemory = 100M
IndexMemory = 100M
NoOfReplicas = 2
DataDir = /usr/local/mysql/var/mysql-cluster
```

```
[ndbd]
Id = 1
HostName = 192.168.0.1

[ndbd]
Id = 2
HostName = 192.168.0.2

[mgm]
HostName = 192.168.0.10
Id = 10

[api]
Id=20
HostName = 192.168.0.20

[api]
Id=21
HostName = 192.168.0.21
```

**Note**

We have left a gap in the sequence between data node IDs and other nodes. This make it easier later to assign node IDs that are not already in use to data nodes which are newly added.

We also assume that you have already started the cluster using the appropriate command line or [my.cnf](#) options, and that running `SHOW` in the management client produces output similar to what is shown here:

```
-- NDB Cluster -- Management Client --
ndb_mgm> SHOW
Connected to Management Server at: 192.168.0.10:1186
Cluster Configuration

[ndbd(NDB)] 2 node(s)
id=1 @192.168.0.1 (5.1.47-ndb-7.1.8, Nodegroup: 0, Master)
id=2 @192.168.0.2 (5.1.47-ndb-7.1.8, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)
id=10 @192.168.0.10 (5.1.47-ndb-7.1.8)

[mysqld(API)] 2 node(s)
id=20 @192.168.0.20 (5.1.47-ndb-7.1.8)
id=21 @192.168.0.21 (5.1.47-ndb-7.1.8)
```

Finally, we assume that the cluster contains a single `NDBCLUSTER` table created as shown here:

```
USE n;

CREATE TABLE ips (
 id BIGINT NOT NULL AUTO_INCREMENT PRIMARY KEY,
 country_code CHAR(2) NOT NULL,
 type CHAR(4) NOT NULL,
 ip_address varchar(15) NOT NULL,
 addresses BIGINT UNSIGNED DEFAULT NULL,
 date BIGINT UNSIGNED DEFAULT NULL
) ENGINE NDBCLUSTER;
```

The memory usage and related information shown later in this section was generated after inserting approximately 50000 rows into this table.

**Note**

In this example, we show the single-threaded `ndbd` being used for the data node processes. However—beginning with MySQL Cluster NDB 7.0.4 ([Bug#43108](#))—you can also apply this example, if you are using the multi-threaded `ndbmt` by substituting `ndbmt` for `ndbd` wherever it appears in the steps that follow.

**Step 1: Update configuration file.** Open the cluster global configuration file in a text editor and add `[ndbd]` sections corresponding to the 2 new data nodes. (We give these data nodes IDs 3 and 4, and assume that they are to be run on host machines at addresses 192.168.0.3 and 192.168.0.4, respectively.) After you have added the new sections, the contents of the `config.ini` file should look like what is shown here, where the additions to the file are shown in bold type:

```
[ndbd_default]
DataMemory = 100M
IndexMemory = 100M
NoOfReplicas = 2
DataDir = /usr/local/mysql/var/mysql-cluster

[ndbd]
Id = 1
HostName = 192.168.0.1

[ndbd]
Id = 2
HostName = 192.168.0.2
```

```
[ndbd]
Id = 3
HostName = 192.168.0.3

[ndbd]
Id = 4
HostName = 192.168.0.4

[mgm]
HostName = 192.168.0.10
Id = 10

[api]
Id=20
HostName = 192.168.0.20

[api]
Id=21
HostName = 192.168.0.21
```

Once you have made the necessary changes, save the file.

**Step 2: Restart the management server.** Restarting the cluster management server requires that you issue separate commands to stop the management server and then to start it again, as follows:

1. Stop the management server using the management client `STOP` command, as shown here:

```
ndb_mgm> 10 STOP
Node 10 has shut down.
Disconnecting to allow Management Server to shutdown
shell>
```

2. Because shutting down the management server causes the management client to terminate, you must start the management server from the system shell. For simplicity, we assume that `config.ini` is in the same directory as the management server binary, but in practice, you must supply the correct path to the configuration file. You must also supply the `--reload` or `-initial` option so that the management server reads the new configuration from the file rather than its configuration cache. If your shell's current directory is also the same as the directory where the management server binary is located, then you can invoke the management server as shown here:

```
shell> ndb_mgmd -f config.ini --reload
2008-12-08 17:29:23 [MgmSrvr] INFO -- NDB Cluster Management Server. 5.1.47-ndb-7.1.8
2008-12-08 17:29:23 [MgmSrvr] INFO -- Reading cluster configuration from 'config.ini'
```

If you check the output of `SHOW` in the management client after restarting the `ndb_mgm` process, you should now see something like this:

```
-- NDB Cluster -- Management Client --
ndb_mgm> SHOW
Connected to Management Server at: 192.168.0.10:1186
Cluster Configuration

[ndbd(NDB)] 2 node(s)
id=1 @192.168.0.1 (5.1.47-ndb-7.1.8, Nodegroup: 0, Master)
id=2 @192.168.0.2 (5.1.47-ndb-7.1.8, Nodegroup: 0)
id=3 (not connected, accepting connect from 192.168.0.3)
id=4 (not connected, accepting connect from 192.168.0.4)

[ndb_mgmd(MGM)] 1 node(s)
id=10 @192.168.0.10 (5.1.47-ndb-7.1.8)

[mysqld(API)] 2 node(s)
id=20 @192.168.0.20 (5.1.47-ndb-7.1.8)
id=21 @192.168.0.21 (5.1.47-ndb-7.1.8)
```

**Step 3: Perform a rolling restart of the existing data nodes.** This step can be accomplished entirely within the cluster management client using the `RESTART` command, as shown here:

```
ndb_mgm> 1 RESTART
Node 1: Node shutdown initiated
Node 1: Node shutdown completed, restarting, no start.
Node 1 is being restarted

ndb_mgm> Node 1: Start initiated (version 7.0.19)
Node 1: Started (version 7.0.19)

ndb_mgm> 2 RESTART
Node 2: Node shutdown initiated
Node 2: Node shutdown completed, restarting, no start.
Node 2 is being restarted
```

```
ndb_mgm> Node 2: Start initiated (version 7.0.19)
ndb_mgm> Node 2: Started (version 7.0.19)
```

### Important

After issuing each `X RESTART` command, wait until the management client reports `Node X: Started (version ...)` before proceeding any further.

**Step 4: Perform a rolling restart of all cluster API nodes.** Shut down and restart each MySQL server acting as an SQL node in the cluster using `mysqladmin shutdown` followed by `mysqld_safe` (or another startup script). This should be similar to what is shown here, where `password` is the MySQL `root` password for a given MySQL server instance:

```
shell> mysqladmin -uroot -ppassword shutdown
081208 20:19:56 mysqld_safe mysqld from pid file
/usr/local/mysql/var/tonfisk.pid ended
shell> mysqld_safe --ndbcluster --ndb-connectstring=192.168.0.10 &
081208 20:20:06 mysqld_safe Logging to '/usr/local/mysql/var/tonfisk.err'.
081208 20:20:06 mysqld_safe Starting mysqld daemon with databases
from /usr/local/mysql/var
```

Of course, the exact input and output depend on how and where MySQL is installed on the system, as well as which options you choose to start it (and whether or not some or all of these options are specified in a `my.cnf` file).

**Step 5: Perform an initial start of the new data nodes.** From a system shell on each of the hosts for the new data nodes, start the data nodes as shown here, using the `--initial` option:

```
shell> ndbd -c 192.168.0.10 --initial
```

### Note

Unlike the case with restarting the existing data nodes, you can start the new data nodes concurrently; you do not need to wait for one to finish starting before starting the other.

*Wait until both of the new data nodes have started before proceeding with the next step.* Once the new data nodes have started, you can see in the output of the management client `SHOW` command that they do not yet belong to any node group (as indicated with bold type here):

```
ndb_mgm> SHOW
Connected to Management Server at: 192.168.0.10:1186
Cluster Configuration

[ndbd(NDB)] 2 node(s)
id=1 @192.168.0.1 (5.1.47-ndb-7.1.8, Nodegroup: 0, Master)
id=2 @192.168.0.2 (5.1.47-ndb-7.1.8, Nodegroup: 0)
id=3 @192.168.0.3 (5.1.47-ndb-7.1.8, no nodegroup)
id=4 @192.168.0.4 (5.1.47-ndb-7.1.8, no nodegroup)

[ndb_mgmd(MGM)] 1 node(s)
id=10 @192.168.0.10 (5.1.47-ndb-7.1.8)

[mysqld(API)] 2 node(s)
id=20 @192.168.0.20 (5.1.47-ndb-7.1.8)
id=21 @192.168.0.21 (5.1.47-ndb-7.1.8)
```

**Step 6: Create a new node group.** You can do this by issuing a `CREATE NODEGROUP` command in the cluster management client. This command takes as its argument a comma-separated list of the node IDs of the data nodes to be included in the new node group, as shown here:

```
ndb_mgm> CREATE NODEGROUP 3,4
Nodegroup 1 created
```

By issuing `SHOW` again, you can verify that data nodes 3 and 4 have joined the new node group (again indicated in bold type):

```
ndb_mgm> SHOW
Connected to Management Server at: 192.168.0.10:1186
Cluster Configuration

[ndbd(NDB)] 2 node(s)
id=1 @192.168.0.1 (5.1.47-ndb-7.1.8, Nodegroup: 0, Master)
id=2 @192.168.0.2 (5.1.47-ndb-7.1.8, Nodegroup: 0)
id=3 @192.168.0.3 (5.1.47-ndb-7.1.8, Nodegroup: 1)
id=4 @192.168.0.4 (5.1.47-ndb-7.1.8, Nodegroup: 1)

[ndb_mgmd(MGM)] 1 node(s)
id=10 @192.168.0.10 (5.1.47-ndb-7.1.8)

[mysqld(API)] 2 node(s)
id=20 @192.168.0.20 (5.1.47-ndb-7.1.8)
```

```
id=21 @192.168.0.21 (5.1.47-ndb-7.1.8)
```

**Step 7: Redistribute cluster data.** When a node group is created, existing data and indexes are not automatically distributed to the new node group's data nodes, as you can see by issuing the appropriate [REPORT](#) command in the management client:

```
ndb_mgm> ALL REPORT MEMORY
Node 1: Data usage is 5%(177 32K pages of total 3200)
Node 1: Index usage is 0%(108 8K pages of total 12832)
Node 2: Data usage is 5%(177 32K pages of total 3200)
Node 2: Index usage is 0%(108 8K pages of total 12832)
Node 3: Data usage is 0%(0 32K pages of total 3200)
Node 3: Index usage is 0%(0 8K pages of total 12832)
Node 4: Data usage is 0%(0 32K pages of total 3200)
Node 4: Index usage is 0%(0 8K pages of total 12832)
```

By using [ndb\\_desc](#) with the **-p** option, which causes the output to include partitioning information, you can see that the table still uses only 2 partitions (in the [Per partition info](#) section of the output, shown here in bold text):

```
shell> ndb_desc -c 192.168.0.10 -d n ips -p
-- ips --
Version: 1
Fragment type: 9
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: no
Number of attributes: 6
Number of primary keys: 1
Length of frm data: 340
Row Checksum: 1
Row GCI: 1
SingleUserMode: 0
ForceVarPart: 1
FragmentCount: 2
TableStatus: Retrieved
-- Attributes --
id Bigint PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY AUTO_INCR
country_code Char(2;latin1_swedish_ci) NOT NULL AT=FIXED ST=MEMORY
type Char(4;latin1_swedish_ci) NOT NULL AT=FIXED ST=MEMORY
ip_address Varchar(15;latin1_swedish_ci) NOT NULL AT=SHORT_VAR ST=MEMORY
addresses Bigunsigned NULL AT=FIXED ST=MEMORY
date Bigunsigned NULL AT=FIXED ST=MEMORY

-- Indexes --

1 26329 26329 1605632 557056

NDBT_ProgramExit: 0 - OK
```

You can cause the data to be redistributed among all of the data nodes by performing, for each [NDBCLUSTER](#) table, an [ALTER ONLINE TABLE ... REORGANIZE PARTITION](#) statement in the [mysql](#) client. After issuing the statement [ALTER ONLINE TABLE ips REORGANIZE PARTITION](#), you can see using [ndb\\_desc](#) that the data for this table is now stored using 4 partitions, as shown here (with the relevant portions of the output in bold type):

```
shell> ndb_desc -c 192.168.0.10 -d n ips -p
-- ips --
Version: 16777217
Fragment type: 9
K Value: 6
Min load factor: 78

3	13093	13093	819200	294912

NDBT\_ProgramExit: 0 - OK

### Note

Normally, `ALTER [ONLINE] TABLE table_name REORGANIZE PARTITION` is used with a list of partition identifiers and a set of partition definitions to create a new partitioning scheme for a table that has already been explicitly partitioned. Its use here to redistribute data onto a new MySQL Cluster node group is an exception in this regard; when used in this way, only the name of the table is used following the `TABLE` keyword, and no other keywords or identifiers follow `REORGANIZE PARTITION`.

Prior to MySQL Cluster NDB 6.4.3, `ALTER ONLINE TABLE ... REORGANIZE PARTITION` with no `partition_names INTO (partition_definitions)` option did not work correctly with Disk Data tables or with in-memory `NDBCLUSTER` tables having one or more disk-based columns. ([Bug#42549](#))

For more information, see [Section 12.1.7, “ALTER TABLE Syntax”](#).

Also, for each table, the `ALTER ONLINE TABLE` statement should be followed by an `OPTIMIZE TABLE` to reclaim wasted space. You can obtain a list of all `NDBCLUSTER` tables using the following query against the `INFORMATION_SCHEMA.TABLES` table:

```
SELECT TABLE_SCHEMA, TABLE_NAME
 FROM INFORMATION_SCHEMA.TABLES
 WHERE ENGINE = 'NDBCLUSTER';
```

### Note

The `INFORMATION_SCHEMA.TABLES.ENGINE` value for a MySQL Cluster table is always `NDBCLUSTER`, regardless of whether the `CREATE TABLE` statement used to create the table (or `ALTER TABLE` statement used to convert an existing table from a different storage engine) used `NDB` or `NDBCLUSTER` in its `ENGINE` option.

You can see after performing these statements in the output of `ALL REPORT MEMORY` that the data and indexes are now redistributed between all cluster data nodes, as shown here:

```
ndb_mgm> ALL REPORT MEMORY
Node 1: Data usage is 5%(176 32K pages of total 3200)
Node 1: Index usage is 0%(76 8K pages of total 12832)
Node 2: Data usage is 5%(176 32K pages of total 3200)
Node 2: Index usage is 0%(76 8K pages of total 12832)
Node 3: Data usage is 2%(80 32K pages of total 3200)
Node 3: Index usage is 0%(51 8K pages of total 12832)
Node 4: Data usage is 2%(80 32K pages of total 3200)
Node 4: Index usage is 0%(50 8K pages of total 12832)
```

### Note

Since only one DDL operation on `NDBCLUSTER` tables can be executed at a time, you must wait for each `ALTER ONLINE TABLE ... REORGANIZE PARTITION` statement to finish before issuing the next one.

It is not necessary to issue `ALTER ONLINE TABLE ... REORGANIZE PARTITION` statements for `NDBCLUSTER` tables created *after* the new data nodes have been added; data added to such tables is distributed among all data nodes automatically. However, in `NDBCLUSTER` tables that existed *prior to* the addition of the new nodes, neither existing nor new data is distributed using the new nodes until these tables have been reorganized using `ALTER ONLINE TABLE ... REORGANIZE PARTITION`.

**Alternative procedure, without rolling restart.** It is possible to avoid the need for a rolling restart by configuring the extra data nodes, but not starting them, when first starting the cluster. We assume, as before, that you wish to start with two data nodes—nodes 1 and 2—in one node group and later to expand the cluster to four data nodes, by adding a second node group consisting of nodes 3 and 4:

```
[ndbd default]
DataMemory = 100M
IndexMemory = 100M
NoOfReplicas = 2
DataDir = /usr/local/mysql/var/mysql-cluster

[ndbd]
Id = 1
HostName = 192.168.0.1

[ndbd]
Id = 2
```

```

HostName = 192.168.0.2
Id = 3
HostName = 192.168.0.3

[ndbd]
Id = 4
HostName = 192.168.0.4

[mgm]
HostName = 192.168.0.10
Id = 10

[api]
Id=20
HostName = 192.168.0.20

[api]
Id=21
HostName = 192.168.0.21

```

In this case, you must perform the initial start of the cluster using the `--nowait-nodes` option with `ndbd` (or `ndbmtd` in MySQL Cluster NDB 7.0.4 and later) for each of the data nodes that you wish to have online immediately, so that the cluster does not wait for the remaining nodes to start:

```
shell> ndbd -c 192.168.0.10 --initial --nowait-nodes=3,4
```

When you are ready to add the second node group, you need only perform the following additional steps:

1. Start data nodes 3 and 4, invoking the data node process once for each new node:

```
shell> ndbd -c 192.168.0.10 --initial
```

2. Issue the appropriate `CREATE NODEGROUP` command in the management client:

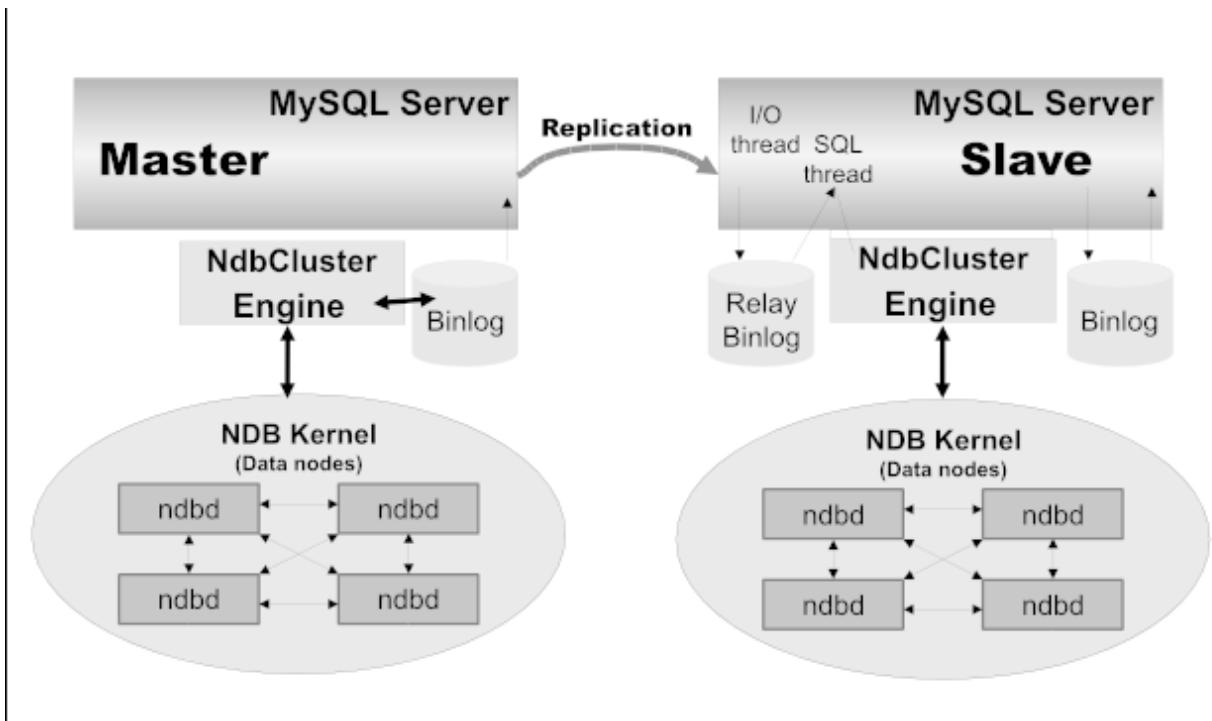

```
ndb_mgm> CREATE NODEGROUP 3,4
```

3. In the `mysql` client, issue `ALTER ONLINE TABLE ... REORGANIZE PARTITION` and `OPTIMIZE TABLE` statements for each existing `NDBCLUSTER` table. (As noted elsewhere in this section, existing MySQL Cluster tables cannot use the new nodes for data distribution until this has been done.)

## 17.6. MySQL Cluster Replication

Previous to MySQL 5.1.6, *asynchronous replication*, more usually referred to simply as “replication”, was not available when using MySQL Cluster. MySQL 5.1.6 introduces master-slave replication of this type for MySQL Cluster databases. This section explains how to set up and manage a configuration wherein one group of computers operating as a MySQL Cluster replicates to a second computer or group of computers. We assume some familiarity on the part of the reader with standard MySQL replication as discussed elsewhere in this Manual. (See [Chapter 16, Replication](#)).

Normal (non-clustered) replication involves a “master” server and a “slave” server, the master being the source of the operations and data to be replicated and the slave being the recipient of these. In MySQL Cluster, replication is conceptually very similar but can be more complex in practice, as it may be extended to cover a number of different configurations including replicating between two complete clusters. Although a MySQL Cluster itself depends on the `NDBCLUSTER` storage engine for clustering functionality, it is not necessary to use the Cluster storage engine on the slave. However, for maximum availability, it is possible to replicate from one MySQL Cluster to another, and it is this type of configuration that we discuss, as shown in the following figure:

In this scenario, the replication process is one in which successive states of a master cluster are logged and saved to a slave cluster. This process is accomplished by a special thread known as the NDB binlog injector thread, which runs on each MySQL server and produces a binary log ([binlog](#)). This thread ensures that all changes in the cluster producing the binary log—and not just those changes that are effected through the MySQL Server—are inserted into the binary log with the correct serialization order. We refer to the MySQL replication master and replication slave servers as replication servers or replication nodes, and the data flow or line of communication between them as a *replication channel*.

For information about performing point-in-time recovery with MySQL Cluster and MySQL Cluster Replication, see [Section 17.6.9.2, “Point-In-Time Recovery Using MySQL Cluster Replication”](#).

### 17.6.1. MySQL Cluster Replication: Abbreviations and Symbols

Throughout this section, we use the following abbreviations or symbols for referring to the master and slave clusters, and to processes and commands run on the clusters or cluster nodes:

Symbol or Abbreviation	Description (Refers to...)
<i>M</i>	The cluster serving as the (primary) replication master
<i>S</i>	The cluster acting as the (primary) replication slave
<code>shellM&gt;</code>	Shell command to be issued on the master cluster
<code>mysqlM&gt;</code>	MySQL client command issued on a single MySQL server running as an SQL node on the master cluster
<code>mysqlM*&gt;</code>	MySQL client command to be issued on all SQL nodes participating in the replication master cluster
<code>shellS&gt;</code>	Shell command to be issued on the slave cluster
<code>mysqlS&gt;</code>	MySQL client command issued on a single MySQL server running as an SQL node on the slave cluster
<code>mysqlS*&gt;</code>	MySQL client command to be issued on all SQL nodes participating in the replication slave cluster
<i>C</i>	Primary replication channel
<i>C'</i>	Secondary replication channel
<i>M'</i>	Secondary replication master
<i>S'</i>	Secondary replication slave

### 17.6.2. MySQL Cluster Replication: Assumptions and General Requirements

A replication channel requires two MySQL servers acting as replication servers (one each for the master and slave). For example, this means that in the case of a replication setup with two replication channels (to provide an extra channel for redundancy), there will be a total of four replication nodes, two per cluster.

Replication of a MySQL Cluster as described in this section and those following is dependent on row-based replication. This means that the replication master MySQL server must be started with `--binlog-format=ROW` or `--binlog-format=MIXED`, as described in [Section 17.6.6, “Starting MySQL Cluster Replication \(Single Replication Channel\)”](#). For general information about row-based replication, see [Section 16.1.2, “Replication Formats”](#).

### Important

If you attempt to use MySQL Cluster Replication with `--binlog-format=STATEMENT`, replication fails to work properly because the `ndb_binlog_index` table on the master and the `epoch` column of the `ndb_apply_status` table on the slave are not updated (see [Section 17.6.4, “MySQL Cluster Replication Schema and Tables”](#)). Instead, only updates on the MySQL server acting as the replication master propagate to the slave, and no updates from any other SQL nodes on the master cluster are replicated.

In all MySQL Cluster NDB 6.x and 7.x releases, the default value for the `--binlog-format` option is `MIXED`.

Each MySQL server used for replication in either cluster must be uniquely identified among all the MySQL replication servers participating in either cluster (you cannot have replication servers on both the master and slave clusters sharing the same ID). This can be done by starting each SQL node using the `--server-id=id` option, where `id` is a unique integer. Although it is not strictly necessary, we will assume for purposes of this discussion that all MySQL installations are the same version.

In any event, both MySQL servers involved in replication must be compatible with one another with respect to both the version of the replication protocol used and the SQL feature sets which they support; the simplest and easiest way to assure that this is the case is to use the same MySQL version for all servers involved. Note that in many cases it is not possible to replicate to a slave running a version of MySQL with a lower version number than that of the master (see [Section 16.4.2, “Replication Compatibility Between MySQL Versions”](#), for details).

We assume that the slave server or cluster is dedicated to replication of the master, and that no other data is being stored on it.

### Note

It is possible to replicate a MySQL Cluster using statement-based replication. However, in this case, the following restrictions apply:

- All updates to data rows on the cluster acting as the master must be directed to a single MySQL server.
- It is not possible to replicate a cluster using multiple simultaneous MySQL replication processes.
- Only changes made at the SQL level are replicated.

These are in addition to the other limitations of statement-based replication as opposed to row-based replication; see [Section 16.1.2.1, “Comparison of Statement-Based and Row-Based Replication”](#), for more specific information concerning the differences between the two replication formats.

## 17.6.3. Known Issues in MySQL Cluster Replication

The following are known problems or issues when using replication with MySQL Cluster in MySQL 5.1 (including MySQL Cluster NDB 6.X and 7.X through 7.1):

- **Loss of master-slave connection.** A loss of connection can occur either between the replication master SQL node and the replication slave SQL node, or between the replication master SQL node and the data nodes in the master cluster. In the latter case, this can occur not only as a result of loss of physical connection (for example, a broken network cable), but due to the overflow of data node event buffers; if the SQL node is too slow to respond, it may be dropped by the cluster (this is controllable to some degree by adjusting the `MaxBufferedEpochs` and `TimeBetweenEpochs` configuration parameters). If this occurs, *it is entirely possible for new data to be inserted into the master cluster without being recorded in the replication master’s binary log*. For this reason, to guarantee high availability, it is extremely important to maintain a backup replication channel, to monitor the primary channel, and to fail over to the secondary replication channel when necessary to keep the slave cluster synchronized with the master. MySQL Cluster is not designed to perform such monitoring on its own; for this, an external application is required.

Prior to MySQL 5.1.18, a MySQL Cluster replication slave `mysqld` had no way of detecting that the connection from the master had been interrupted. For this reason, it was possible for the slave to become inconsistent with the master.

Beginning with MySQL 5.1.18, the replication master issues a “gap” event when connecting or reconnecting to the master cluster. (A gap event is a type of “incident event,” which indicates an incident that occurs that affects the contents of the data-

base but that cannot easily be represented as a set of changes. Examples of incidents are server crashes, database resynchronization, (some) software updates, and (some) hardware changes.) When the slave encounters a gap in the replication log, it stops with an error message. This message is available in the output of `SHOW SLAVE STATUS`, and indicates that the SQL thread has stopped due to an incident registered in the replication stream, and that manual intervention is required. See [Section 17.6.8, “Implementing Failover with MySQL Cluster Replication”](#), for more information about what to do in such circumstances.

### Important

Because MySQL Cluster is not designed on its own to monitor replication status or provide failover, if high availability is a requirement for the slave server or cluster, then you must set up multiple replication lines, monitor the master `mysqld` on the primary replication line, and be prepared fail over to a secondary line if and as necessary. This must be done manually, or possibly by means of a third-party application. For information about implementing this type of setup, see [Section 17.6.7, “Using Two Replication Channels for MySQL Cluster Replication”](#), and [Section 17.6.8, “Implementing Failover with MySQL Cluster Replication”](#).

However, if you are replicating from a standalone MySQL server to a MySQL Cluster, one channel is usually sufficient.

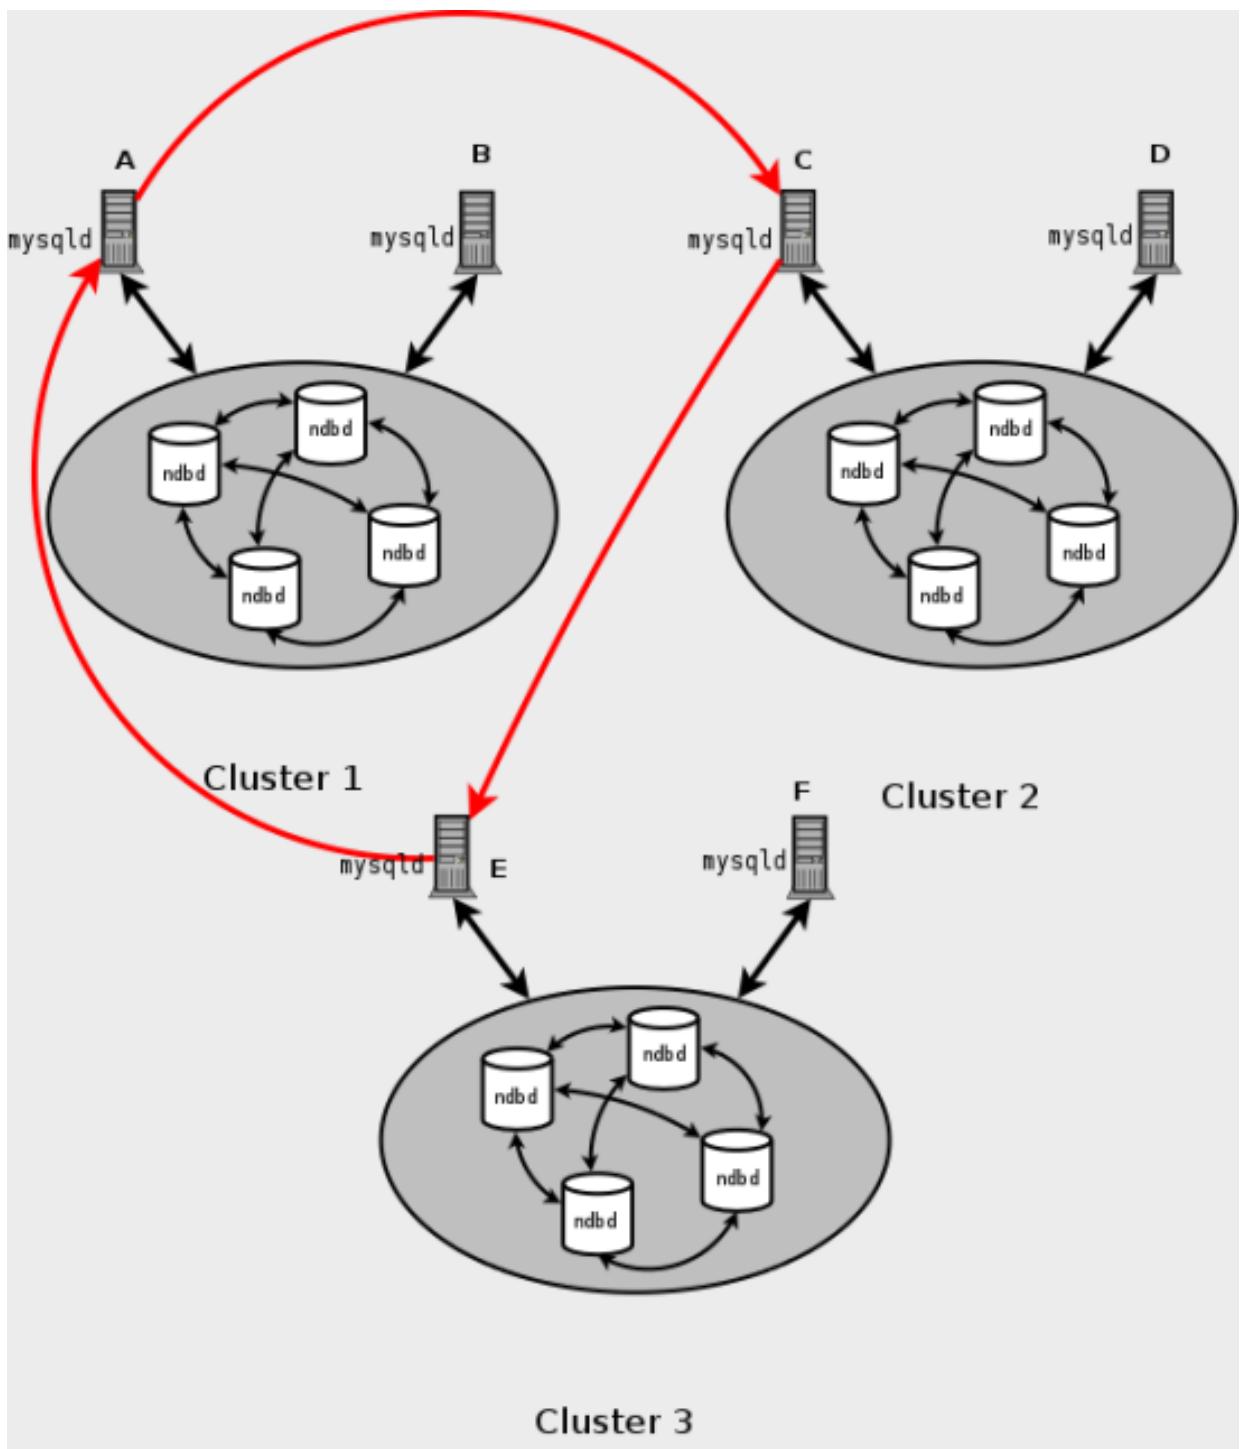

- **Multi-byte character sets.** Previously, there were several known issues with regard to the use of multi-byte characters sets with MySQL Cluster Replication. These were resolved in MySQL 5.1.21, MySQL Cluster NDB 6.2.14, and MySQL Cluster NDB 6.3.11. (See [Bug#27404](#) and [Bug#29562](#).)
- **Circular replication.** Prior to MySQL 5.1.18, circular replication was not supported with MySQL Cluster replication, due to the fact that all log events created in a particular MySQL Cluster were wrongly tagged with the server ID of the MySQL server used as master and not with the server ID of the originating server.

Beginning with MySQL 5.1.18, this limitation is lifted, as discussed in the next few paragraphs, in which we consider the example of a replication setup involving three MySQL Clusters numbered 1, 2, and 3, in which Cluster 1 acts as the replication master for Cluster 2, Cluster 2 acts as the master for Cluster 3, and Cluster 3 acts as the master for Cluster 1. Each cluster has two SQL nodes, with SQL nodes A and B belonging to Cluster 1, SQL nodes C and D belonging to Cluster 2, and SQL nodes E and F belonging to Cluster 3.

Circular replication using these clusters is supported as long as:

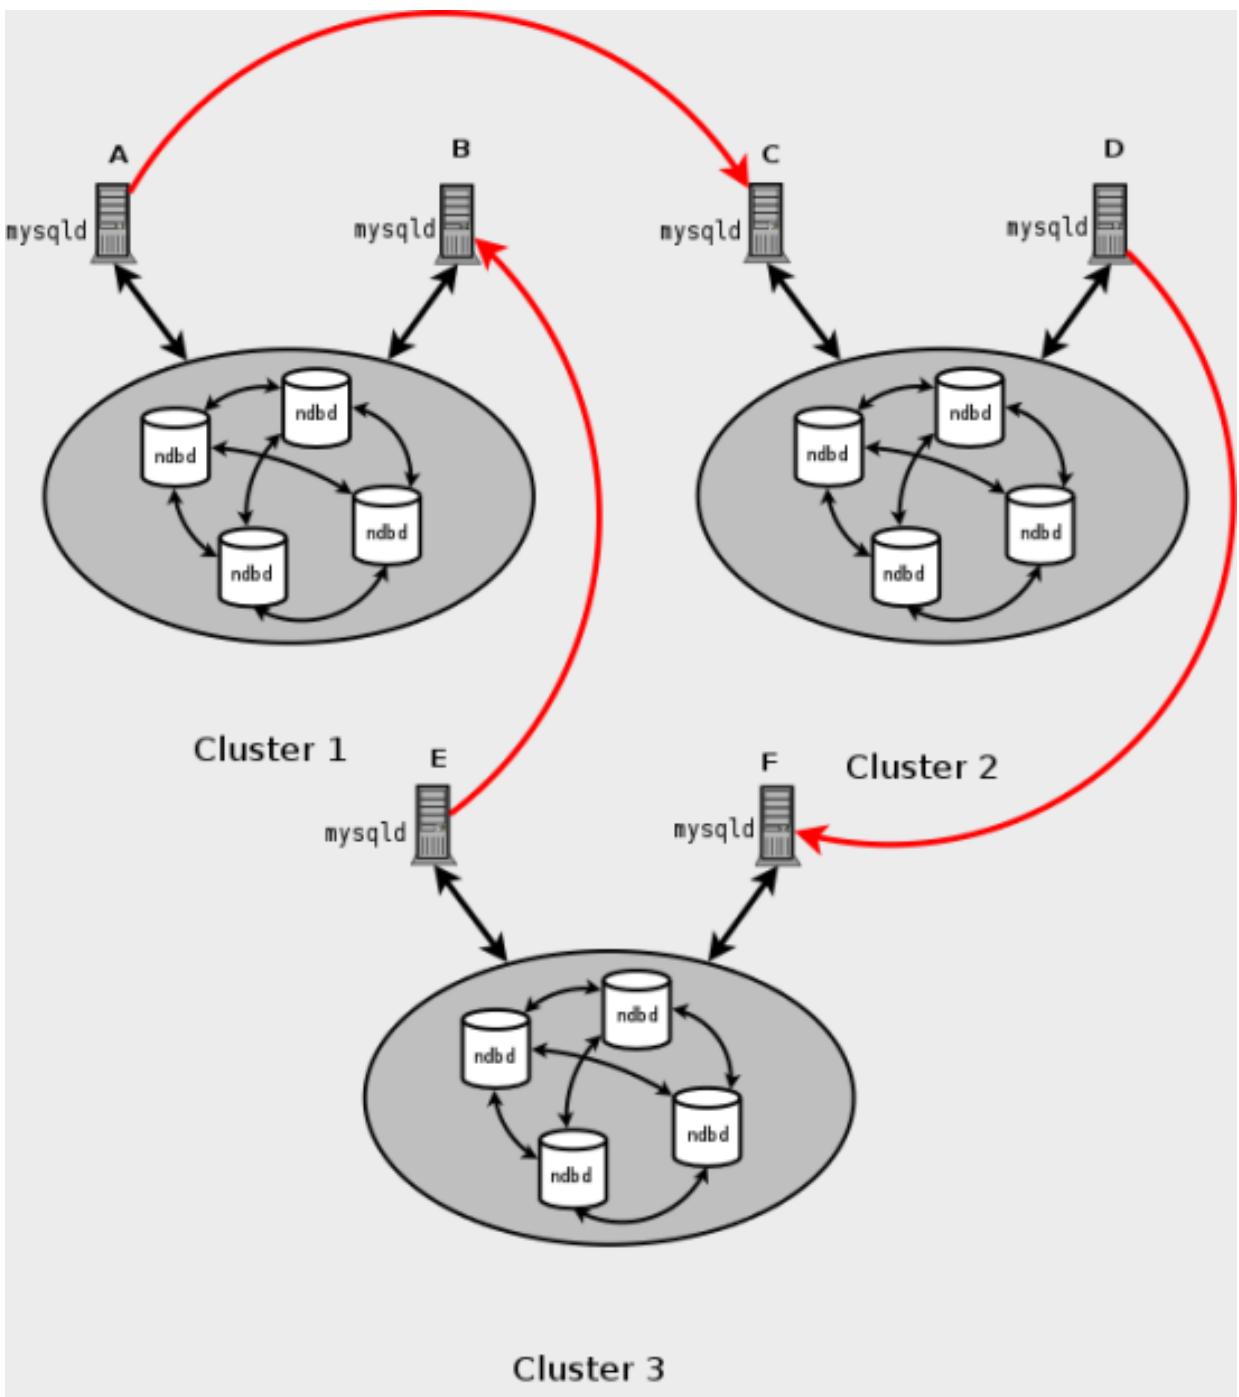

- The SQL nodes on all masters and slaves are the same
- All SQL nodes acting as replication masters and slaves are started using the `--log-slave-updates` option

This type of circular replication setup is shown in the following diagram:

In this scenario, SQL node A in Cluster 1 replicates to SQL node C in Cluster 2; SQL node C replicates to SQL node E in Cluster 3; SQL node E replicates to SQL node A. In other words, the replication line (indicated by the red arrows in the diagram) directly connects all SQL nodes used as replication masters and slaves.

It should also be possible to set up circular replication in which not all master SQL nodes are also slaves, as shown here:

In this case, different SQL nodes in each cluster are used as replication masters and slaves. However, you must *not* start any of the SQL nodes using `--log-slave-updates` (see the [description of this option](#) for more information). This type of circular replication scheme for MySQL Cluster, in which the line of replication (again indicated by the red arrows in the diagram) is discontinuous, should be possible, but it should be noted that it has not yet been thoroughly tested and must therefore still be considered experimental.

#### Note

Beginning with MySQL 5.1.24, the `NDB` storage engine uses *idempotent execution mode*, which suppresses duplicate-key and other errors that otherwise break circular replication of MySQL Cluster. This is equivalent to setting the global `slave_exec_mode` system variable to `IDEMPOTENT`. This is also required for multi-master replication when using MySQL Cluster. ([Bug#31609](#))

It is not necessary to set `slave_exec_mode` in MySQL Cluster replication; MySQL Cluster does this automatically for all `NDB` tables and ignores any attempts to set this variable explicitly.

- **MySQL Cluster replication and primary keys.** In MySQL 5.1.6, only those `NDB` tables having explicit primary keys could be replicated. This limitation was lifted in MySQL 5.1.7. However, in the event of a node failure, errors in replication of `NDB` tables without primary keys can still occur, due to the possibility of duplicate rows being inserted in such cases. For this reason, it is highly recommended that all `NDB` tables being replicated have primary keys.
- **MySQL Cluster Replication and Unique Keys.** Operations that update values of unique key columns of `NDB` tables can result in duplicate-key errors when replicated. This is because row events in the binary log are ordered according to the partitioning of the base table, which means that they may appear in a different order from that in which they were originally executed.

Consider an `NDB` table `t` which is created and populated on the master (and replicated to a slave MySQL Cluster) as shown here:

```
CREATE TABLE t (
 p INT PRIMARY KEY,
 c INT,
 UNIQUE KEY u (c)
) ENGINE NDB;

INSERT INTO t
VALUES (1,1), (2,2), (3,3), (4,4), (5,5);
```

The following `UPDATE` statement succeeds on the master; on the master, the rows affected are processed in the order determined by the `ORDER BY` clause and the ordering is done over the entire table:

```
UPDATE t SET c = c - 1 ORDER BY p;
```

However, the same statement can fail with a constraint violation or duplicate key error on the slave, because the ordering of the row updates is determined on a per-partition basis, rather than for the table as a whole. (Recall that in MySQL 5.1.6 and later—including all MySQL Cluster NDB 6.x and 7.x releases—every `NDB` table is implicitly partitioned by key when it is created—see [Section 18.2.4, “KEY Partitioning”](#), for more information).

- **Restarting with `--initial`.** Restarting the cluster with the `--initial` option causes the sequence of GCI and epoch numbers to start over from 0. (This is generally true of MySQL Cluster and not limited to replication scenarios involving Cluster.) The MySQL servers involved in replication should in this case be restarted. After this, you should use the `RESET MASTER` and `RESET SLAVE` statements to clear the invalid `ndb_binlog_index` and `ndb_apply_status` tables, respectively.
- **`auto_increment_offset` and `auto_increment_increment` variables.** The use of the `auto_increment_offset` and `auto_increment_increment` server system variables is supported beginning with MySQL 5.1.20. Previously, these produced unpredictable results when used with `NDB` tables or MySQL Cluster replication.
- **Replication from `NDBCLOUD` to other storage engines.** If you attempt to replicate from a MySQL Cluster to a slave that uses a storage engine that does not handle its own binary logging, the replication process aborts with the error `BINARY LOGGING NOT POSSIBLE ... STATEMENT CANNOT BE WRITTEN ATOMICALLY SINCE MORE THAN ONE ENGINE INVOLVED AND AT LEAST ONE ENGINE IS SELF-LOGGING` (Error 1595). It is possible to work around this issue in one of the following ways:
  - **Turn off binary logging on the slave.** This can be accomplished by setting `sql_log_bin = 0`.
  - **Change the storage engine used for the `mysql.ndb_apply_status` table.** Causing this table to use an engine that does not handle its own binary logging can also eliminate the conflict. This can be done by issuing a statement such as `ALTER TABLE mysql.ndb_apply_status ENGINE=MyISAM` on the slave. It is safe to do this when using a non-`NDB` storage engine on the slave, since you do not then need to worry about keeping multiple slave SQL nodes synchronized.
  - **Filter out changes to the `mysql.ndb_apply_status` table on the slave.** This can be done by starting the slave SQL node with the option `--replicate-ignore-table=mysql.ndb_apply_status`. If you need for other tables to be ignored by replication, you might wish to use an appropriate `--replicate-wild-ignore-table` option instead.

## Important

You should *not* disable replication or binary logging of `mysql.ndb_apply_status` or change the storage engine used for this table when replicating from one MySQL Cluster to another. See [Replication and binary log filtering rules with replication between MySQL Clusters](#), for details.

- **Replication from `NDB` to a different storage engine.** For replication from `NDB` to a different storage engine, the relationship between the two databases must be a simple master-slave one. This means that circular or master-master replication is not supported between MySQL Cluster and other storage engines. However, the MySQL Cluster database can simultaneously replicate to multiple slave MySQL Cluster databases.

In addition, it is not possible to configure more than one replication channel when replicating between MySQL Cluster and a different storage engine. If MySQL Cluster is the master then it is still possible to have more than one MySQL Server maintain

a binary log of all changes; however, for the slave to change masters (fail over), the new master-slave relationship must be explicitly defined on the slave.

- **Replication from NDB to a nontransactional storage engine.** When replicating from NDB to a nontransactional storage engine such as MyISAM, you may encounter unnecessary duplicate key errors when replicating `INSERT ... ON DUPLICATE KEY UPDATE` statements. You can suppress these in MySQL Cluster NDB 6.2 by using `--ndb-log-update-as-write=0`, which forces updates to be logged as writes (rather than as updates).

You should also be aware that, when replicating from NDB to a storage engine that does not implement transactions (such as MyISAM), if the slave fails in applying one or more rows changes from a transaction, it does not roll back the rest of the transaction. Because of this, it cannot be guaranteed that transactional consistency will be maintained on the slave in this type of scenario.

- **Replication and binary log filtering rules with replication between MySQL Clusters.** If you are using any of the options `--replicate-do-*`, `--replicate-ignore-*`, `--binlog-do-db`, or `--binlog-ignore-db` to filter databases or tables being replicated, care must be taken not to block replication or binary logging of the `mysql.ndb_apply_status`, which is required for replication between MySQL Clusters to operate properly. In particular, you must keep in mind the following:

1. Using `--replicate-do-db=db_name` (and no other `--replicate-do-*` or `--replicate-ignore-*` options) means that *only* tables in database `db_name` are replicated. In this case, you should also use `--replicate-do-db=mysql`, `--binlog-do-db=mysql`, or `--replicate-do-table=mysql.ndb_apply_status` to ensure that `mysql.ndb_apply_status` is populated on slaves.

Using `--binlog-do-db=db_name` (and no other `--binlog-do-db` options) means that changes *only* to tables in database `db_name` are written to the binary log. In this case, you should also use `--replicate-do-db=mysql`, `--binlog-do-db=mysql`, or `--replicate-do-table=mysql.ndb_apply_status` to ensure that `mysql.ndb_apply_status` is populated on slaves.

2. Using `--replicate-ignore-db=mysql` means that no tables in the `mysql` database are replicated. In this case, you should also use `--replicate-do-table=mysql.ndb_apply_status` to ensure that `mysql.ndb_apply_status` is replicated.

Using `--binlog-ignore-db=mysql` means that no changes to tables in the `mysql` database are written to the binary log. In this case, you should also use `--replicate-do-table=mysql.ndb_apply_status` to ensure that `mysql.ndb_apply_status` is replicated.

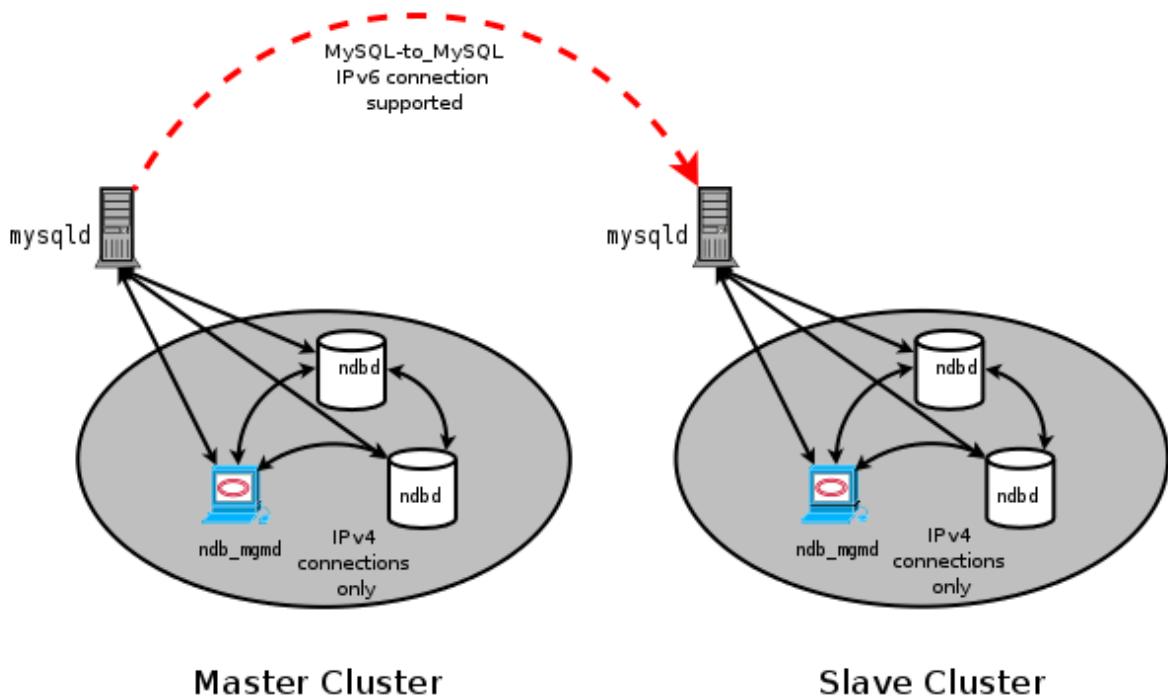

You should also remember that:

1. Each replication filtering rule requires its own `--replicate-do-*` or `--replicate-ignore-*` option, and that multiple rules cannot be expressed in a single replication filtering option. For information about these rules, see [Section 16.1.3, “Replication and Binary Logging Options and Variables”](#).
2. Each binary log filtering rule requires its own `--binlog-do-db` or `--binlog-ignore-db` option, and that multiple rules cannot be expressed in a single binary log filtering option. For information about these rules, see [Section 5.2.4, “The Binary Log”](#).

### Note

If you are replicating a MySQL Cluster to a slave that uses a storage engine other than NDBCLUSTER, the considerations just given previously may not apply. See [Replication from NDBCLUSTER to other storage engines](#) elsewhere in this section for details.

- **MySQL Cluster Replication and IPv6.** Currently, the NDB API and MGM API do not support IPv6. However, beginning with MySQL Cluster NDB 6.4.1, MySQL Servers—including those acting as SQL nodes in a MySQL Cluster—can use IPv6 to contact other MySQL Servers. This means that you can replicate between MySQL Clusters using IPv6 to connect the master and slave SQL nodes as shown by the dotted arrow in the following diagram:

However, all connections originating *within* the MySQL Cluster—shown in the diagram by solid arrows—must use IPv4.

All MySQL Cluster data nodes, management servers, and management clients must be accessible from one another using IPv4. In addition, SQL nodes must use IPv4 to communicate with the cluster. There is not currently any support in the NDB and MGM APIs for IPv6, which means that any applications written using these APIs must also make all connections using IPv4.

- **Attribute promotion and demotion.** Formerly, support in MySQL Cluster for type conversions between columns of similar but different types on the master and the slave was extremely limited. However, starting with MySQL Cluster NDB 6.3.33, 7.0.14, and 7.1.3, MySQL Cluster Replication includes support for attribute promotion and demotion. The implementation of the latter distinguishes between lossy and non-lossy type conversions, and their use on the slave can be controlled by setting the `slave_type_conversions` global server system variable.

For more information about attribute promotion and demotion in MySQL Cluster, see [Attribute promotion and demotion \(MySQL Cluster\)](#).

## 17.6.4. MySQL Cluster Replication Schema and Tables

Replication in MySQL Cluster makes use of a number of dedicated tables in the `mysql` database on each MySQL Server instance acting as an SQL node in both the cluster being replicated and the replication slave (whether the slave is a single server or a cluster). These tables are created during the MySQL installation process by the `mysql_install_db` script, and include a table for storing the binary log's indexing data. Since the `ndb_binlog_index` table is local to each MySQL server and does not participate in clustering, it uses the `MyISAM` storage engine. This means that it must be created separately on each `mysqld` participating in the master cluster. (However, the binlog itself contains updates from all MySQL servers in the cluster to be replicated.) This table is defined as follows:

```
CREATE TABLE `ndb_binlog_index` (
 `Position` BIGINT(20) UNSIGNED NOT NULL,
 `File` VARCHAR(255) NOT NULL,
 `epoch` BIGINT(20) UNSIGNED NOT NULL,
 `inserts` BIGINT(20) UNSIGNED NOT NULL,
 `updates` BIGINT(20) UNSIGNED NOT NULL,
 `deletes` BIGINT(20) UNSIGNED NOT NULL,
 `schemaops` BIGINT(20) UNSIGNED NOT NULL,
 PRIMARY KEY (`epoch`)
) ENGINE=MYISAM DEFAULT CHARSET=latin1;
```

### Important

Prior to MySQL 5.1.14, the `ndb_binlog_index` table was known as `binlog_index`, and was kept in a separate

`cluster` database, which in MySQL 5.1.7 and earlier was known as the `cluster_rePLICATION` database. Similarly, the `ndb_apply_status` and `ndb_schema` tables were known as `apply_status` and `schema`, and were also found in the `cluster` (earlier `cluster_rePLICATION`) database. However, beginning with MySQL 5.1.14, all MySQL Cluster replication tables reside in the `mysql` system database.

Information about how this change affects upgrades from MySQL Cluster 5.1.13 and earlier to 5.1.14 and later versions can be found in [Section C.1.43, “Changes in MySQL 5.1.14 \(05 December 2006\)”.](#)

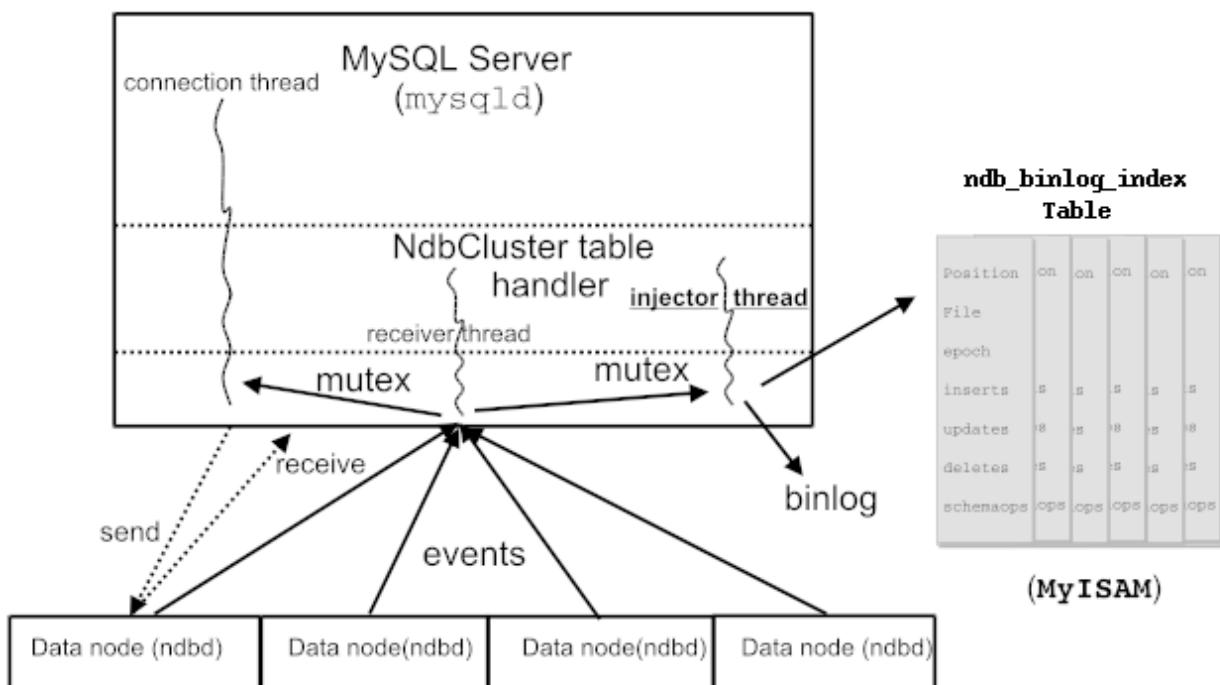

Beginning with MySQL Cluster NDB 6.3.2, this table has been changed to facilitate 3-way replication recovery. Two columns `orig_server_id` and `orig_epoch` have been added to this table; when `mysqld` is started with the `--ndb-log-orig` option, these columns store, respectively, the ID of the server on which the event originated and the epoch in which the event took place on the originating server. In addition, the table's primary key now includes these two columns. The modified table definition is shown here:

```
CREATE TABLE `ndb_binlog_index` (
 `Position` BIGINT(20) UNSIGNED NOT NULL,
 `File` VARCHAR(255) NOT NULL,
 `epoch` BIGINT(20) UNSIGNED NOT NULL,
 `inserts` INT(10) UNSIGNED NOT NULL,
 `updates` INT(10) UNSIGNED NOT NULL,
 `deletes` INT(10) UNSIGNED NOT NULL,
 `schemaops` INT(10) UNSIGNED NOT NULL,
 `orig_server_id` INT(10) UNSIGNED NOT NULL,
 `orig_epoch` BIGINT(20) UNSIGNED NOT NULL,
 `gci` INT(10) UNSIGNED NOT NULL,
 PRIMARY KEY (`epoch`, `orig_server_id`, `orig_epoch`)
) ENGINE=MyISAM DEFAULT CHARSET=latin1;
```

The `gci` column was added in MySQL Cluster NDB 6.2.6 and MySQL Cluster NDB 6.3.2.

The following figure shows the relationship of the MySQL Cluster replication master server, its binlog injector thread, and the `mysql.ndb_binlog_index` table.

## MySQL Replication Between Clusters, Injecting into Binlog

An additional table, named `ndb_apply_status`, is used to keep a record of the operations that have been replicated from the master to the slave. Unlike the case with `ndb_binlog_index`, the data in this table is not specific to any one SQL node in the (slave) cluster, and so `ndb_apply_status` can use the `NDBCLUSTER` storage engine, as shown here:

```
CREATE TABLE `ndb_apply_status` (
 `server_id` INT(10) UNSIGNED NOT NULL,
```

```

`epoch` BIGINT(20) UNSIGNED NOT NULL,
`log_name` VARCHAR(255) CHARACTER SET latin1 COLLATE latin1_bin NOT NULL,
`start_pos` BIGINT(20) UNSIGNED NOT NULL,
`end_pos` BIGINT(20) UNSIGNED NOT NULL,
PRIMARY KEY (`server_id`) USING HASH
) ENGINE=NDCLUSTER DEFAULT CHARSET=latin1;

```

This table is populated only on slaves; on the master, no [DataMemory](#) is allocated to it. Since this table is populated from data originating on the master, it should be allowed to replicate; any replication filtering or binary log filtering rules that inadvertently prevent the slave from updating [ndb\\_apply\\_status](#) or the master from writing into the binary log may prevent replication between clusters from operating properly. For more information about potential problems arising from such filtering rules, see [Replication and binary log filtering rules with replication between MySQL Clusters](#).

The `log_name`, `start_pos`, and `end_pos` columns were added in MySQL 5.1.18.

### Important

If you are using MySQL Cluster replication, see [Section 17.2.5.2, “MySQL Cluster 5.1 and MySQL Cluster NDB 6.x/7.x Upgrade and Downgrade Compatibility”](#) before upgrading to MySQL 5.1.18 or later from an earlier version.

The `ndb_binlog_index` and `ndb_apply_status` tables are created in the `mysql` database because they should not be explicitly replicated by the user. User intervention is normally not required to create or maintain either of these tables, since both `ndb_binlog_index` and the `ndb_apply_status` are maintained by the `NDB` binary log (binlog) injector thread. This keeps the master `mysqld` process updated to changes performed by the `NDB` storage engine. The `NDB binlog injector thread` receives events directly from the `NDB` storage engine. The `NDB` injector is responsible for capturing all the data events within the cluster, and ensures that all events which change, insert, or delete data are recorded in the `ndb_binlog_index` table. The slave I/O thread transfers the events from the master's binary log to the slave's relay log.

However, it is advisable to check for the existence and integrity of these tables as an initial step in preparing a MySQL Cluster for replication. It is possible to view event data recorded in the binary log by querying the `mysql.ndb_binlog_index` table directly on the master. This can be also be accomplished using the `SHOW BINLOG EVENTS` statement on either the replication master or slave MySQL servers. (See [Section 12.4.5.3, “SHOW BINLOG EVENTS Syntax”](#).)

You can also obtain useful information from the output of `SHOW ENGINE NDB STATUS`.

The `ndb_schema` table is used to track schema changes made to `NDB` tables. It is defined as shown here:

```

CREATE TABLE ndb_schema (
 `db` VARBINARY(63) NOT NULL,
 `name` VARBINARY(63) NOT NULL,
 `slock` BINARY(32) NOT NULL,
 `query` BLOB NOT NULL,
 `node_id` INT UNSIGNED NOT NULL,
 `epoch` BIGINT UNSIGNED NOT NULL,
 `id` INT UNSIGNED NOT NULL,
 `version` INT UNSIGNED NOT NULL,
 `type` INT UNSIGNED NOT NULL,
 PRIMARY KEY USING HASH (db,name)
) ENGINE=NDB DEFAULT CHARSET=latin1;

```

Unlike the two tables previously mentioned in this section, the `ndb_schema` table is not visible either to MySQL `SHOW` statements, or in any `INFORMATION_SCHEMA` tables; however, it can be seen in the output of `ndb_show_tables`, as shown here:

```

shell> ndb_show_tables -t 2
+----+-----+-----+-----+-----+-----+
| id | type | state | logging | database | schema | name |
+----+-----+-----+-----+-----+-----+
| 4 | UserTable | Online | Yes | mysql | def | ndb_apply_status |
| 5 | UserTable | Online | Yes | ndbworld | def | City |
| 6 | UserTable | Online | Yes | ndbworld | def | Country |
| 3 | UserTable | Online | Yes | mysql | def | NDB$BLOB_2_3 |
| 7 | UserTable | Online | Yes | ndbworld | def | CountryLanguage |
| 2 | UserTable | Online | Yes | mysql | def | ndb_schema |
+----+-----+-----+-----+-----+-----+

```

`NDBT_ProgramExit: 0 - OK`

It is also possible to `SELECT` from this table in `mysql` and other MySQL client applications, as shown here:

```

mysql> SELECT * FROM mysql.ndb_schema WHERE name='City' \G
***** 1. row *****
 db: ndbworld
 name: City
 slock:
 query: alter table City engine=ndb
node_id: 4
epoch: 0
 id: 0
version: 0
 type: 7
1 row in set (0.00 sec)

```

This can sometimes be useful when debugging applications.

**Note**

When performing schema changes on `NDB` tables, applications should wait until the `ALTER TABLE` statement has returned in the MySQL client connection that issued the statement before attempting to use the updated definition of the table.

The `ndb_schema` table was added in MySQL 5.1.8.

Beginning with MySQL 5.1.14, if the `ndb_apply_status` table or the `ndb_schema` table does not exist on the slave, `ndb_restore` re-creates the missing table or tables ([Bug#14612](#)).

Conflict resolution for MySQL Cluster Replication requires the presence of an additional `mysql.ndb_replication` table. Currently, this table must be created manually. For information about how to do this, see [Section 17.6.11, “MySQL Cluster Replication Conflict Resolution”](#).

## 17.6.5. Preparing the MySQL Cluster for Replication

Preparing the MySQL Cluster for replication consists of the following steps:

1. Check all MySQL servers for version compatibility (see [Section 17.6.2, “MySQL Cluster Replication: Assumptions and General Requirements”](#)).
2. Create a slave account on the master Cluster with the appropriate privileges:

```
mysqlM> GRANT REPLICATION SLAVE
 -> ON *.* TO 'slave_user'@'slave_host'
 -> IDENTIFIED BY 'slave_password';
```

In the previous statement, `slave_user` is the slave account user name, `slave_host` is the host name or IP address of the replication slave, and `slave_password` is the password to assign to this account.

For example, to create a slave user account with the name “`myslave`,” logging in from the host named “`rep-slave`,” and using the password “`53cr37`,” use the following `GRANT` statement:

```
mysqlM> GRANT REPLICATION SLAVE
 -> ON *.* TO 'myslave'@'rep-slave'
 -> IDENTIFIED BY '53cr37';
```

For security reasons, it is preferable to use a unique user account—not employed for any other purpose—for the replication slave account.

3. Configure the slave to use the master. Using the MySQL Monitor, this can be accomplished with the `CHANGE MASTER TO` statement:

```
mysqlS> CHANGE MASTER TO
 -> MASTER_HOST='master_host',
 -> MASTER_PORT=master_port,
 -> MASTER_USER='slave_user',
 -> MASTER_PASSWORD='slave_password';
```

In the previous statement, `master_host` is the host name or IP address of the replication master, `master_port` is the port for the slave to use for connecting to the master, `slave_user` is the user name set up for the slave on the master, and `slave_password` is the password set for that user account in the previous step.

For example, to tell the slave to replicate from the MySQL server whose host name is “`rep-master`,” using the replication slave account created in the previous step, use the following statement:

```
mysqlS> CHANGE MASTER TO
 -> MASTER_HOST='rep-master',
 -> MASTER_PORT=3306,
 -> MASTER_USER='myslave',
 -> MASTER_PASSWORD='53cr37';
```

For a complete list of clauses that can be used with this statement, see [Section 12.5.2.1, “`CHANGE MASTER TO` Syntax”](#).

You can also configure the slave to use the master by setting the corresponding startup options in the slave server's `my.cnf` file. To configure the slave in the same way as the preceding example `CHANGE MASTER TO` statement, the following information would need to be included in the slave's `my.cnf` file:

```
[mysqld]
master-host=rep-master
master-port=3306
```

```
master-user=myslave
master-password=53cr37
```

For additional options that can be set in `my.cnf` for replication slaves, see [Section 16.1.3, “Replication and Binary Logging Options and Variables”](#).

### Note

To provide replication backup capability, you will also need to add an `ndb-connectstring` option to the slave's `my.cnf` file prior to starting the replication process. See [Section 17.6.9, “MySQL Cluster Backups With MySQL Cluster Replication”](#), for details.

4. If the master cluster is already in use, you can create a backup of the master and load this onto the slave to cut down on the amount of time required for the slave to synchronize itself with the master. If the slave is also running MySQL Cluster, this can be accomplished using the backup and restore procedure described in [Section 17.6.9, “MySQL Cluster Backups With MySQL Cluster Replication”](#).

```
ndb-connectstring=management_host[:port]
```

In the event that you are *not* using MySQL Cluster on the replication slave, you can create a backup with this command on the replication master:

```
shell> mysqldump --master-data=1
```

Then import the resulting data dump onto the slave by copying the dump file over to the slave. After this, you can use the `mysql` client to import the data from the dumpfile into the slave database as shown here, where `dump_file` is the name of the file that was generated using `mysqldump` on the master, and `db_name` is the name of the database to be replicated:

```
shell> mysql -u root -p db_name < dump_file
```

For a complete list of options to use with `mysqldump`, see [Section 4.5.4, “mysqldump — A Database Backup Program”](#).

### Note

If you copy the data to the slave in this fashion, you should make sure that the slave is started with the `--skip-slave-start` option on the command line, or else include `skip-slave-start` in the slave's `my.cnf` file to keep it from trying to connect to the master to begin replicating before all the data has been loaded. Once the data loading has completed, follow the additional steps outlined in the next two sections.

5. Ensure that each MySQL server acting as a replication master is configured with a unique server ID, and with binary logging enabled, using the row format. (See [Section 16.1.2, “Replication Formats”](#).) These options can be set either in the master server's `my.cnf` file, or on the command line when starting the master `mysqld` process. See [Section 17.6.6, “Starting MySQL Cluster Replication \(Single Replication Channel\)”](#), for information regarding the latter option.

## 17.6.6. Starting MySQL Cluster Replication (Single Replication Channel)

This section outlines the procedure for starting MySQL Cluster replication using a single replication channel.

1. Start the MySQL replication master server by issuing this command:

```
shell> mysqld --ndbcluster --server-id=id \
--log-bin --binlog-format=ROW &
```

In the previous statement, `id` is this server's unique ID (see [Section 17.6.2, “MySQL Cluster Replication: Assumptions and General Requirements”](#)). This starts the server's `mysqld` process with binary logging enabled using the proper logging format.

### Note

You can also start the master with `--binlog-format=MIXED`, in which case row-based replication is used automatically when replicating between clusters.

2. Start the MySQL replication slave server as shown here:

```
shell> mysqld --ndbcluster --server-id=id &
```

In the previous statement, `id` is the slave server's unique ID. It is not necessary to enable logging on the replication slave.

### Note

You should use the `--skip-slave-start` option with this command or else you should include `skip-slave-start` in the slave server's `my.cnf` file, unless you want replication to begin immediately. With the use of this option, the start of replication is delayed until the appropriate `START SLAVE` statement has been issued, as explained in Step 4 below.

3. It is necessary to synchronize the slave server with the master server's replication binlog. If binary logging has not previously been running on the master, run the following statement on the slave:

```
mysql> CHANGE MASTER TO
-> MASTER_LOG_FILE='',
-> MASTER_LOG_POS=4;
```

This instructs the slave to begin reading the master's binary log from the log's starting point. Otherwise—that is, if you are loading data from the master using a backup—see [Section 17.6.8, “Implementing Failover with MySQL Cluster Replication”](#), for information on how to obtain the correct values to use for `MASTER_LOG_FILE` and `MASTER_LOG_POS` in such cases.

4. Finally, you must instruct the slave to begin applying replication by issuing this command from the `mysql` client on the replication slave:

```
mysql> START SLAVE;
```

This also initiates the transmission of replication data from the master to the slave.

It is also possible to use two replication channels, in a manner similar to the procedure described in the next section; the differences between this and using a single replication channel are covered in [Section 17.6.7, “Using Two Replication Channels for MySQL Cluster Replication”](#).

Beginning with MySQL Cluster NDB 6.2.3, it is possible to improve cluster replication performance by enabling *batched updates*. This can be accomplished by starting slave `mysqld` processes with the `--slave-allow-batching` option. Normally, updates are applied as soon as they are received. However, the use of batching causes updates to be applied in 32 KB batches, which can result in higher throughput and less CPU usage, particularly where individual updates are relatively small.

### Note

Slave batching works on a per-epoch basis; updates belonging to more than one transaction can be sent as part of the same batch.

All outstanding updates are applied when the end of an epoch is reached, even if the updates total less than 32 KB.

Batching can be turned on and off at runtime. To activate it at runtime, you can use either of these two statements:

```
SET GLOBAL slave_allow_batching = 1;
SET GLOBAL slave_allow_batching = ON;
```

If a particular batch causes problems (such as a statement whose effects do not appear to be replicated correctly), slave batching can be deactivated using either of the following statements:

```
SET GLOBAL slave_allow_batching = 0;
SET GLOBAL slave_allow_batching = OFF;
```

You can check whether slave batching is currently being used by means of an appropriate `SHOW VARIABLES` statement, like this one:

```
mysql> SHOW VARIABLES LIKE 'slave%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| slave_allow_batching | ON |
| slave_compressed_protocol | OFF |
| slave_load_tmpdir | /tmp |
| slave_net_timeout | 3600 |
| slave_skip_errors | OFF |
| slave_transaction_retries | 10 |
+-----+-----+
6 rows in set (0.00 sec)
```

## 17.6.7. Using Two Replication Channels for MySQL Cluster Replication

In a more complete example scenario, we envision two replication channels to provide redundancy and thereby guard against possible failure of a single replication channel. This requires a total of four replication servers, two masters for the master cluster and two slave servers for the slave cluster. For purposes of the discussion that follows, we assume that unique identifiers are assigned as shown here:

Server ID	Description
1	Master - primary replication channel ( $M$ )
2	Master - secondary replication channel ( $M'$ )
3	Slave - primary replication channel ( $S$ )
4	Slave - secondary replication channel ( $S'$ )

Setting up replication with two channels is not radically different from setting up a single replication channel. First, the `mysqld` processes for the primary and secondary replication masters must be started, followed by those for the primary and secondary slaves. Then the replication processes may be initiated by issuing the `START SLAVE` statement on each of the slaves. The commands and the order in which they need to be issued are shown here:

1. Start the primary replication master:

```
shellM> mysqld --ndbcluster --server-id=1 \
--log-bin --binlog-format=row &
```

2. Start the secondary replication master:

```
shellM'> mysqld --ndbcluster --server-id=2 \
--log-bin --binlog-format=row &
```

3. Start the primary replication slave server:

```
shellS> mysqld --ndbcluster --server-id=3 \
--skip-slave-start &
```

4. Start the secondary replication slave:

```
shellS'> mysqld --ndbcluster --server-id=4 \
--skip-slave-start &
```

5. Finally, initiate replication on the primary channel by executing the `START SLAVE` statement on the primary slave as shown here:

```
mysqlS> START SLAVE;
```

### Warning

Only the primary channel is to be started at this point. The secondary replication channel is to be started only in the event that the primary replication channel fails, as described in [Section 17.6.8, “Implementing Failover with MySQL Cluster Replication”](#). Running multiple replication channels simultaneously can result in unwanted duplicate records being created on the replication slaves.

As mentioned previously, it is not necessary to enable binary logging on replication slaves.

## 17.6.8. Implementing Failover with MySQL Cluster Replication

In the event that the primary Cluster replication process fails, it is possible to switch over to the secondary replication channel. The following procedure describes the steps required to accomplish this.

1. Obtain the time of the most recent global checkpoint (GCP). That is, you need to determine the most recent epoch from the `ndb_apply_status` table on the slave cluster, which can be found using the following query:

```
mysqlS'> SELECT @latest:=MAX(epoch)
-> FROM mysql.ndb_apply_status;
```

2. Using the information obtained from the query shown in Step 1, obtain the corresponding records from the

`ndb_binlog_index` table on the master cluster as shown here:

```
mysqlM' > SELECT
 -> @file:=SUBSTRING_INDEX(File, '/', -1),
 -> @pos:=Position
 -> FROM mysql.ndb_binlog_index
 -> WHERE epoch > @latest
 -> ORDER BY epoch ASC LIMIT 1;
```

These are the records saved on the master since the failure of the primary replication channel. We have employed a user variable `@latest` here to represent the value obtained in Step 1. Of course, it is not possible for one `mysqld` instance to access user variables set on another server instance directly. These values must be “plugged in” to the second query manually or in application code.

3. Now it is possible to synchronize the secondary channel by running the following query on the secondary slave server:

```
mysqlS' > CHANGE MASTER TO
 -> MASTER_LOG_FILE='@file',
 -> MASTER_LOG_POS=@pos;
```

Again we have employed user variables (in this case `@file` and `@pos`) to represent the values obtained in Step 2 and applied in Step 3; in practice these values must be inserted manually or using application code that can access both of the servers involved.

### Note

`@file` is a string value such as `'/var/log/mysqlreplication-master-bin.00001'`, and so must be quoted when used in SQL or application code. However, the value represented by `@pos` must *not* be quoted. Although MySQL normally attempts to convert strings to numbers, this case is an exception.

4. You can now initiate replication on the secondary channel by issuing the appropriate command on the secondary slave `mysqld`:

```
mysqlS' > START SLAVE;
```

Once the secondary replication channel is active, you can investigate the failure of the primary and effect repairs. The precise actions required to do this will depend upon the reasons for which the primary channel failed.

### Warning

The secondary replication channel is to be started only if and when the primary replication channel has failed. Running multiple replication channels simultaneously can result in unwanted duplicate records being created on the replication slaves.

If the failure is limited to a single server, it should (in theory) be possible to replicate from `M` to `S'`, or from `M'` to `S`; however, this has not yet been tested.

## 17.6.9. MySQL Cluster Backups With MySQL Cluster Replication

This section discusses making backups and restoring from them using MySQL Cluster replication. We assume that the replication servers have already been configured as covered previously (see [Section 17.6.5, “Preparing the MySQL Cluster for Replication”](#), and the sections immediately following). This having been done, the procedure for making a backup and then restoring from it is as follows:

1. There are two different methods by which the backup may be started.

- **Method A.** This method requires that the cluster backup process was previously enabled on the master server, prior to starting the replication process. This can be done by including the following line in a `[mysql_cluster]` section in the `my.cnf` file, where `management_host` is the IP address or host name of the NDB management server for the master cluster, and `port` is the management server's port number:

```
ndb-connectstring=management_host[:port]
```

### Note

The port number needs to be specified only if the default port (1186) is not being used. See [Section 17.2.1.2, “MySQL Cluster Multi-Computer Configuration”](#), for more information about ports and port allocation in MySQL Cluster. In this case, the backup can be started by executing this statement on the replication master:

```
shellM> ndb_mgm -e "START BACKUP"
```

- **Method B.** If the `my.cnf` file does not specify where to find the management host, you can start the backup process by passing this information to the NDB management client as part of the `START BACKUP` command. This can be done as shown here, where `management_host` and `port` are the host name and port number of the management server:

```
shellM> ndb_mgm management_host:port -e "START BACKUP"
```

In our scenario as outlined earlier (see [Section 17.6.5, “Preparing the MySQL Cluster for Replication”](#)), this would be executed as follows:

```
shellM> ndb_mgm rep-master:1186 -e "START BACKUP"
```

2. Copy the cluster backup files to the slave that is being brought on line. Each system running an `ndbd` process for the master cluster will have cluster backup files located on it, and *all* of these files must be copied to the slave to ensure a successful restore. The backup files can be copied into any directory on the computer where the slave management host resides, so long as the MySQL and NDB binaries have read permissions in that directory. In this case, we will assume that these files have been copied into the directory `/var/BACKUPS/BACKUP-1`.

It is not necessary that the slave cluster have the same number of `ndbd` processes (data nodes) as the master; however, it is highly recommended this number be the same. It *is* necessary that the slave be started with the `--skip-slave-start` option, to prevent premature startup of the replication process.

3. Create any databases on the slave cluster that are present on the master cluster that are to be replicated to the slave.

### Important

A `CREATE DATABASE` (or `CREATE SCHEMA`) statement corresponding to each database to be replicated must be executed on each SQL node in the slave cluster.

4. Reset the slave cluster using this statement in the MySQL Monitor:

```
mysqlS> RESET SLAVE;
```

It is important to make sure that the slave's `apply_status` table does not contain any records prior to running the restore process. You can accomplish this by running this SQL statement on the slave:

```
mysqlS> DELETE FROM mysql.ndb_apply_status;
```

5. You can now start the cluster restoration process on the replication slave using the `ndb_restore` command for each backup file in turn. For the first of these, it is necessary to include the `-m` option to restore the cluster metadata:

```
shellS> ndb_restore -c slave_host:port -n node-id \
 -b backup-id -m -r dir
```

`dir` is the path to the directory where the backup files have been placed on the replication slave. For the `ndb_restore` commands corresponding to the remaining backup files, the `-m` option should *not* be used.

For restoring from a master cluster with four data nodes (as shown in the figure in [Section 17.6, “MySQL Cluster Replication”](#)) where the backup files have been copied to the directory `/var/BACKUPS/BACKUP-1`, the proper sequence of commands to be executed on the slave might look like this:

```
shellS> ndb_restore -c rep-slave:1186 -n 2 -b 1 -m \
 -r ./var/BACKUPS/BACKUP-1
shellS> ndb_restore -c rep-slave:1186 -n 3 -b 1 \
 -r ./var/BACKUPS/BACKUP-1
shellS> ndb_restore -c rep-slave:1186 -n 4 -b 1 \
 -r ./var/BACKUPS/BACKUP-1
shellS> ndb_restore -c rep-slave:1186 -n 5 -b 1 -e \
 -r ./var/BACKUPS/BACKUP-1
```

### Important

The `-e` (or `--restore-epoch`) option in the final invocation of `ndb_restore` in this example is required in order that the epoch is written to the slave `mysql.ndb_apply_status`. Without this information, the slave will not be able to synchronize properly with the master. (See [Section 17.4.17, “ndb\\_restore — Restore a MySQL Cluster Backup”](#).)

6. Now you need to obtain the most recent epoch from the `ndb_apply_status` table on the slave (as discussed in [Section 17.4.17, “ndb\\_restore — Restore a MySQL Cluster Backup”](#)):

tion 17.6.8, “Implementing Failover with MySQL Cluster Replication”):

```
mysqlS> SELECT @latest:=MAX(epoch)
 FROM mysql.ndb_apply_status;
```

7. Using `@latest` as the epoch value obtained in the previous step, you can obtain the correct starting position `@pos` in the correct binary log file `@file` from the master's `mysql.ndb_binlog_index` table using the query shown here:

```
mysqlM> SELECT
 --> @file:=SUBSTRING_INDEX(File, '/', -1),
 --> @pos:=Position
 --> FROM mysql.ndb_binlog_index
 --> WHERE epoch > @latest
 --> ORDER BY epoch ASC LIMIT 1;
```

In the event that there is currently no replication traffic, you can get this information by running `SHOW MASTER STATUS` on the master and using the value in the `Position` column for the file whose name has the suffix with the greatest value for all files shown in the `File` column. However, in this case, you must determine this and supply it in the next step manually or by parsing the output with a script.

8. Using the values obtained in the previous step, you can now issue the appropriate `CHANGE MASTER TO` statement in the slave's `mysql` client:

```
mysqlS> CHANGE MASTER TO
 --> MASTER_LOG_FILE='@file',
 --> MASTER_LOG_POS=@pos;
```

9. Now that the slave “knows” from what point in which `binlog` file to start reading data from the master, you can cause the slave to begin replicating with this standard MySQL statement:

```
mysqlS> START SLAVE;
```

To perform a backup and restore on a second replication channel, it is necessary only to repeat these steps, substituting the host names and IDs of the secondary master and slave for those of the primary master and slave replication servers where appropriate, and running the preceding statements on them.

For additional information on performing Cluster backups and restoring Cluster from backups, see [Section 17.5.3, “Online Backup of MySQL Cluster”](#).

### 17.6.9.1. MySQL Cluster Replication: Automating Synchronization of the Replication Slave to the Master Binary Log

It is possible to automate much of the process described in the previous section (see [Section 17.6.9, “MySQL Cluster Backups With MySQL Cluster Replication”](#)). The following Perl script `reset-slave.pl` serves as an example of how you can do this.

```
#!/user/bin/perl -w

## 17.6.9.2. Point-In-Time Recovery Using MySQL Cluster Replication

*Point-in-time* recovery—that is, recovery of data changes made since a given point in time—is performed after restoring a full backup that returns the server to its state when the backup was made. Performing point-in-time recovery of MySQL Cluster tables with MySQL Cluster and MySQL Cluster Replication can be accomplished using a native NDB data backup (taken by issuing `CREATE BACKUP` in the `ndb_mgm` client) and restoring the `mysql.ndb_binlog_index` table (from a dump made using `mysqldump`).

To perform point-in-time recovery of MySQL Cluster, it is necessary to follow the steps shown here:

1. Back up all NDB databases in the cluster, using the `START BACKUP` command in the `ndb_mgm` client (see [Section 17.5.3, “Online Backup of MySQL Cluster”](#)).
  2. At some later point, prior to restoring the cluster, make a backup of the `mysql.ndb_binlog_index` table. It is probably simplest to use `mysqldump` for this task. Also back up the binary log files at this time.
- This backup should be updated regularly—perhaps even hourly—depending on your needs.
3. (*Catastrophic failure or error occurs.*)
  4. Locate the last known good backup.
  5. Clear the data node filesystems (using `ndbd --initial` or, in MySQL Cluster NDB 7.0 and later, `ndbmtd --initial`).

### Note

MySQL Cluster Disk Data tablespace and log files are not removed by `--initial`. You must delete these manually.

6. Use `DROP TABLE` or `TRUNCATE TABLE` with the `mysql.ndb_binlog_index` table.
7. Execute `ndb_restore`, restoring all data. You must include the `--restore_epoch` option when you run `ndb_restore`, so that the `ndb_apply_status` table is populated correctly. (See [Section 17.4.17, “ndb\\_restore —](#)

[Restore a MySQL Cluster Backup](#)”, for more information.)

8. Restore the `ndb_binlog_index` table from the output of `mysqldump` and restore the binary log files from backup, if necessary.
9. Find the epoch applied most recently—that is, the maximum `epoch` column value in the `ndb_apply_status` table—as the user variable `@LATEST_EPOCH` (emphasized):

```
SELECT @LAST_EPOCH:=MAX(epoch)
 FROM mysql.ndb_apply_status;
```

10. Find the latest binary log file (`@FIRST_FILE`) and position (`Position` column value) within this file that correspond to `@LATEST_EPOCH` in the `ndb_binlog_index` table:

```
SELECT Position, @FIRST_FILE:=File
 FROM mysql.ndb_binlog_index
 WHERE epoch > @LAST_EPOCH ORDER BY epoch ASC LIMIT 1;
```

11. Using `mysqlbinlog`, replay the binary log events from the given file and position up to the point of the failure. (See [Section 4.6.7, “mysqlbinlog — Utility for Processing Binary Log Files”](#).)

See also [Section 6.5, “Point-in-Time \(Incremental\) Recovery Using the Binary Log”](#), for more information about the binary log, replication, and incremental recovery.

## 17.6.10. MySQL Cluster Replication: Multi-Master and Circular Replication

Beginning with MySQL 5.1.18, it is possible to use MySQL Cluster in multi-master replication, including circular replication between a number of MySQL Clusters.

### Note

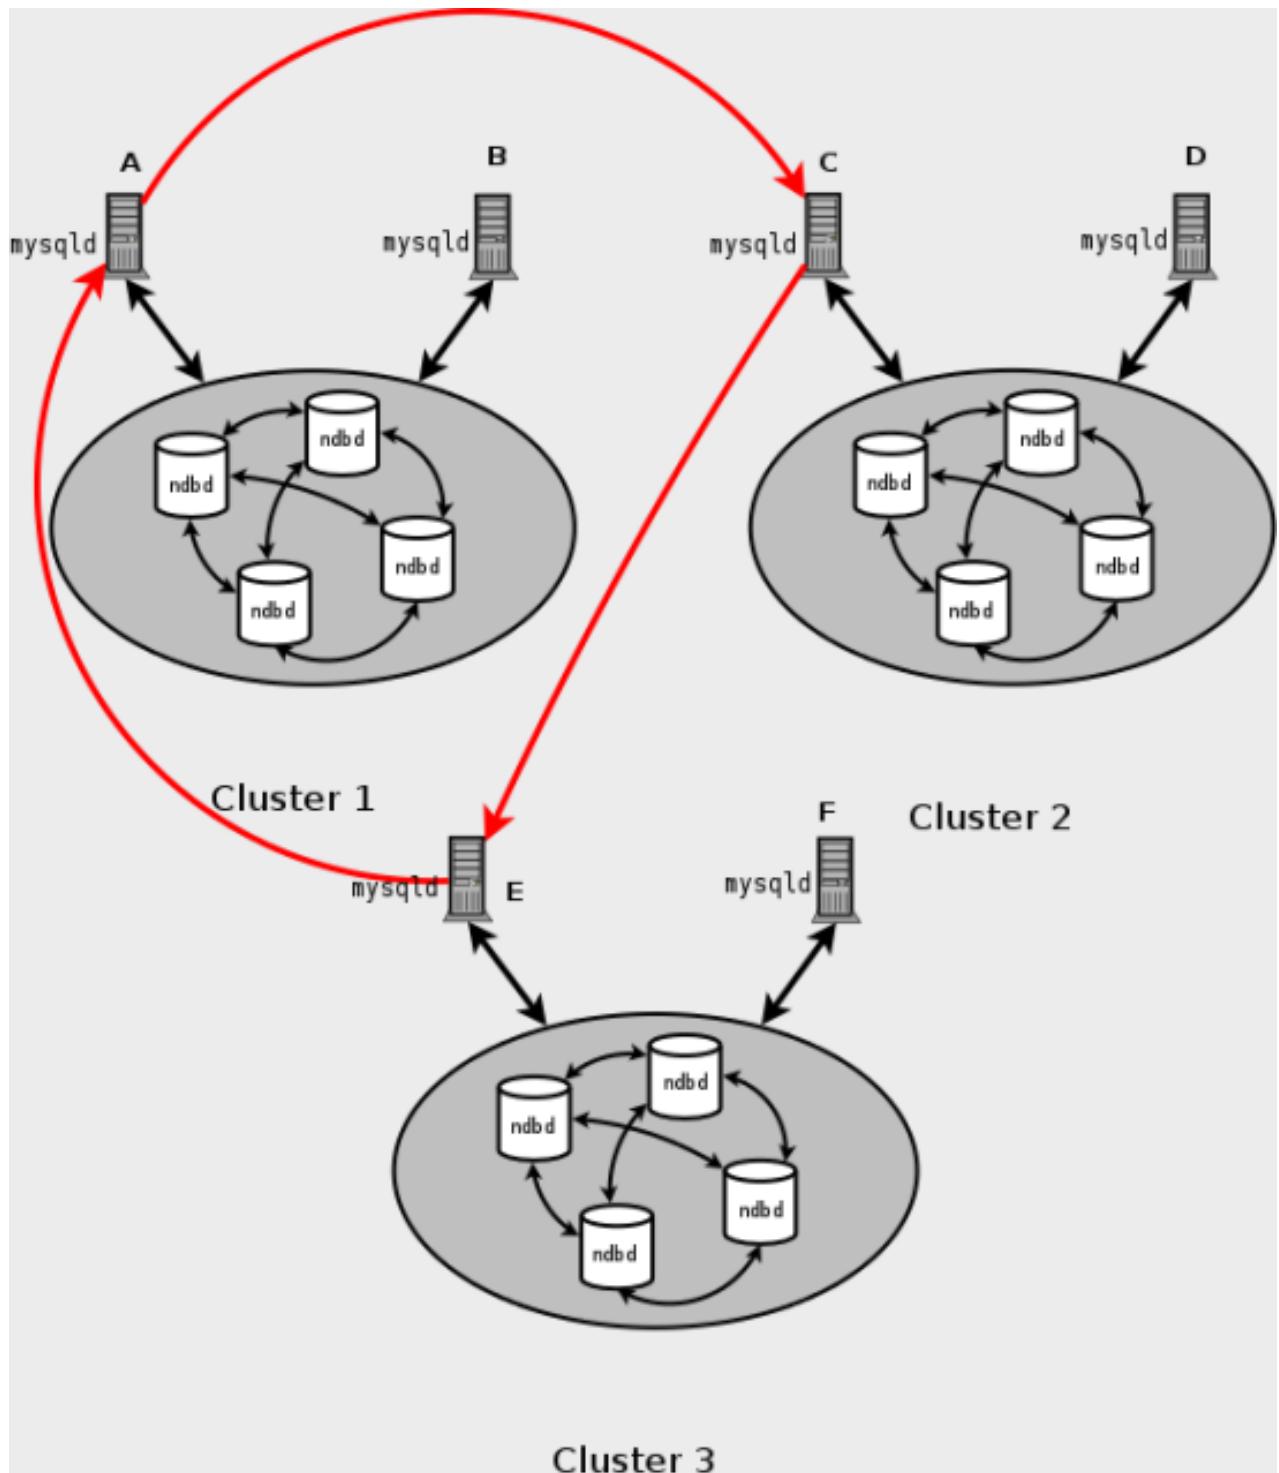

Prior to MySQL 5.1.18, multi-master replication including circular replication was not supported with MySQL Cluster replication. This was because log events created in a particular MySQL Cluster were wrongly tagged with the server ID of the master rather than the server ID of the originating server.

**Circular replication example.** In the next few paragraphs we consider the example of a replication setup involving three MySQL Clusters numbered 1, 2, and 3, in which Cluster 1 acts as the replication master for Cluster 2, Cluster 2 acts as the master for Cluster 3, and Cluster 3 acts as the master for Cluster 1. Each cluster has two SQL nodes, with SQL nodes A and B belonging to Cluster 1, SQL nodes C and D belonging to Cluster 2, and SQL nodes E and F belonging to Cluster 3.

Circular replication using these clusters is supported as long as:

- The SQL nodes on all masters and slaves are the same
- All SQL nodes acting as replication masters and slaves are started using the `--log-slave-updates` option

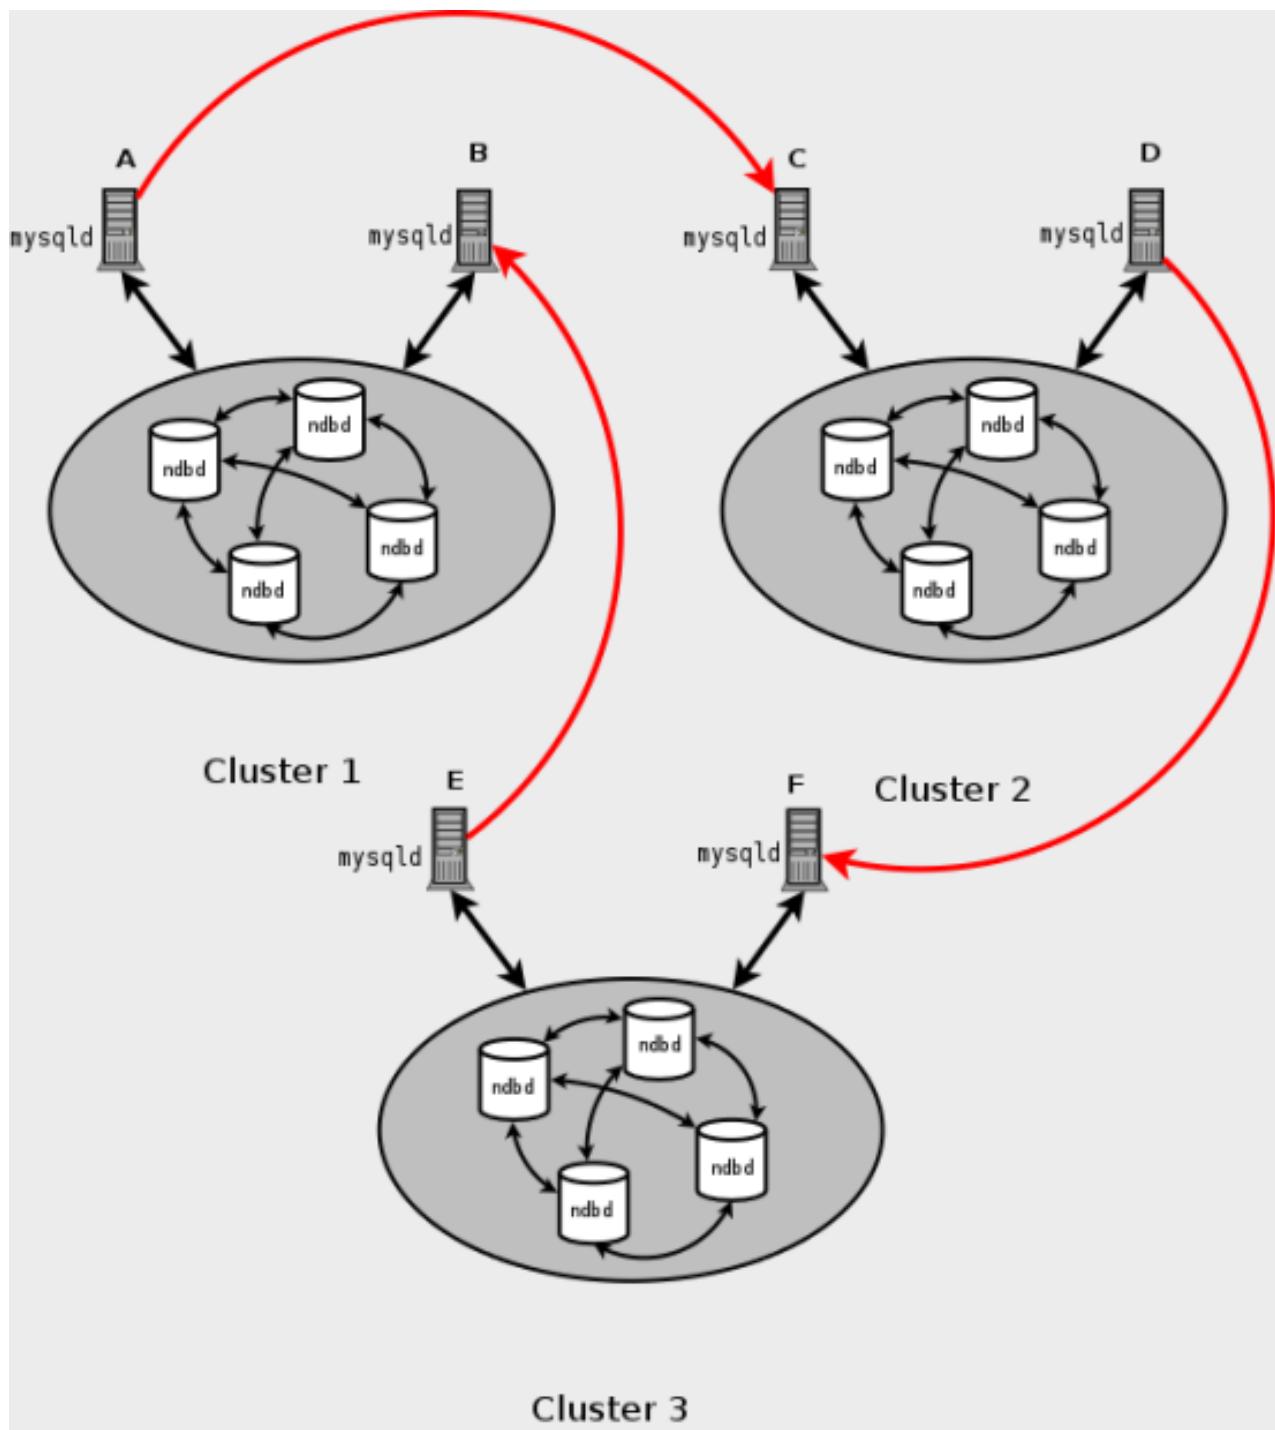

This type of circular replication setup is shown in the following diagram:

### Cluster 3

In this scenario, SQL node A in Cluster 1 replicates to SQL node C in Cluster 2; SQL node C replicates to SQL node E in Cluster 3; SQL node E replicates to SQL node A. In other words, the replication line (indicated by the red arrows in the diagram) directly connects all SQL nodes used as replication masters and slaves.

It is also possible to set up circular replication in such a way that not all master SQL nodes are also slaves, as shown here:

In this case, different SQL nodes in each cluster are used as replication masters and slaves. However, you must *not* start any of the SQL nodes using `--log-slave-updates` (see the [description of this option](#) for more information). This type of circular replication scheme for MySQL Cluster, in which the line of replication (again indicated by the red arrows in the diagram) is discontinuous, should be possible, but it should be noted that it has not yet been thoroughly tested and must therefore still be considered experimental.

### Important

Beginning with MySQL 5.1.24, you should execute the following statement before starting circular replication:

```
mysql> SET GLOBAL SLAVE_EXEC_MODE = 'IDEMPOTENT';
```

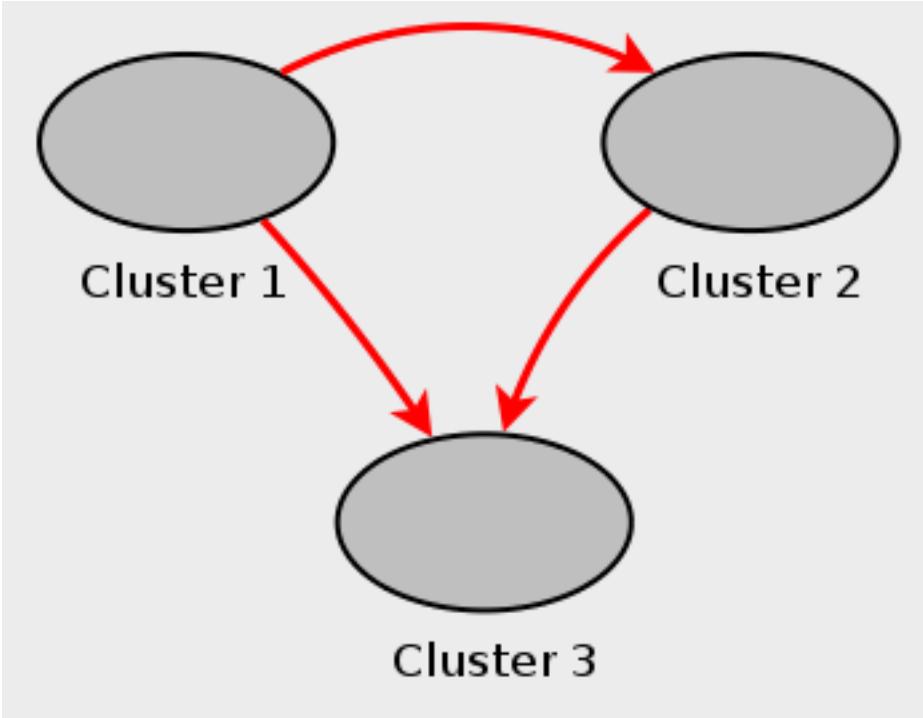

This is necessary to suppress duplicate-key and other errors that otherwise break circular replication in MySQL Cluster. `IDEMPOTENT` mode is also required for multi-master replication when using MySQL Cluster. ([Bug#31609](#))

See `slave_exec_mode`, for more information.

**Using NDB-native backup and restore to initialize a slave MySQL Cluster.** When setting up circular replication, it is possible to initialize the slave cluster by using the management client `BACKUP` command on one MySQL Cluster to create a backup and then applying this backup on another MySQL Cluster using `ndb_restore`. However, this does not automatically create binary logs on the second MySQL Cluster's SQL node acting as the replication slave. In order to cause the binary logs to be created, you must issue a `SHOW TABLES` statement on that SQL node; this should be done prior to running `START SLAVE`.

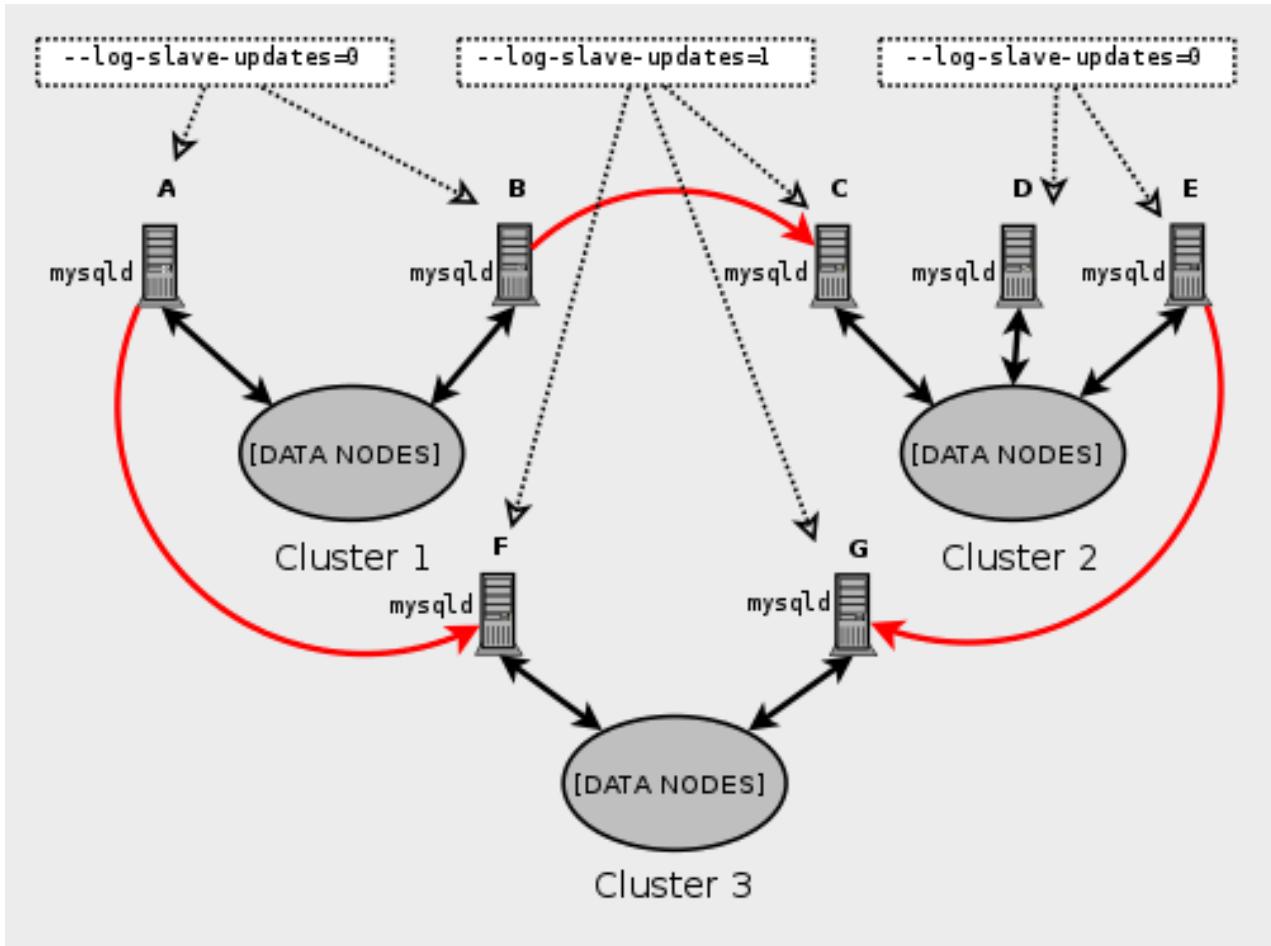

This is a known issue which we intend to address in a future release.

**Multi-master failover example.** In this section, we discuss failover in a multi-master MySQL Cluster replication setup with three MySQL Clusters having server IDs 1, 2, and 3. In this scenario, Cluster 1 replicates to Clusters 2 and 3; Cluster 2 also replicates to Cluster 3. This relationship is shown here:

In other words, data replicates from Cluster 1 to Cluster 3 through 2 different routes: directly, and by way of Cluster 2.

Not all MySQL servers taking part in multi-master replication must act as both master and slave, and a given MySQL Cluster might use different SQL nodes for different replication channels. Such a case is shown here:

MySQL servers acting as replication slaves must be run with the `--log-slave-updates` option. Which `mysqld` processes require this option is also shown in the preceding diagram.

### Note

Using the `--log-slave-updates` option has no effect on servers not being run as replication slaves.

The need for failover arises when one of the replicating clusters goes down. In this example, we consider the case where Cluster 1 is lost to service, and so Cluster 3 loses 2 sources of updates from Cluster 1. Because replication between MySQL Clusters is asynchronous, there is no guarantee that Cluster 3's updates originating directly from Cluster 1 are more recent than those received through Cluster 2. You can handle this by ensuring that Cluster 3 catches up to Cluster 2 with regard to updates from Cluster 1. In terms of MySQL servers, this means that you need to replicate any outstanding updates from MySQL server C to server F.

On server C, perform the following queries:

```
mysqlC> SELECT @latest:=MAX(epoch)
 -> FROM mysql.ndb_apply_status
 -> WHERE server_id=1;

mysqlC> SELECT
 -> @file:=SUBSTRING_INDEX(File, '/', -1),
 -> @pos:=Position
 -> FROM mysql.ndb_binlog_index
 -> WHERE orig_epoch >= @latest
 -> AND orig_server_id = 1
 -> ORDER BY epoch ASC LIMIT 1;
```

Copy over the values for `@file` and `@pos` manually from server C to server F (or have your application perform the equivalent). Then, on server F, execute the following `CHANGE MASTER TO` statement:

```
mysqlF> CHANGE MASTER TO
 -> MASTER_HOST = 'serverC'
 -> MASTER_LOG_FILE='@file',
 -> MASTER_LOG_POS=@pos;
```

Once this has been done, you can issue a `START SLAVE` statement on MySQL server F, and any missing updates originating from server B will be replicated to server F.

Beginning with MySQL Cluster MySQL Cluster NDB 6.1.29, MySQL Cluster NDB 6.3.31, MySQL Cluster NDB 7.0.11, and MySQL Cluster NDB 7.1.0, the `CHANGE MASTER TO` statement also supports an `IGNORE_SERVER_IDS` option which takes a comma-separated list of server IDs and causes events originating from the corresponding servers to be ignored. For more information, see [Section 12.5.2.1, “`CHANGE MASTER TO` Syntax”](#), and [Section 12.4.5.36, “`SHOW SLAVE STATUS` Syntax”](#).

## 17.6.11. MySQL Cluster Replication Conflict Resolution

When using a replication setup involving multiple masters (including circular replication), it is possible that different masters may try to update the same row on the slave with different data. Conflict resolution in MySQL Cluster Replication provides a means of resolving such conflicts by permitting a user-defined resolution column to be used to determine whether or not an update to the row on a given master should be applied on the slave. (This column is sometimes referred to as a “timestamp” column, even though this column’s type cannot be `TIMESTAMP`, as explained later in this section.) Different methods can be used to compare resolution column values on the slave when conflicts occur, as explained later in this section; the method used can be set on a per-table basis.

### Important

Conflict resolution as described in this section is always applied on a row-by-row basis rather than a transactional basis. In addition, it is the application’s responsibility to ensure that the resolution column is correctly populated with relevant values, so that the resolution function can make the appropriate choice when determining whether to apply an update.

**Requirements.** Preparations for conflict resolution must be made on both the master and the slave:

- On the master writing the binlogs, you must determine which columns are sent (all columns or only those that have been updated). This is done for the MySQL Server as a whole by applying the `mysqld` startup option `--ndb-log-updated-only` (described later in this section) or on a per-table basis by entries in the `mysql.ndb_replication` table.

### Note

If you are replicating tables with very large columns (such as `TEXT` or `BLOB` columns), `--ndb-log-updated-only` can also be useful for reducing the size of the master and slave binary logs and avoiding possible replication failures due to exceeding `max_allowed_packet`.

See [Section 16.4.1.18, “Replication and `max\_allowed\_packet`”](#), for more information about this issue.

- On the slave, you must determine which type of conflict resolution to apply (“latest timestamp wins”, “same timestamp wins”, or none). This is done using the `mysql.ndb_replication` system table, on a per-table basis.

If only some but not all columns are sent, then the master and slave can diverge.

### Note

We refer to the column used for determining updates as a “timestamp” column, but the data type of this column is never `TIMESTAMP`; rather, its data type should be `INT` (`INTEGER`) or `BIGINT`. This column should be `UNSIGNED` and `NOT NULL`.

**Master column control.** We can see update operations in terms of “before” and “after” images—that is, the states of the table before and after the update is applied. Normally, when updating a table with a primary key, the “before” image is not of great interest; however, when we need to determine on a per-update basis whether or not to use the updated values on a replication slave, we need to make sure that both images are written to the master’s binary log. This is done with the `--ndb-log-update-as-write` option for `mysqld`, as described later in this section.

### Important

Whether logging of complete rows or of updated columns only is done is decided when the MySQL server is started, and cannot be changed online; you must either restart `mysqld`, or start a new `mysqld` instance with different logging options.

#### Logging full or partial rows (`--ndb-log-updated-only` option)

<b>Version Introduced</b>	5.1.19-ndb-6.3.0
<b>Command-Line Format</b>	<code>--ndb-log-updated-only</code>
<b>Config-File Format</b>	<code>ndb_log_updated_only</code>
<b>Variable Name</b>	<code>ndb_log_updated_only</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes

Permitted Values	
Type	boolean
Default	ON

For purposes of conflict resolution, there are two basic methods of logging rows, as determined by the setting of the `--ndb-log-updated-only` option for `mysqld`:

- Log complete rows
- Log only column data that has been updated—that is, column data whose value has been set, regardless of whether or not this value was actually changed. This is the default behavior.

It is more efficient to log updated columns only; however, if you need to log full rows, you can do so by setting `--ndb-log-updated-only` to 0 or OFF.

#### Logging changed data as updates (`--ndb-log-update-as-write` option)

Version Introduced	5.1.22-ndb-6.2.5
Command-Line Format	<code>--ndb-log-update-as-write</code>
Config-File Format	<code>ndb-log-update-as-write</code>
Variable Name	<code>ndb_log_update_as_write</code>
Variable Scope	Global
Dynamic Variable	Yes
	Permitted Values
	Type boolean
	Default ON

Either of these logging methods can be configured to be done with or without the “before” image as determined by the setting of another MySQL Server option `--ndb-log-update-as-write`. Because conflict resolution is done in the MySQL Server’s update handler, it is necessary to control logging on the master such that updates are updates and not writes; that is, such that updates are treated as changes in existing rows rather than the writing of new rows (even though these replace existing rows). This option is turned on by default; to turn it off, start the server with `--ndb-log-update-as-write=0` or `--ndb-log-update-as-write=OFF`.

**Conflict resolution control.** Conflict resolution is usually enabled on the server where conflicts can occur. Like logging method selection, it is enabled by entries in the `mysql.ndb_replication` table.

The `ndb_replication` system table. To enable conflict resolution, it is necessary to create an `ndb_replication` table in the `mysql` system database on the master, the slave, or both, depending on the conflict resolution type and method to be employed. This table is used to control logging and conflict resolution functions on a per-table basis, and has one row per table involved in replication. `ndb_replication` is created and filled with control information on the server where the conflict is to be resolved. In a simple master-slave setup where data can also be changed locally on the slave this will typically be the slave. In a more complex master-master (2-way) replication schema this will usually be all of the masters involved. Each row in `mysql.ndb_replication` corresponds to a table being replicated, and specifies how to log and resolve conflicts (that is, which conflict resolution function, if any, to use) for that table. The definition of the `mysql.ndb_replication` table is shown here:

```
CREATE TABLE mysql.ndb_replication (
 db VARBINARY(63),
 table_name VARBINARY(63),
 server_id INT UNSIGNED,
 binlog_type INT UNSIGNED,
 conflict_fn VARBINARY(128),
 PRIMARY KEY USING HASH (db, table_name, server_id)
) ENGINE=NDB
PARTITION BY KEY(db,table_name);
```

The columns in this table are described in the following list:

- **db.** The name of the database containing the table to be replicated.
- **table\_name.** The name of the table to be replicated.

- **server\_id**. The unique server ID of the MySQL instance (SQL node) where the table resides.
- **binlog\_type**. The type of binary logging to be employed. This is determined as shown in the following table:

Value	Internal Value	Description
0	NBT_DEFAULT	Use server default
1	NBT_NO_LOGGING	Do not log this table in the binary log
2	NBT_UPDATED_ONLY	Only updated attributes are logged
3	NBT_FULL	Log full row, even if not updated (MySQL server default behavior)
4	NBT_USE_UPDATE	(For generating NBT_UPDATED_ONLY_USE_UPDATE and NBT_FULL_USE_UPDATE values only—not intended for separate use)
5	[Not used]	---
6	NBT_UPDATED_ONLY_USE_UPDA TE (equal to NBT_UPDATED_ONLY   NBT_USE_UPDATE)	Use updated attributes, even if values are unchanged
7	NBT_FULL_USE_UPDATE (equal to NBT_FULL   NBT_USE_UPDATE)	Use full row, even if values are unchanged

- **conflict\_fn**. The conflict resolution function to be applied. This function must be specified as one of the following:
  - **NDB\$OLD(column\_name)**. If the value of *column\_name* is the same on both the master and the slave, then the update is applied; otherwise, the update is not applied on the slave and an exception is written to the log. This is illustrated by the following pseudocode:

```
if (master_old_column_value == slave_current_column_value)
 perform_update();
else
 log_exception();
```

This function can be used for “same value wins” conflict resolution. This type of conflict resolution ensures that updates are not applied on the slave from the wrong master.

### Important

The column value from the master’s “before” image is used by this function.

This conflict resolution function is available beginning with MySQL Cluster NDB 6.3.4.

- **NDB\$MAX(column\_name)**. If the “timestamp” column value for a given row coming from the master is higher than that on the slave, it is applied; otherwise it is not applied on the slave. This is illustrated by the following pseudocode:

```
if (master_new_column_value > slave_current_column_value)
 perform_update();
```

This function can be used for “greatest timestamp wins” conflict resolution. This type of conflict resolution ensures that, in the event of a conflict, the version of the row that was most recently updated is the version that persists.

### Important

The column value from the master’s “after” image is used by this function.

This conflict resolution function is available beginning with MySQL Cluster NDB 6.3.0.

- **NDB\$MAX\_DELETE\_WIN(column\_name)**. This is a variation on **NDB\$MAX()**. Due to the fact that no timestamp is available for a delete operation, a delete using **NDB\$MAX()** is in fact processed as **NDB\$OLD**. However, for some use cases, this is not optimal. For **NDB\$MAX\_DELETE\_WIN()**, if the “timestamp” column value for a given row adding or updating an existing row coming from the master is higher than that on the slave, it is applied; however, delete operations are treated as always having the higher value. This is illustrated by the following pseudocode:

```
if ((master_new_column_value > slave_current_column_value)
 ||
 operation_type == "delete")
 perform_update();
```

This function can be used for “greatest timestamp, delete wins” conflict resolution. This type of conflict resolution ensures

that, in the event of a conflict, the version of the row that was deleted or (otherwise) most recently updated is the version that persists.

This conflict resolution function is available beginning with MySQL Cluster NDB 6.3.31 and MySQL Cluster NDB 7.0.11.

### Note

As with `NDB$MAX()`, the column value from the master's "after" image is the value used by this function.

- `NULL`. Indicates that conflict resolution is not to be used for the corresponding table.

**Status information.** Beginning with MySQL Cluster NDB 6.3.3, a server status variable `Ndb_conflict_fn_max` provides a count of the number of times that a row was not applied on the current SQL node due to "greatest timestamp wins" conflict resolution since the last time that `mysqld` was started.

Beginning with MySQL Cluster NDB 6.3.4, the number of times that a row was not applied as the result of "same timestamp wins" conflict resolution on a given `mysqld` since the last time it was restarted is given by the global status variable `Ndb_conflict_fn_old`. In addition to incrementing `Ndb_conflict_fn_old`, the primary key of the row that was not used is inserted into an *exceptions table*, as explained later in this section.

**Additional requirements for "Same timestamp wins" conflict resolution.** To use the `NDB$OLD()` conflict resolution function, it is also necessary to create an exceptions table corresponding to each `NDB` table for which this type of conflict resolution is to be employed. The name of this table is that of the table for which "same timestamp wins" conflict resolution is to be applied, with the string `$EX` appended. (For example, if the name of the original table is `mytable`, the name of the corresponding exception table name should be `mytable$EX`.) This table is created as follows:

```
CREATE TABLE original_table$EX (
 server_id INT UNSIGNED,
 master_server_id INT UNSIGNED,
 master_epoch BIGINT UNSIGNED,
 count INT UNSIGNED,
 original_table_pk_columns,
 [additional_columns],
 PRIMARY KEY(server_id, master_server_id, master_epoch, count)
) ENGINE=NDB;
```

The first four columns are required. Following these columns, the columns making up the original table's primary key should be copied in the order in which they are used to define the primary key of the original table.

### Note

The names of the first four columns and the columns matching the original table's primary key columns are not critical; however, we suggest for reasons of clarity and consistency, that you use the names shown here for the `server_id`, `master_server_id`, `master_epoch`, and `count` columns, and that you use the same names as in the original table for the columns matching those in the original table's primary key.

The data types for the columns duplicating the primary key columns of the original table should be the same as for (or larger than) the original columns.

Additional columns may optionally be defined following these columns, but not before any of them; any such extra columns cannot be `NOT NULL`. The exception table's primary key must be defined as shown. The exception table must use the `NDB` storage engine. An example of use for `NDB$OLD()` and an exception table is given later in this section.

### Important

The `mysql.ndb_replication` table is read when a data table is set up for replication, so the row corresponding to a table to be replicated must be inserted into `mysql.ndb_replication` before the table to be replicated is created.

**Examples.** The following examples assume that you have already a working MySQL Cluster replication setup, as described in Section 17.6.5, “Preparing the MySQL Cluster for Replication”, and Section 17.6.6, “Starting MySQL Cluster Replication (Single Replication Channel)”.

- **`NDB$MAX()` example.** Suppose you wish to enable "greatest timestamp wins" conflict resolution on table `test.t1`, using column `mycol` as the "timestamp". This can be done using the following steps:

1. Make sure that you have started the master `mysqld` with `--ndb-log-update-as-write=OFF`.
2. On the master, perform this `INSERT` statement:

```
INSERT INTO mysql.ndb_replication
VALUES ('test', 't1', 0, NULL, 'NDB$MAX(mycol)');
```

Inserting a 0 into the `server_id` indicates that all SQL nodes accessing this table should use conflict resolution. If you want to use conflict resolution on a specific `mysqld` only, use the actual server ID.

Inserting `NULL` into the `binlog_type` column has the same effect as inserting 0 (`NBT_DEFAULT`); the server default is used.

3. Create the `test.t1` table:

```
CREATE TABLE test.t1 (
 mycol INT UNSIGNED,
) ENGINE=NDB;
```

Now, when updates are done on this table, conflict resolution will be applied, and the version of the row having the greatest value for `mycol` will be written to the slave.

### Note

Other `binlog_type` options—such as `NBT_UPDATED_ONLY_USE_UPDATE` should be used to control logging on the master using the `ndb_replication` table rather than by using command-line options.

- **`NDB$OLD()` example.** Suppose an `NDB` table such as the one defined here is being replicated, and you wish to enable “same timestamp wins” conflict resolution for updates to this table:

```
CREATE TABLE test.t2 (
 a INT UNSIGNED NOT NULL,
 b CHAR(25) NOT NULL,
 mycol INT UNSIGNED NOT NULL,
 PRIMARY KEY pk (a, b)
) ENGINE=NDB;
```

The following steps are required, in the order shown:

1. First—and *prior* to creating `test.t2`—you must insert a row into the `mysql.ndb_replication` table, as shown here:

```
INSERT INTO mysql.ndb_replication
VALUES ('test', 't2', 0, NULL, 'NDB$OLD(mycol)');
```

Possible values for the `binlog_type` column are shown earlier in this section. The value '`NDB$OLD(mycol)`' should be inserted into the `conflict_fn` column.

2. Create an appropriate exceptions table for `test.t2`. The table creation statement shown here includes all required columns; any additional columns must be declared following these columns, and before the definition of the table's primary key.

```
CREATE TABLE test.t2$EX (
 server_id SMALLINT UNSIGNED,
 master_server_id INT UNSIGNED,
 master_epoch BIGINT UNSIGNED,
 count BIGINT UNSIGNED,
 a INT UNSIGNED NOT NULL,
 b CHAR(25) NOT NULL,
 [additional_columns],
 PRIMARY KEY(server_id, master_server_id, master_epoch, count)
) ENGINE=NDB;
```

3. Create the table `test.t2` as shown previously.

These steps must be followed for every table for which you wish to perform conflict resolution using `NDB$OLD()`. For each such table, there must be a corresponding row in `mysql.ndb_replication`, and there must be an exceptions table in the same database as the table being replicated.

## 17.7. Changes in MySQL Cluster NDB 6.X and 7.X

This section contains changelog information for MySQL Cluster releases that use versions 6.1, 6.2, 6.3, 7.0, and 7.1 of the `NDB-CLUSTER` storage engine.

### Note

Version 7.0 of the `NDBCLUSTER` storage engine was previously known as “NDB 6.4”. For more information, see [Section 17.7.2, “Changes in MySQL Cluster NDB 7.0”](#).

Each MySQL Cluster release is based on a mainline MySQL 5.1 release and a particular version of the `NDBCLUSTER` storage engine, as shown in the version string returned by executing `SELECT VERSION()` in the `mysql` client, or by executing the `ndb_mgm` client `SHOW` or `STATUS` command; for more information, see [Chapter 17, MySQL Cluster NDB 6.X/7.X](#).

For general information about features added in MySQL Cluster, see [Section 17.1.4, “MySQL Cluster Development History”](#). For a complete list of all bugfixes and feature changes in MySQL Cluster, please refer to the changelog section for each individual MySQL Cluster release.

An overview of features added in MySQL 5.1 not specific to MySQL Cluster can be found here: [Section 1.5, “What Is New in MySQL 5.1”](#). For a complete list of all bugfixes and features changes made in MySQL 5.1 that are not specific to MySQL Cluster, see [Section C.1, “Changes in Release 5.1.x \(Production\)”](#).

This section contains changelogs for individual MySQL Cluster NDB 6.X and 7.X releases.

For long-format changelogs covering each MySQL Cluster NDB 6.X and 7.X series, see [Section 17.7.6, “Release Series Changelogs: MySQL Cluster NDB 6.X and 7.X”](#).

## 17.7.1. Changes in MySQL Cluster NDB 7.1

This section contains change history information for MySQL Cluster releases based on version 7.1 of the `NDBCLUSTER` storage engine, currently in development.

For an overview of new features added in MySQL Cluster NDB 7.1, see [Section 17.1.4.1, “MySQL Cluster Development in MySQL Cluster NDB 7.1”](#).

### 17.7.1.1. Changes in MySQL Cluster NDB 7.1.8 (5.1.47-ndb-7.1.8) (Not yet released)

MySQL Cluster NDB 7.1.6 is a new release of MySQL Cluster, incorporating new features in the `NDBCLUSTER` storage engine and fixing recently discovered bugs in MySQL Cluster NDB 7.1.7 and previous MySQL Cluster releases.

**Obtaining MySQL Cluster NDB 7.1.** The latest MySQL Cluster NDB 7.1 binaries for supported platforms can be obtained from <http://dev.mysql.com/downloads/cluster/>. Source code for the latest MySQL Cluster NDB 7.1 release can be obtained from the same location.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.47 (see [Section C.1.4, “Changes in MySQL 5.1.47 \(06 May 2010\)”](#)).

Functionality added or changed:

- `mysqldump` as supplied with MySQL Cluster now has an `--add-drop-trigger` option which adds a `DROP TRIGGER IF EXISTS` statement before each dumped trigger definition. ([Bug#5691](#))

See also [Bug#34325](#).

Bugs fixed:

- Under certain rare conditions, attempting to start more than one `ndb_mgmd` process simultaneously using the `--reload` option caused a race condition such that none of the `ndb_mgmd` processes could start. ([Bug#56844](#))
- When distributing `CREATE TABLE` and `DROP TABLE` operations among several SQL nodes attached to a MySQL Cluster, the `LOCK_OPEN` lock normally protecting `mysqld`'s internal table list is released so that other queries or DML statements are not blocked. However, to make sure that other DDL is not executed simultaneously, a global schema lock (implemented as a row-level lock by `NDB`) is used, such that all operations that can modify the state of the `mysqld` internal table list also need to acquire this global schema lock. The `SHOW TABLE STATUS` statement did not acquire this lock. ([Bug#56841](#))
- MySQL Cluster stores, for each row in each `NDB` table, a Global Checkpoint Index (GCI) which identifies the last committed transaction that modified the row. As such, a GCI can be thought of as a coarse-grained row version.

Due to changes in the format used by `NDB` to store local checkpoints (LCPs) in MySQL Cluster NDB 6.3.11, it could happen that, following cluster shutdown and subsequent recovery, the GCI values for some rows could be changed unnecessarily; this could possibly, over the course of many node or system restarts (or both), lead to an inconsistent database. ([Bug#56770](#))

- When multiple SQL nodes were connected to the cluster and one of them stopped in the middle of a DDL operation, the

`mysqld` process issuing the DDL timed out with the error `DISTRIBUTING TBL_NAME TIMED OUT. IGNORING.` ([Bug#56763](#))

- An online `ALTER TABLE ... ADD COLUMN` operation that changed the table schema such that the number of 32-bit words used for the bitmask allocated to each DML operation increased during a transaction in DML which was performed prior to DDL which was followed by either another DML operation or—if using replication—a commit, led to data node failure.

This was because the data node did not take into account that the bitmask for the before-image was smaller than the current bitmask, which caused the node to crash. ([Bug#56524](#))

- On Windows, a data node refused to start in some cases unless the `ndbd.exe` executable was invoked using an absolute rather than a relative path. ([Bug#56257](#))
- The failure of a data node during some scans could cause other data nodes to fail. ([Bug#54945](#))
- Exhausting the number of available commit-ack markers (controlled by the `MaxNoOfConcurrentTransactions` parameter) led to a data node crash. ([Bug#54944](#))
- When running a `SELECT` on an `NDB` table with `BLOB` or `TEXT` columns, memory was allocated for the columns but was not freed until the end of the `SELECT`. This could cause problems with excessive memory usage when dumping (using for example `mysqldump`) tables with such columns and having many rows, large column values, or both. ([Bug#52313](#))

See also [Bug#56488](#), [Bug#50310](#).

- **Cluster Replication:** When an SQL node starts, as part of setting up replication, it subscribes to data events from all data nodes using a `SUB_START_REQ` (subscription start request) signal. Atomicity of `SUB_START_REQ` is implemented such that, if any of the nodes returns an error, a `SUB_STOP_REQ` (subscription stop request) is sent to any nodes that replied with a `SUB_START_CONF` (subscription start confirmation). However, if all data nodes returned an error, `SUB_STOP_REQ` was not sent to any of them. This caused `mysqld` to hang when restarting (while waiting for a response), and subsequent data node restarts to hang as well. ([Bug#56579](#))

### 17.7.1.2. Changes in MySQL Cluster NDB 7.1.7 (5.1.47-ndb-7.1.7) (03 September 2010)

MySQL Cluster NDB 7.1.7 is a new release of MySQL Cluster, incorporating new features in the `NDBCLUSTER` storage engine and fixing recently discovered bugs in MySQL Cluster NDB 7.1.6 and previous MySQL Cluster releases.

**Obtaining MySQL Cluster NDB 7.1.** The latest MySQL Cluster NDB 7.1 binaries for supported platforms can be obtained from <http://dev.mysql.com/downloads/cluster/>. Source code for the latest MySQL Cluster NDB 7.1 release can be obtained from the same location.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.47 (see [Section C.1.4, “Changes in MySQL 5.1.47 \(06 May 2010\)”](#)).

Functionality added or changed:

- **Important Change:** More finely-grained control over restart-on-failure behavior is provided with two new data node configuration parameters `MaxStartFailRetries` and `StartFailRetryDelay`. `MaxStartFailRetries` limits the total number of retries made before giving up on starting the data node; `StartFailRetryDelay` sets the number of seconds between retry attempts.

These parameters are used only if `StopOnError` is set to 0.

For more information, see [Section 17.3.2.6, “Defining MySQL Cluster Data Nodes”](#). ([Bug#54341](#))

Bugs fixed:

- **Important Change:** It is no longer possible to make a dump of the `ndbinfo` database using `mysqldump`. ([Bug#54316](#))
- `ndb_restore` always reported 0 for the `GCPStop` (end point of the backup). Now it provides useful binary log position and epoch information. ([Bug#56298](#))
- The `LockExecuteThreadToCPU` configuration parameter was not handled correctly for CPU ID values greater than 255. ([Bug#56185](#))
- Following a failure of the master data node, the new master sometimes experienced a race condition which caused the node to terminate with a `GcpStop` error. ([Bug#56044](#))

- Trying to create a table having a `BLOB` or `TEXT` column with `DEFAULT ''` failed with the error `ILLEGAL NULL ATTRIBUTE`. (An empty default is allowed and ignored by `MyISAM`; `NDB` should do the same.) ([Bug#55121](#))
- `ndb_mgmd --nodaemon` logged to the console in addition to the configured log destination. ([Bug#54779](#))
- The warning `MAXNOFEXECUTIONTHREADS (#) > LOCKEXECUTETHREADTOCPU COUNT (#), THIS COULD CAUSE CONTENTION` could be logged when running `ndbd`, even though the condition described can occur only when using `ndbmtd`. ([Bug#54342](#))
- Startup messages previously written by `ndb_mgmd` to `stdout` are now written to the cluster log instead when `LogDestination` is set. ([Bug#47595](#))
- The graceful shutdown of a data node could sometimes cause transactions to be aborted unnecessarily. ([Bug#18538](#))  
See also [Bug#55641](#).
- **Cluster Replication:** The graceful shutdown of a data node in the master cluster could sometimes cause rows to be skipped when writing transactions to the binary log, leading to an inconsistent slave cluster. ([Bug#55641](#))  
See also [Bug#18538](#).
- **Cluster Replication:** Specifying the `--expire_logs_days` option when there were old binary logs to delete caused SQL nodes to crash on startup. ([Bug#41751](#))

### 17.7.1.3. Changes in MySQL Cluster NDB 7.1.6 (5.1.47-ndb-7.1.6) (16 August 2010)

MySQL Cluster NDB 7.1.6 is a new release of MySQL Cluster, incorporating new features in the `NDBCCLUSTER` storage engine and fixing recently discovered bugs in MySQL Cluster NDB 7.1.5 and previous MySQL Cluster releases.

**Obtaining MySQL Cluster NDB 7.1.** The latest MySQL Cluster NDB 7.1 binaries for supported platforms can be obtained from <http://dev.mysql.com/downloads/cluster/>. Source code for the latest MySQL Cluster NDB 7.1 release can be obtained from the same location.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.47 (see [Section C.1.4, “Changes in MySQL 5.1.47 \(06 May 2010\)”](#)).

Functionality added or changed:

- Added the `DictTrace` data node configuration parameter, for use in debugging NDB code. For more information, see [Section 17.3.2.6, “Defining MySQL Cluster Data Nodes”](#). ([Bug#55963](#))
- Added the `--server-id-bits` option for `mysqld` and `mysqlbinlog`.

For `mysqld`, the `--server-id-bits` option indicates the number of least significant bits within the 32-bit server ID which actually identify the server. Indicating that the server ID uses less than 32 bits permits the remaining bits to be used for other purposes by NDB API applications using the Event API and `NdbOperation::OperationOptions::AnyValue`.

For `mysqlbinlog`, the `--server-id-bits` option tells `mysqlbinlog` how to interpret the server IDs in the binary log when the binary log was written by a `mysqld` having its `server_id_bits` set to less than the maximum (32). ([Bug#52305](#))

Bugs fixed:

- **Cluster API: Important Change:** The poll and select calls made by the MGM API were not interrupt-safe; that is, a signal caught by the process while waiting for an event on one or more sockets returned error -1 with `errno` set to `EINTR`. This caused problems with MGM API functions such as `ndb_mgm_logevent_get_next()` and `ndb_mgm_get_status2()`.

To fix this problem, the internal `ndb_socket_poller::poll()` function has been made `EINTR`-safe.

The old version of this function has been retained as `poll_unsafe()`, for use by those parts of NDB that do not need the `EINTR`-safe version of the function. ([Bug#55906](#))

- The TCP configuration parameters `HostName1` and `HostName2` were not displayed in the output of `ndb_config -configinfo`. ([Bug#55839](#))
- When another data node failed, a given data node `DBTC` kernel block could time out while waiting for `DBDIH` to signal com-

mits of pending transactions, leading to a crash. Now in such cases the timeout generates a prinout, and the data node continues to operate. ([Bug#55715](#))

- Using the `--disable-config-cache` option with `ndb_mgmd` caused a memory leak. ([Bug#55205](#))
- The `configure.js` option `WITHOUT_DYNAMIC_PLUGINS=TRUE` was ignored when building MySQL Cluster for Windows using `CMake`. Among the effects of this issue was that `CMake` attempted to build the `InnoDB` storage engine as a plugin (`.DLL` file) even though the `InnoDB Plugin` is not currently supported by MySQL Cluster. ([Bug#54913](#))
- It was possible for a `DROP DATABASE` statement to remove `NDB` hidden blob tables without removing the parent tables, with the result that the tables, although hidden to MySQL clients, were still visible in the output of `ndb_show_tables` but could not be dropped using `ndb_drop_table`. ([Bug#54788](#))
- An excessive number of timeout warnings (normally used only for debugging) were written to the data node logs. ([Bug#53987](#))
- **Disk Data:** As an optimization when inserting a row to an empty page, the page is not read, but rather simply initialized. However, this optimization was performed in all cases when an empty row was inserted, even though it should have been done only if it was the first time that the page had been used by a table or fragment. This is because, if the page had been in use, and then all records had been released from it, the page still needed to be read to learn its log sequence number (LSN).

This caused problems only if the page had been flushed using an incorrect LSN and the data node failed before any local checkpoint was completed—which would removed any need to apply the undo log, hence the incorrect LSN was ignored.

The user-visible result of the incorrect LSN was that it caused the data node to fail during a restart. It was perhaps also possible (although not conclusively proven) that this issue could lead to incorrect data. ([Bug#54986](#))

- **Cluster API:** Calling `NdbTransaction::refresh()` did not update the timer for `TransactionInactiveTimeout`. ([Bug#54724](#))

#### 17.7.1.4. Changes in MySQL Cluster NDB 7.1.5 (5.1.47-ndb-7.1.5) (25 June 2010)

MySQL Cluster NDB 7.1.5 is a new release of MySQL Cluster, incorporating new features in the `NDBCLUSTER` storage engine and fixing recently discovered bugs in MySQL Cluster NDB 7.1.4 and previous MySQL Cluster releases.

**Obtaining MySQL Cluster NDB 7.1.** The latest MySQL Cluster NDB 7.1 binaries for supported platforms can be obtained from <http://dev.mysql.com/downloads/cluster/>. Source code for the latest MySQL Cluster NDB 7.1 release can be obtained from the same location.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.47 (see [Section C.1.4, “Changes in MySQL 5.1.47 \(06 May 2010\)”](#)).

Functionality added or changed:

- Restrictions on some types of mismatches in column definitions when restoring data using `ndb_restore` have been relaxed. These include the following types of mismatches:
  - Different `COLUMN_FORMAT` settings (`FIXED, DYNAMIC, DEFAULT`)
  - Different `STORAGE` settings (`MEMORY, DISK`)
  - Different default values
  - Different distribution key settings

Now, when one of these types of mismatches in column definitions is encountered, `ndb_restore` no longer stops with an error; instead, it accepts the data and inserts it into the target table, while issuing a warning to the user.

For more information, see [Section 17.4.17, “`ndb\_restore` — Restore a MySQL Cluster Backup”](#). ([Bug#54423](#))

See also [Bug#53810](#), [Bug#54178](#), [Bug#54242](#), [Bug#54279](#).

- It is now possible to install management node and data node processes as Windows services. (See [Section 17.2.2.4, “Installing MySQL Cluster Processes as Windows Services”](#), for more information.) In addition, data node processes on Windows are now maintained by angel processes, just as they are on other platforms supported by MySQL Cluster.

Bugs fixed:

- The disconnection of all API nodes (including SQL nodes) during an `ALTER TABLE` caused a memory leak. ([Bug#54685](#))
- If a node shutdown (either in isolation or as part of a system shutdown) occurred directly following a local checkpoint, it was possible that this local checkpoint would not be used when restoring the cluster. ([Bug#54611](#))
- The setting for `BuildIndexThreads` was ignored by `ndbmtd`, which made it impossible to use more than 4 cores for re-building indexes. ([Bug#54521](#))
- When adding multiple new node groups to a MySQL Cluster, it was necessary for each new node group to add only the nodes to be assigned to the new node group, create that node group using `CREATE NODEGROUP`, then repeat this process for each new node group to be added to the cluster. The fix for this issue makes it possible to add all of the new nodes at one time, and then issue several `CREATE NODEGROUP` commands in succession. ([Bug#54497](#))
- When performing an online alter table where 2 or more SQL nodes connected to the cluster were generating binary logs, an incorrect message could be sent from the data nodes, causing `mysqld` processes to crash. This problem was often difficult to detect, because restarting SQL node or data node processes could clear the error, and because the crash in `mysqld` did not occur until several minutes after the erroneous message was sent and received. ([Bug#54168](#))
- A table having the maximum number of attributes permitted could not be backed up using the `ndb_mgm` client.

#### Note

The maximum number of attributes supported per table is not the same for all MySQL Cluster releases. See [Section 17.1.5.5, “Limits Associated with Database Objects in MySQL Cluster”](#), to determine the maximum that applies in the release which you are using.

([Bug#54155](#))

- The presence of duplicate `[tcp]` sections in the `config.ini` file caused the management server to crash. Now in such cases, `ndb_mgmd` fails gracefully with an appropriate error message. ([Bug#49400](#))
  - The two MySQL Server options, `--ndb-wait-connected` and `--ndb-wait-setup`, did not set the corresponding system variables. ([Bug#48402](#))
  - **Cluster Replication:** An error in an `NDB` internal byte mask value could lead to corruption of replicated `BIT` column values. ([Bug#54005](#))
- See also [Bug#53622](#).
- **Cluster API:** When using the NDB API, it was possible to rename a table with the same name as that of an existing table.

#### Note

This issue did not affect table renames executed using SQL on MySQL servers acting as MySQL Cluster API nodes.

([Bug#54651](#))

- **Cluster API:** An excessive number of client connections, such that more than 1024 file descriptors, sockets, or both were open, caused NDB API applications to crash. ([Bug#34303](#))

### 17.7.1.5. Changes in MySQL Cluster NDB 7.1.4b (5.1.44-ndb-7.1.4b) (18 June 2010)

This release replaces MySQL Cluster NDB 7.1.4, fixing a critical issue in that version that was discovered shortly after its release ([Bug#54242](#)), as well as MySQL Cluster NDB 7.1.4a, which was not actually released due to [Bug#54516](#) being found during testing. Users of MySQL Cluster NDB 7.1.3 or MySQL Cluster NDB 7.1.4 should upgrade to the 7.1.4b release as soon as possible.

**Obtaining MySQL Cluster NDB 7.1.4b.** The latest MySQL Cluster NDB 7.1 binaries for supported platforms can be obtained from <http://dev.mysql.com/downloads/cluster/>. Source code for the latest MySQL Cluster NDB 7.1 release can be obtained from the same location.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.44 (see [Section C.1.8, “Changes in MySQL 5.1.44 \(04 February 2010\)”](#)).

Functionality added or changed:

- **Important Change:** Commercial binary releases of MySQL Cluster NDB 7.1 now include support for the `InnoDB` storage engine. ([Bug#52945](#))

The patch for the following bugs was reverted: [Bug#31989](#).

Bugs fixed:

- **Cluster API:** The value of an internal constant used in the implementation of the `NdbOperation` and `NdbScanOperation` classes, causing MySQL Cluster NDB 7.0 NDB API applications compiled against MySQL Cluster NDB 7.0.14 or earlier to fail when run with MySQL Cluster 7.0.15, and MySQL Cluster NDB 7.1 NDB API applications compiled against MySQL Cluster NDB 7.1.3 or earlier to break when used with MySQL Cluster 7.1.4. ([Bug#54516](#))

### 17.7.1.6. Changes in MySQL Cluster NDB 7.1.4a (5.1.44-ndb-7.1.4a) (Not released)

This was intended as a replacement release for MySQL Cluster NDB 7.1.4, fixing a critical issue in that version that was discovered shortly after its release ([Bug#54242](#)); however, MySQL Cluster NDB 7.1.4a was not actually released due to [Bug#54516](#) being found during testing. Users of MySQL Cluster NDB 7.1.3 or MySQL Cluster NDB 7.1.4 should upgrade to the 7.1.4b release as soon as possible.

The latest MySQL Cluster NDB 7.1 binaries for supported platforms can be obtained from <http://dev.mysql.com/downloads/cluster/>. Source code for the latest MySQL Cluster NDB 7.1 release can be obtained from the same location.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.44 (see [Section C.1.8, “Changes in MySQL 5.1.44 \(04 February 2010\)”](#)).

Bugs fixed:

- When using `mysqldump` to back up and restore schema information while using `ndb_restore` for restoring only the data, restoring to MySQL Cluster NDB 7.1.4 from an older version failed on tables having columns with default values. This was because versions of MySQL Cluster prior to MySQL Cluster NDB 7.1.4 did not have native support for default values.

In addition, the MySQL Server supports `TIMESTAMP` columns having dynamic default values, such as `DEFAULT CURRENT_TIMESTAMP`; however, the current implementation of NDB-native default values permits only a constant default value.

To fix this issue, the manner in which NDB treats `TIMESTAMP` columns is reverted to its pre-NDB-7.1.4 behavior (obtaining the default value from `mysqlid` rather than `NDBCLUSTER`) except where a `TIMESTAMP` column uses a constant default, as in the case of a column declared as `TIMESTAMP DEFAULT 0` or `TIMESTAMP DEFAULT 20100607174832`. ([Bug#54242](#))

### 17.7.1.7. Changes in MySQL Cluster NDB 7.1.4 (5.1.44-ndb-7.1.4) (31 May 2010)

MySQL Cluster NDB 7.1.4 is a new release of MySQL Cluster, incorporating new features in the `NDBCLUSTER` storage engine and fixing recently discovered bugs in MySQL Cluster NDB 7.1.3 and previous MySQL Cluster releases.

**Obtaining MySQL Cluster NDB 7.1.** The latest MySQL Cluster NDB 7.1 binaries for supported platforms can be obtained from <http://dev.mysql.com/downloads/cluster/>. Source code for the latest MySQL Cluster NDB 7.1 release can be obtained from the same location.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.44 (see [Section C.1.8, “Changes in MySQL 5.1.44 \(04 February 2010\)”](#)).

Functionality added or changed:

- **Important Change:** The maximum number of attributes (columns plus indexes) per table has increased to 512.
- A `--wait-nodes` option has been added for `ndb_waiter`. When this option is used, the program waits only for the nodes having the listed IDs to reach the desired state. For more information, see [Section 17.4.22, “ndb\\_waiter — Wait for MySQL Cluster to Reach a Given Status”](#). ([Bug#52323](#))
- As part of this change, new methods relating to default values have been added to the `Column` and `Table` classes in the NDB API. For more information, see `Column::getDefaultValue()`, `Column::setDefaultValue()`, and `Table::hasDefaultValues()`. ([Bug#30529](#))
- Added the MySQL Cluster management server option `--config-cache`, which makes it possible to enable and disable configuration caching. This option is turned on by default; to disable configuration caching, start `ndb_mgmd` with `-`

`--config-cache=0`, or with `--skip-config-cache`. See Section 17.4.4, “`ndb_mgmd` — The MySQL Cluster Management Server Daemon”, for more information.

- Added the `--skip-unknown-objects` option for `ndb_restore`. This option causes `ndb_restore` to ignore any schema objects which it does not recognize. Currently, this is useful chiefly for restoring native backups made from a cluster running MySQL Cluster NDB 7.0 to a cluster running MySQL Cluster NDB 6.3.

Bugs fixed:

- Cluster API: Incompatible Change:** The default behavior of the NDB API Event API has changed as follows:

Previously, when creating an `NdbDictionary::Event`, DDL operations (alter and drop operations on tables) were automatically reported on any event operation that used this event, but as a result of this change, this is no longer the case. Instead, you must now invoke the event's `setReport()` method, with the new `EventReport` value `ER_DDL`, to get this behavior.

For existing NDB API applications where you wish to retain the old behavior, you must update the code as indicated previously, then recompile, following an upgrade. Otherwise, DDL operations are no longer reported after upgrading `libndbclient`.

For more information, see [The `Event::EventReport` Type](#), and [Event::setReport\(\)](#). ([Bug#53308](#))

- After creating `NDB` tables until creation of a table failed due to `NDB` error 905 `OUT OF ATTRIBUTE RECORDS (INCREASE MAXNOFATTRIBUTES)`, then increasing `MaxNoOfAttributes` and restarting all management node and data node processes, attempting to drop and re-create one of the tables failed with the error `OUT OF TABLE RECORDS...`, even when sufficient table records were available. ([Bug#53944](#))

See also [Bug#52055](#).

- Creating a Disk Data table, dropping it, then creating an in-memory table and performing a restart, could cause data node processes to fail with errors in the `DBTUP` kernel block if the new table's internal ID was the same as that of the old Disk Data table. This could occur because undo log handling during the restart did not check that the table having this ID was now in-memory only. ([Bug#53935](#))
- A table created while `ndb_table_no_logging` was enabled was not always stored to disk, which could lead to a data node crash with `ERROR OPENING DIH SCHEMA FILES FOR TABLE`. ([Bug#53934](#))
- An internal buffer allocator used by `NDB` has the form `alloc(wanted, minimum)` and attempts to allocate `wanted` pages, but is permitted to allocate a smaller number of pages, between `wanted` and `minimum`. However, this allocator could sometimes allocate fewer than `minimum` pages, causing problems with multi-threaded building of ordered indexes. ([Bug#53580](#))
- When compiled with support for `epoll` but this functionality is not available at runtime, MySQL Cluster tries to fall back to use the `select()` function in its place. However, an extra `ndbout_c()` call in the transporter registry code caused `ndbd` to fail instead. ([Bug#53482](#))
- The value set for the `ndb_mgmd` option `--ndb-nodeid` was not verified prior to use as being within the permitted range (1 to 255, inclusive), leading to a crash of the management server. ([Bug#53412](#))
- `NDB` truncated a column declared as `DECIMAL(65, 0)` to a length of 64. Now such a column is accepted and handled correctly. In cases where the maximum length (65) is exceeded, `NDB` now raises an error instead of truncating. ([Bug#53352](#))
- When an `NDB` log handler failed, the memory allocated to it was freed twice. ([Bug#53200](#))
- Setting `DataMemory` higher than 4G on 32-bit platforms caused `ndbd` to crash, instead of failing gracefully with an error. ([Bug#52536](#), [Bug#50928](#))
- When the `LogDestination` parameter was set using with a relative path, the management server failed to store its value unless started with `--initial` or `--reload`. ([Bug#52268](#))
- When creating an index, `NDB` failed to check whether the internal ID allocated to the index was within the permissible range, leading to an assertion. This issue could manifest itself as a data node failure with `NDB` error 707 (`NO MORE TABLE METADATA RECORDS (INCREASE MAXNOFTABLES)`), when creating tables in rapid succession (for example, by a script, or when importing from `mysqldump`), even with a relatively high value for `MaxNoOfTables` and a relatively low number of tables. ([Bug#52055](#))
- `ndb_restore` did not raise any errors if hashmap creation failed during execution. ([Bug#51434](#))
- Specifying the node ID as part of the `--ndb-connectstring` option to `mysqld` was not handled correctly.

The fix for this issue includes the following changes:

- Multiple occurrences of any of the `mysqld` options `--ndb-connectstring`, `--ndb-mgmd-host`, and `--ndb-nodeid` are now handled in the same way as with other MySQL server options, in that the value set in the last occurrence of the option is the value that is used by `mysqld`.

Now, if `--ndb-nodeid` is used, its value overrides that of any `nodeid` setting used in `--ndb-connectstring`. For example, starting `mysqld` with `--ndb-connectstring=nodeid=1,10.100.1.100 --ndb-nodeid=3` now produces the same result as starting it with `--ndb-connectstring=nodeid=3,10.100.1.100`.

- The 1024-character limit on the length of the connectstring is removed, and `--ndb-connectstring` is now handled in this regard in the same way as other `mysqld` options.
- In the NDB API, a new constructor for `Ndb_cluster_connection` is added which takes as arguments a connectstring and the node ID to force the API node to use. See `Ndb_cluster_connection Class Constructor`, for more information.

(Bug#44299)

- NDB did not distinguish correctly between table names differing only by lettercase when `lower_case_table_names` was set to 0. (Bug#33158)
- `ndb_mgm -e "ALL STATUS"` erroneously reported that data nodes remained in start phase 0 until they had actually started.
- **Replication:** A buffer overrun in the handling of `DATE` column values could cause `mysqlbinlog` to fail when reading back logs containing certain combinations of DML on a table having a `DATE` column followed by dropping the table. (Bug#52202)
- **Cluster Replication:** Replication failed after a restart of the slave SQL node, due to an error in writing the `master.info` file. (Bug#52859)
- `ALTER TABLE` did not work correctly where the name of the table, the database, or both contained special characters, causing the MySQL server to crash. (Bug#52225)

See also Bug#53409, Bug#14959.

- The performance of MySQL applications using non-persistent client connections was adversely affected due to many of these connections being kept waiting for an excessive length of time in cleanup phase while being closed. (Bug#48832)
- The MySQL client library mishandled `EINPROGRESS` errors for connections in nonblocking mode. This could lead to replication failures on hosts capable of resolving both IPv4 and IPv6 network addresses, when trying to resolve `localhost`. (Bug#37267)

See also Bug#44344.

## 17.7.1.8. Changes in MySQL Cluster NDB 7.1.3 (5.1.44-ndb-7.1.3) (12 April 2010 General Availability)

MySQL Cluster NDB 7.1.3 is the first *General Availability* release in the MySQL Cluster NDB 7.1 release series, incorporating new features in the `NDBCLUSTER` storage engine and fixing recently discovered bugs in MySQL Cluster NDB 7.1.2-beta and previous MySQL Cluster releases.

**Obtaining MySQL Cluster NDB 7.1.** The latest MySQL Cluster NDB 7.1 binaries for supported platforms can be obtained from <http://dev.mysql.com/downloads/cluster/>. Source code for the latest MySQL Cluster NDB 7.1 release can be obtained from the same location.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.x, MySQL Cluster NDB 7.0, and MySQL Cluster NDB 7.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.44 (see [Section C.1.8, “Changes in MySQL 5.1.44 \(04 February 2010\)”](#)).

Functionality added or changed:

- **Incompatible Change:** The schema for the `memoryusage` table of the `ndbinfo` information database has changed, as detailed in the following list:
  - The `max` column has been renamed to `total`.
  - The `used` and `total` (formerly `max`) columns now display values in bytes rather than memory pages.

- Added the columns `used_pages` and `total_pages` to show the amount of a resource used and total amount available in pages.
- The size of the memory pages used for calculating data memory (`used_pages` and `total_pages` columns) is now 32K rather than 16K.

For more information, see [Section 17.5.8.6, “The `ndbinfo memoryusage` Table”](#).

- **Important Change:** The experimental `ndbinfo.pools` table has been removed. Information useful to MySQL Cluster administration that was contained in this table should be available from other `ndbinfo` tables. See [Section 17.5.8, “The `ndbinfo` MySQL Cluster Information Database”](#), for additional information.
- **Important Note:** MySQL Cluster 7.1 is now supported for production use on Windows platforms.

## Important

Some limitations specific to Windows remain; the most important of these are given in the following list:

- There is not yet any Windows installer for MySQL Cluster; you must extract, place, configure, and start the necessary MySQL Cluster executables manually.
- MySQL Cluster processes cannot yet be installed as Windows services. This means that each process executable must be run from a command prompt, and cannot be backgrounded. If you close the command prompt window in which you started the process, the process terminates.
- There is as yet no “angel” process for data nodes; if a data node process quits, it must be restarted manually.
- `ndb_error_reporter` is not yet available on Windows.
- The multi-threaded data node process (`ndbmtd`) is not yet included in the binary distribution. However, it should be built automatically if you build MySQL Cluster from source.

As with MySQL Cluster on other supported platforms, you cannot build MySQL Cluster for Windows from the MySQL Server 5.1 sources; you must use the source code from the MySQL Cluster NDB 7.1 tree.

- **Cluster Replication: Replication:** MySQL Cluster Replication now supports attribute promotion and demotion for row-based replication between columns of different but similar types on the master and the slave. For example, it is possible to promote an `INT` column on the master to a `BIGINT` column on the slave, and to demote a `TEXT` column to a `VARCHAR` column.

The implementation of type demotion distinguishes between lossy and non-lossy type conversions, and their use on the slave can be controlled by setting the `slave_type_conversions` global server system variable.

For more information about attribute promotion and demotion for row-based replication in MySQL Cluster, see [Attribute promotion and demotion \(MySQL Cluster\)](#). ([Bug#47163](#), [Bug#46584](#))

Bugs fixed:

- If a node or cluster failure occurred while `mysqld` was scanning the `ndb.ndb_schema` table (which it does when attempting to connect to the cluster), insufficient error handling could lead to a crash by `mysqld` in certain cases. This could happen in a MySQL Cluster with a great many tables, when trying to restart data nodes while one or more `mysqld` processes were restarting. ([Bug#52325](#))
- In MySQL Cluster NDB 7.0 and later, DDL operations are performed within schema transactions; the NDB kernel code for starting a schema transaction checks that all data nodes are at the same version before permitting a schema transaction to start. However, when a version mismatch was detected, the client was not actually informed of this problem, which caused the client to hang. ([Bug#52228](#))
- After running a mixed series of node and system restarts, a system restart could hang or fail altogether. This was caused by setting the value of the newest completed global checkpoint too low for a data node performing a node restart, which led to the node reporting incorrect GCI intervals for its first local checkpoint. ([Bug#52217](#))
- When performing a complex mix of node restarts and system restarts, the node that was elected as master sometimes required optimized node recovery due to missing `REDO` information. When this happened, the node crashed with `FAILURE TO RECREATE OBJECT ... DURING RESTART, ERROR 721` (because the `DBDICTIONARY` restart code was run twice). Now when this occurs, node takeover is executed immediately, rather than being made to wait until the remaining data nodes have started. ([Bug#52135](#))

See also [Bug#48436](#).

- The internal variable `ndb_new_handler`, which is no longer used, has been removed. ([Bug#51858](#))
- `ha_ndbcluster.cc` was not compiled with the same `SAFEMALLOC` and `SAFE_MUTEX` flags as the MySQL Server. ([Bug#51857](#))
- When debug compiling MySQL Cluster on Windows, the mysys library was not compiled with `-DSAFEMALLOC` and `-DSAFE_MUTEX`, due to the fact that `my_socket.c` was misnamed as `my_socket.cc`. ([Bug#51856](#))
- Some values shown in the `ndbinfo.memoryusage` table did not match corresponding values shown by the `ndb_mgm` client `ALL REPORT MEMORYUSAGE` command. ([Bug#51735](#))
- The redo log protects itself from being filled up by periodically checking how much space remains free. If insufficient redo log space is available, it sets the state `TAIL_PROBLEM` which results in transactions being aborted with error code 410 (`OUT_OF_REDO_LOG`). However, this state was not set following a node restart, which meant that if a data node had insufficient redo log space following a node restart, it could crash a short time later with `FATAL_ERROR_DUE_TO_END_OF_REDO_LOG`. Now, this space is checked during node restarts. ([Bug#51723](#))
- Restoring a MySQL Cluster backup between platforms having different endianness failed when also restoring metadata and the backup contained a hashmap not already present in the database being restored to. This issue was discovered when trying to restore a backup made on Solaris/SPARC to a MySQL Cluster running on Solaris/x86, but could conceivably occur in other cases where the endianness of the platform on which the backup was taken differed from that of the platform being restored to. ([Bug#51432](#))
- A `mysqld`, when attempting to access the `ndbinfo` database, crashed if could not contact the management server. ([Bug#51067](#))
- The `mysql` client `system` command did not work properly. This issue was only known to affect the version of the `mysql` client that was included with MySQL Cluster NDB 7.0 and MySQL Cluster NDB 7.1 releases. ([Bug#48574](#))
- **Cluster API: Packaging:** The file `META-INF/services/org.apache.openjpa.lib.conf.ProductDerivation` was missing from the `clusterjpa` JAR file. This could cause setting `openjpa.BrokerFactory` to “`ndb`” to be rejected. ([Bug#52106](#))
- **Disk Data:** Inserts of blob column values into a MySQL Cluster Disk Data table that exhausted the tablespace resulted in misleading `NO SUCH TUPLE` error messages rather than the expected error `TABLESPACE FULL`.

This issue appeared similar to [Bug#48113](#), but had a different underlying cause. ([Bug#52201](#))

- **Disk Data:** DDL operations on Disk Data tables having a relatively small `UNDO_BUFFER_SIZE` could fail unexpectedly.
- **Cluster Replication:** The `--ndb-log-empty-epochs` option did not work correctly. ([Bug#49559](#))
- **Cluster Replication:** When `mysqld` was started with `--binlog-do-db` or `--binlog-ignore-db`, no `LOST_EVENTS` incident was written to the binary log. ([Bug#47096](#))
- **Cluster API:** A number of issues were corrected in the NDB API coding examples found in the `storage/ndb/ndbapi-examples` directory in the MySQL Cluster source tree. These included possible endless recursion in `ndbapi_scan.cpp` as well as problems running some of the examples on systems using Windows or Mac OS due to the letter case used for some table names. ([Bug#30552](#), [Bug#30737](#))

## 17.7.1.9. Changes in MySQL Cluster NDB 7.1.2 (5.1.41-ndb-7.1.2) (02 March 2010)

MySQL Cluster NDB 7.1.2 is a new beta release of MySQL Cluster, incorporating new features in the `NDBCLUSTER` storage engine and fixing recently discovered bugs in MySQL Cluster NDB 7.1.1 and previous MySQL Cluster releases.

**Obtaining MySQL Cluster NDB 7.1.** The latest MySQL Cluster NDB 7.1 binaries for supported platforms can be obtained from <http://dev.mysql.com/downloads/cluster/>. Source code for the latest MySQL Cluster NDB 7.1 release can be obtained from the same location.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, 6.3, and 7.0 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.41 (see [Section C.1.12, “Changes in MySQL 5.1.41 \(05 November 2009\)”](#)).

Functionality added or changed:

- **Cluster API:** It is now possible to determine, using the `ndb_desc` utility or the NDB API, which data nodes contain replicas of which partitions. For `ndb_desc`, a new `--extra-node-info` option is added to cause this information to be included in its output. A new method `NdbDictionary::Object::Table::getFragmentNodes()` is added to the NDB API for obtaining this information programmatically. ([Bug#51184](#))

- Numeric codes used in management server status update messages in the cluster logs have been replaced with text descriptions. ([Bug#49627](#))  
See also [Bug#44248](#).
- A new configuration parameter `HeartbeatThreadPriority` makes it possible to select between a first-in, first-out or round-round scheduling policy for management node and API node heartbeat threads, as well as to set the priority of these threads. See [Section 17.3.2.5, “Defining a MySQL Cluster Management Server”](#), or [Section 17.3.2.7, “Defining SQL and Other API Nodes in a MySQL Cluster”](#), for more information. ([Bug#49617](#))
- Start phases are now written to the data node logs. ([Bug#49158](#))
- Formerly, the `REPORT` and `DUMP` commands returned output to all `ndb_mgm` clients connected to the same MySQL Cluster. Now, these commands return their output only to the `ndb_mgm` client that actually issued the command. ([Bug#40865](#))
- **Disk Data:** The `ndb_desc` utility can now show the extent space and free extent space for subordinate `BLOB` and `TEXT` columns (stored in hidden `BLOB` tables by NDB). A `--blob-info` option has been added for this program that causes `ndb_desc` to generate a report for each subordinate `BLOB` table. For more information, see [Section 17.4.9, “ndb\\_desc — Describe NDB Tables”](#). ([Bug#50599](#))

Bugs fixed:

- **Important Change:** The `DATA_MEMORY` column of the `ndbinfo.memoryusage` table was renamed to `memory_type`. ([Bug#50926](#))
- When deciding how to divide the REDO log, the `DBDIH` kernel block saved more than was needed to restore the previous local checkpoint, which could cause REDO log space to be exhausted prematurely (NDB error 410). ([Bug#51547](#))
- DML operations can fail with NDB error 1220 (`REDO LOG FILES OVERLOADED...`) if the opening and closing of REDO log files takes too much time. If this occurred as a GCI marker was being written in the REDO log while REDO log file 0 was being opened or closed, the error could persist until a GCP stop was encountered. This issue could be triggered when there was insufficient REDO log space (for example, with configuration parameter settings `NoOfFragmentLogFile = 6` and `FragmentLogFileSize = 6M`) with a load including a very high number of updates. ([Bug#51512](#))

See also [Bug#20904](#).

- An attempted online upgrade from a MySQL Cluster NDB 6.3 or 7.0 release to a MySQL Cluster NDB 7.1 release failed, as the first upgraded data node rejected the remaining data nodes as using incompatible versions. ([Bug#51429](#))
- A side effect of the `ndb_restore --disable-indexes` and `--rebuild-indexes` options is to change the schema versions of indexes. When a `mysqld` later tried to drop a table that had been restored from backup using one or both of these options, the server failed to detect these changed indexes. This caused the table to be dropped, but the indexes to be left behind, leading to problems with subsequent backup and restore operations. ([Bug#51374](#))
- The output of the `ndb_mgm` client `REPORT BACKUPSTATUS` command could sometimes contain errors due to uninitialized data. ([Bug#51316](#))
- Setting `IndexMemory` greater than 2GB could cause data nodes to crash while starting. ([Bug#51256](#))
- `ndb_restore` crashed while trying to restore a corrupted backup, due to missing error handling. ([Bug#51223](#))
- The `ndb_restore` message `Successfully created index `PRIMARY`...` was directed to `stderr` instead of `stdout`. ([Bug#51037](#))
- An initial restart of a data node configured with a large amount of memory could fail with a `POINTER TOO LARGE` error. ([Bug#51027](#))

This regression was introduced by [Bug#47818](#).

- When using `NoOfReplicas` equal to 1 or 2, if data nodes from one node group were restarted 256 times and applications were running traffic such that it would encounter NDB error 1204 (`TEMPORARY FAILURE, DISTRIBUTION CHANGED`), the live node in the node group would crash, causing the cluster to crash as well. The crash occurred only when the error was encountered on the 256th restart; having the error on any previous or subsequent restart did not cause any problems. ([Bug#50930](#))
- A `GROUP BY` query against NDB tables sometimes did not use any indexes unless the query included a `FORCE INDEX` option. With this fix, indexes are used by such queries (where otherwise possible) even when `FORCE INDEX` is not specified. ([Bug#50736](#))
- `ndbmtd` started on a single-core machine could sometimes fail with a `JOB BUFFER FULL` error when `MaxNoOfExecution-`

`Threads` was set greater than `LockExecuteThreadToCPU`. Now a warning is logged when this occurs. ([Bug#50582](#))

- The following issues were fixed in the `ndb_mgm` client `REPORT MEMORYUSAGE` command:
  - The client sometimes inserted extra `ndb_mgm>` prompts within the output.
  - For data nodes running `ndbmtd`, `IndexMemory` was reported before `DataMemory`.
  - Also for data nodes running `ndbmtd`, there were multiple `IndexMemory` entries listed in the output.
- ([Bug#50196](#))
- Issuing a command in the `ndb_mgm` client after it had lost its connection to the management server could cause the client to crash. ([Bug#49219](#))
- Replication of a MySQL Cluster using multi-threaded data nodes could fail with forced shutdown of some data nodes due to the fact that `ndbmtd` exhausted `LongMessageBuffer` much more quickly than `ndbd`. After this fix, passing of replication data between the `DBTUP` and `SUMA` NDB kernel blocks is done using `DataMemory` rather than `LongMessageBuffer`.  
Until you can upgrade, you may be able to work around this issue by increasing the `LongMessageBuffer` setting; doubling the default should be sufficient in most cases. ([Bug#46914](#))
- Information about several management client commands was missing from (that is, truncated in) the output of the `HELP` command. ([Bug#46114](#))
- A `SELECT` requiring a sort could fail with the error `CAN'T FIND RECORD IN 'TABLE'` when run concurrently with a `DELETE` from the same table. ([Bug#45687](#))
- When the `MemReportFrequency` configuration parameter was set in `config.ini`, the `ndb_mgm` client `REPORT MEMORYUSAGE` command printed its output multiple times. ([Bug#37632](#))
- `ndb_mgm -e "... REPORT ..."` did not write any output to `stdout`.

The fix for this issue also prevents the cluster log from being flooded with `INFO` messages when `DataMemory` usage reaches 100%, and insures that when the usage is decreased, an appropriate message is written to the cluster log. ([Bug#31542](#), [Bug#44183](#), [Bug#49782](#))

- **Disk Data:** The error message returned after attempting to execute `ALTER LOGFILE GROUP` on an nonexistent logfile group did not indicate the reason for the failure. ([Bug#51111](#))
- **Cluster API:** An issue internal to `ndb_mgm` could cause problems when trying to start a large number of data nodes at the same time. ([Bug#51273](#))
- **Cluster API:** When reading blob data with lock mode `LM_SimpleRead`, the lock was not upgraded as expected. ([Bug#51034](#))

## 17.7.1.10. Changes in MySQL Cluster NDB 7.1.1 (5.1.41-ndb-7.1.1) (01 February 2010 beta)

MySQL Cluster NDB 7.1.1 is a new beta release of MySQL Cluster, incorporating new features in the `NDBCLUSTER` storage engine and fixing recently discovered bugs in MySQL Cluster NDB 7.0 and previous MySQL Cluster releases.

**Obtaining MySQL Cluster NDB 7.1.** The latest MySQL Cluster NDB 7.1 binaries for supported platforms can be obtained from <http://dev.mysql.com/downloads/cluster/>. Source code for the latest MySQL Cluster NDB 7.1 release can be obtained from the same location.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, 6.3, and 7.0 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.41 (see [Section C.1.12, “Changes in MySQL 5.1.41 \(05 November 2009\)”](#)).

### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- The `ndbinfo` database is added to provide MySQL Cluster metadata in real time. The tables making up this database contain information about memory, buffer, and other resource usage, as well as configuration parameters and settings, event counts, and other useful data. Access to `ndbinfo` is done by executing standard SQL queries on its tables using the `mysql` command-line

client or other MySQL client application. No special setup procedures are required; `ndbinfo` is created automatically and visible in the output of `SHOW DATABASES` when the MySQL Server is connected to a MySQL Cluster.

For more information about `ndbinfo`, see [Section 17.5.8, “The ndbinfo MySQL Cluster Information Database”](#).

- **Cluster API:** ClusterJ 1.0 and ClusterJPA 1.0 are now available for programming Java applications with MySQL Cluster. ClusterJ is a Java connector providing an object-relational API for performing high-speed operations such as primary key lookups on a MySQL Cluster database, but does not require the use of the MySQL Server or JDBC (Connector/J). ClusterJ uses a new library NdbJTie which enables direct access from Java to the NDB API and thus to the `NDBCLUSTER` storage engine. ClusterJPA is a new implementation of OpenJPA, and can use either a JDBC connection to a MySQL Cluster SQL node (MySQL Server) or a direct connection to MySQL Cluster using NdbJTie, depending on availability and operational performance.

ClusterJ, ClusterJPA, and NdbJTie require Java 1.5 or 1.6, and MySQL Cluster NDB 7.0 or later.

All necessary libraries and other files for ClusterJ, ClusterJPA, and NdbJTie can be found in the MySQL Cluster NDB 7.1.1 or later distribution.

Bugs fixed:

- When a primary key lookup on an `NDB` table containing one or more `BLOB` columns was executed in a transaction, a shared lock on any blob tables used by the `NDB` table was held for the duration of the transaction. (This did not occur for indexed or non-indexed `WHERE` conditions.)

Now in such cases, the lock is released after all `BLOB` data has been read. ([Bug#49190](#))

### 17.7.1.11. Changes in MySQL Cluster NDB 7.1.0 (5.1.39-ndb-7.1.0) (Not released alpha)

This version was for testing and internal use only, and not officially released.

Functionality added or changed:

- **Important Change:** The default value of the `DiskIOThreadPool` data node configuration parameter has changed from 8 to 2.
- **Cluster Replication:** In circular replication, it was sometimes possible for an event to propagate such that it would be reapplied on all servers. This could occur when the originating server was removed from the replication circle and so could no longer act as the terminator of its own events, as normally happens in circular replication.

To prevent this from occurring, a new `IGNORE_SERVER_IDS` option is introduced for the `CHANGE MASTER TO` statement. This option takes a list of replication server IDs; events having a server ID which appears in this list are ignored and not applied. For more information, see [Section 12.5.2.1, “`CHANGE MASTER TO` Syntax”](#).

In conjunction with the introduction of `IGNORE_SERVER_IDS`, `SHOW SLAVE STATUS` has two new fields. `Replicate_Ignore_Server_Ids` displays information about ignored servers. `Master_Server_Id` displays the `server_id` value from the master. ([Bug#47037](#))

See also [Bug#25998](#), [Bug#27808](#).

Bugs fixed:

- **Important Change:** The `--with-ndb-port-base` option for `configure` has been removed. It is now handled as an unknown and invalid option if you attempt to use it when configuring a build of MySQL Cluster. ([Bug#47941](#))

See also [Bug#38502](#).

- The value set by the `--ndb-cluster-connection-pool` option was not shown in the output of `SHOW STATUS LIKE 'NDB%'`. ([Bug#44118](#))
- When building storage engines on Windows it was not possible to specify additional libraries within the CMake file required for the build. An `_${engine}_LIBS` macro has been included in the files to support these additional storage-engine specific libraries. ([Bug#47797](#))
- When building a pluggable storage engine on Windows, the engine name could be based on the directory name where the engine was located, rather than the configured storage engine name. ([Bug#47795](#))

- Installation of MySQL on Windows would fail to set the correct location for the character set files, which could lead to `mysqld` and `mysql` failing to initialize properly. ([Bug#17270](#))

## 17.7.2. Changes in MySQL Cluster NDB 7.0

This section contains change history information for MySQL Cluster releases based on version 7.0 of the `NDBCLUSTER` storage engine.

### Important

Previously, version 7.0 of `NDBCLUSTER` was known as version 6.4, and early development versions of MySQL Cluster NDB 7.0 were known as “MySQL Cluster 6.4”. The first four releases in this series were identified using NDB 6.4.x version numbers (NDB 6.4.0 through NDB 6.4.3).

MySQL Cluster NDB 7.0.4 is the fifth release in this series. All future MySQL Cluster NDB 7.0 releases will use NDB 7.0.x version numbers.

Users running MySQL Cluster NDB 6.4.3 should upgrade to MySQL Cluster NDB 7.0.4 (or a later MySQL Cluster NDB 7.0 release).

For an overview of new features added in MySQL Cluster NDB 7.0, see [Section 17.1.4.2, “MySQL Cluster Development in MySQL Cluster NDB 7.0”](#).

When upgrading to a MySQL Cluster NDB 7.0 release from earlier MySQL Cluster releases, you should be aware of the following issues:

- To perform an online upgrade to MySQL Cluster NDB 7.0 from a MySQL Cluster NDB 6.3 release, you must upgrade to MySQL Cluster NDB 7.0.6 or later. See [Section 17.2.5.2, “MySQL Cluster 5.1 and MySQL Cluster NDB 6.x/7.x Upgrade and Downgrade Compatibility”](#), for more information.
- You cannot use a mix of MySQL Cluster NDB 7.0 and earlier binaries, except as part of an online upgrade (where this is supported). You should replace all existing MySQL Cluster executables with the MySQL Cluster NDB 7.0 versions.
- NDB API applications built against previous MySQL Cluster versions (NDB 6.3 and earlier) must be recompiled against the MySQL Cluster NDB 7.0 sources.

### 17.7.2.1. Changes in MySQL Cluster NDB 7.0.19 (5.1.47-ndb-7.0.19) (Not yet released)

This release incorporates new features in the `NDBCLUSTER` storage engine and fixes recently discovered bugs in MySQL Cluster NDB 7.0.18.

**Obtaining MySQL Cluster NDB 7.0.** The latest MySQL Cluster NDB 7.0 binaries for supported platforms can be obtained from <http://dev.mysql.com/downloads/cluster/>. Source code for the latest MySQL Cluster NDB 7.0 release can be obtained from the same location. You can also access the MySQL Cluster NDB 7.0 development source tree at <https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.0>.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, 6.3, and 7.0 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.47 (see [Section C.1.4, “Changes in MySQL 5.1.47 \(06 May 2010\)”](#)).

### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- `mysqldump` as supplied with MySQL Cluster now has an `--add-drop-trigger` option which adds a `DROP TRIGGER IF EXISTS` statement before each dumped trigger definition. ([Bug#55691](#))

See also [Bug#34325](#).

Bugs fixed:

- Under certain rare conditions, attempting to start more than one `ndb_mgmd` process simultaneously using the `--reload` option caused a race condition such that none of the `ndb_mgmd` processes could start. ([Bug#56844](#))
- When distributing `CREATE TABLE` and `DROP TABLE` operations among several SQL nodes attached to a MySQL Cluster, the `LOCK_OPEN` lock normally protecting `mysqld`'s internal table list is released so that other queries or DML statements are not blocked. However, to make sure that other DDL is not executed simultaneously, a global schema lock (implemented as a row-level lock by `NDB`) is used, such that all operations that can modify the state of the `mysqld` internal table list also need to acquire this global schema lock. The `SHOW TABLE STATUS` statement did not acquire this lock. ([Bug#56841](#))
- MySQL Cluster stores, for each row in each `NDB` table, a Global Checkpoint Index (GCI) which identifies the last committed transaction that modified the row. As such, a GCI can be thought of as a coarse-grained row version.

Due to changes in the format used by `NDB` to store local checkpoints (LCPs) in MySQL Cluster NDB 6.3.11, it could happen that, following cluster shutdown and subsequent recovery, the GCI values for some rows could be changed unnecessarily; this could possibly, over the course of many node or system restarts (or both), lead to an inconsistent database. ([Bug#56770](#))

- When multiple SQL nodes were connected to the cluster and one of them stopped in the middle of a DDL operation, the `mysqld` process issuing the DDL timed out with the error `DISTRIBUTING TBL_NAME TIMED OUT. IGNORING.` ([Bug#56763](#))
- An online `ALTER TABLE ... ADD COLUMN` operation that changed the table schema such that the number of 32-bit words used for the bitmask allocated to each DML operation increased during a transaction in DML which was performed prior to DDL which was followed by either another DML operation or—if using replication—a commit, led to data node failure.

This was because the data node did not take into account that the bitmask for the before-image was smaller than the current bitmask, which caused the node to crash. ([Bug#56524](#))

- On Windows, a data node refused to start in some cases unless the `ndbd.exe` executable was invoked using an absolute rather than a relative path. ([Bug#56257](#))
- The failure of a data node during some scans could cause other data nodes to fail. ([Bug#54945](#))
- Exhausting the number of available commit-ack markers (controlled by the `MaxNoOfConcurrentTransactions` parameter) led to a data node crash. ([Bug#54944](#))
- When running a `SELECT` on an `NDB` table with `BLOB` or `TEXT` columns, memory was allocated for the columns but was not freed until the end of the `SELECT`. This could cause problems with excessive memory usage when dumping (using for example `mysqldump`) tables with such columns and having many rows, large column values, or both. ([Bug#52313](#))

See also [Bug#56488](#), [Bug#50310](#).

- **Cluster Replication:** When an SQL node starts, as part of setting up replication, it subscribes to data events from all data nodes using a `SUB_START_REQ` (subscription start request) signal. Atomicity of `SUB_START_REQ` is implemented such that, if any of the nodes returns an error, a `SUB_STOP_REQ` (subscription stop request) is sent to any nodes that replied with a `SUB_START_CONF` (subscription start confirmation). However, if all data nodes returned an error, `SUB_STOP_REQ` was not sent to any of them. This caused `mysqld` to hang when restarting (while waiting for a response), and subsequent data node re-starts to hang as well. ([Bug#56579](#))

### 17.7.2.2. Changes in MySQL Cluster NDB 7.0.18 (5.1.47-ndb-7.0.18) (03 September 2010)

This release incorporates new features in the `NDBCLUSTER` storage engine and fixes recently discovered bugs in MySQL Cluster NDB 7.0.17.

**Obtaining MySQL Cluster NDB 7.0.** The latest MySQL Cluster NDB 7.0 binaries for supported platforms can be obtained from <http://dev.mysql.com/downloads/cluster/>. Source code for the latest MySQL Cluster NDB 7.0 release can be obtained from the same location. You can also access the MySQL Cluster NDB 7.0 development source tree at <https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.0>.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, 6.3, and 7.0 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.47 (see [Section C.1.4, “Changes in MySQL 5.1.47 \(06 May 2010\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **Important Change:** More finely-grained control over restart-on-failure behavior is provided with two new data node configuration parameters `MaxStartFailRetries` and `StartFailRetryDelay`. `MaxStartFailRetries` limits the total number of retries made before giving up on starting the data node; `StartFailRetryDelay` sets the number of seconds between retry attempts.

These parameters are used only if `StopOnError` is set to 0.

For more information, see [Section 17.3.2.6, “Defining MySQL Cluster Data Nodes”](#). ([Bug#54341](#))

Bugs fixed:

- `ndb_restore` always reported 0 for the `GCPStop` (end point of the backup). Now it provides useful binary log position and epoch information. ([Bug#56298](#))
- The `LockExecuteThreadToCPU` configuration parameter was not handled correctly for CPU ID values greater than 255. ([Bug#56185](#))
- Following a failure of the master data node, the new master sometimes experienced a race condition which caused the node to terminate with a `GcpStop` error. ([Bug#56044](#))
- Trying to create a table having a `BLOB` or `TEXT` column with `DEFAULT ''` failed with the error `ILLEGAL NULL ATTRIBUTE`. (An empty default is allowed and ignored by `MyISAM`; `NDB` should do the same.) ([Bug#55121](#))
- `ndb_mgmd --nodaemon` logged to the console in addition to the configured log destination. ([Bug#54779](#))
- The warning `MAXNOOFEVENTS (#) > LOCKEXECUTETHREADTOCPU COUNT (#), THIS COULD CAUSE CONTENTION` could be logged when running `ndbd`, even though the condition described can occur only when using `ndbmtd`. ([Bug#54342](#))
- Startup messages previously written by `ndb_mgmd` to `stdout` are now written to the cluster log instead when `LogDestination` is set. ([Bug#47595](#))
- The graceful shutdown of a data node could sometimes cause transactions to be aborted unnecessarily. ([Bug#18538](#))

See also [Bug#55641](#).

- **Cluster Replication:** The graceful shutdown of a data node in the master cluster could sometimes cause rows to be skipped when writing transactions to the binary log, leading to an inconsistent slave cluster. ([Bug#55641](#))

See also [Bug#18538](#).

- **Cluster Replication:** Specifying the `--expire_logs_days` option when there were old binary logs to delete caused SQL nodes to crash on startup. ([Bug#41751](#))

### 17.7.2.3. Changes in MySQL Cluster NDB 7.0.17 (5.1.47-ndb-7.0.17) (16 August 2010)

This release incorporates new features in the `NDBCLUSTER` storage engine and fixes recently discovered bugs in MySQL Cluster NDB 7.0.16.

**Obtaining MySQL Cluster NDB 7.0.17.** The latest MySQL Cluster NDB 7.0 binaries for supported platforms can be obtained from <http://dev.mysql.com/downloads/cluster/>. Source code for the latest MySQL Cluster NDB 7.0 release can be obtained from the same location. You can also access the MySQL Cluster NDB 7.0 development source tree at <https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.0>.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, 6.3, and 7.0 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.47 (see [Section C.1.4, “Changes in MySQL 5.1.47 \(06 May 2010\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- Added the `DictTrace` data node configuration parameter, for use in debugging NDB code. For more information, see [Section 17.3.2.6, “Defining MySQL Cluster Data Nodes”](#). ([Bug#55963](#))

- Added the `--server-id-bits` option for `mysqld` and `mysqlbinlog`.

For `mysqld`, the `--server-id-bits` option indicates the number of least significant bits within the 32-bit server ID which actually identify the server. Indicating that the server ID uses less than 32 bits permits the remaining bits to be used for other purposes by NDB API applications using the Event API and `NdbOperation::OperationOptions::AnyValue`.

For `mysqlbinlog`, the `--server-id-bits` option tells `mysqlbinlog` how to interpret the server IDs in the binary log when the binary log was written by a `mysqld` having its `server_id_bits` set to less than the maximum (32). ([Bug#52305](#))

Bugs fixed:

- **Cluster API: Important Change:** The poll and select calls made by the MGM API were not interrupt-safe; that is, a signal caught by the process while waiting for an event on one or more sockets returned error -1 with `errno` set to `EINTR`. This caused problems with MGM API functions such as `ndb_mgm_logevent_get_next()` and `ndb_mgm_get_status2()`.

To fix this problem, the internal `ndb_socket_poller::poll()` function has been made `EINTR`-safe.

The old version of this function has been retained as `poll_unsafe()`, for use by those parts of NDB that do not need the `EINTR`-safe version of the function. ([Bug#55906](#))

- The TCP configuration parameters `HostName1` and `HostName2` were not displayed in the output of `ndb_config --configinfo`. ([Bug#55839](#))
- When another data node failed, a given data node `DBTC` kernel block could time out while waiting for `DBDIH` to signal commits of pending transactions, leading to a crash. Now in such cases the timeout generates a prinout, and the data node continues to operate. ([Bug#55715](#))
- Using the `--disable-config-cache` option with `ndb_mgmd` caused a memory leak. ([Bug#55205](#))
- The `configure.js` option `WITHOUT_DYNAMIC_PLUGINS=TRUE` was ignored when building MySQL Cluster for Windows using `CMake`. Among the effects of this issue was that `CMake` attempted to build the `InnoDB` storage engine as a plugin (`.DLL` file) even though the `InnoDB Plugin` is not currently supported by MySQL Cluster. ([Bug#54913](#))
- It was possible for a `DROP DATABASE` statement to remove `NDB` hidden blob tables without removing the parent tables, with the result that the tables, although hidden to MySQL clients, were still visible in the output of `ndb_show_tables` but could not be dropped using `ndb_drop_table`. ([Bug#54788](#))
- An excessive number of timeout warnings (normally used only for debugging) were written to the data node logs. ([Bug#53987](#))
- **Disk Data:** As an optimization when inserting a row to an empty page, the page is not read, but rather simply initialized. However, this optimization was performed in all cases when an empty row was inserted, even though it should have been done only if it was the first time that the page had been used by a table or fragment. This is because, if the page had been in use, and then all records had been released from it, the page still needed to be read to learn its log sequence number (LSN).

This caused problems only if the page had been flushed using an incorrect LSN and the data node failed before any local checkpoint was completed—which would removed any need to apply the undo log, hence the incorrect LSN was ignored.

The user-visible result of the incorrect LSN was that it caused the data node to fail during a restart. It was perhaps also possible (although not conclusively proven) that this issue could lead to incorrect data. ([Bug#54986](#))

- **Cluster API:** Calling `NdbTransaction::refresh()` did not update the timer for `TransactionInactiveTimeout`. ([Bug#54724](#))

#### 17.7.2.4. Changes in MySQL Cluster NDB 7.0.16 (5.1.47-ndb-7.0.16) (25 June 2010)

This release incorporates new features in the `NDBCLUSTER` storage engine and fixes recently discovered bugs in MySQL Cluster NDB 7.0.15.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, 6.3, and 7.0 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.47 (see [Section C.1.4, “Changes in MySQL 5.1.47 \(06 May 2010\)”](#)).

##### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- Restrictions on some types of mismatches in column definitions when restoring data using `ndb_restore` have been relaxed. These include the following types of mismatches:
  - Different `COLUMN_FORMAT` settings (`FIXED`, `DYNAMIC`, `DEFAULT`)
  - Different `STORAGE` settings (`MEMORY`, `DISK`)
  - Different default values
  - Different distribution key settings

Now, when one of these types of mismatches in column definitions is encountered, `ndb_restore` no longer stops with an error; instead, it accepts the data and inserts it into the target table, while issuing a warning to the user.

For more information, see [Section 17.4.17, “`ndb\_restore` — Restore a MySQL Cluster Backup”](#). ([Bug#54423](#))

See also [Bug#53810](#), [Bug#54178](#), [Bug#54242](#), [Bug#54279](#).

- Introduced the `HeartbeatOrder` data node configuration parameter, which can be used to set the order in which heartbeats are transmitted between data nodes. This parameter can be useful in situations where multiple data nodes are running on the same host and a temporary disruption in connectivity between hosts would otherwise cause the loss of a node group, leading to failure of the cluster. ([Bug#52182](#))
- It is now possible to install management node and data node processes as Windows services. (See [Section 17.2.2.4, “Installing MySQL Cluster Processes as Windows Services”](#), for more information.) In addition, data node processes on Windows are now maintained by angel processes, just as they are on other platforms supported by MySQL Cluster.

Bugs fixed:

- The disconnection of all API nodes (including SQL nodes) during an `ALTER TABLE` caused a memory leak. ([Bug#54685](#))
- If a node shutdown (either in isolation or as part of a system shutdown) occurred directly following a local checkpoint, it was possible that this local checkpoint would not be used when restoring the cluster. ([Bug#54611](#))
- The setting for `BuildIndexThreads` was ignored by `ndbmtd`, which made it impossible to use more than 4 cores for re-building indexes. ([Bug#54521](#))
- When adding multiple new node groups to a MySQL Cluster, it was necessary for each new node group to add only the nodes to be assigned to the new node group, create that node group using `CREATE NODEGROUP`, then repeat this process for each new node group to be added to the cluster. The fix for this issue makes it possible to add all of the new nodes at one time, and then issue several `CREATE NODEGROUP` commands in succession. ([Bug#54497](#))
- When performing an online alter table where 2 or more SQL nodes connected to the cluster were generating binary logs, an incorrect message could be sent from the data nodes, causing `mysqld` processes to crash. This problem was often difficult to detect, because restarting SQL node or data node processes could clear the error, and because the crash in `mysqld` did not occur until several minutes after the erroneous message was sent and received. ([Bug#54168](#))
- A table having the maximum number of attributes permitted could not be backed up using the `ndb_mgm` client.

### Note

The maximum number of attributes supported per table is not the same for all MySQL Cluster releases. See [Section 17.1.5.5, “Limits Associated with Database Objects in MySQL Cluster”](#), to determine the maximum that applies in the release which you are using.

([Bug#54155](#))

- During initial node restarts, initialization of the REDO log was always performed 1 node at a time, during start phase 4. Now this is done during start phase 2, so that the initialization can be performed in parallel, thus decreasing the time required for initial restarts involving multiple nodes. ([Bug#50062](#))
- The presence of duplicate `[tcp]` sections in the `config.ini` file caused the management server to crash. Now in such cases, `ndb_mgmd` fails gracefully with an appropriate error message. ([Bug#49400](#))
- The two MySQL Server options, `--ndb-wait-connected` and `--ndb-wait-setup`, did not set the corresponding system variables. ([Bug#48402](#))

- **Cluster Replication:** An error in an `NDB` internal byte mask value could lead to corruption of replicated `BIT` column values. ([Bug#54005](#))

See also [Bug#53622](#).

- **Cluster API:** When using the NDB API, it was possible to rename a table with the same name as that of an existing table.

#### Note

This issue did not affect table renames executed using SQL on MySQL servers acting as MySQL Cluster API nodes. ([Bug#54651](#))

- **Cluster API:** An excessive number of client connections, such that more than 1024 file descriptors, sockets, or both were open, caused NDB API applications to crash. ([Bug#34303](#))

### 17.7.2.5. Changes in MySQL Cluster NDB 7.0.15b (5.1.44-ndb-7.0.15b) (18 June 2010)

This release replaces MySQL Cluster NDB 7.0.15, fixing a critical issue in that version that was discovered shortly after its release ([Bug#54242](#)), as well as MySQL Cluster NDB 7.0.15a, which was not actually released due to [Bug#54516](#) being found during testing. Users of MySQL Cluster NDB 7.0.14 or MySQL Cluster NDB 7.0.15 should upgrade to the 7.0.15b release as soon as possible.

**Obtaining MySQL Cluster NDB 7.0.15b.** The latest MySQL Cluster NDB 7.0 binaries for supported platforms can be obtained from <http://dev.mysql.com/downloads/cluster/>. Source code for the latest MySQL Cluster NDB 7.0 release can be obtained from the same location.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.44 (see [Section C.1.8, “Changes in MySQL 5.1.44 \(04 February 2010\)”](#)).

Bugs fixed:

- **Cluster API:** The value of an internal constant used in the implementation of the `NdbOperation` and `NdbScanOperation` classes, causing MySQL Cluster NDB 7.0 NDB API applications compiled against MySQL Cluster NDB 7.0.14 or earlier to fail when run with MySQL Cluster 7.0.15, and MySQL Cluster NDB 7.1 NDB API applications compiled against MySQL Cluster NDB 7.1.3 or earlier to break when used with MySQL Cluster 7.1.4. ([Bug#54516](#))

### 17.7.2.6. Changes in MySQL Cluster NDB 7.0.15a (5.1.44-ndb-7.0.15a) (Not released)

This was intended as a replacement release for MySQL Cluster NDB 7.0.15, fixing a critical issue in that version that was discovered shortly after its release ([Bug#54242](#)); however, MySQL Cluster NDB 7.0.15a was not actually released due to [Bug#54516](#) being found during testing. Users of MySQL Cluster NDB 7.0.14 or MySQL Cluster NDB 7.0.15 should upgrade to the 7.0.15b release as soon as possible.

The latest MySQL Cluster NDB 7.0 binaries for supported platforms can be obtained from <http://dev.mysql.com/downloads/cluster/>. Source code for the latest MySQL Cluster NDB 7.0 release can be obtained from the same location.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.44 (see [Section C.1.8, “Changes in MySQL 5.1.44 \(04 February 2010\)”](#)).

Bugs fixed:

- When using `mysqldump` to back up and restore schema information while using `ndb_restore` for restoring only the data, restoring to MySQL Cluster NDB 7.1.4 from an older version failed on tables having columns with default values. This was because versions of MySQL Cluster prior to MySQL Cluster NDB 7.1.4 did not have native support for default values.

In addition, the MySQL Server supports `TIMESTAMP` columns having dynamic default values, such as `DEFAULT CURRENT_TIMESTAMP`; however, the current implementation of `NDB`-native default values permits only a constant default value.

To fix this issue, the manner in which `NDB` treats `TIMESTAMP` columns is reverted to its pre-NDB-7.1.4 behavior (obtaining the default value from `mysqlid` rather than `NDBCLUSTER`) except where a `TIMESTAMP` column uses a constant default, as in the case of a column declared as `TIMESTAMP DEFAULT 0` or `TIMESTAMP DEFAULT 20100607174832`. ([Bug#54242](#))

## 17.7.2.7. Changes in MySQL Cluster NDB 7.0.15 (5.1.44-ndb-7.0.15) (31 May 2010)

This release incorporates new features in the `NDBCLUSTER` storage engine and fixes recently discovered bugs in MySQL Cluster NDB 7.0.14.

**Obtaining MySQL Cluster NDB 7.0.15.** The latest MySQL Cluster NDB 7.0 binaries for supported platforms can be obtained from <http://dev.mysql.com/downloads/cluster/>. Source code for the latest MySQL Cluster NDB 7.0 release can be obtained from the same location. You can also access the MySQL Cluster NDB 7.0 development source tree at <https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.0>.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, 6.3, and 7.0 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.44 (see [Section C.1.8, “Changes in MySQL 5.1.44 \(04 February 2010\)”](#)).

### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **Important Change:** The maximum number of attributes (columns plus indexes) per table has increased to 512.
- A `--wait-nodes` option has been added for `ndb_waiter`. When this option is used, the program waits only for the nodes having the listed IDs to reach the desired state. For more information, see [Section 17.4.22, “`ndb\_waiter` — Wait for MySQL Cluster to Reach a Given Status”](#). ([Bug#52323](#))
- As part of this change, new methods relating to default values have been added to the `Column` and `Table` classes in the NDB API. For more information, see `Column::getDefaultValue()`, `Column::setDefaultValue()`, and `Table::hasDefaultValues()`. ([Bug#30529](#))
- Added the MySQL Cluster management server option `--config-cache`, which makes it possible to enable and disable configuration caching. This option is turned on by default; to disable configuration caching, start `ndb_mgmd` with `--config-cache=0`, or with `--skip-config-cache`. See [Section 17.4.4, “`ndb\_mgmd` — The MySQL Cluster Management Server Daemon”](#), for more information.
- Added the `--skip-unknown-objects` option for `ndb_restore`. This option causes `ndb_restore` to ignore any schema objects which it does not recognize. Currently, this is useful chiefly for restoring native backups made from a cluster running MySQL Cluster NDB 7.0 to a cluster running MySQL Cluster NDB 6.3.

Bugs fixed:

- After creating `NDB` tables until creation of a table failed due to `NDB` error `905 OUT OF ATTRIBUTE RECORDS (INCREASE MAXNOOFATTRIBUTES)`, then increasing `MaxNoOfAttributes` and restarting all management node and data node processes, attempting to drop and re-create one of the tables failed with the error `OUT OF TABLE RECORDS...`, even when sufficient table records were available. ([Bug#53944](#))

See also [Bug#52055](#).

- Creating a Disk Data table, dropping it, then creating an in-memory table and performing a restart, could cause data node processes to fail with errors in the `DBTUP` kernel block if the new table's internal ID was the same as that of the old Disk Data table. This could occur because undo log handling during the restart did not check that the table having this ID was now in-memory only. ([Bug#53935](#))
- A table created while `ndb_table_no_logging` was enabled was not always stored to disk, which could lead to a data node crash with `ERROR OPENING DIH SCHEMA FILES FOR TABLE`. ([Bug#53934](#))
- An internal buffer allocator used by `NDB` has the form `alloc(wanted, minimum)` and attempts to allocate `wanted` pages, but is permitted to allocate a smaller number of pages, between `wanted` and `minimum`. However, this allocator could sometimes allocate fewer than `minimum` pages, causing problems with multi-threaded building of ordered indexes. ([Bug#53580](#))
- When compiled with support for `epoll` but this functionality is not available at runtime, MySQL Cluster tries to fall back to use the `select()` function in its place. However, an extra `ndbout_c()` call in the transporter registry code caused `ndbd` to fail instead. ([Bug#53482](#))
- The value set for the `ndb_mgmd` option `--ndb-nodeid` was not verified prior to use as being within the permitted range (1

to 255, inclusive), leading to a crash of the management server. ([Bug#53412](#))

- NDB truncated a column declared as `DECIMAL(65, 0)` to a length of 64. Now such a column is accepted and handled correctly. In cases where the maximum length (65) is exceeded, NDB now raises an error instead of truncating. ([Bug#53352](#))
- When an NDB log handler failed, the memory allocated to it was freed twice. ([Bug#53200](#))
- Setting `DataMemory` higher than 4G on 32-bit platforms caused `ndbd` to crash, instead of failing gracefully with an error. ([Bug#52536](#), [Bug#50928](#))
- When the `LogDestination` parameter was set using with a relative path, the management server failed to store its value unless started with `--initial` or `--reload`. ([Bug#52268](#))
- When creating an index, NDB failed to check whether the internal ID allocated to the index was within the permissible range, leading to an assertion. This issue could manifest itself as a data node failure with NDB error 707 (`NO MORE TABLE METADATA RECORDS (INCREASE MAXNOOFTABLES)`), when creating tables in rapid succession (for example, by a script, or when importing from `mysqldump`), even with a relatively high value for `MaxNoOfTables` and a relatively low number of tables. ([Bug#52055](#))
- `ndb_restore` did not raise any errors if hashmap creation failed during execution. ([Bug#51434](#))
- Specifying the node ID as part of the `--ndb-connectstring` option to `mysqld` was not handled correctly.

The fix for this issue includes the following changes:

- Multiple occurrences of any of the `mysqld` options `--ndb-connectstring`, `--ndb-mgmd-host`, and `--ndb-nodeid` are now handled in the same way as with other MySQL server options, in that the value set in the last occurrence of the option is the value that is used by `mysqld`.

Now, if `--ndb-nodeid` is used, its value overrides that of any `nodeid` setting used in `--ndb-connectstring`. For example, starting `mysqld` with `--ndb-connectstring=nodeid=1,10.100.1.100 --ndb-nodeid=3` now produces the same result as starting it with `--ndb-connectstring=nodeid=3,10.100.1.100`.

- The 1024-character limit on the length of the connectstring is removed, and `--ndb-connectstring` is now handled in this regard in the same way as other `mysqld` options.
- In the NDB API, a new constructor for `Ndb_cluster_connection` is added which takes as arguments a connectstring and the node ID to force the API node to use. See `Ndb_cluster_connection Class Constructor`, for more information.

([Bug#44299](#))

- NDB did not distinguish correctly between table names differing only by lettercase when `lower_case_table_names` was set to 0. ([Bug#33158](#))
- `ndb_mgm -e "ALL STATUS"` erroneously reported that data nodes remained in start phase 0 until they had actually started.
- **Replication:** A buffer overrun in the handling of `DATE` column values could cause `mysqlbinlog` to fail when reading back logs containing certain combinations of DML on a table having a `DATE` column followed by dropping the table. ([Bug#52202](#))
- **Cluster Replication:** Replication failed after a restart of the slave SQL node, due to an error in writing the `master.info` file. ([Bug#52859](#))
- `ALTER TABLE` did not work correctly where the name of the table, the database, or both contained special characters, causing the MySQL server to crash. ([Bug#52225](#))

See also [Bug#53409](#), [Bug#14959](#).

- The performance of MySQL applications using non-persistent client connections was adversely affected due to many of these connections being kept waiting for an excessive length of time in cleanup phase while being closed. ([Bug#48832](#))
- The MySQL client library mishandled `EINPROGRESS` errors for connections in nonblocking mode. This could lead to replication failures on hosts capable of resolving both IPv4 and IPv6 network addresses, when trying to resolve `localhost`. ([Bug#37267](#))

See also [Bug#44344](#).

## 17.7.2.8. Changes in MySQL Cluster NDB 7.0.14 (5.1.44-ndb-7.0.14) (31 March 2010)

This release incorporates new features in the `NDBCLUSTER` storage engine and fixes recently discovered bugs in MySQL Cluster

NDB 7.0.13.

**Obtaining MySQL Cluster NDB 7.0.14.** The latest MySQL Cluster NDB 7.0 binaries for supported platforms can be obtained from <http://dev.mysql.com/downloads/cluster/>. Source code for the latest MySQL Cluster NDB 7.0 release can be obtained from the same location. You can also access the MySQL Cluster NDB 7.0 development source tree at <https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.0>.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, 6.3, and 7.0 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.44 (see [Section C.1.8, “Changes in MySQL 5.1.44 \(04 February 2010\)”,](#)).

### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **Cluster API:** It is now possible to determine, using the `ndb_desc` utility or the NDB API, which data nodes contain replicas of which partitions. For `ndb_desc`, a new `--extra-node-info` option is added to cause this information to be included in its output. A new method `NdbDictionary::Object::Table::getFragmentNodes()` is added to the NDB API for obtaining this information programmatically. ([Bug#51184](#))
- Formerly, the `REPORT` and `DUMP` commands returned output to all `ndb_mgm` clients connected to the same MySQL Cluster. Now, these commands return their output only to the `ndb_mgm` client that actually issued the command. ([Bug#40865](#))
- **Cluster Replication: Replication:** MySQL Cluster Replication now supports attribute promotion and demotion for row-based replication between columns of different but similar types on the master and the slave. For example, it is possible to promote an `INT` column on the master to a `BIGINT` column on the slave, and to demote a `TEXT` column to a `VARCHAR` column.

The implementation of type demotion distinguishes between lossy and non-lossy type conversions, and their use on the slave can be controlled by setting the `slave_type_conversions` global server system variable.

For more information about attribute promotion and demotion for row-based replication in MySQL Cluster, see [Attribute promotion and demotion \(MySQL Cluster\)](#). ([Bug#47163](#), [Bug#46584](#))

Bugs fixed:

- **Cluster API: Incompatible Change:** The default behavior of the NDB API Event API has changed as follows:

Previously, when creating an `NdbDictionary::Event`, DDL operations (alter and drop operations on tables) were automatically reported on any event operation that used this event, but as a result of this change, this is no longer the case. Instead, you must now invoke the event's `setReport()` method, with the new `EventReport` value `ER_DDL`, to get this behavior.

For existing NDB API applications where you wish to retain the old behavior, you must update the code as indicated previously, then recompile, following an upgrade. Otherwise, DDL operations are no longer reported after upgrading `libndbclient`.

For more information, see [The Event ::EventReport Type](#), and [Event ::setReport\(\)](#). ([Bug#53308](#))

- If a node or cluster failure occurred while `mysqld` was scanning the `ndb.ndb_schema` table (which it does when attempting to connect to the cluster), insufficient error handling could lead to a crash by `mysqld` in certain cases. This could happen in a MySQL Cluster with a great many tables, when trying to restart data nodes while one or more `mysqld` processes were restarting. ([Bug#52325](#))
- In MySQL Cluster NDB 7.0 and later, DDL operations are performed within schema transactions; the NDB kernel code for starting a schema transaction checks that all data nodes are at the same version before permitting a schema transaction to start. However, when a version mismatch was detected, the client was not actually informed of this problem, which caused the client to hang. ([Bug#52228](#))
- After running a mixed series of node and system restarts, a system restart could hang or fail altogether. This was caused by setting the value of the newest completed global checkpoint too low for a data node performing a node restart, which led to the node reporting incorrect GCI intervals for its first local checkpoint. ([Bug#52217](#))
- When performing a complex mix of node restarts and system restarts, the node that was elected as master sometimes required optimized node recovery due to missing `REDO` information. When this happened, the node crashed with `FAILURE TO RECREATE OBJECT ... DURING RESTART, ERROR 721` (because the `DBDICT` restart code was run twice). Now when this occurs, node takeover is executed immediately, rather than being made to wait until the remaining data nodes have started. ([Bug#52135](#))

See also [Bug#48436](#).

- The internal variable `ndb_new_handler`, which is no longer used, has been removed. ([Bug#51858](#))
  - `ha_ndbcluster.cc` was not compiled with the same `SAFEMALLOC` and `SAFE_MUTEX` flags as the MySQL Server. ([Bug#51857](#))
  - When debug compiling MySQL Cluster on Windows, the `mysys` library was not compiled with `-DSAFEMALLOC` and `-DSAFE_MUTEX`, due to the fact that `my_socket.c` was misnamed as `my_socket.cc`. ([Bug#51856](#))
  - The redo log protects itself from being filled up by periodically checking how much space remains free. If insufficient redo log space is available, it sets the state `TAIL_PROBLEM` which results in transactions being aborted with error code 410 (`OUT_OF_REDO_LOG`). However, this state was not set following a node restart, which meant that if a data node had insufficient redo log space following a node restart, it could crash a short time later with `FATAL_ERROR_DUE_TO_END_OF_REDO_LOG`. Now, this space is checked during node restarts. ([Bug#51723](#))
  - Restoring a MySQL Cluster backup between platforms having different endianness failed when also restoring metadata and the backup contained a hashmap not already present in the database being restored to. This issue was discovered when trying to restore a backup made on Solaris/SPARC to a MySQL Cluster running on Solaris/x86, but could conceivably occur in other cases where the endianness of the platform on which the backup was taken differed from that of the platform being restored to. ([Bug#51432](#))
  - The output of the `ndb_mgm` client `REPORT BACKUPSTATUS` command could sometimes contain errors due to uninitialized data. ([Bug#51316](#))
  - A `GROUP BY` query against `NDB` tables sometimes did not use any indexes unless the query included a `FORCE INDEX` option. With this fix, indexes are used by such queries (where otherwise possible) even when `FORCE INDEX` is not specified. ([Bug#50736](#))
  - The following issues were fixed in the `ndb_mgm` client `REPORT MEMORYUSAGE` command:
    - The client sometimes inserted extra `ndb_mgm>` prompts within the output.
    - For data nodes running `ndbmtd`, `IndexMemory` was reported before `DataMemory`.
    - Also for data nodes running `ndbmtd`, there were multiple `IndexMemory` entries listed in the output.
- ([Bug#50196](#))
- Issuing a command in the `ndb_mgm` client after it had lost its connection to the management server could cause the client to crash. ([Bug#49219](#))
  - The `mysql` client `system` command did not work properly. This issue was only known to affect the version of the `mysql` client that was included with MySQL Cluster NDB 7.0 and MySQL Cluster NDB 7.1 releases. ([Bug#48574](#))
  - The internal `ErrorReporter::formatMessage()` method could in some cases cause a buffer overflow. ([Bug#47120](#))
  - Information about several management client commands was missing from (that is, truncated in) the output of the `HELP` command. ([Bug#46114](#))
  - The `ndb_print_backup_file` utility failed to function, due to a previous internal change in the NDB code. ([Bug#41512](#), [Bug#48673](#))
  - When the `MemReportFrequency` configuration parameter was set in `config.ini`, the `ndb_mgm` client `REPORT MEMORYUSAGE` command printed its output multiple times. ([Bug#37632](#))
  - `ndb_mgm -e ".... REPORT ...."` did not write any output to `stdout`.

The fix for this issue also prevents the cluster log from being flooded with `INFO` messages when `DataMemory` usage reaches 100%, and insures that when the usage is decreased, an appropriate message is written to the cluster log. ([Bug#31542](#), [Bug#44183](#), [Bug#49782](#))

- **Replication:** Metadata for `GEOMETRY` fields was not properly stored by the slave in its definitions of tables. ([Bug#49836](#))
- See also [Bug#48776](#).
- **Replication:** Column length information generated by `InnoDB` did not match that generated by `MyISAM`, which caused invalid metadata to be written to the binary log when trying to replicate `BIT` columns. ([Bug#49618](#))
  - **Disk Data:** Inserts of blob column values into a MySQL Cluster Disk Data table that exhausted the tablespace resulted in mis-

leading `NO SUCH TUPLE` error messages rather than the expected error `TABLESPACE FULL`.

This issue appeared similar to [Bug#48113](#), but had a different underlying cause. ([Bug#52201](#))

- **Disk Data:** The error message returned after attempting to execute `ALTER LOGFILE GROUP` on an nonexistent logfile group did not indicate the reason for the failure. ([Bug#51111](#))
- **Disk Data:** DDL operations on Disk Data tables having a relatively small `UNDO_BUFFER_SIZE` could fail unexpectedly.
- **Cluster Replication:** The `--ndb-log-empty-epochs` option did not work correctly. ([Bug#49559](#))
- **Cluster Replication:** When `mysqld` was started with `--binlog-do-db` or `--binlog-ignore-db`, no `LOST_EVENTS` incident was written to the binary log. ([Bug#47096](#))
- **Cluster API:** When reading blob data with lock mode `LM_SimpleRead`, the lock was not upgraded as expected. ([Bug#51034](#))
- **Cluster API:** A number of issues were corrected in the NDB API coding examples found in the `storage/ndb/ndbapi-examples` directory in the MySQL Cluster source tree. These included possible endless recursion in `ndbapi_scan.cpp` as well as problems running some of the examples on systems using Windows or Mac OS due to the letter case used for some table names. ([Bug#30552](#), [Bug#30737](#))
- On some Unix/Linux platforms, an error during build from source could be produced, referring to a missing `LT_INIT` program. This is due to versions of `libtool` 2.1 and earlier. ([Bug#51009](#))
- 1) In rare cases, if a thread was interrupted during a `FLUSH PRIVILEGES` operation, a debug assertion occurred later due to improper diagnostics area setup. 2) A `KILL` operation could cause a console error message referring to a diagnostic area state without first ensuring that the state existed. ([Bug#33982](#))

### 17.7.2.9. Changes in MySQL Cluster NDB 7.0.13 (5.1.41-ndb-7.0.13) (04 March 2010)

This release incorporates new features in the `NDBCLUSTER` storage engine and fixes recently discovered bugs in MySQL Cluster NDB 7.0.12.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, 6.3, and 7.0 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.41 (see [Section C.1.12, “Changes in MySQL 5.1.41 \(05 November 2009\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- A new configuration parameter `HeartbeatThreadPriority` makes it possible to select between a first-in, first-out or round-round scheduling policy for management node and API node heartbeat threads, as well as to set the priority of these threads. See [Section 17.3.2.5, “Defining a MySQL Cluster Management Server”](#), or [Section 17.3.2.7, “Defining SQL and Other API Nodes in a MySQL Cluster”](#), for more information. ([Bug#49617](#))
- Start phases are now written to the data node logs. ([Bug#49158](#))
- **Disk Data:** The `ndb_desc` utility can now show the extent space and free extent space for subordinate `BLOB` and `TEXT` columns (stored in hidden `BLOB` tables by NDB). A `--blob-info` option has been added for this program that causes `ndb_desc` to generate a report for each subordinate `BLOB` table. For more information, see [Section 17.4.9, “ndb\\_desc — Describe NDB Tables”](#). ([Bug#50599](#))

Bugs fixed:

- When performing a system restart of a MySQL Cluster where multi-threaded data nodes were in use, there was a slight risk that the restart would hang due to incorrect serialization of signals passed between LQH instances and proxies; some signals were sent using a proxy, and others directly, which meant that the order in which they were sent and received could not be guaranteed. If signals arrived in the wrong order, this could cause one or more data nodes to hang. Now all signals that need to be sent and received in the same order are sent using the same path. ([Bug#51645](#))
- When one or more data nodes read their LCPs and applied undo logs significantly faster than others, this could lead to a race condition causing system restarts of data nodes to hang. This could most often occur when using both `ndbd` and `ndbmt` pro-

cesses for the data nodes. ([Bug#51644](#))

- When deciding how to divide the REDO log, the `DBDIH` kernel block saved more than was needed to restore the previous local checkpoint, which could cause REDO log space to be exhausted prematurely (NDB error 410). ([Bug#51547](#))
- DML operations can fail with NDB error 1220 (`REDO LOG FILES OVERLOADED...`) if the opening and closing of REDO log files takes too much time. If this occurred as a GCI marker was being written in the REDO log while REDO log file 0 was being opened or closed, the error could persist until a GCP stop was encountered. This issue could be triggered when there was insufficient REDO log space (for example, with configuration parameter settings `NoOfFragmentLogFiles = 6` and `FragmentLogFileSize = 6M`) with a load including a very high number of updates. ([Bug#51512](#))

See also [Bug#20904](#).

- A side effect of the `ndb_restore --disable-indexes` and `--rebuild-indexes` options is to change the schema versions of indexes. When a `mysqld` later tried to drop a table that had been restored from backup using one or both of these options, the server failed to detect these changed indexes. This caused the table to be dropped, but the indexes to be left behind, leading to problems with subsequent backup and restore operations. ([Bug#51374](#))
- `ndb_restore` crashed while trying to restore a corrupted backup, due to missing error handling. ([Bug#51223](#))
- The `ndb_restore` message `Successfully created index `PRIMARY`...` was directed to `stderr` instead of `stdout`. ([Bug#51037](#))
- When using `NoOfReplicas` equal to 1 or 2, if data nodes from one node group were restarted 256 times and applications were running traffic such that it would encounter NDB error 1204 (`TEMPORARY FAILURE, DISTRIBUTION CHANGED`), the live node in the node group would crash, causing the cluster to crash as well. The crash occurred only when the error was encountered on the 256th restart; having the error on any previous or subsequent restart did not cause any problems. ([Bug#50930](#))
- Replication of a MySQL Cluster using multi-threaded data nodes could fail with forced shutdown of some data nodes due to the fact that `ndbmtd` exhausted `LongMessageBuffer` much more quickly than `ndbd`. After this fix, passing of replication data between the `DBTUP` and `SUMA` NDB kernel blocks is done using `DataMemory` rather than `LongMessageBuffer`.

Until you can upgrade, you may be able to work around this issue by increasing the `LongMessageBuffer` setting; doubling the default should be sufficient in most cases. ([Bug#46914](#))

- A `SELECT` requiring a sort could fail with the error `CAN'T FIND RECORD IN 'TABLE'` when run concurrently with a `DELETE` from the same table. ([Bug#45687](#))
- Cluster API:** An issue internal to `ndb_mgm` could cause problems when trying to start a large number of data nodes at the same time. ([Bug#51273](#))

## 17.7.2.10. Changes in MySQL Cluster NDB 7.0.12b (5.1.41-ndb-7.0.12b) (18 February 2010)

This is a replacement release for MySQL Cluster NDB 7.0.12a, fixing a critical issue in that version that was discovered shortly after its release ([Bug#51256](#)). MySQL Cluster NDB 7.0.12b is identical in all other respects to MySQL Cluster NDB 7.0.12 and MySQL Cluster NDB 7.0.12a. Users of MySQL Cluster NDB 7.0.12 or MySQL Cluster NDB 7.0.12a (only) should upgrade to the 7.0.12b release as soon as possible.

This is a testing release only, for the purpose of testing the fix for [Bug#49190](#) (now also incorporating the fix for [Bug#51027](#) and [Bug#51256](#)). This release is otherwise identical to MySQL Cluster NDB 7.0.11b; users of MySQL Cluster NDB 7.0.11 or MySQL Cluster NDB 7.0.11a who are not interested in testing this change should upgrade to MySQL Cluster NDB 7.0.11b (if they have not done so already), then wait until MySQL Cluster NDB 7.0.13 becomes available.

**Obtaining MySQL Cluster NDB 7.0.12a.** This is a source-only release. You can obtain the GPL source code for MySQL Cluster NDB 7.0.12a from [ftp://ftp.mysql.com/pub/mysql/download/cluster\\_telco/mysql-5.1.41-ndb-7.0.12a/](ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/mysql-5.1.41-ndb-7.0.12a/). You can also access the MySQL Cluster NDB 7.0 development source tree at <https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.0>.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 7.0 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.41 (see [Section C.1.12, “Changes in MySQL 5.1.41 \(05 November 2009\)](#)”).

### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- An initial restart of a data node configured with a large amount of memory could fail with a `POINTER TOO LARGE` error. ([Bug#51027](#))

This regression was introduced by [Bug#47818](#).

### 17.7.2.11. Changes in MySQL Cluster NDB 7.0.12a (5.1.41-ndb-7.0.12a) (15 February 2010)

#### Note

MySQL Cluster NDB 7.0.12a was withdrawn shortly after release, due to [Bug#51256](#). Users of the original 7.0.12 release should upgrade to MySQL Cluster NDB 7.0.12b, which fixes this issue (and others). Users of MySQL Cluster NDB 7.0.11 or MySQL Cluster NDB 7.0.11a should upgrade to MySQL Cluster NDB 7.0.11b, if they have not done so already.

This is a replacement release for MySQL Cluster NDB 7.0.12, fixing a critical issue in that version that was discovered shortly after its release ([Bug#51027](#)). MySQL Cluster NDB 7.0.12a is identical in all other respects to MySQL Cluster NDB 7.0.12. Users of MySQL Cluster NDB 7.0.12 (only) should upgrade to the 7.0.12a release as soon as possible.

This is a testing release only, for the purpose of testing the fix for [Bug#49190](#) (now also incorporating the fix for [Bug#51027](#)). This release is otherwise identical to MySQL Cluster NDB 7.0.11b; users of MySQL Cluster NDB 7.0.11 or MySQL Cluster NDB 7.0.11a who are not interested in testing this change should upgrade to MySQL Cluster NDB 7.0.11b (if they have not done so already), then wait until MySQL Cluster NDB 7.0.13 becomes available.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 7.0 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.41 (see [Section C.1.12, “Changes in MySQL 5.1.41 \(05 November 2009\)”](#)).

#### Note

Bugs fixed:

- An initial restart of a data node configured with a large amount of memory could fail with a `POINTER TOO LARGE` error. ([Bug#51027](#))

This regression was introduced by [Bug#47818](#).

### 17.7.2.12. Changes in MySQL Cluster NDB 7.0.12 (5.1.41-ndb-7.0.12) (03 February 2010)

#### Note

MySQL Cluster NDB 7.0.12 was withdrawn shortly after release, due to [Bug#51027](#). Users of the original 7.0.12 release should upgrade to MySQL Cluster NDB 7.0.12b, which fixes this issue (and others). Users of MySQL Cluster NDB 7.0.11 or MySQL Cluster NDB 7.0.11a should upgrade to MySQL Cluster NDB 7.0.11b, if they have not done so already.

This is a testing release only, for the purpose of testing the fix for [Bug#49190](#). This release is otherwise identical to MySQL Cluster NDB 7.0.11b; users of MySQL Cluster NDB 7.0.11 or MySQL Cluster NDB 7.0.11a who are not interested in testing this change should upgrade to MySQL Cluster NDB 7.0.11b (if they have not done so already), then wait until MySQL Cluster NDB 7.0.13 becomes available.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, 6.3, and 7.0 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.41 (see [Section C.1.12, “Changes in MySQL 5.1.41 \(05 November 2009\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- Numeric codes used in management server status update messages in the cluster logs have been replaced with text descriptions. ([Bug#49627](#))

See also [Bug#44248](#).

Bugs fixed:

- `ndbmtd` started on a single-core machine could sometimes fail with a `JOB BUFFER FULL` error when `MaxNoOfExecution-Threads` was set greater than `LockExecuteThreadToCPU`. Now a warning is logged when this occurs. ([Bug#50582](#))
- When a primary key lookup on an `NDB` table containing one or more `BLOB` columns was executed in a transaction, a shared lock on any blob tables used by the `NDB` table was held for the duration of the transaction. (This did not occur for indexed or non-indexed `WHERE` conditions.)

Now in such cases, the lock is released after all `BLOB` data has been read. ([Bug#49190](#))

### 17.7.2.13. Changes in MySQL Cluster NDB 7.0.11b (5.1.41-ndb-7.0.11b) (18 February 2010)

This is a replacement release for MySQL Cluster NDB 7.0.11a, fixing a critical issue in that version that was discovered shortly after its release ([Bug#51256](#)). MySQL Cluster NDB 7.0.11b is identical in all other respects to MySQL Cluster NDB 7.0.11a. Users of MySQL Cluster NDB 7.0.11 or MySQL Cluster NDB 7.0.11a should upgrade to the 7.0.11b release as soon as possible. Users of previous MySQL Cluster NDB 7.0 releases should bypass the 7.0.11 and 7.0.11a releases, and upgrade to 7.0.11b instead.

**Obtaining MySQL Cluster NDB 7.0.11b.** This is a source-only release. You can obtain the GPL source code for MySQL Cluster NDB 7.0.11b from [ftp://ftp.mysql.com/pub/mysql/download/cluster\\_telco/mysql-5.1.41-ndb-7.0.11b/](ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/mysql-5.1.41-ndb-7.0.11b/). You can also access the MySQL Cluster NDB 7.0 development source tree at <https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.0>.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 7.0 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.41 (see [Section C.1.12, “Changes in MySQL 5.1.41 \(05 November 2009\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- Setting `IndexMemory` greater than 2GB could cause data nodes to crash while starting. ([Bug#51256](#))

### 17.7.2.14. Changes in MySQL Cluster NDB 7.0.11a (5.1.41-ndb-7.0.11a) (15 February 2010)

This is a replacement release for MySQL Cluster NDB 7.0.11, fixing a critical issue in that version that was discovered shortly after its release ([Bug#51027](#)). MySQL Cluster NDB 7.0.11a is identical in all other respects to MySQL Cluster NDB 7.0.11. Users of MySQL Cluster NDB 7.0.11 should upgrade to the 7.0.11a release as soon as possible. Users of previous MySQL Cluster NDB 7.0 releases should bypass the 7.0.11 release and upgrade to 7.0.11a instead.

**Obtaining MySQL Cluster NDB 7.0.11a.** This is a source-only release. You can obtain the GPL source code for MySQL Cluster NDB 7.0.11a from [ftp://ftp.mysql.com/pub/mysql/download/cluster\\_telco/mysql-5.1.41-ndb-7.0.11a/](ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/mysql-5.1.41-ndb-7.0.11a/). You can also access the MySQL Cluster NDB 7.0 development source tree at <https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.0>.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 7.0 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.41 (see [Section C.1.12, “Changes in MySQL 5.1.41 \(05 November 2009\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- An initial restart of a data node configured with a large amount of memory could fail with a `POINTER TOO LARGE` error. ([Bug#51027](#))

This regression was introduced by [Bug#47818](#).

## 17.7.2.15. Changes in MySQL Cluster NDB 7.0.11 (5.1.41-ndb-7.0.11) (02 February 2010)

### Note

MySQL Cluster NDB 7.0.11 was withdrawn shortly after release, due to [Bug#51027](#). Users should upgrade to MySQL Cluster NDB 7.0.11a, which fixes this issue.

This release incorporates new features in the `NDBCLUSTER` storage engine and fixes recently discovered bugs in MySQL Cluster NDB 7.0.10.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, 6.3, and 7.0 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.39 (see [Section C.1.12, “Changes in MySQL 5.1.41 \(05 November 2009\)”](#)).

### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **Important Change:** The maximum permitted value of the `ndb_autoincrement_prefetch_sz` system variable has been increased from 256 to 65536. ([Bug#50621](#))
- Added multi-threaded ordered index building capability during system restarts or node restarts, controlled by the `BuildIndexThreads` data node configuration parameter (also introduced in this release).
- **Cluster Replication:** Due to the fact that no timestamp is available for delete operations, a delete using `NDB$MAX()` is actually processed as `NDB$OLD`. However, because this is not optimal for some use cases, `NDB$MAX_DELETE_WIN()` is added as a conflict resolution function; if the “timestamp” column value for a given row adding or updating an existing row coming from the master is higher than that on the slave, it is applied (as with `NDB$MAX()`); however, delete operations are treated as always having the higher value.

See `NDB$MAX_DELETE_WIN(column_name)`, for more information. ([Bug#50650](#))

- **Cluster Replication:** In circular replication, it was sometimes possible for an event to propagate such that it would be reapplied on all servers. This could occur when the originating server was removed from the replication circle and so could no longer act as the terminator of its own events, as normally happens in circular replication.

To prevent this from occurring, a new `IGNORE_SERVER_IDS` option is introduced for the `CHANGE MASTER TO` statement. This option takes a list of replication server IDs; events having a server ID which appears in this list are ignored and not applied. For more information, see [Section 12.5.2.1, “`CHANGE MASTER TO` Syntax”](#).

In conjunction with the introduction of `IGNORE_SERVER_IDS`, `SHOW SLAVE STATUS` has two new fields. `Replicate_Ignore_Server_Ids` displays information about ignored servers. `Master_Server_Id` displays the `server_id` value from the master. ([Bug#47037](#))

See also [Bug#25998](#), [Bug#27808](#).

Bugs fixed:

- Initial start of partitioned nodes did not work correctly. This issue was observed in MySQL Cluster NDB 7.0 only. ([Bug#50661](#))
- The `CREATE NODEGROUP` client command in `ndb_mgm` could sometimes cause the forced shutdown of a data node. ([Bug#50594](#))
- Local query handler information was not reported or written to the cluster log correctly. This issue is thought to have been introduced in MySQL Cluster NDB 7.0.10. ([Bug#50467](#))
- Online upgrades from MySQL Cluster NDB 7.0.9b to MySQL Cluster NDB 7.0.10 did not work correctly. Current MySQL Cluster NDB 7.0 users should upgrade directly to MySQL Cluster NDB 7.0.11 or later.

This issue is not known to have affected MySQL Cluster NDB 6.3, and it should be possible to upgrade from MySQL Cluster NDB 6.3 to MySQL Cluster NDB 7.0.10 without problems. See [Section 17.2.5.2, “MySQL Cluster 5.1 and MySQL Cluster NDB 6.x/7.x Upgrade and Downgrade Compatibility”](#), for more information. ([Bug#50433](#))

- Dropping unique indexes in parallel while they were in use could cause node and cluster failures. ([Bug#50118](#))

- When attempting to join a running cluster whose management server had been started with the `--nowait-nodes` option and having SQL nodes with dynamically allocated node IDs, a second management server failed with spurious `INTERNAL ERROR: FOUND DYNAMIC PORTS WITH VALUE IN CONFIG...` error messages. ([Bug#49807](#))
- When setting the `LockPagesInMainMemory` configuration parameter failed, only the error `FAILED TO MEMLOCK PAGES...` was returned. Now in such cases the operating system's error code is also returned. ([Bug#49724](#))
- If a query on an `NDB` table compared a constant string value to a column, and the length of the string was greater than that of the column, condition pushdown did not work correctly. (The string was truncated to fit the column length before being pushed down.) Now in such cases, the condition is no longer pushed down. ([Bug#49459](#))
- `ndbmted` was not built on Windows (`CMake` did not provide a build target for it). ([Bug#49325](#))
- Performing intensive inserts and deletes in parallel with a high scan load could cause a data node crashes due to a failure in the `DBACC` kernel block. This was because checking for when to perform bucket splits or merges considered the first 4 scans only. ([Bug#48700](#))
- During Start Phases 1 and 2, the `STATUS` command sometimes (falsely) returned `Not Connected` for data nodes running `ndbmted`. ([Bug#47818](#))
- When performing a `DELETE` that included a left join from an `NDB` table, only the first matching row was deleted. ([Bug#47054](#))
- Under some circumstances, the `DBTC` kernel block could send an excessive number of commit and completion messages which could lead to a job buffer filling up and node failure. This was especially likely to occur when using `ndbmted` with a single data node. ([Bug#45989](#))
- `mysqld` could sometimes crash during a commit while trying to handle NDB Error 4028 `NODE FAILURE CAUSED ABORT OF TRANSACTION`. ([Bug#38577](#))
- When setting `LockPagesInMainMemory`, the stated memory was not allocated when the node was started, but rather only when the memory was used by the data node process for other reasons. ([Bug#37430](#))
- Trying to insert more rows than would fit into an `NDB` table caused data nodes to crash. Now in such situations, the insert fails gracefully with error 633 `TABLE FRAGMENT HASH INDEX HAS REACHED MAXIMUM POSSIBLE SIZE`. ([Bug#34348](#))
- On Mac OS X or Windows, sending a `SIGHUP` signal to the server or an asynchronous flush (triggered by `flush_time`) caused the server to crash. ([Bug#47525](#))
- The `ARCHIVE` storage engine lost records during a bulk insert. ([Bug#46961](#))
- When using the `ARCHIVE` storage engine, `SHOW TABLE STATUS` displayed incorrect information for `Max_data_length`, `Data_length` and `Avg_row_length`. ([Bug#29203](#))

### 17.7.2.16. Changes in MySQL Cluster NDB 7.0.10 (5.1.39-ndb-7.0.10) (15 December 2009)

This release incorporates new features in the `NDBCLUSTER` storage engine and fixes recently discovered bugs in MySQL Cluster NDB 7.0.9a.

**Obtaining MySQL Cluster NDB 7.0.10.** The latest MySQL Cluster NDB 7.0 binaries for supported platforms can be obtained from <http://dev.mysql.com/downloads/cluster/>. Source code for the latest MySQL Cluster NDB 7.0 release can be obtained from the same location. You can also access the MySQL Cluster NDB 7.0 development source tree at <https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.0>.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, 6.3, and 7.0 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.39 (see [Section C.1.15, “Changes in MySQL 5.1.39 \(04 September 2009\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- Added the `ndb_mgmd --nowait-nodes` option, which permits a cluster that is configured to use multiple management servers to be started using fewer than the number configured. This is most likely to be useful when a cluster is configured with two management servers and you wish to start the cluster using only one of them.

See [Section 17.4.4, “`ndb\_mgmd` — The MySQL Cluster Management Server Daemon”](#), for more information. ([Bug#48669](#))

- This enhanced functionality is supported for upgrades from MySQL Cluster NDB 6.3 when the `NDB` engine version is 6.3.29 or later. ([Bug#48528](#), [Bug#49163](#))
  - The output from `ndb_config --configinfo --xml` now indicates, for each configuration parameter, the following restart type information:
    - Whether a system restart or a node restart is required when resetting that parameter;
    - Whether cluster nodes need to be restarted using the `--initial` option when resetting the parameter.
- ([Bug#47366](#))

Bugs fixed:

- Node takeover during a system restart occurs when the REDO log for one or more data nodes is out of date, so that a node restart is invoked for that node or those nodes. If this happens while a `mysqld` process is attached to the cluster as an SQL node, the `mysqld` takes a global schema lock (a row lock), while trying to set up cluster-internal replication.

However, this setup process could fail, causing the global schema lock to be held for an excessive length of time, which made the node restart hang as well. As a result, the `mysqld` failed to set up cluster-internal replication, which led to tables being read only, and caused one node to hang during the restart.

### Note

This issue could actually occur in MySQL Cluster NDB 7.0 only, but the fix was also applied MySQL Cluster NDB 6.3, in order to keep the two codebases in alignment.

([Bug#49560](#))

- Sending `SIGHUP` to a `mysqld` running with the `--ndbcluster` and `--log-bin` options caused the process to crash instead of refreshing its log files. ([Bug#49515](#))
- If the master data node receiving a request from a newly-started API or data node for a node ID died before the request has been handled, the management server waited (and kept a mutex) until all handling of this node failure was complete before responding to any other connections, instead of responding to other connections as soon as it was informed of the node failure (that is, it waited until it had received a `NF_COMPLETEREP` signal rather than a `NODE_FAILREP` signal). On visible effect of this misbehavior was that it caused management client commands such as `SHOW` and `ALL STATUS` to respond with unnecessary slowness in such circumstances. ([Bug#49207](#))
- Attempting to create more than 11435 tables failed with Error 306 (`OUT OF FRAGMENT RECORDS IN DIH`). ([Bug#49156](#))
- When evaluating the options `--include-databases`, `--include-tables`, `--exclude-databases`, and `--exclude-tables`, the `ndb_restore` program overwrote the result of the database-level options with the result of the table-level options rather than merging these results together, sometimes leading to unexpected and unpredictable results.

As part of the fix for this problem, the semantics of these options have been clarified; because of this, the rules governing their evaluation have changed slightly. These changes be summed up as follows:

- All `--include-*` and `--exclude-*` options are now evaluated from right to left in the order in which they are passed to `ndb_restore`.
- All `--include-*` and `--exclude-*` options are now cumulative.
- In the event of a conflict, the first (rightmost) option takes precedence.

For more detailed information and examples, see [Section 17.4.17, “`ndb\_restore` — Restore a MySQL Cluster Backup”](#). ([Bug#48907](#))

- When performing tasks that generated large amounts of I/O (such as when using `ndb_restore`), an internal memory buffer could overflow, causing data nodes to fail with signal 6.

Subsequent analysis showed that this buffer was not actually required, so this fix removes it. ([Bug#48861](#))

- Exhaustion of send buffer memory or long signal memory caused data nodes to crash. Now an appropriate error message is provided instead when this situation occurs. ([Bug#48852](#))
- In some situations, when it was not possible for an SQL node to start a schema transaction (necessary, for instance, as part of an online `ALTER TABLE`), `NDBCLUSTER` did not correctly indicate the error to the MySQL server, which led `mysqld` to crash. ([Bug#48841](#))

- Under certain conditions, accounting of the number of free scan records in the local query handler could be incorrect, so that during node recovery or a local checkpoint operations, the LQH could find itself lacking a scan record that is expected to find, causing the node to crash. ([Bug#48697](#))

See also [Bug#48564](#).

- The creation of an ordered index on a table undergoing DDL operations could cause a data node crash under certain timing-dependent conditions. ([Bug#48604](#))
- During an LCP master takeover, when the newly elected master did not receive a `COPY_GCI` LCP protocol message but other nodes participating in the local checkpoint had received one, the new master could use an uninitialized variable, which caused it to crash. ([Bug#48584](#))
- When running many parallel scans, a local checkpoint (which performs a scan internally) could find itself not getting a scan record, which led to a data node crash. Now an extra scan record is reserved for this purpose, and a problem with obtaining the scan record returns an appropriate error (error code 489, `TOO MANY ACTIVE SCANS`). ([Bug#48564](#))
- During a node restart, logging was enabled on a per-fragment basis as the copying of each fragment was completed but local checkpoints were not enabled until all fragments were copied, making it possible to run out of redo log file space (`NDB` error code 410) before the restart was complete. Now logging is enabled only after all fragments have been copied, just prior to enabling local checkpoints. ([Bug#48474](#))
- When using very large transactions containing many inserts, `ndbmttd` could fail with `Signal 11` without an easily detectable reason, due to an internal variable being uninitialized in the event that the `LongMessageBuffer` was overloaded. Now, the variable is initialized in such cases, avoiding the crash, and an appropriate error message is generated. ([Bug#48441](#))

See also [Bug#46914](#).

- A data node crashing while restarting, followed by a system restart could lead to incorrect handling of redo log metadata, causing the system restart to fail with `ERROR WHILE READING REDO LOG`. ([Bug#48436](#))
- Starting a `mysqld` process with `--ndb-nodeid` (either as a command-line option or by assigning it a value in `my.cnf`) caused the `mysqld` to get only the corresponding connection from the `[mysqld]` section in the `config.ini` file having the matching ID, even when connection pooling was enabled (that is, when the `mysqld` process was started with `-ndb-cluster-connection-pool` set greater than 1). ([Bug#48405](#))

See also [Bug#27644](#), [Bug#38590](#), [Bug#41592](#).

- The configuration check that each management server runs to verify that all connected `ndb_mgmd` processes have the same configuration could fail when a configuration change took place while this check was in progress. Now in such cases, the configuration check is rescheduled for a later time, after the change is complete. ([Bug#48143](#))
- When employing `NDB` native backup to back up and restore an empty `NDB` table that used a non-sequential `AUTO_INCREMENT` value, the `AUTO_INCREMENT` value was not restored correctly. ([Bug#48005](#))
- `ndb_config --xml --configinfo` now indicates that parameters belonging in the `[SCI]`, `[SCI DEFAULT]`, `[SHM]`, and `[SHM DEFAULT]` sections of the `config.ini` file are deprecated or experimental, as appropriate. ([Bug#47365](#))
- `NDB` stores blob column data in a separate, hidden table that is not accessible from MySQL. If this table was missing for some reason (such as accidental deletion of the file corresponding to the hidden table) when making a MySQL Cluster native backup, `ndb_restore` crashed when attempting to restore the backup. Now in such cases, `ndb_restore` fails with the error message `TABLE TABLE_NAME HAS BLOB COLUMN (COLUMN_NAME) WITH MISSING PARTS TABLE IN BACKUP` instead. ([Bug#47289](#))
- In MySQL Cluster NDB 7.0, `ndb_config` and `ndb_error_reporter` were printing warnings about management and data nodes running on the same host to `stdout` instead of `stderr`, as was the case in earlier MySQL Cluster release series. ([Bug#44689](#), [Bug#49160](#))

See also [Bug#25941](#).

- `DROP DATABASE` failed when there were stale temporary `NDB` tables in the database. This situation could occur if `mysqld` crashed during execution of a `DROP TABLE` statement after the table definition had been removed from `NDBCLUSTER` but before the corresponding `.ndb` file had been removed from the crashed SQL node's data directory. Now, when `mysqld` executes `DROP DATABASE`, it checks for these files and removes them if there are no corresponding table definitions for them found in `NDBCLUSTER`. ([Bug#44529](#))
- Creating an `NDB` table with an excessive number of large `BIT` columns caused the cluster to fail. Now, an attempt to create such a table is rejected with error 791 (`TOO MANY TOTAL BITS IN BITFIELDS`). ([Bug#42046](#))

See also [Bug#42047](#).

- When a long-running transaction lasting long enough to cause Error 410 (`REDO LOG FILES OVERLOADED`) was later committed or rolled back, it could happen that `NDBCLUSTER` was not able to release the space used for the REDO log, so that the error condition persisted indefinitely.

The most likely cause of such transactions is a bug in the application using MySQL Cluster. This fix should handle most cases where this might occur. ([Bug#36500](#))

- Deprecation and usage information obtained from `ndb_config --configinfo` regarding the `PortNumber` and `ServerPort` configuration parameters was improved. ([Bug#24584](#))
- **Disk Data:** When running a write-intensive workload with a very large disk page buffer cache, CPU usage approached 100% during a local checkpoint of a cluster containing Disk Data tables. ([Bug#49532](#))
- **Disk Data:** `NDBCLUSTER` failed to provide a valid error message if it failed to commit schema transactions during an initial start if the cluster was configured using the `InitialLogFileGroup` parameter. ([Bug#48517](#))
- **Disk Data:** In certain limited cases, it was possible when the cluster contained Disk Data tables for `ndbmtd` to crash during a system restart. ([Bug#48498](#))

See also [Bug#47832](#).

- **Disk Data:** Repeatedly creating and then dropping Disk Data tables could eventually lead to data node failures. ([Bug#45794](#), [Bug#48910](#))
- **Disk Data:** When a crash occurs due to a problem in Disk Data code, the currently active page list is printed to `stdout` (that is, in one or more `ndb_nodeid_out.log` files). One of these lists could contain an endless loop; this caused a printout that was effectively never-ending. Now in such cases, a maximum of 512 entries is printed from each list. ([Bug#42431](#))
- **Disk Data:** When the `FileSystemPathUndoFiles` configuration parameter was set to an non-existent path, the data nodes shut down with the generic error code 2341 (`INTERNAL PROGRAM ERROR`). Now in such cases, the error reported is error 2815 (`FILE NOT FOUND`).
- **Cluster Replication:** When `expire_logs_days` was set, the thread performing the purge of the log files could deadlock, causing all binary log operations to stop. ([Bug#49536](#))
- **Cluster API:** When a DML operation failed due to a uniqueness violation on an `NDB` table having more than one unique index, it was difficult to determine which constraint caused the failure; it was necessary to obtain an `NdbError` object, then decode its `details` property, which could lead to memory management issues in application code.

To help solve this problem, a new API method `Ndb::getNdbErrorDetail()` is added, providing a well-formatted string containing more precise information about the index that caused the unique constraint violation. The following additional changes are also made in the NDB API:

- Use of `NdbError.details` is now deprecated in favor of the new method.
- The `NdbDictionary::listObjects()` method has been modified to provide more information.

For more information, see `Ndb::getNdbErrorDetail()`, [The NdbError Structure](#), and `Dictionary::listObjects()`. ([Bug#48851](#))

- **Cluster API:** When using blobs, calling `getBlobHandle()` requires the full key to have been set using `equal()`, because `getBlobHandle()` must access the key for adding blob table operations. However, if `getBlobHandle()` was called without first setting all parts of the primary key, the application using it crashed. Now, an appropriate error code is returned instead. ([Bug#28116](#), [Bug#48973](#))
- The `mysql_real_connect()` C API function only attempted to connect to the first IP address returned for a hostname. This could be a problem if a hostname mapped to multiple IP address and the server was not bound to the first one returned. Now `mysql_real_connect()` attempts to connect to all IPv4 or IPv6 addresses that a domain name maps to. ([Bug#45017](#))

See also [Bug#47757](#).

## 17.7.2.17. Changes in MySQL Cluster NDB 7.0.9b (5.1.39-ndb-7.0.9b) (10 November 2009)

This release includes a fix for [Bug#48651](#), which was discovered in MySQL Cluster NDB 7.0.9a shortly after release. The MySQL Cluster NDB 7.0.9b release is identical in all other respects to MySQL Cluster NDB 7.0.9a. Users who have already installed MySQL Cluster NDB 7.0.9a should upgrade to MySQL Cluster NDB 7.0.9b as soon as possible; users seeking to upgrade from any other previous MySQL Cluster 7.0 release should upgrade to MySQL Cluster NDB 7.0.9b instead.

**Obtaining MySQL Cluster NDB 7.0.9b.** The latest MySQL Cluster NDB 7.0 binaries for supported platforms can be obtained from <http://dev.mysql.com/downloads/cluster/>. Source code for the latest MySQL Cluster NDB 7.0 release can be obtained from

the same location. You can also access the MySQL Cluster NDB 7.0 development source tree at <https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.0>.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, 6.3, and 7.0 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.39 (see [Section C.1.15, “Changes in MySQL 5.1.39 \(04 September 2009\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- Using a large number of small fragment log files could cause `NDBCLUSTER` to crash while trying to read them during a restart. This issue was first observed with 1024 fragment log files of 16 MB each. ([Bug#48651](#))

### 17.7.2.18. Changes in MySQL Cluster NDB 7.0.9a (5.1.39-ndb-7.0.9a) (05 November 2009)

#### Important

MySQL Cluster NDB 7.0.9a was pulled shortly after release due to [Bug#48651](#). Users seeking to upgrade from a previous MySQL Cluster NDB 7.0 release should instead use MySQL Cluster NDB 7.0.9b, which contains a fix for this bug, in addition to all bugfixes and improvements made in MySQL Cluster NDB 7.0.9a.

This release includes a fix for [Bug#48531](#), which was discovered in MySQL Cluster NDB 7.0.9 shortly after release. The MySQL Cluster NDB 7.0.9a release is identical in all other respects to MySQL Cluster NDB 7.0.9. Users who have already installed MySQL Cluster NDB 7.0.9 should upgrade to MySQL Cluster NDB 7.0.9a as soon as possible; users seeking to upgrade from any other previous MySQL Cluster 7.0 release should upgrade to MySQL Cluster NDB 7.0.9a instead.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, 6.3, and 7.0 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.39 (see [Section C.1.15, “Changes in MySQL 5.1.39 \(04 September 2009\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- When the combined length of all names of tables using the `NDB` storage engine was greater than or equal to 1024 bytes, issuing the `START BACKUP` command in the `ndb_mgm` client caused the cluster to crash. ([Bug#48531](#))

### 17.7.2.19. Changes in MySQL Cluster NDB 7.0.9 (5.1.39-ndb-7.0.9) (31 October 2009)

#### Important

MySQL Cluster NDB 7.0.9 and 7.0.9a were pulled shortly after being released due to [Bug#48531](#) and [Bug#48651](#). Users seeking to upgrade from a previous MySQL Cluster NDB 7.0 release should instead use MySQL Cluster NDB 7.0.9b, which contains fixes for these critical bugs, in addition to all bugfixes and improvements made in MySQL Cluster NDB 7.0.9.

This release incorporates new features in the `NDBCLUSTER` storage engine and fixes recently discovered bugs in MySQL Cluster NDB 7.0.8a.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, 6.3, and 7.0 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.39 (see [Section C.1.15, “Changes in MySQL 5.1.39 \(04 September 2009\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **Performance:** Significant improvements in redo log handling and other filesystem operations can yield a considerable reduction in the time required for restarts. While actual restart times observed in a production setting will naturally vary according to database size, hardware, and other conditions, our own preliminary testing shows that these optimizations can yield startup times that are faster than those typical of previous MySQL Cluster releases by a factor of 50 or more.

Bugs fixed:

- **Important Change:** The `--with-ndb-port-base` option for `configure` did not function correctly, and has been deprecated. Attempting to use this option produces the warning `IGNORING DEPRECATED OPTION --WITH-NDB-PORT-BASE`.

Beginning with MySQL Cluster NDB 7.1.0, the deprecation warning itself is removed, and the `--with-ndb-port-base` option is simply handled as an unknown and invalid option if you try to use it. ([Bug#47941](#))

See also [Bug#38502](#).

- After upgrading a MySQL Cluster containing tables having unique indexes from an NDB 6.3 release to an NDB 7.0 release, attempts to create new unique indexes failed with `INCONSISTENT TRIGGER` errors (error code `293`).

For more information (including a workaround for previous MySQL Cluster NDB 7.0 releases), see [Section 17.2.5.2, “MySQL Cluster 5.1 and MySQL Cluster NDB 6.x/7.x Upgrade and Downgrade Compatibility”](#). ([Bug#48416](#))

- When a data node failed to start due to inability to recreate or drop objects during schema restoration (for example: insufficient memory was available to the data node process on account of issues not directly related to MySQL Cluster on the host machine), the reason for the failure was not provided. Now in such cases, a more informative error message is logged. ([Bug#48232](#))
- A table that was created following an upgrade from a MySQL Cluster NDB 6.3 release to MySQL Cluster NDB 7.0 (starting with version 6.4.0) or later was dropped by a system restart. This was due to a change in the format of `NDB` schema files and the fact that the upgrade of the format of existing `NDB` 6.3 schema files to the `NDB` 7.0 format failed to change the version number contained in the file; this meant that a system restart re-ran the upgrade routine, which interpreted the newly-created table as an uncommitted table (which by definition ought not to be saved). Now the version number of upgraded `NDB` 6.3 schema files is set correctly during the upgrade process. ([Bug#48227](#))
- In certain cases, performing very large inserts on `NDB` tables when using `ndbmtd` caused the memory allocations for ordered or unique indexes (or both) to be exceeded. This could cause aborted transactions and possibly lead to data node failures. ([Bug#48037](#))

See also [Bug#48113](#).

- For `UPDATE IGNORE` statements, batching of updates is now disabled. This is because such statements failed when batching of updates was employed if any updates violated a unique constraint, to the fact a unique constraint violation could not be handled without aborting the transaction. ([Bug#48036](#))
- Starting a data node with a very large amount of `DataMemory` (approximately 90G or more) could lead to crash of the node due to job buffer congestion. ([Bug#47984](#))
- In some cases, `ndbmtd` could allocate more space for the undo buffer than was actually available, leading to a failure in the `LGMAN` kernel block and subsequent failure of the data node. ([Bug#47966](#))
- When an `UPDATE` statement was issued against an `NDB` table where an index was used to identify rows but no data was actually changed, the `NDB` storage returned zero found rows.

For example, consider the table created and populated using these statements:

```
CREATE TABLE t1
(
 c1 INT NOT NULL,
 c2 INT NOT NULL,
 PRIMARY KEY(c1),
 KEY(c2)
)
ENGINE = NDB;

INSERT INTO t1 VALUES(1, 1);
```

The following `UPDATE` statements, even though they did not change any rows, each still matched a row, but this was reported incorrectly in both cases, as shown here:

```
mysql> UPDATE t1 SET c2 = 1 WHERE c1 = 1;
Query OK, 0 rows affected (0.00 sec)
Rows matched: 0 Changed: 0 Warnings: 0
```

```
mysql> UPDATE t1 SET c1 = 1 WHERE c2 = 1;
Query OK, 0 rows affected (0.00 sec)
Rows matched: 0 Changed: 0 Warnings: 0
```

Now in such cases, the number of rows matched is correct. (In the case of each of the example `UPDATE` statements just shown, this is displayed as Rows matched: 1, as it should be.)

This issue could affect `UPDATE` statements involving any indexed columns in `NDB` tables, regardless of the type of index (including `KEY`, `UNIQUE KEY`, and `PRIMARY KEY`) or the number of columns covered by the index. ([Bug#47955](#))

- On Solaris, shutting down a management node failed when issuing the command to do so from a client connected to a different management node. ([Bug#47948](#))
- After changing the value of `DiskSyncSize` to 4294967039 (the maximum) in the `config.ini` file and reloading the cluster configuration, the new value was displayed in the update information written into the cluster log as a signed number instead of unsigned. ([Bug#47944](#))

See also [Bug#47932](#).

- On Solaris 10 for SPARC, `ndb_mgmd` failed to parse the `config.ini` file when the `DiskSyncSize` configuration parameter, whose permitted range of values is 32768 to 4294967039, was set equal to 4294967040 (which is also the value of the internal constant `MAX_INT_RNIL`), nor could `DiskSyncSize` be set successfully any higher than the minimum value. ([Bug#47932](#))

See also [Bug#47944](#).

- Setting `FragmentLogFile` to a value greater than 256 MB led to errors when trying to read the redo log file. ([Bug#47908](#))
- `SHOW CREATE TABLE` did not display the `AUTO_INCREMENT` value for `NDB` tables having `AUTO_INCREMENT` columns. ([Bug#47865](#))
- An optimization in MySQL Cluster NDB 7.0 causes the `DBDICTIONARY` kernel block to copy several tables at a time when synchronizing the data dictionary to a newly-started node; previously, this was done one table at a time. However, when `NDB` tables were sufficiently large and numerous, the internal buffer for storing them could fill up, causing a data node crash.

In testing, it was found that having 100 `NDB` tables with 128 columns each was enough to trigger this issue. ([Bug#47859](#))

- Under some circumstances, when a scan encountered an error early in processing by the `DBTC` kernel block (see [The DBTC Block](#)), a node could crash as a result. Such errors could be caused by applications sending incorrect data, or, more rarely, by a `DROP TABLE` operation executed in parallel with a scan. ([Bug#47831](#))
- When starting a node and synchronizing tables, memory pages were allocated even for empty fragments. In certain situations, this could lead to insufficient memory. ([Bug#47782](#))
- During an upgrade, newer nodes (NDB kernel block `DBTUP`) could in some cases try to use the long signal format for communication with older nodes (`DBUTIL` kernel block) that did not understand the newer format, causing older data nodes to fail after restarting. ([Bug#47740](#))
- A very small race-condition between `NODE_FAILREP` and `LQH_TRANSREQ` signals when handling node failure could lead to operations (locks) not being taken over when they should have been, and subsequently becoming stale. This could lead to node restart failures, and applications getting into endless lock-conflicts with operations that were not released until the node was restarted. ([Bug#47715](#))

See also [Bug#41297](#).

- In some cases, the MySQL Server tried to use an error status whose value had never been set. The problem in the code that caused this, in `hostname.cc`, manifested when using debug builds of `mysqld` in MySQL Cluster replication.

This fix brings MySQL Cluster's error handling in `hostname.cc` in line with what is implemented in MySQL 5.4. ([Bug#47548](#))

- `configure` failed to honor the `--with-zlib-dir` option when trying to build MySQL Cluster from source. ([Bug#47223](#))
- Performing a system restart of the cluster after having performed a table reorganization which added partitions caused the cluster to become inconsistent, possibly leading to a forced shutdown, in either of the following cases:
  1. When a local checkpoint was in progress but had not yet completed, new partitions were not restored; that is, data that was supposed to be moved could be lost instead, leading to an inconsistent cluster. This was due to an issue whereby the `DB-DIH` kernel block did not save the new table definition and instead used the old one (the version having fewer partitions).

2. When the most recent LCP had completed, ordered indexes and unlogged tables were still not saved (since these did not participate in the LCP). In this case, the cluster crashed during a subsequent system restart, due to the inconsistency between the main table and the ordered index.

Now, `DBDIH` is forced in such cases to use the version of the table definition held by the `DBDICT` kernel block, which was (already) correct and up to date. ([Bug#46585](#))

- `ndbd` was not built correctly when compiled using `gcc` 4.4.0. (The `ndbd` binary was built, but could not be started.) ([Bug#46113](#))
- `ndb_mgmd` failed to close client connections that had timed out. After running for some time, a race condition could develop in the management server, due to `ndb_mgmd` having exhausted all of its file descriptors in this fashion. ([Bug#45497](#))

See also [Bug#47712](#).

- If a node failed while sending a fragmented long signal, the receiving node did not free long signal assembly resources that it had allocated for the fragments of the long signal that had already been received. ([Bug#44607](#))
- Numeric configuration parameters set in `my.cnf` were interpreted as signed rather than unsigned values. The effect of this was that values of 2G or more were truncated with the warning `[MGRSRV] WARNING: OPTION 'OPT_NAME': SIGNED VALUE OPT_VALUE ADJUSTED TO 2147483647`. Now such parameter values are treated as unsigned, so that this truncation does not take place.

This issue did not effect parameters set in `config.ini`. ([Bug#44448](#))

- When starting a cluster with a great many tables, it was possible for MySQL client connections as well as the slave SQL thread to issue DML statements against MySQL Cluster tables before `mysqld` had finished connecting to the cluster and making all tables writeable. This resulted in `TABLE ... IS READ ONLY` errors for clients and the Slave SQL thread.

This issue is fixed by introducing the `--ndb-wait-setup` option for the MySQL server. This provides a configurable maximum amount of time that `mysqld` waits for all `NDB` tables to become writeable, before enabling MySQL clients or the slave SQL thread to connect. ([Bug#40679](#))

See also [Bug#46955](#).

- When building MySQL Cluster, it was possible to configure the build using `--with-ndb-port` without supplying a port number. Now in such cases, `configure` fails with an error. ([Bug#38502](#))

See also [Bug#47941](#).

- When the MySQL server SQL mode included `STRICT_TRANS_TABLES`, storage engine warnings and error codes specific to `NDB` were returned when errors occurred, instead of the MySQL server errors and error codes expected by some programming APIs (such as Connector/J) and applications. ([Bug#35990](#))
- When a copying operation exhausted the available space on a data node while copying large `BLOB` columns, this could lead to failure of the data node and a `TABLE IS FULL` error on the SQL node which was executing the operation. Examples of such operations could include an `ALTER TABLE` that changed an `INT` column to a `BLOB` column, or a bulk insert of `BLOB` data that failed due to running out of space or to a duplicate key error. ([Bug#34583](#), [Bug#48040](#))

See also [Bug#41674](#), [Bug#45768](#).

- **Replication:** When `mysqlbinlog --verbose` was used to read a binary log that had been recorded using the row-based format, the output for events that updated some but not all columns of tables was not correct. ([Bug#47323](#))
- **Disk Data:** A local checkpoint of an empty fragment could cause a crash during a system restart which was based on that LCP. ([Bug#47832](#))

See also [Bug#41915](#).

- **Disk Data:** Multi-threaded data nodes could in some cases attempt to access the same memory structure in parallel, in a non-safe manner. This could result in data node failure when running `ndbmtd` while using Disk Data tables. ([Bug#44195](#))

See also [Bug#46507](#).

- **Cluster Replication:** When using multiple active replication channels, it was sometimes possible that a node group would fail on the slave cluster, causing the slave cluster to shut down. ([Bug#47935](#))
- **Cluster Replication:** When recording a binary log using the `--ndb-log-update-as-write` and `-ndb-log-updated-only` options (both enabled by default) and later attempting to apply that binary log with `mysqlbinlog`, any operations that were played back from the log but which updated only some (but not all) columns caused any

columns that were not updated to be reset to their default values. ([Bug#47674](#))

See also [Bug#47323](#), [Bug#46662](#).

- **Cluster Replication:** `mysqlbinlog` failed to apply correctly a binary log that had been recorded using `--ndb-log-update-as-write=1`. ([Bug#46662](#))  
See also [Bug#47323](#), [Bug#47674](#).
- **Cluster API:** If an NDB API program reads the same column more than once, it is possible exceed the maximum permissible message size, in which case the operation should be aborted due to NDB error 880 TRIED TO READ TOO MUCH – TOO MANY GETVALUE CALLS, however due to a change introduced in MySQL Cluster NDB 6.3.18, the check for this was not done correctly, which instead caused a data node crash. ([Bug#48266](#))
- **Cluster API:** The NDB API methods `Dictionary::listEvents()`, `Dictionary::listIndexes()`, `Dictionary::listObjects()`, and `NdbOperation::getErrorLine()` formerly had both `const` and non-`const` variants. The non-`const` versions of these methods have been removed. In addition, the `NdbOperation::getBlobHandle()` method has been re-implemented to provide consistent internal semantics. ([Bug#47798](#))
- **Cluster API:** A duplicate read of a column caused NDB API applications to crash. ([Bug#45282](#))
- **Cluster API:** The error handling shown in the example file `ndbapi_scan.cpp` included with the MySQL Cluster distribution was incorrect. ([Bug#39573](#))
- Installation of MySQL on Windows would fail to set the correct location for the character set files, which could lead to `mysqld` and `mysql` failing to initialize properly. ([Bug#17270](#))

## 17.7.2.20. Changes in MySQL Cluster NDB 7.0.8a (5.1.37-ndb-7.0.8a) (07 October 2009)

This release includes a fix for [Bug#47844](#), which was discovered in MySQL Cluster NDB 7.0.8 shortly after release. The MySQL Cluster NDB 7.0.8a release is identical in all other respects to MySQL Cluster NDB 7.0.8. Users who have already installed MySQL Cluster NDB 7.0.8 should upgrade to MySQL Cluster NDB 7.0.8a as soon as possible; users seeking to upgrade from MySQL Cluster NDB 7.0.7 or another previous MySQL Cluster 7.0 release should upgrade to MySQL Cluster NDB 7.0.8a instead.

**Obtaining MySQL Cluster NDB 7.0.8a.** The latest MySQL Cluster NDB 7.0 binaries for supported platforms can be obtained from <http://dev.mysql.com/downloads/cluster/>. Source code for the latest MySQL Cluster NDB 7.0 release can be obtained from the same location. You can also access the MySQL Cluster NDB 7.0 development source tree at <https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.0>.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, 6.3, and 7.0 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.37 (see [Section C.1.18](#), “Changes in MySQL 5.1.37 (13 July 2009)”).

### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- The disconnection of an API or SQL node having a node ID greater than 49 caused a forced shutdown of the cluster. ([Bug#47844](#))
- The error message text for NDB error code 410 (REDO LOG FILES OVERLOADED...) was truncated. ([Bug#23662](#))

## 17.7.2.21. Changes in MySQL Cluster NDB 7.0.8 (5.1.37-ndb-7.0.8) (30 September 2009)

### Important

MySQL Cluster NDB 7.0.8 was pulled shortly after release due to [Bug#47844](#). Users seeking to upgrade from a previous MySQL Cluster NDB 7.0 release should instead use MySQL Cluster NDB 7.0.8a, which contains a fix for this bug, in addition to all bugfixes and improvements made in MySQL Cluster NDB 7.0.8.

This release incorporates new features in the `NDBCLUSTER` storage engine and fixes recently discovered bugs in MySQL Cluster NDB 7.0.7.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, 6.3, and 7.0 releases, as

well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.37 (see [Section C.1.18, “Changes in MySQL 5.1.37 \(13 July 2009\)”](#)).

### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- A new option `--log-name` is added for `ndb_mgmd`. This option can be used to provide a name for the current node and then to identify it in messages written to the cluster log. For more information, see [Section 17.4.4, “`ndb\_mgmd` — The MySQL Cluster Management Server Daemon”](#). ([Bug#47643](#))
- `--config-dir` is now accepted by `ndb_mgmd` as an alias for the `--configdir` option. ([Bug#42013](#))
- **Disk Data:** Two new columns have been added to the output of `ndb_desc` to make it possible to determine how much of the disk space allocated to a given table or fragment remains free. (This information is not available from the `INFORMATION_SCHEMA.FILES` table, since the `FILES` table applies only to Disk Data files.) For more information, see [Section 17.4.9, “`ndb\_desc` — Describe NDB Tables”](#). ([Bug#47131](#))

Bugs fixed:

- **Important Change:** Previously, the MySQL Cluster management node and data node programs, when run on Windows platforms, required the `--nodaemon` option to produce console output. Now, these programs run in the foreground when invoked from the command line on Windows, which is the same behavior that `mysqld.exe` displays on Windows. ([Bug#45588](#))
- **Cluster Replication: Important Change:** In a MySQL Cluster acting as a replication slave and having multiple SQL nodes, only the SQL node receiving events directly from the master recorded DDL statements in its binary logs unless this SQL node also had binary logging enabled; otherwise, other SQL nodes in the slave cluster failed to log DDL statements, regardless of their individual `--log-bin` settings.

The fix for this issue aligns binary logging of DDL statements with that of DML statements. In particular, you should take note of the following:

- DDL and DML statements on the master cluster are logged with the server ID of the server that actually writes the log.
- DDL and DML statements on the master cluster are logged by any attached `mysqld` that has binary logging enabled.
- Replicated DDL and DML statements on the slave are logged by any attached `mysqld` that has both `--log-bin` and `--log-slave-updates` enabled.
- Replicated DDL and DML statements are logged with the server ID of the original (master) MySQL server by any attached `mysqld` that has both `--log-bin` and `--log-slave-updates` enabled.

**Affect on upgrades.** When upgrading from a previous MySQL CLuster release, you should perform either one of the following:

- a. Upgrade servers that are performing binary logging before those that are not; do not perform any DDL on “old” SQL nodes until all SQL nodes have been upgraded.
- b. Make sure that `--log-slave-updates` is enabled on all SQL nodes performing binary logging prior to the upgrade, so that all DDL is captured.

### Note

Logging of DML statements was not affected by this issue.

([Bug#45756](#))

- The following issues with error logs generated by `ndbmtd` were addressed:
  1. The version string was sometimes truncated, or even not shown, depending on the number of threads in use (the more threads, the worse the problem). Now the version string is shown in full, as well as the filenames for all tracefiles (where available).
  2. In the event of a crash, the thread number of the thread that crashed was not printed. Now this information is supplied, if available.

([Bug#47629](#))

- `mysqld` allocated an excessively large buffer for handling `BLOB` values due to overestimating their size. (For each row, enough space was allocated to accommodate *every* `BLOB` or `TEXT` column value in the result set.) This could adversely affect performance when using tables containing `BLOB` or `TEXT` columns; in a few extreme cases, this issue could also cause the host system to run out of memory unexpectedly. ([Bug#47574](#))

See also [Bug#47572](#), [Bug#47573](#).

- `NDBCLUSTER` uses a dynamically-allocated buffer to store `BLOB` or `TEXT` column data that is read from rows in MySQL Cluster tables.

When an instance of the `NDBCLUSTER` table handler was recycled (this can happen due to table definition cache pressure or to operations such as `FLUSH TABLES` or `ALTER TABLE`), if the last row read contained blobs of zero length, the buffer was not freed, even though the reference to it was lost. This resulted in a memory leak.

For example, consider the table defined and populated as shown here:

```
CREATE TABLE t (a INT PRIMARY KEY, b LONGTEXT) ENGINE=NDB;
INSERT INTO t VALUES (1, REPEAT('F', 20000));
INSERT INTO t VALUES (2, ''');
```

Now execute repeatedly a `SELECT` on this table, such that the zero-length `LONGTEXT` row is last, followed by a `FLUSH TABLES` statement (which forces the handler object to be re-used), as shown here:

```
SELECT a, length(b) FROM bl ORDER BY a;
FLUSH TABLES;
```

Prior to the fix, this resulted in a memory leak proportional to the size of the stored `LONGTEXT` value each time these two statements were executed. ([Bug#47573](#))

See also [Bug#47572](#), [Bug#47574](#).

- Large transactions involving joins between tables containing `BLOB` columns used excessive memory. ([Bug#47572](#))

See also [Bug#47573](#), [Bug#47574](#).

- After an `NDB` table had an `ALTER ONLINE TABLE` operation performed on it in a MySQL Cluster running a MySQL Cluster NDB 6.3.x release, it could not be upgraded online to a MySQL Cluster NDB 7.0.x release. This issue was detected using MySQL Cluster NDB 6.3.20, but is likely to effect any MySQL Cluster NDB 6.3.x release supporting online DDL operations. ([Bug#47542](#))
- When using multi-threaded data nodes (`ndbmtd`) with `NoOfReplicas` set to a value greater than 2, attempting to restart any of the data nodes caused a forced shutdown of the entire cluster. ([Bug#47530](#))
- A variable was left uninitialized while a data node copied data from its peers as part of its startup routine; if the starting node died during this phase, this could lead a crash of the cluster when the node was later restarted. ([Bug#47505](#))
- Handling of `LQH_TRANS_REQ` signals was done incorrectly in `DBLQH` when the transaction coordinator failed during a `LQH_TRANS_REQ` session. This led to incorrect handling of multiple node failures, particularly when using `ndbmtd`. ([Bug#47476](#))
- The NDB kernel's parser (in `ndb/src/common/util/Parser.cpp`) did not interpret the backslash ("\\") character correctly. ([Bug#47426](#))
- During an online alter table operation, the new table definition was made available for users during the prepare-phase when it should only be exposed during and after a commit. This issue could affect NDB API applications, `mysqld` processes, or data node processes. ([Bug#47375](#))
- Aborting an online add column operation (for example, due to resource problems on a single data node, but not others) could lead to a forced node shutdown. ([Bug#47364](#))
- Clients attempting to connect to the cluster during shutdown could sometimes cause the management server to crash. ([Bug#47325](#))
- The size of the table descriptor pool used in the `DBTUP` kernel block was incorrect. This could lead to a data node crash when an LQH sent a `CREATE_TAB_REF` signal. ([Bug#47215](#))

See also [Bug#44908](#).

- When a data node restarts, it first runs the redo log until reaching the latest restorable global checkpoint; after this it scans the remainder of the redo log file, searching for entries that should be invalidated so they are not used in any subsequent restarts. (It is possible, for example, if restoring GCI number 25, that there might be entries belonging to GCI 26 in the redo log.) However, under certain rare conditions, during the invalidation process, the redo log files themselves were not always closed while scanning ahead in the redo log. In rare cases, this could lead to `MaxNoOfOpenFiles` being exceeded, causing the data node to crash. ([Bug#47171](#))
- For very large values of `MaxNoOfTables + MaxNoOfAttributes`, the calculation for `StringMemory` could overflow when creating large numbers of tables, leading to NDB error 773 (OUT OF STRING MEMORY, PLEASE MODIFY STRINGMEMORY CONFIG PARAMETER), even when `StringMemory` was set to 100 (100 percent). ([Bug#47170](#))
- The default value for the `StringMemory` configuration parameter, unlike other MySQL Cluster configuration parameters, was not set in `ndb/src/mgmsrv/ConfigInfo.cpp`. ([Bug#47166](#))
- Signals from a failed API node could be received after an `API_FAILREQ` signal (see [Operations and Signals](#)) has been received from that node, which could result in invalid states for processing subsequent signals. Now, all pending signals from a failing API node are processed before any `API_FAILREQ` signal is received. ([Bug#47039](#))

See also [Bug#44607](#).

- When reloading the management server configuration, only the last changed parameter was logged. ([Bug#47036](#))
- When using `ndbmtd`, a parallel `DROP TABLE` operation could cause data nodes to have different views of which tables should be included in local checkpoints; this discrepancy could lead to a node failure during an LCP. ([Bug#46873](#))
- Using triggers on `NDB` tables caused `ndb_autoincrement_prefetch_sz` to be treated as having the NDB kernel's internal default value (32) and the value for this variable as set on the cluster's SQL nodes to be ignored. ([Bug#46712](#))
- Now, when started with `--initial --reload`, `ndb_mgmd` tries to copy the configuration of an existing `ndb_mgmd` process with a confirmed configuration. This works only if the configuration files used by both management nodes are exactly the same. ([Bug#45495](#), [Bug#46488](#))

See also [Bug#42015](#).

- On Windows, `ndbd --initial` could hang in an endless loop while attempting to remove directories. ([Bug#45402](#))
- For multi-threaded data nodes, insufficient fragment records were allocated in the `DBDIH` NDB kernel block, which could lead to error 306 when creating many tables; the number of fragment records allocated did not take into account the number of LQH instances. ([Bug#44908](#))
- Running an `ALTER TABLE` statement while an NDB backup was in progress caused `mysqld` to crash. ([Bug#44695](#))
- When performing auto-discovery of tables on individual SQL nodes, `NDBCLUSTER` attempted to overwrite existing `MyISAM.frm` files and corrupted them.

**Workaround.** In the `mysql` client, create a new table (`t2`) with same definition as the corrupted table (`t1`). Use your system shell or file manager to rename the old `.MYD` file to the new file name (for example, `mv t1.MYD t2.MYD`). In the `mysql` client, repair the new table, drop the old one, and rename the new table using the old file name (for example, `RENAME TABLE t2 TO t1`).

([Bug#42614](#))

- When started with the `--initial` and `--reload` options, if `ndb_mgmd` could not find a configuration file or connect to another management server, it appeared to hang. Now, when trying to fetch its configuration from another management node, `ndb_mgmd` checks and signals (`Trying to get configuration from other mgmd(s)`) each 30 seconds that it has not yet done so. ([Bug#42015](#))

See also [Bug#45495](#).

- Running `ndb_restore` with the `--print` or `--print_log` option could cause it to crash. ([Bug#40428](#), [Bug#33040](#))
- An insert on an `NDB` table was not always flushed properly before performing a scan. One way in which this issue could manifest was that `LAST_INSERT_ID()` sometimes failed to return correct values when using a trigger on an `NDB` table. ([Bug#38034](#))
- When a data node received a `TAKE_OVERTCCONF` signal from the master before that node had received a `NODE_FAILREP`, a race condition could in theory result. ([Bug#37688](#))

See also [Bug#25364](#), [Bug#28717](#).

- Some joins on large `NDB` tables having `TEXT` or `BLOB` columns could cause `mysqld` processes to leak memory. The joins did

not need to reference the `TEXT` or `BLOB` columns directly for this issue to occur. ([Bug#36701](#))

- On Mac OS X 10.5, commands entered in the management client failed and sometimes caused the client to hang, although management client commands invoked using the `--execute` (or `-e`) option from the system shell worked normally.

For example, the following command failed with an error and hung until killed manually, as shown here:

```
ndb_mgm> SHOW
WARNING, EVENT THREAD STARTUP FAILED, DEGRADED PRINTOUTS AS RESULT, ERRNO=36
^C
```

However, the same management client command, invoked from the system shell as shown here, worked correctly:

```
shell> ndb_mgm -e "SHOW"
```

([Bug#35751](#))

See also [Bug#34438](#).

- **Replication:** In some cases, a `STOP SLAVE` statement could cause the replication slave to crash. This issue was specific to MySQL on Windows or Macintosh platforms. ([Bug#45238](#), [Bug#45242](#), [Bug#45243](#), [Bug#46013](#), [Bug#46014](#), [Bug#46030](#))

See also [Bug#40796](#).

- **Disk Data:** Calculation of free space for Disk Data table fragments was sometimes done incorrectly. This could lead to unnecessary allocation of new extents even when sufficient space was available in existing ones for inserted data. In some cases, this might also lead to crashes when restarting data nodes.

### Note

This miscalculation was not reflected in the contents of the `INFORMATION_SCHEMA.FILES` table, as it applied to extents allocated to a fragment, and not to a file.

([Bug#47072](#))

- **Cluster API:** In some circumstances, if an API node encountered a data node failure between the creation of a transaction and the start of a scan using that transaction, then any subsequent calls to `startTransaction()` and `closeTransaction()` could cause the same transaction to be started and closed repeatedly. ([Bug#47329](#))
- **Cluster API:** Performing multiple operations using the same primary key within the same `NdbTransaction::execute()` call could lead to a data node crash.

### Note

This fix does not make change the fact that performing multiple operations using the same primary key within the same `execute()` is not supported; because there is no way to determine the order of such operations, the result of such combined operations remains undefined.

([Bug#44065](#))

See also [Bug#44015](#).

- **API:** The fix for [Bug#24507](#) could lead in some cases to client application failures due to a race condition. Now the server waits for the “dummy” thread to return before exiting, thus making sure that only one thread can initialize the POSIX threads library. ([Bug#42850](#))

## 17.7.2.22. Changes in MySQL Cluster NDB 7.0.7 (5.1.35-ndb-7.0.7) (26 August 2009)

This release incorporates new features in the `NDBCLUSTER` storage engine and fixes recently discovered bugs in MySQL Cluster NDB 7.0.6.

**Obtaining MySQL Cluster NDB 7.0.7.** The latest MySQL Cluster NDB 7.0 binaries for supported platforms can be obtained from <http://dev.mysql.com/downloads/cluster/>. Source code for the latest MySQL Cluster NDB 7.0 release can be obtained from the same location. You can also access the MySQL Cluster NDB 7.0 development source tree at <https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.0>.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, 6.3, and 7.0 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.35 (see [Section C.1.20](#), “Changes in MySQL 5.1.35 (13 May 2009)”).

**Note**

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **Important Change:** The default value of the `DiskIOThreadPool` data node configuration parameter has changed from 8 to 2.
- On Solaris platforms, the MySQL Cluster management server and NDB API applications now use `CLOCK_REALTIME` as the default clock. ([Bug#46183](#))
- Formerly, node IDs were represented in the cluster log using a complex hexadecimal/binary encoding scheme. Now, node IDs are reported in the cluster log using numbers in standard decimal notation. ([Bug#44248](#))
- A new option `--exclude-missing-columns` has been added for the `ndb_restore` program. In the event that any tables in the database or databases being restored to have fewer columns than the same-named tables in the backup, the extra columns in the backup's version of the tables are ignored. For more information, see [Section 17.4.17, “ndb\\_restore — Restore a MySQL Cluster Backup”](#). ([Bug#43139](#))

**Note**

This issue, originally resolved in MySQL 5.1.16, re-occurred due to a later (unrelated) change. The fix has been re-applied.

([Bug#25984](#))

- Previously, it was possible to disable arbitration only by setting `ArbitrationRank` to 0 on all management and API nodes. A new data node configuration parameter `Arbitration` simplifies this task; to disable arbitration, you can now use `Arbitration = Disabled` in the `[ndbd default]` section of the `config.ini` file.

It is now also possible to configure arbitration in such a way that the cluster waits until the time determined by `ArbitrationTimeout` passes for an external manager to perform arbitration instead of handling it internally. This can be done by setting `Arbitration = WaitExternal` in the `[ndbd default]` section of the `config.ini` file.

The default value for the Arbitration parameter is `Default`, which permits arbitration to proceed normally, as determined by the `ArbitrationRank` settings for the management and API nodes.

For more information, see [Section 17.3.2.6, “Defining MySQL Cluster Data Nodes”](#).

Bugs fixed:

- **Important Change:** The IPv6 loopback address `::1` was interpreted as a hostname rather than a numeric IP address.

In addition, the IPv6-enabled server on Windows interpreted the hostname `localhost` as `::1` only, which failed to match the default '`root'@'127.0.0.1'` account in the `mysql.user` privilege table.

**Note**

As a result of this fix, a '`root'@'::1'` account is added to the `mysql.user` table as one of the default accounts created during MySQL installation.

([Bug#43006](#))

See also [Bug#38247](#), [Bug#45283](#), [Bug#45584](#), [Bug#45606](#).

- **Packaging:** The `pkg` installer for MySQL Cluster on Solaris did not perform a complete installation due to an invalid directory reference in the post-install script. ([Bug#41998](#))
- The output from `ndb_config --configinfo --xml` contained quote characters (") within quoted XML attributes, causing it to be not well-formed. ([Bug#46891](#))
- When using multi-threaded data node processes (`ndbmtd`), it was possible for LQH threads to continue running even after all `NDB` tables had been dropped. This meant that dropping the last remaining `NDB` table during a local checkpoint could cause multi-threaded data nodes to fail. ([Bug#46890](#))

- During a global checkpoint, LQH threads could run unevenly, causing a circular buffer overflow by the Subscription Manager, which led to data node failure. ([Bug#46782](#))  
See also [Bug#46123](#), [Bug#46723](#), [Bug#45612](#).
- Restarting the cluster following a local checkpoint and an online `ALTER TABLE` on a non-empty table caused data nodes to crash. ([Bug#46651](#))
- A combination of index creation and drop operations (or creating and dropping tables having indexes) with node and system restarts could lead to a crash. ([Bug#46552](#))
- Following an upgrade from MySQL Cluster NDB 6.3.x to MySQL Cluster NDB 7.0.6, DDL and backup operations failed. ([Bug#46494](#), [Bug#46563](#))
- Full table scans failed to execute when the cluster contained more than 21 table fragments.

### Note

The number of table fragments in the cluster can be calculated as the number of data nodes, times 8 (that is, times the value of the internal constant `MAX_FRAG_PER_NODE`), divided by the number of replicas. Thus, when `NoOfReplicas = 1` at least 3 data nodes were required to trigger this issue, and when `NoOfReplicas = 2` at least 4 data nodes were required to do so.

([Bug#46490](#))

- Killing MySQL Cluster nodes immediately following a local checkpoint could lead to a crash of the cluster when later attempting to perform a system restart.

The exact sequence of events causing this issue was as follows:

1. Local checkpoint occurs.
2. Immediately following the LCP, kill the master data node.
3. Kill the remaining data nodes within a few seconds of killing the master.
4. Attempt to restart the cluster.

([Bug#46412](#))

- Creating an index when the cluster had run out of table records could cause data nodes to crash. ([Bug#46295](#))
- Ending a line in the `config.ini` file with an extra semicolon character (`;`) caused reading the file to fail with a parsing error. ([Bug#46242](#))
- When combining an index scan and a delete with a primary key delete, the index scan and delete failed to initialize a flag properly. This could in rare circumstances cause a data node to crash. ([Bug#46069](#))
- `OPTIMIZE TABLE` on an `NDB` table could in some cases cause SQL and data nodes to crash. This issue was observed with both `ndbd` and `ndbmttd`. ([Bug#45971](#))
- The `AutoReconnect` configuration parameter for API nodes (including SQL nodes) has been added. This is intended to prevent API nodes from re-using allocated node IDs during cluster restarts. For more information, see [Section 17.3.2.7, “Defining SQL and Other API Nodes in a MySQL Cluster”](#).

This fix also introduces two new methods of the `Ndb_cluster_connection` class in the NDB API. For more information, see `Ndb_cluster_connection::set_auto_reconnect()`, and `Ndb_cluster_connection::get_auto_reconnect()`. ([Bug#45921](#))

- DML statements run during an upgrade from MySQL Cluster NDB 6.3 to NDB 7.0 were not handled correctly. ([Bug#45917](#))
- On Windows, the internal `basestring_vsprintf()` function did not return a POSIX-compliant value as expected, causing the management server to crash when trying to start a MySQL Cluster with more than 4 data nodes. ([Bug#45733](#))
- The signals used by `ndb_restore` to send progress information about backups to the cluster log accessed the cluster transporter without using any locks. Because of this, it was theoretically possible that these signals could be interfered with by heartbeat signals if both were sent at the same time, causing the `ndb_restore` messages to be corrupted. ([Bug#45646](#))
- Due to changes in the way that `NDBCLUSTER` handles schema changes (implementation of schema transactions) in MySQL Cluster NDB 7.0, it was not possible to create MySQL Cluster tables having more than 16 indexes using a single `CREATE TABLE` statement.

This issue occurs only in MySQL Cluster NDB 7.0 releases prior to 7.0.7 (including releases numbered NDB 6.4.x).

If you are not yet able to upgrade from an earlier MySQL Cluster NDB 7.0 release, you can work around this problem by creating the table without any indexes, then adding the indexes using a separate `CREATE INDEX` statement for each index. ([Bug#45525](#))

- `storage/ndb/src/common/util/CMakeLists.txt` did not build the `BaseString-t` test program for Windows as the equivalent `storage/ndb/src/common/util/Makefile.am` does when building MySQL Cluster on Unix platforms. ([Bug#45099](#))
- Problems could arise when using `VARCHAR` columns whose size was greater than 341 characters and which used the `utf8_unicode_ci` collation. In some cases, this combination of conditions could cause certain queries and `OPTIMIZE TABLE` statements to crash `mysqld`. ([Bug#45053](#))
- The warning message `POSSIBLE BUG IN DBDIH::EXECBLOCK_COMMIT_ORD ...` could sometimes appear in the cluster log. This warning is obsolete, and has been removed. ([Bug#44563](#))
- Debugging code causing `ndbd` to use file compression on NTFS filesystems failed with an error. (The code was removed.) This issue affected debug builds of MySQL Cluster on Windows platforms only. ([Bug#44418](#))
- `ALTER TABLE REORGANIZE PARTITION` could fail with Error 741 (`UNSUPPORTED ALTER TABLE`) if the appropriate hash-map was not present. This could occur when adding nodes online; for example, when going from 2 data nodes to 3 data nodes with `NoOfReplicas=1`, or from 4 data nodes to 6 data nodes with `NoOfReplicas=2`. ([Bug#44301](#))
- Previously, a `GCP STOP` event was written to the cluster log as an `INFO` event. Now it is logged as a `WARNING` event instead. ([Bug#43853](#))
- In some cases, `OPTIMIZE TABLE` on an `NDB` table did not free any `DataMemory`. ([Bug#43683](#))
- If the cluster crashed during the execution of a `CREATE LOGFILE GROUP` statement, the cluster could not be restarted afterward. ([Bug#36702](#))

See also [Bug#34102](#).

- **Disk Data: Partitioning:** An `NDBCLUSTER` table created with a very large value for the `MAX_ROWS` option could—if this table was dropped and a new table with fewer partitions, but having the same table ID, was created—cause `ndbd` to crash when performing a system restart. This was because the server attempted to examine each partition whether or not it actually existed. ([Bug#45154](#))
- **Disk Data:** If the value set in the `config.ini` file for `FileSystemPathDD`, `FileSystemPathDataFiles`, or `FileSystemPathUndoFiles` was identical to the value set for `FileSystemPath`, that parameter was ignored when starting the data node with `--initial` option. As a result, the Disk Data files in the corresponding directory were not removed when performing an initial start of the affected data node or data nodes. ([Bug#46243](#))
- For an IPv6-enabled MySQL server, privileges specified using standard IPv4 addresses for hosts were not matched (only IPv4-mapped addresses were handled correctly).

As part of the fix for this bug, a new build option `--disable-ipv6` has been introduced. Compiling MySQL with this option causes all IPv6-specific code in the server to be ignored.

### Important

If the server has been compiled using `--disable-ipv6`, it is not able to resolve hostnames correctly when run in an IPv6 environment. ([Bug#45606](#))

See also [Bug#38247](#), [Bug#43006](#), [Bug#45283](#), [Bug#45584](#).

- The hostname cache failed to work correctly. ([Bug#45584](#))

See also [Bug#38247](#), [Bug#43006](#), [Bug#45283](#), [Bug#45606](#).

- The number of connection errors from a given host as counted by the server was periodically reset, with the result that `max_connect_errors` was never reached and invalid hosts were never blocked from trying to connect. ([Bug#45283](#))

See also [Bug#38247](#), [Bug#43006](#), [Bug#45584](#), [Bug#45606](#).

- An IPv6-enabled MySQL server did not resolve the IP addresses of incoming connections correctly, with the result that a connection that attempted to match any privilege table entries using fully-qualified domain names for hostnames or hostnames using wildcards were dropped. ([Bug#38247](#))

See also [Bug#43006](#), [Bug#45283](#), [Bug#45584](#), [Bug#45606](#).

### 17.7.2.23. Changes in MySQL Cluster NDB 7.0.6 (5.1.34-ndb-7.0.6) (26 May 2009)

This release incorporates new features in the `NDBCLUSTER` storage engine and fixes recently discovered bugs in MySQL Cluster NDB 7.0.5.

**Obtaining MySQL Cluster NDB 7.0.5.** The latest MySQL Cluster NDB 7.0 binaries for supported platforms can be obtained from <http://dev.mysql.com/downloads/cluster/>. Source code for the latest MySQL Cluster NDB 7.0 release can be obtained from the same location. You can also access the MySQL Cluster NDB 7.0 development source tree at <https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.0>.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, 6.3, and 7.0 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.34 (see [Section C.1.22, “Changes in MySQL 5.1.34 \(02 April 2009\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- The `ndb_config` utility program can now provide an offline dump of all MySQL Cluster configuration parameters including information such as default and permitted values, brief description, and applicable section of the `config.ini` file. A dump in text format is produced when running `ndb_config` with the new `--configinfo` option, and in XML format when the options `--configinfo --xml` are used together. For more information and examples, see [Section 17.4.6, “`ndb\_config` — Extract MySQL Cluster Configuration Information”](#).

Bugs fixed:

- **Important Change: Partitioning:** User-defined partitioning of an `NDBCLUSTER` table without any primary key sometimes failed, and could cause `mysqld` to crash.

Now, if you wish to create an `NDBCLUSTER` table with user-defined partitioning, the table must have an explicit primary key, and all columns listed in the partitioning expression must be part of the primary key. The hidden primary key used by the `NDBCLUSTER` storage engine is not sufficient for this purpose. However, if the list of columns is empty (that is, the table is defined using `PARTITION BY [LINEAR] KEY()`), then no explicit primary key is required.

This change does not effect the partitioning of tables using any storage engine other than `NDBCLUSTER`. ([Bug#40709](#))

- **Important Change:** Previously, the configuration parameter `NoOfReplicas` had no default value. Now the default for `NoOfReplicas` is 2, which is the recommended value in most settings. ([Bug#44746](#))
- **Important Note:** It was not possible to perform an online upgrade from any MySQL Cluster NDB 6.x release to MySQL Cluster NDB 7.0.5 or any to earlier MySQL Cluster NDB 7.0 release.

With this fix, it is possible in MySQL Cluster NDB 7.0.6 and later to perform online upgrades from MySQL Cluster NDB 6.3.8 and later MySQL Cluster NDB 6.3 releases, or from MySQL Cluster NDB 7.0.5 or later MySQL Cluster NDB 7.0 releases. Online upgrades to MySQL Cluster NDB 7.0 releases previous to MySQL Cluster NDB 7.0.6 from earlier MySQL Cluster releases remain unsupported; online upgrades from MySQL Cluster NDB 7.0 releases previous to MySQL Cluster NDB 7.0.5 (including NDB 6.4.x beta releases) to later MySQL Cluster NDB 7.0 releases also remain unsupported. ([Bug#44294](#))

- An internal NDB API buffer was not properly initialized. ([Bug#44977](#))
- When a data node had written its GCI marker to the first page of a megabyte, and that node was later killed during restart after having processed that page (marker) but before completing a LCP, the data node could fail with filesystem errors. ([Bug#44952](#))

See also [Bug#42564](#), [Bug#44291](#).

- When restarting a data nodes, management and API nodes reconnecting to it failed to re-use existing ports that had already been dynamically allocated for communications with that data node. ([Bug#44866](#))
- When `ndb_config` could not find the file referenced by the `--config-file` option, it tried to read `my.cnf` instead, then failed with a misleading error message. ([Bug#44846](#))

- When a data node was down so long that its most recent local checkpoint depended on a global checkpoint that was no longer restorable, it was possible for it to be unable to use optimized node recovery when being restarted later. ([Bug#44844](#))

See also [Bug#26913](#).

- Online upgrades to MySQL Cluster NDB 7.0 from a MySQL Cluster NDB 6.3 release could fail due to changes in the handling of key lengths and unique indexes during node recovery. ([Bug#44827](#))

- `ndb_config --xml` did not output any entries for the `HostName` parameter. In addition, the default listed for `MaxNoOfFiles` was outside the permitted range of values. ([Bug#44749](#))

See also [Bug#44685](#), [Bug#44746](#).

- The output of `ndb_config --xml` did not provide information about all sections of the configuration file. ([Bug#44685](#))

See also [Bug#44746](#), [Bug#44749](#).

- Use of `__builtin_expect()` had the side effect that compiler warnings about misuse of `=` (assignment) instead of `==` in comparisons were lost when building in debug mode. This is no longer employed when configuring the build with the `-with-debug` option. ([Bug#44570](#))

See also [Bug#44567](#).

- Inspection of the code revealed that several assignment operators (`=`) were used in place of comparison operators (`==`) in `Db-dihMain.cpp`. ([Bug#44567](#))

See also [Bug#44570](#).

- When using large numbers of configuration parameters, the management server took an excessive amount of time (several minutes or more) to load these from the configuration cache when starting. This problem occurred when there were more than 32 configuration parameters specified, and became progressively worse with each additional multiple of 32 configuration parameters. ([Bug#44488](#))

- Building the MySQL Cluster NDB 7.0 tree failed when using the `icc` compiler. ([Bug#44310](#))

- SSL connections to SQL nodes failed on big-endian platforms. ([Bug#44295](#))

- Signals providing node state information (`NODE_STATE REP` and `CHANGE_NODE_STATE REQ`) were not propagated to all blocks of `ndbmtl`. This could cause the following problems:

- Inconsistent redo logs when performing a graceful shutdown;
- Data nodes crashing when later restarting the cluster, data nodes needing to perform node recovery during the system restart, or both.

([Bug#44291](#))

See also [Bug#42564](#).

- An NDB internal timing function did not work correctly on Windows and could cause `mysqld` to fail on some AMD processors, or when running inside a virtual machine. ([Bug#44276](#))

- It was possible for NDB API applications to insert corrupt data into the database, which could subsequently lead to data node crashes. Now, stricter checking is enforced on input data for inserts and updates. ([Bug#44132](#))

- `ndb_restore` failed when trying to restore data on a big-endian machine from a backup file created on a little-endian machine. ([Bug#44069](#))

- Repeated starting and stopping of data nodes could cause `ndb_mgmd` to fail. This issue was observed on Solaris/SPARC. ([Bug#43974](#))

- A number of incorrectly formatted output strings in the source code caused compiler warnings. ([Bug#43878](#))

- When trying to use a data node with an older version of the management server, the data node crashed on startup. ([Bug#43699](#))

- In some cases, data node restarts during a system restart could fail due to insufficient redo log space. ([Bug#43156](#))

- `NDBCLUSTER` did not build correctly on Solaris 9 platforms. ([Bug#39080](#))

See also [Bug#39036](#), [Bug#39038](#).

- The output of `ndbd --help` did not provide clear information about the program's `--initial` and `--initial-start`

options. ([Bug#28905](#))

- It was theoretically possible for the value of a nonexistent column to be read as `NULL`, rather than causing an error. ([Bug#27843](#))
- **Disk Data:** During a checkpoint, restore points are created for both the on-disk and in-memory parts of a Disk Data table. Under certain rare conditions, the in-memory restore point could include or exclude a row that should have been in the snapshot. This would later lead to a crash during or following recovery.

This issue was somewhat more likely to be encountered when using `ndbmtd`. ([Bug#41915](#))

See also [Bug#47832](#).

- **Disk Data:** This fix supercedes and improves on an earlier fix made for this bug in MySQL 5.1.18. ([Bug#24521](#))
- **Cluster Replication:** A failure when setting up replication events could lead to subsequent data node failures. ([Bug#44915](#))

## 17.7.2.24. Changes in MySQL Cluster NDB 7.0.5 (5.1.32-ndb-7.0.5) (20 April 2009 General Availability)

This *General Availability* (GA) release incorporates new features in the `NDBCLUSTER` storage engine and fixes recently discovered bugs in MySQL Cluster NDB 7.0.4.

**Obtaining MySQL Cluster NDB 7.0.5.** The latest MySQL Cluster NDB 7.0 binaries for supported platforms can be obtained from <http://dev.mysql.com/downloads/cluster/>. Source code for the latest MySQL Cluster NDB 7.0 release can be obtained from the same location. You can also access the MySQL Cluster NDB 7.0 development source tree at <https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-7.0>.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, 6.3, and 6.4 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.32 (see [Section C.1.24, “Changes in MySQL 5.1.32 \(14 February 2009\)](#)”).

### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- Two new server status variables `Ndb_scan_count` and `Ndb_pruned_scan_count` have been introduced. `Ndb_scan_count` gives the number of scans executed since the cluster was last started. `Ndb_pruned_scan_count` gives the number of scans for which `NDBCLUSTER` was able to use partition pruning. Together, these variables can be used to help determine in the MySQL server whether table scans are pruned by `NDBCLUSTER`. ([Bug#44153](#))

Bugs fixed:

- **Important Note:** Due to problem discovered after the code freeze for this release, it is not possible to perform an online upgrade from any MySQL Cluster NDB 6.x release to MySQL Cluster NDB 7.0.5 or any earlier MySQL Cluster NDB 7.0 release.

This issue is fixed in MySQL Cluster NDB 7.0.6 and later for upgrades from MySQL Cluster NDB 6.3.8 and later MySQL Cluster NDB 6.3 releases, or from MySQL Cluster NDB 7.0.5. ([Bug#44294](#))

- **Cluster Replication:** If data node failed during an event creation operation, there was a slight risk that a surviving data node could send an invalid table reference back to NDB, causing the operation to fail with a false Error 723 (`NO SUCH TABLE`). This could take place when a data node failed as a `mysqld` process was setting up MySQL Cluster Replication. ([Bug#43754](#))
- **Cluster API:** The following issues occurred when performing an online (rolling) upgrade of a cluster to a version of MySQL Cluster that supports configuration caching from a version that does not:

1. When using multiple management servers, after upgrading and restarting one `ndb_mgmd`, any remaining management servers using the previous version of `ndb_mgmd` could not synchronize their configuration data.

2. The MGM API `ndb_mgm_get_configuration()` function failed to obtain configuration data.

([Bug#43641](#))

- If the number of fragments per table rises above a certain threshold, the `DBDIH` kernel block's on-disk table-definition grows large enough to occupy 2 pages. However, in MySQL Cluster NDB 7.0 (including MySQL Cluster NDB 6.4 releases), only 1 page was actually written, causing table definitions stored on disk to be incomplete.

This issue was not observed in MySQL Cluster release series prior to MySQL Cluster NDB 7.0. ([Bug#44135](#))

- `TransactionDeadlockDetectionTimeout` values less than 100 were treated as 100. This could cause scans to time out unexpectedly. ([Bug#44099](#))
- The file `ndberror.c` contained a C++-style comment, which caused builds to fail with some C compilers. ([Bug#44036](#))
- A race condition could occur when a data node failed to restart just before being included in the next global checkpoint. This could cause other data nodes to fail. ([Bug#43888](#))
- The setting for `ndb_use_transactions` was ignored. This issue was only known to occur in MySQL Cluster NDB 6.4.3 and MySQL Cluster NDB 7.0.4. ([Bug#43236](#))
- When a data node process had been killed after allocating a node ID, but before making contact with any other data node processes, it was not possible to restart it due to a node ID allocation failure.

This issue could effect either `ndbd` or `ndbmtd` processes. ([Bug#43224](#))

This regression was introduced by [Bug#42973](#).

- `ndb_restore` crashed when trying to restore a backup made to a MySQL Cluster running on a platform having different endianness from that on which the original backup was taken. ([Bug#39540](#))
- PID files for the data and management node daemons were not removed following a normal shutdown. ([Bug#37225](#))
- `ndb_restore --print_data` did not handle `DECIMAL` columns correctly. ([Bug#37171](#))
- Invoking the management client `START BACKUP` command from the system shell (for example, as `ndb_mgm -e "START BACKUP"`) did not work correctly, unless the backup ID was included when the command was invoked.

Now, the backup ID is no longer required in such cases, and the backup ID that is automatically generated is printed to stdout, similar to how this is done when invoking `START BACKUP` within the management client. ([Bug#31754](#))

- When aborting an operation involving both an insert and a delete, the insert and delete were aborted separately. This was because the transaction coordinator did not know that the operations affected on same row, and, in the case of a committed-read (tuple or index) scan, the abort of the insert was performed first, then the row was examined after the insert was aborted but before the delete was aborted. In some cases, this would leave the row in a inconsistent state. This could occur when a local checkpoint was performed during a backup. This issue did not affect primary key operations or scans that used locks (these are serialized).

After this fix, for ordered indexes, all operations that follow the operation to be aborted are now also aborted.

- **Disk Data:** When using multi-threaded data nodes, `DROP TABLE` statements on Disk Data tables could hang. ([Bug#43825](#))
- **Disk Data:** This fix completes one that was made for this issue in MySQL Cluster NDB-7.0.4, which did not rectify the problem in all cases. ([Bug#43632](#))
- **Cluster Replication:** When creating or altering a table an `NdbEventOperation` is created by the `mysqld` process to monitor the table for subsequent logging in the binlog. If this happened during a node restart there was a chance that the reference count on this event operation object could be incorrect, which could lead to an assert in debug MySQL Cluster builds. ([Bug#43752](#))
- **Cluster API:** If the largest offset of a `RecordSpecification` used for an `NdbRecord` object was for the `NULL` bits (and thus not a column), this offset was not taken into account when calculating the size used for the `RecordSpecification`. This meant that the space for the `NULL` bits could be overwritten by key or other information. ([Bug#43891](#))
- **Cluster API:** `BIT` columns created using the native NDB API format that were not created as nullable could still sometimes be overwritten, or cause other columns to be overwritten.

This issue did not effect tables having `BIT` columns created using the `mysqld` format (always used by MySQL Cluster SQL nodes). ([Bug#43802](#))

## 17.7.2.25. Changes in MySQL Cluster NDB 7.0.4 (5.1.32-ndb-7.0.4) (18 March 2008)

This is a new Beta development release, incorporating new features in the `NDBCLUSTER` storage engine and fixing recently discovered bugs in MySQL Cluster NDB 6.4.3. All feature additions and bugfixes that were made in MySQL Cluster releases having

NDB 6.4.x release numbers are included in MySQL Cluster 7.0.4.

### Important

MySQL Cluster NDB 7.0.4 is the successor to MySQL Cluster NDB 6.4.3. Users running MySQL Cluster NDB 6.4.3 should upgrade to MySQL Cluster NDB 7.0.4 or a later 7.0.x release.

**Obtaining MySQL Cluster NDB 7.0.4.** MySQL Cluster NDB 7.0.4 is a source-only release. You can obtain the source code from [ftp://ftp.mysql.com/pub/mysql/download/cluster\\_telco/mysql-5.1.32-ndb-7.0.4/](ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/mysql-5.1.32-ndb-7.0.4/).

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, 6.3, and 6.4 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.32 (see [Section C.1.24, “Changes in MySQL 5.1.32 \(14 February 2009\)](#)”).

### Note

This Beta release, as any other pre-production release, should not be installed on *production* level systems or systems with critical data. Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **Important Change:** The default values for a number of MySQL Cluster configuration parameters relating to memory usage and buffering have changed. These parameters include `RedoBuffer`, `LongMessageBuffer`, `BackupMemory`, `BackupDataBufferSize`, `BackupLogBufferSize`, `BackupWriteSize`, `BackupMaxWriteSize`, `SendBufferMemory` (when applied to TCP transporters), and `ReceiveBufferMemory`.

For more information, see [Section 17.3, “MySQL Cluster Configuration”](#).

- When restoring from backup, `ndb_restore` now reports the last global checkpoint reached when the backup was taken. ([Bug#37384](#))

Bugs fixed:

- **Cluster API:** Partition pruning did not work correctly for queries involving multiple range scans.

As part of the fix for this issue, several improvements have been made in the NDB API, including the addition of a new `NdbScanOperation::getPruned()` method, a new variant of `NdbIndexScanOperation::setBound()`, and a new `Ndb::PartitionSpec` data structure. For more information about these changes, see `NdbScanOperation::getPruned()`, `NdbIndexScanOperation::setBound`, and [The PartitionSpec Structure](#). ([Bug#37934](#))

- `TimeBetweenLocalCheckpoints` was measured from the end of one local checkpoint to the beginning of the next, rather than from the beginning of one LCP to the beginning of the next. This meant that the time spent performing the LCP was not taken into account when determining the `TimeBetweenLocalCheckpoints` interval, so that LCPs were not started often enough, possibly causing data nodes to run out of redo log space prematurely. ([Bug#43567](#))
- The management server failed to start correctly in daemon mode. ([Bug#43559](#))
- Following a `DROP NODEGROUP` command, the output of `SHOW` in the `ndb_mgm` client was not updated to reflect the fact that the data nodes affected by this command were no longer part of a node group. ([Bug#43413](#))
- Using indexes containing variable-sized columns could lead to internal errors when the indexes were being built. ([Bug#43226](#))
- When using `ndbmtd`, multiple data node failures caused the remaining data nodes to fail as well. ([Bug#43109](#))
- It was not possible to add new data nodes to the cluster online using multi-threaded data node processes (`ndbmtd`). ([Bug#43108](#))
- Some queries using combinations of logical and comparison operators on an indexed column in the `WHERE` clause could fail with the error `GOT_ERROR 4541 'INDEXBOUND HAS NO BOUND INFORMATION' FROM NDBCLUSTER`. ([Bug#42857](#))
- **Disk Data:** When using multi-threaded data nodes, dropping a Disk Data table followed by a data node restart led to a crash. ([Bug#43632](#))
- **Disk Data:** When using `ndbmtd`, repeated high-volume inserts (on the order of 10000 rows inserted at a time) on a Disk Data table would eventually lead to a data node crash. ([Bug#41398](#))
- **Disk Data:** When a log file group had an undo log file whose size was too small, restarting data nodes failed with `READ UNDERFLOW` errors.

As a result of this fix, the minimum permitted `INITIAL_SIZE` for an undo log file is now `1M` (1 megabyte). ([Bug#29574](#))

- **Cluster API:** The default `NdbRecord` structures created by `NdbDictionary` could have overlapping null bits and data fields. ([Bug#43590](#))
- **Cluster API:** When performing insert or write operations, `NdbRecord` permits key columns to be specified in both the key record and in the attribute record. Only one key column value for each key column should be sent to the NDB kernel, but this was not guaranteed. This is now ensured as follows: For insert and write operations, key column values are taken from the key record; for scan takeover update operations, key column values are taken from the attribute record. ([Bug#42238](#))
- **Cluster API:** Ordered index scans using `NdbRecord` formerly expressed a `BoundEQ` range as separate lower and upper bounds, resulting in 2 copies of the column values being sent to the NDB kernel.

Now, when a range is specified by `NdbScanOperation::setBound()`, the passed pointers, key lengths, and inclusive bits are compared, and only one copy of the equal key columns is sent to the kernel. This makes such operations more efficient, as half the amount of `KeyInfo` is now sent for a `BoundEQ` range as before. ([Bug#38793](#))

## 17.7.2.26. Changes in MySQL Cluster NDB 6.4.3 (5.1.32-ndb-6.4.3) (23 February 2009)

This is a new Beta development release, incorporating new features in the `NDBCLUSTER` storage engine and fixing recently discovered bugs in MySQL Cluster NDB 6.4.2.

### Important

The successor version to MySQL Cluster NDB 6.4.3 is MySQL Cluster NDB 7.0.4. See [Section 17.7.2.25, “Changes in MySQL Cluster NDB 7.0.4 \(5.1.32-ndb-7.0.4\) \(18 March 2008\)](#).

**Obtaining MySQL Cluster NDB 6.4.3.** MySQL Cluster NDB 6.4.3 is a source-only release. You can obtain the source code from [ftp://ftp.mysql.com/pub/mysql/download/cluster\\_telco/mysql-5.1.32-ndb-6.4.3/](http://ftp.mysql.com/pub/mysql/download/cluster_telco/mysql-5.1.32-ndb-6.4.3/).

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, 6.3, and 6.4 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.32 (see [Section C.1.24, “Changes in MySQL 5.1.32 \(14 February 2009\)](#)”).

### Note

This Beta release, as any other pre-production release, should not be installed on *production* level systems or systems with critical data. Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **Important Change: Replication:** `RESET MASTER` and `RESET SLAVE` now reset the values shown for `Last_IO_Error`, `Last_IO_Errno`, `Last_SQL_Error`, and `Last_SQL_Errno` in the output of `SHOW SLAVE STATUS`. ([Bug#34654](#))

See also [Bug#44270](#).

- A new data node configuration parameter `MaxLCPStartDelay` has been introduced to facilitate parallel node recovery by causing a local checkpoint to be delayed while recovering nodes are synchronizing data dictionaries and other meta-information. For more information about this parameter, see [Section 17.3.2.6, “Defining MySQL Cluster Data Nodes”](#). ([Bug#43053](#))
- New options are introduced for `ndb_restore` for determining which tables or databases should be restored:
  - `--include-tables` and `--include-databases` can be used to restore specific tables or databases.
  - `--exclude-tables` and `--exclude-databases` can be used to exclude the specified tables or databases from being restored.

For more information about these options, see [Section 17.4.17, “`ndb\_restore` — Restore a MySQL Cluster Backup”](#). ([Bug#40429](#))

- **Disk Data:** It is now possible to specify default locations for Disk Data data files and undo log files, either together or separately, using the data node configuration parameters `FileSystemPathDD`, `FileSystemPathDataFiles`, and `FileSystemPathUndoFiles`. For information about these configuration parameters, see [Disk Data filesystem parameters](#).

It is also now possible to specify a log file group, tablespace, or both, that is created when the cluster is started, using the `InitialLogFileGroup` and `InitialTablespace` data node configuration parameters. For information about these config-

uration parameters, see [Disk Data object creation parameters](#).

Bugs fixed:

- **Performance:** Updates of the `SYSTAB_0` system table to obtain a unique identifier did not use transaction hints for tables having no primary key. In such cases the NDB kernel used a cache size of 1. This meant that each insert into a table not having a primary key required an update of the corresponding `SYSTAB_0` entry, creating a potential performance bottleneck.

With this fix, inserts on `NDB` tables without primary keys can be under some conditions be performed up to 100% faster than previously. ([Bug#39268](#))

- **Important Note:** It is not possible in this release to install the `InnoDB` plugin if `InnoDB` support has been compiled into `mysqld`. ([Bug#42610](#))

This regression was introduced by [Bug#29263](#).

- **Packaging:** Packages for MySQL Cluster were missing the `libndbclient.so` and `libndbclient.a` files. ([Bug#42278](#))
- **Partitioning:** Executing `ALTER TABLE ... REORGANIZE PARTITION` on an `NDBCLUSTER` table having only one partition caused `mysqld` to crash. ([Bug#41945](#))

See also [Bug#40389](#).

- Backup IDs greater than  $2^{31}$  were not handled correctly, causing negative values to be used in backup directory names and printouts. ([Bug#43042](#))
- When using `ndbmtd`, NDB kernel threads could hang while trying to start the data nodes with `LockPagesInMainMemory` set to 1. ([Bug#43021](#))
- When using multiple management servers and starting several API nodes (possibly including one or more SQL nodes) whose connectstrings listed the management servers in different order, it was possible for 2 API nodes to be assigned the same node ID. When this happened it was possible for an API node not to get fully connected, consequently producing a number of errors whose cause was not easily recognizable. ([Bug#42973](#))
- When using multi-threaded data nodes, `IndexMemory`, `MaxNoOfLocalOperations`, and `MaxNoOfLocalScans` were effectively multiplied by the number of local query handlers in use by each `ndbmtd` instance. ([Bug#42765](#))

See also [Bug#42215](#).

- `ndb_error_reporter` worked correctly only with GNU `tar`. (With other versions of `tar`, it produced empty archives.) ([Bug#42753](#))
- Triggers on `NDBCLUSTER` tables caused such tables to become locked. ([Bug#42751](#))

See also [Bug#16229](#), [Bug#18135](#).

- When performing more than 32 index or tuple scans on a single fragment, the scans could be left hanging. This caused unnecessary timeouts, and in addition could possibly lead to a hang of an LCP. ([Bug#42559](#))
- A data node failure that occurred between calls to `NdbIndexScanOperation::readTuples(SF_OrderBy)` and `NdbTransaction::Execute()` was not correctly handled; a subsequent call to `nextResult()` caused a null pointer to be dereferenced, leading to a segfault in `mysqld`. ([Bug#42545](#))
- If the cluster configuration cache file was larger than 32K, the management server would not start. ([Bug#42543](#))
- Issuing `SHOW GLOBAL STATUS LIKE 'NDB%'` before `mysqld` had connected to the cluster caused a segmentation fault. ([Bug#42458](#))
- When using `ndbmtd` for all data nodes, repeated failures of one data node during DML operations caused other data nodes to fail. ([Bug#42450](#))
- Data node failures that occurred before all data nodes had connected to the cluster were not handled correctly, leading to additional data node failures. ([Bug#42422](#))
- When using multi-threaded data nodes, their `DataMemory` and `IndexMemory` usage as reported was multiplied by the number of local query handlers (worker threads), making it appear that much more memory was being used than was actually the case. ([Bug#42215](#))

See also [Bug#42765](#).

- Given a MySQL Cluster containing no data (that is, whose data nodes had all been started using `--initial`, and into which no data had yet been imported) and having an empty backup directory, executing `START BACKUP` with a user-specified backup ID caused the data nodes to crash. ([Bug#41031](#))
- In some cases, `NDB` did not check correctly whether tables had changed before trying to use the query cache. This could result in a crash of the debug MySQL server. ([Bug#40464](#))
- Disk Data:** It was not possible to add an in-memory column online to a table that used a table-level or column-level `STORAGE DISK` option. The same issue prevented `ALTER ONLINE TABLE ... REORGANIZE PARTITION` from working on Disk Data tables. ([Bug#42549](#))
- Disk Data:** Repeated insert and delete operations on disk-based tables could lead to failures in the NDB Tablespace Manager (`TSMAN` kernel block). ([Bug#40344](#))
- Disk Data:** Creating a Disk Data tablespace with a very large extent size caused the data nodes to fail. The issue was observed when using extent sizes of 100 MB and larger. ([Bug#39096](#))
- Disk Data:** Trying to execute a `CREATE LOGFILE GROUP` statement using a value greater than `150M` for `UNDO_BUFFER_SIZE` caused data nodes to crash.

As a result of this fix, the upper limit for `UNDO_BUFFER_SIZE` is now `600M`; attempting to set a higher value now fails gracefully with an error. ([Bug#34102](#))

See also [Bug#36702](#).

- Disk Data:** When attempting to create a tablespace that already existed, the error message returned was `TABLE OR INDEX WITH GIVEN NAME ALREADY EXISTS.` ([Bug#32662](#))
- Disk Data:** Using a path or filename longer than 128 characters for Disk Data undo log files and tablespace data files caused a number of issues, including failures of `CREATE LOGFILE GROUP`, `ALTER LOGFILE GROUP`, `CREATE TABLESPACE`, and `ALTER TABLESPACE` statements, as well as crashes of management nodes and data nodes.  
With this fix, the maximum length for path and file names used for Disk Data undo log files and tablespace data files is now the same as the maximum for the operating system. ([Bug#31769](#), [Bug#31770](#), [Bug#31772](#))
- Disk Data:** Attempting to perform a system restart of the cluster where there existed a logfile group without and undo log files caused the data nodes to crash.

### Note

While issuing a `CREATE LOGFILE GROUP` statement without an `ADD UNDOFILE` option fails with an error in the MySQL server, this situation could arise if an SQL node failed during the execution of a valid `CREATE LOGFILE GROUP` statement; it is also possible to create a logfile group without any undo log files using the NDB API.

([Bug#17614](#))

- Cluster Replication:** Being disconnected from the cluster while setting up the binary log caused `mysqld` to hang or crash. ([Bug#43045](#))
- Cluster Replication:** Primary key updates on `MyISAM` and `InnoDB` tables failed to replicate to `NDBCLUSTER` tables. ([Bug#42921](#))
- Cluster API:** Some error messages from `ndb_mgmd` contained newline (`\n`) characters. This could break the MGM API protocol, which uses the newline as a line separator. ([Bug#43104](#))
- Cluster API:** When using an ordered index scan without putting all key columns in the read mask, this invalid use of the NDB API went undetected, which resulted in the use of uninitialized memory. ([Bug#42591](#))

## 17.7.2.27. Changes in MySQL Cluster NDB 6.4.2 (5.1.31-ndb-6.4.2) (28 January 2009)

This is a new Beta development release, incorporating new features in the `NDBCLUSTER` storage engine and fixing recently discovered bugs in MySQL Cluster NDB 6.4.1.

**Obtaining MySQL Cluster NDB 6.4.2.** MySQL Cluster NDB 6.4.2 is a source-only release. You can obtain the source code from [http://ftp.mysql.com/pub/mysql/download/cluster\\_telco/mysql-5.1.31-ndb-6.4.2/](http://ftp.mysql.com/pub/mysql/download/cluster_telco/mysql-5.1.31-ndb-6.4.2/).

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, 6.3, and 6.4 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.31 (see [Section C.1.26, "Changes in MySQL 5.1.31 \(19 January 2009\)"](#)).

**Note**

This Beta release, as any other pre-production release, should not be installed on *production* level systems or systems with critical data. Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- Connections using IPv6 were not handled correctly by `mysqld`. ([Bug#42413](#))

See also [Bug#42412](#), [Bug#38247](#).

- When a cluster backup failed with Error 1304 (Node `node_id1`: Backup request from `node_id2` failed to start), no clear reason for the failure was provided.

As part of this fix, MySQL Cluster now retries backups in the event of sequence errors. ([Bug#42354](#))

See also [Bug#22698](#).

- Issuing `SHOW ENGINE NDBCLUSTER STATUS` on an SQL node before the management server had connected to the cluster caused `mysqld` to crash. ([Bug#42264](#))
- When using `ndbmtd`, setting `MaxNoOfThreads` to a value higher than the actual number of cores available and with insufficient `SharedGlobalMemory` caused the data nodes to crash.

The fix for this issue changes the behavior of `ndbmtd` such that its internal job buffers no longer rely on `SharedGlobalMemory`. ([Bug#42254](#))

## 17.7.2.28. Changes in MySQL Cluster NDB 6.4.1 (5.1.31-ndb-6.4.1) (21 January 2009)

This is a new Beta development release, incorporating new features in the `NDBCLUSTER` storage engine and fixing recently discovered bugs in MySQL Cluster NDB 6.4.0.

**Obtaining MySQL Cluster NDB 6.4.1.** MySQL Cluster NDB 6.4.1 is a source-only release. You can obtain the source code from [ftp://ftp.mysql.com/pub/mysql/download/cluster\\_telco/mysql-5.1.31-ndb-6.4.1/](ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/mysql-5.1.31-ndb-6.4.1/).

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, 6.3, and 6.4 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.31 (see [Section C.1.26, “Changes in MySQL 5.1.31 \(19 January 2009\)”](#)).

**Note**

This Beta release, as any other pre-production release, should not be installed on *production* level systems or systems with critical data. Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **Important Change:** Formerly, when the management server failed to create a transporter for a data node connection, `net_write_timeout` seconds elapsed before the data node was actually permitted to disconnect. Now in such cases the disconnection occurs immediately. ([Bug#41965](#))

See also [Bug#41713](#).

- Formerly, when using MySQL Cluster Replication, records for “empty” epochs—that is, epochs in which no changes to `NDBCLUSTER` data or tables took place—were inserted into the `ndb_apply_status` and `ndb_binlog_index` tables on the slave even when `--log-slave-updates` was disabled. Beginning with MySQL Cluster NDB 6.2.16 and MySQL Cluster NDB 6.3.13 this was changed so that these “empty” epochs were no longer logged. However, it is now possible to re-enable the older behavior (and cause “empty” epochs to be logged) by using the `--ndb-log-empty-epochs` option. For more information, see [Section 16.1.3.3, “Replication Slave Options and Variables”](#).

See also [Bug#37472](#).

- **Cluster Replication:** IPv6 networking is now supported between MySQL Cluster SQL nodes. This means that it is now possible to replicate between instances of MySQL Cluster using IPv6 addresses.

**Important**

Currently, other MySQL Cluster processes (`ndbd`, `ndbmt`, `ndb_mgmd`, and `ndb_mgm`) do not support IPv6 connections. This means that all MySQL Cluster data nodes, management servers, and management clients must connect to and be accessible from one another using IPv4. In addition, SQL nodes must use IPv4 to communicate with the cluster. There is also not yet any support in the NDB and MGM APIs for IPv6, which means that applications written using the MySQL Cluster APIs must make connections using IPv4. For more information, see [Section 17.6.3, “Known Issues in MySQL Cluster Replication”](#).

Bugs fixed:

- A maximum of 11 `TUP` scans were permitted in parallel. ([Bug#42084](#))
- The management server could hang after attempting to halt it with the `STOP` command in the management client. ([Bug#42056](#))

See also [Bug#40922](#).

- When using `ndbmt`, one thread could flood another thread, which would cause the system to stop with a `JOB BUFFER FULL` condition (currently implemented as an abort). This could be caused by committing or aborting a large transaction (50000 rows or more) on a single data node running `ndbmt`. To prevent this from happening, the number of signals that can be accepted by the system threads is calculated before executing them, and only executing them if sufficient space is found. ([Bug#42052](#))
- MySQL Cluster would not compile when using `libwrap`. This issue was known to occur only in MySQL Cluster NDB 6.4.0. ([Bug#41918](#))
- Trying to execute an `ALTER ONLINE TABLE ... ADD COLUMN` statement while inserting rows into the table caused `mysqld` to crash. ([Bug#41905](#))
- When a data node connects to the management server, the node sends its node ID and transporter type; the management server then verifies that there is a transporter set up for that node and that it is in the correct state, and then sends back an acknowledgement to the connecting node. If the transporter was not in the correct state, no reply was sent back to the connecting node, which would then hang until a read timeout occurred (60 seconds). Now, if the transporter is not in the correct state, the management server acknowledges this promptly, and the node immediately disconnects. ([Bug#41713](#))

See also [Bug#41965](#).

- Issuing `EXIT` in the management client sometimes caused the client to hang. ([Bug#40922](#))
- In the event that a MySQL Cluster backup failed due to file permissions issues, conflicting reports were issued in the management client. ([Bug#34526](#))
- If all data nodes were shut down, MySQL clients were unable to access `NDBCLUSTER` tables and data even after the data nodes were restarted, unless the MySQL clients themselves were restarted. ([Bug#33626](#))

## 17.7.2.29. Changes in MySQL Cluster NDB 6.4.0 (5.1.30-ndb-6.4.0) (22 December 2008 Beta)

This is a new Beta development release, incorporating new features in the `NDBCLUSTER` storage engine and fixing recently discovered bugs in previous MySQL Cluster releases.

**Obtaining MySQL Cluster NDB 6.4.0.** MySQL Cluster NDB 6.4.0 is a source-only release. You can obtain the source code from [ftp://ftp.mysql.com/pub/mysql/download/cluster\\_telco/mysql-5.1.30-ndb-6.4.0/](ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/mysql-5.1.30-ndb-6.4.0/).

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1, 6.2, and 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.30 (see [Section C.1.27, “Changes in MySQL 5.1.30 \(14 November 2008 General Availability\)”](#)).

### Note

This Beta release, as any other pre-production release, should not be installed on *production* level systems or systems with critical data. Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **Important Change:** MySQL Cluster now caches its configuration data. This means that, by default, the management server only reads the global configuration file (usually named `config.ini`) the first time that it is started, and does not automatically re-read the this file when restarted. This behavior can be controlled using new management server options (`--config-dir`, `--initial`, and `--reload`) that have been added for this purpose. For more information, see [Sec-](#)

tion 17.3.2, “MySQL Cluster Configuration Files”, and Section 17.4.4, “`ndb_mgmd` — The MySQL Cluster Management Server Daemon”.

- It is now possible while in Single User Mode to restart all data nodes using `ALL RESTART` in the management client. Restarting of individual nodes while in Single User Mode remains not permitted. ([Bug#31056](#))

- It is now possible to add data nodes to a MySQL Cluster online—that is, to a running MySQL Cluster without shutting it down.

For information about the procedure for adding data nodes online, see Section 17.5.11, “Adding MySQL Cluster Data Nodes Online”.

- A multi-threaded version of the MySQL Cluster data node daemon is now available. The multi-threaded `ndbmtd` binary is similar to `ndbd` and functions in much the same way, but is intended for use on machines with multiple CPU cores.

For more information, see Section 17.4.3, “`ndbmtd` — The MySQL Cluster Data Node Daemon (Multi-Threaded)”.

- It is now possible when performing a cluster backup to determine whether the backup matches the state of the data when the backup began or when it ended, using the new `START BACKUP` options `SNAPSHOTSTART` and `SNAPSHOTEND` in the management client. See Section 17.5.3.2, “Using The MySQL Cluster Management Client to Create a Backup”, for more information.

- **Cluster API:** Two new `Ndb_cluster_connection` methods have been added to help in diagnosing problems with NDB API client connections. The `get_latest_error()` method tells whether or not the latest connection attempt succeeded; if the attempt failed, `get_latest_error_msg()` provides an error message giving the reason. For more information, see `Ndb_cluster_connection::get_latest_error()`, and `Ndb_cluster_connection::get_latest_error_msg()`.

Bugs fixed:

- API nodes disconnected too aggressively from cluster when data nodes were being restarted. This could sometimes lead to the API node being unable to access the cluster at all during a rolling restart. ([Bug#41462](#))
- When long signal buffer exhaustion in the `ndbd` process resulted in a signal being dropped, the usual handling mechanism did not take fragmented signals into account. This could result in a crash of the data node because the fragmented signal handling mechanism was not able to work with the missing fragments. ([Bug#39235](#))
- The failure of a master node during a DDL operation caused the cluster to be unavailable for further DDL operations until it was restarted; failures of nonmaster nodes during DLL operations caused the cluster to become completely inaccessible. ([Bug#36718](#))
- Status messages shown in the management client when restarting a management node were inappropriate and misleading. Now, when restarting a management node, the messages displayed are as follows, where `node_id` is the management node's node ID:
 

```
ndb_mgm> node_id RESTART
Shutting down MGM node node_id for restart
Node node_id is being restarted
ndb_mgm>
```

([Bug#29275](#))

- A data node failure when `NoOfReplicas` was greater than 2 caused all cluster SQL nodes to crash. ([Bug#18621](#))
- **Partitioning:** A query on a user-partitioned table caused MySQL to crash, where the query had the following characteristics:
  - The query's `WHERE` clause referenced an indexed column that was also in the partitioning key.
  - The query's `WHERE` clause included a value found in the partition.
  - The query's `WHERE` clause used the `<` or `<>` operators to compare with the indexed column's value with a constant.
  - The query used an `ORDER BY` clause, and the same indexed column was used in the `ORDER BY` clause.
  - The `ORDER BY` clause used an explicit or implicit `ASC` sort priority.

Two examples of such a query are given here, where `a` represents an indexed column used in the table's partitioning key:

1. 

```
SELECT * FROM table WHERE a < constant ORDER BY a;
```

2. 

```
SELECT * FROM table WHERE a <> constant ORDER BY a;
```

(Bug#40954)

This regression was introduced by Bug#30573, Bug#33257, Bug#33555.

## 17.7.3. Changes in MySQL Cluster NDB 6.3

This section contains change history information for MySQL Cluster releases based on version 6.3 of the `NDBCLUSTER` storage engine.

For an overview of new features added in MySQL Cluster NDB 6.3, see [Section 17.1.4.3, “MySQL Cluster Development in MySQL Cluster NDB 6.3”](#).

### 17.7.3.1. Changes in MySQL Cluster NDB 6.3.38 (5.1.47-ndb-6.3.38) (Not yet released)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.3 release.

**Obtaining MySQL Cluster NDB 6.3.** The latest MySQL Cluster NDB 6.3 binaries for supported platforms can be obtained from <http://dev.mysql.com/downloads/cluster/>. Source code for the latest MySQL Cluster NDB 6.3 release can be obtained from the same location. You can also access the MySQL Cluster NDB 6.3 development source tree at <https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-6.3>.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.47 (see [Section C.1.4, “Changes in MySQL 5.1.47 \(06 May 2010\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- `mysqldump` as supplied with MySQL Cluster now has an `--add-drop-trigger` option which adds a `DROP TRIGGER IF EXISTS` statement before each dumped trigger definition. (Bug#55691)

See also Bug#34325.

Bugs fixed:

- When distributing `CREATE TABLE` and `DROP TABLE` operations among several SQL nodes attached to a MySQL Cluster, the `LOCK_OPEN` lock normally protecting `mysqld`'s internal table list is released so that other queries or DML statements are not blocked. However, to make sure that other DDL is not executed simultaneously, a global schema lock (implemented as a row-level lock by `NDB`) is used, such that all operations that can modify the state of the `mysqld` internal table list also need to acquire this global schema lock. The `SHOW TABLE STATUS` statement did not acquire this lock. (Bug#56841)
- MySQL Cluster stores, for each row in each `NDB` table, a Global Checkpoint Index (GCI) which identifies the last committed transaction that modified the row. As such, a GCI can be thought of as a coarse-grained row version.

Due to changes in the format used by `NDB` to store local checkpoints (LCPs) in MySQL Cluster NDB 6.3.11, it could happen that, following cluster shutdown and subsequent recovery, the GCI values for some rows could be changed unnecessarily; this could possibly, over the course of many node or system restarts (or both), lead to an inconsistent database. (Bug#56770)

- When multiple SQL nodes were connected to the cluster and one of them stopped in the middle of a DDL operation, the `mysqld` process issuing the DDL timed out with the error `DISTRIBUTING TBL_NAME TIMED OUT. IGNORING.` (Bug#56763)
- An online `ALTER TABLE ... ADD COLUMN` operation that changed the table schema such that the number of 32-bit words used for the bitmask allocated to each DML operation increased during a transaction in DML which was performed prior to DDL which was followed by either another DML operation or—if using replication—a commit, led to data node failure.

This was because the data node did not take into account that the bitmask for the before-image was smaller than the current bitmask, which caused the node to crash. (Bug#56524)

- The failure of a data node during some scans could cause other data nodes to fail. ([Bug#54945](#))
- Exhausting the number of available commit-ack markers (controlled by the `MaxNoOfConcurrentTransactions` parameter) led to a data node crash. ([Bug#54944](#))
- When running a `SELECT` on an `NDB` table with `BLOB` or `TEXT` columns, memory was allocated for the columns but was not freed until the end of the `SELECT`. This could cause problems with excessive memory usage when dumping (using for example `mysqldump`) tables with such columns and having many rows, large column values, or both. ([Bug#52313](#))

See also [Bug#56488](#), [Bug#50310](#).

- **Cluster Replication:** When an SQL node starts, as part of setting up replication, it subscribes to data events from all data nodes using a `SUB_START_REQ` (subscription start request) signal. Atomicity of `SUB_START_REQ` is implemented such that, if any of the nodes returns an error, a `SUB_STOP_REQ` (subscription stop request) is sent to any nodes that replied with a `SUB_START_CONF` (subscription start confirmation). However, if all data nodes returned an error, `SUB_STOP_REQ` was not sent to any of them. This caused mysqld to hang when restarting (while waiting for a response), and subsequent data node re-starts to hang as well. ([Bug#56579](#))

### 17.7.3.2. Changes in MySQL Cluster NDB 6.3.37 (5.1.47-ndb-6.3.37) (03 September 2010)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.3 release.

**Obtaining MySQL Cluster NDB 6.3.** The latest MySQL Cluster NDB 6.3 binaries for supported platforms can be obtained from <http://dev.mysql.com/downloads/cluster/>. Source code for the latest MySQL Cluster NDB 6.3 release can be obtained from the same location. You can also access the MySQL Cluster NDB 6.3 development source tree at <https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-6.3>.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.47 (see [Section C.1.4, “Changes in MySQL 5.1.47 \(06 May 2010\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **Important Change:** More finely-grained control over restart-on-failure behavior is provided with two new data node configuration parameters `MaxStartFailRetries` and `StartFailRetryDelay`. `MaxStartFailRetries` limits the total number of retries made before giving up on starting the data node; `StartFailRetryDelay` sets the number of seconds between retry attempts.

These parameters are used only if `StopOnError` is set to 0.

For more information, see [Section 17.3.2.6, “Defining MySQL Cluster Data Nodes”](#). ([Bug#54341](#))

Bugs fixed:

- Following a failure of the master data node, the new master sometimes experienced a race condition which caused the node to terminate with a `GcpStop` error. ([Bug#56044](#))
- The warning `MAXNOOFEEXECUTIONTHREADS (#) > LOCKEXECUTETHREADTOCPU COUNT (#), THIS COULD CAUSE CONTENTION` could be logged when running `ndbd`, even though the condition described can occur only when using `ndbmtd`. ([Bug#54342](#))
- The graceful shutdown of a data node could sometimes cause transactions to be aborted unnecessarily. ([Bug#18538](#))

See also [Bug#55641](#).

- **Cluster Replication:** The graceful shutdown of a data node in the master cluster could sometimes cause rows to be skipped when writing transactions to the binary log, leading to an inconsistent slave cluster. ([Bug#55641](#))

See also [Bug#18538](#).

- **Cluster Replication:** Specifying the `--expire_logs_days` option when there were old binary logs to delete caused SQL nodes to crash on startup. ([Bug#41751](#))

### 17.7.3.3. Changes in MySQL Cluster NDB 6.3.36 (5.1.47-ndb-6.3.36) (16 August 2010)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.3 release.

**Obtaining MySQL Cluster NDB 6.3.** The latest MySQL Cluster NDB 6.3 binaries for supported platforms can be obtained from <http://dev.mysql.com/downloads/cluster/>. Source code for the latest MySQL Cluster NDB 6.3 release can be obtained from the same location. You can also access the MySQL Cluster NDB 6.3 development source tree at <https://code.launchpad.net/~mysql/mysql-server/mysql-cluster-6.3>.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.47 (see [Section C.1.4, “Changes in MySQL 5.1.47 \(06 May 2010\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- Added the `DictTrace` data node configuration parameter, for use in debugging NDB code. For more information, see [Section 17.3.2.6, “Defining MySQL Cluster Data Nodes”](#). ([Bug#55963](#))

Bugs fixed:

- Cluster API: Important Change:** The poll and select calls made by the MGM API were not interrupt-safe; that is, a signal caught by the process while waiting for an event on one or more sockets returned error -1 with `errno` set to `EINTR`. This caused problems with MGM API functions such as `ndb_mgm_logevent_get_next()` and `ndb_mgm_get_status2()`.

To fix this problem, the internal `ndb_socket_poller::poll()` function has been made `EINTR`-safe.

The old version of this function has been retained as `poll_unsafe()`, for use by those parts of NDB that do not need the `EINTR`-safe version of the function. ([Bug#55906](#))

- When another data node failed, a given data node `DBTC` kernel block could time out while waiting for `DBDIH` to signal commits of pending transactions, leading to a crash. Now in such cases the timeout generates a prinout, and the data node continues to operate. ([Bug#55715](#))
- The `configure.js` option `WITHOUT_DYNAMIC_PLUGINS=TRUE` was ignored when building MySQL Cluster for Windows using `CMake`. Among the effects of this issue was that `CMake` attempted to build the `InnoDB` storage engine as a plugin (`.DLL` file) even though the `InnoDB Plugin` is not currently supported by MySQL Cluster. ([Bug#54913](#))
- It was possible for a `DROP DATABASE` statement to remove `NDB` hidden blob tables without removing the parent tables, with the result that the tables, although hidden to MySQL clients, were still visible in the output of `ndb_show_tables` but could not be dropped using `ndb_drop_table`. ([Bug#54788](#))
- An excessive number of timeout warnings (normally used only for debugging) were written to the data node logs. ([Bug#53987](#))
- Disk Data:** As an optimization when inserting a row to an empty page, the page is not read, but rather simply initialized. However, this optimization was performed in all cases when an empty row was inserted, even though it should have been done only if it was the first time that the page had been used by a table or fragment. This is because, if the page had been in use, and then all records had been released from it, the page still needed to be read to learn its log sequence number (LSN).

This caused problems only if the page had been flushed using an incorrect LSN and the data node failed before any local checkpoint was completed—which would removed any need to apply the undo log, hence the incorrect LSN was ignored.

The user-visible result of the incorrect LSN was that it caused the data node to fail during a restart. It was perhaps also possible (although not conclusively proven) that this issue could lead to incorrect data. ([Bug#54986](#))

- Cluster Replication:** When inserting rows into the `mysql.ndb_binlog_index` table, duplicate key errors occurred when the size of the epoch number (a 64-bit integer) exceeded  $2^{53}$ . This happened because the `NDB` storage engine handler called the wrong overloaded variant of a MySQL Server internal API (the `Field::store()` method), which resulted in the epoch being mapped to a 64-bit double precision floating point number and a corresponding loss of accuracy for numbers greater than  $2^{53}$ . ([Bug#35217](#))
- Cluster API:** Calling `NdbTransaction::refresh()` did not update the timer for `TransactionInactiveTimeout`. ([Bug#54724](#))

## 17.7.3.4. Changes in MySQL Cluster NDB 6.3.35 (5.1.47-ndb-6.3.35) (25 June 2010)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.3 release.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.47 (see [Section C.1.4, “Changes in MySQL 5.1.47 \(06 May 2010\)”](#)).

### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- Restrictions on some types of mismatches in column definitions when restoring data using `ndb_restore` have been relaxed. These include the following types of mismatches:
  - Different `COLUMN_FORMAT` settings (`FIXED`, `DYNAMIC`, `DEFAULT`)
  - Different `STORAGE` settings (`MEMORY`, `DISK`)
  - Different default values
  - Different distribution key settings

Now, when one of these types of mismatches in column definitions is encountered, `ndb_restore` no longer stops with an error; instead, it accepts the data and inserts it into the target table, while issuing a warning to the user.

For more information, see [Section 17.4.17, “`ndb\_restore` — Restore a MySQL Cluster Backup”](#). ([Bug#54423](#))

See also [Bug#53810](#), [Bug#54178](#), [Bug#54242](#), [Bug#54279](#).

- Introduced the `HeartbeatOrder` data node configuration parameter, which can be used to set the order in which heartbeats are transmitted between data nodes. This parameter can be useful in situations where multiple data nodes are running on the same host and a temporary disruption in connectivity between hosts would otherwise cause the loss of a node group, leading to failure of the cluster. ([Bug#52182](#))

Bugs fixed:

- The disconnection of all API nodes (including SQL nodes) during an `ALTER TABLE` caused a memory leak. ([Bug#54685](#))
- If a node shutdown (either in isolation or as part of a system shutdown) occurred directly following a local checkpoint, it was possible that this local checkpoint would not be used when restoring the cluster. ([Bug#54611](#))
- When performing an online alter table where 2 or more SQL nodes connected to the cluster were generating binary logs, an incorrect message could be sent from the data nodes, causing `mysqld` processes to crash. This problem was often difficult to detect, because restarting SQL node or data node processes could clear the error, and because the crash in `mysqld` did not occur until several minutes after the erroneous message was sent and received. ([Bug#54168](#))
- A table having the maximum number of attributes permitted could not be backed up using the `ndb_mgm` client.

### Note

The maximum number of attributes supported per table is not the same for all MySQL Cluster releases. See [Section 17.1.5.5, “Limits Associated with Database Objects in MySQL Cluster”](#), to determine the maximum that applies in the release which you are using.

([Bug#54155](#))

- During initial node restarts, initialization of the REDO log was always performed 1 node at a time, during start phase 4. Now this is done during start phase 2, so that the initialization can be performed in parallel, thus decreasing the time required for initial restarts involving multiple nodes. ([Bug#50062](#))
- **Cluster Replication:** An error in an `NDB` internal byte mask value could lead to corruption of replicated `BIT` column values. ([Bug#54005](#))

See also [Bug#53622](#).

- **Cluster API:** When using the NDB API, it was possible to rename a table with the same name as that of an existing table.

#### Note

This issue did not affect table renames executed using SQL on MySQL servers acting as MySQL Cluster API nodes.

(Bug#54651)

- **Cluster API:** An excessive number of client connections, such that more than 1024 file descriptors, sockets, or both were open, caused NDB API applications to crash. (Bug#34303)

### 17.7.3.5. Changes in MySQL Cluster NDB 6.3.34 (5.1.44-ndb-6.3.34) (31 May 2010)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.3 release.

This is a source-only release. You can obtain the GPL source code for MySQL Cluster NDB 6.3.34 from [ftp://ftp.mysql.com/pub/mysql/download/cluster\\_telco/mysql-5.1.44-ndb-6.3.34/](http://ftp.mysql.com/pub/mysql/download/cluster_telco/mysql-5.1.44-ndb-6.3.34/).

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.44 (see [Section C.1.8, “Changes in MySQL 5.1.44 \(04 February 2010\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- A `--wait-nodes` option has been added for `ndb_waiter`. When this option is used, the program waits only for the nodes having the listed IDs to reach the desired state. For more information, see [Section 17.4.22, “`ndb\_waiter` — Wait for MySQL Cluster to Reach a Given Status”](#). (Bug#52323)
- Added the `--skip-unknown-objects` option for `ndb_restore`. This option causes `ndb_restore` to ignore any schema objects which it does not recognize. Currently, this is useful chiefly for restoring native backups made from a cluster running MySQL Cluster NDB 7.0 to a cluster running MySQL Cluster NDB 6.3.

Bugs fixed:

- **Cluster API: Incompatible Change:** The default behavior of the NDB API Event API has changed as follows:

Previously, when creating an `NdbDictionary::Event`, DDL operations (alter and drop operations on tables) were automatically reported on any event operation that used this event, but as a result of this change, this is no longer the case. Instead, you must now invoke the event's `setReport()` method, with the new `EventReport` value `ER_DDL`, to get this behavior.

For existing NDB API applications where you wish to retain the old behavior, you must update the code as indicated previously, then recompile, following an upgrade. Otherwise, DDL operations are no longer reported after upgrading `libndbclient`.

For more information, see [The `Event::EventReport` Type](#), and [Event::setReport\(\)](#). (Bug#53308)

- Creating a Disk Data table, dropping it, then creating an in-memory table and performing a restart, could cause data node processes to fail with errors in the `DBTUP` kernel block if the new table's internal ID was the same as that of the old Disk Data table. This could occur because undo log handling during the restart did not check that the table having this ID was now in-memory only. (Bug#53935)
- A table created while `ndb_table_no_logging` was enabled was not always stored to disk, which could lead to a data node crash with `ERROR OPENING DIH SCHEMA FILES FOR TABLE`. (Bug#53934)
- An internal buffer allocator used by `NDB` has the form `alloc(wanted, minimum)` and attempts to allocate `wanted` pages, but is permitted to allocate a smaller number of pages, between `wanted` and `minimum`. However, this allocator could sometimes allocate fewer than `minimum` pages, causing problems with multi-threaded building of ordered indexes. (Bug#53580)
- When compiled with support for `epoll` but this functionality is not available at runtime, MySQL Cluster tries to fall back to use the `select()` function in its place. However, an extra `ndbout_c()` call in the transporter registry code caused `ndbd` to fail instead. (Bug#53482)

- NDB truncated a column declared as `DECIMAL(65, 0)` to a length of 64. Now such a column is accepted and handled correctly. In cases where the maximum length (65) is exceeded, NDB now raises an error instead of truncating. ([Bug#53352](#))
- When a watchdog shutdown occurred due to an error, the process was not terminated quickly enough, sometimes resulting in a hang. (To correct this, the internal `_exit()` function is now called in such situations, rather than `exit()`.) ([Bug#53246](#))
- Setting `DataMemory` higher than 4G on 32-bit platforms caused `ndbd` to crash, instead of failing gracefully with an error. ([Bug#52536](#), [Bug#50928](#))
- NDB did not distinguish correctly between table names differing only by lettercase when `lower_case_table_names` was set to 0. ([Bug#33158](#))
- `ndb_mgm -e "ALL STATUS"` erroneously reported that data nodes remained in start phase 0 until they had actually started.
- **Replication:** A buffer overrun in the handling of `DATE` column values could cause `mysqlbinlog` to fail when reading back logs containing certain combinations of DML on a table having a `DATE` column followed by dropping the table. ([Bug#52202](#))
- **Cluster Replication:** Replication failed after a restart of the slave SQL node, due to an error in writing the `master.info` file. ([Bug#52859](#))
- `ALTER TABLE` did not work correctly where the name of the table, the database, or both contained special characters, causing the MySQL server to crash. ([Bug#52225](#))

See also [Bug#53409](#), [Bug#14959](#).

#### 17.7.3.6. Changes in MySQL Cluster NDB 6.3.33 (5.1.44-ndb-6.3.33) (31 March 2010)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.3 release.

You can obtain the GPL source code and GPL binaries for supported platforms for MySQL Cluster NDB 6.3.33 from <http://dev.mysql.com/downloads/cluster/>.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.44 (see [Section C.1.8, “Changes in MySQL 5.1.44 \(04 February 2010\)”](#)).

##### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **Cluster API:** It is now possible to determine, using the `ndb_desc` utility or the NDB API, which data nodes contain replicas of which partitions. For `ndb_desc`, a new `--extra-node-info` option is added to cause this information to be included in its output. A new method `NdbDictionary::Object::Table::getFragmentNodes()` is added to the NDB API for obtaining this information programmatically. ([Bug#51184](#))
- Formerly, the `REPORT` and `DUMP` commands returned output to all `ndb_mgm` clients connected to the same MySQL Cluster. Now, these commands return their output only to the `ndb_mgm` client that actually issued the command. ([Bug#40865](#))
- **Cluster Replication: Replication:** MySQL Cluster Replication now supports attribute promotion and demotion for row-based replication between columns of different but similar types on the master and the slave. For example, it is possible to promote an `INT` column on the master to a `BIGINT` column on the slave, and to demote a `TEXT` column to a `VARCHAR` column.

The implementation of type demotion distinguishes between lossy and non-lossy type conversions, and their use on the slave can be controlled by setting the `slave_type_conversions` global server system variable.

For more information about attribute promotion and demotion for row-based replication in MySQL Cluster, see [Attribute promotion and demotion \(MySQL Cluster\)](#). ([Bug#47163](#), [Bug#46584](#))

Bugs fixed:

- If a node or cluster failure occurred while `mysqld` was scanning the `ndb.ndb_schema` table (which it does when attempting to connect to the cluster), insufficient error handling could lead to a crash by `mysqld` in certain cases. This could happen in a MySQL Cluster with a great many tables, when trying to restart data nodes while one or more `mysqld` processes were restarting. ([Bug#52325](#))

- After running a mixed series of node and system restarts, a system restart could hang or fail altogether. This was caused by setting the value of the newest completed global checkpoint too low for a data node performing a node restart, which led to the node reporting incorrect GCI intervals for its first local checkpoint. ([Bug#52217](#))
- When performing a complex mix of node restarts and system restarts, the node that was elected as master sometimes required optimized node recovery due to missing `REDO` information. When this happened, the node crashed with `FAILURE TO RECREATE OBJECT ... DURING RESTART, ERROR 721` (because the `DBDICT` restart code was run twice). Now when this occurs, node takeover is executed immediately, rather than being made to wait until the remaining data nodes have started. ([Bug#52135](#))

See also [Bug#48436](#).

- The redo log protects itself from being filled up by periodically checking how much space remains free. If insufficient redo log space is available, it sets the state `TAIL_PROBLEM` which results in transactions being aborted with error code 410 (`OUT OF REDO LOG`). However, this state was not set following a node restart, which meant that if a data node had insufficient redo log space following a node restart, it could crash a short time later with `FATAL ERROR DUE TO END OF REDO LOG`. Now, this space is checked during node restarts. ([Bug#51723](#))
- The output of the `ndb_mgm` client `REPORT BACKUPSTATUS` command could sometimes contain errors due to uninitialized data. ([Bug#51316](#))
- A `GROUP BY` query against `NDB` tables sometimes did not use any indexes unless the query included a `FORCE INDEX` option. With this fix, indexes are used by such queries (where otherwise possible) even when `FORCE INDEX` is not specified. ([Bug#50736](#))
- The `ndb_mgm` client sometimes inserted extra prompts within the output of the `REPORT MEMORYUSAGE` command. ([Bug#50196](#))
- Issuing a command in the `ndb_mgm` client after it had lost its connection to the management server could cause the client to crash. ([Bug#49219](#))
- The `ndb_print_backup_file` utility failed to function, due to a previous internal change in the NDB code. ([Bug#41512](#), [Bug#48673](#))
- When the `MemReportFrequency` configuration parameter was set in `config.ini`, the `ndb_mgm` client `REPORT MEMORYUSAGE` command printed its output multiple times. ([Bug#37632](#))
- `ndb_mgm -e "... REPORT ..."` did not write any output to `stdout`.

The fix for this issue also prevents the cluster log from being flooded with `INFO` messages when `DataMemory` usage reaches 100%, and insures that when the usage is decreased, an appropriate message is written to the cluster log. ([Bug#31542](#), [Bug#44183](#), [Bug#49782](#))

- **Replication:** Metadata for `GEOMETRY` fields was not properly stored by the slave in its definitions of tables. ([Bug#49836](#))

See also [Bug#48776](#).

- **Replication:** Column length information generated by `InnoDB` did not match that generated by `MyISAM`, which caused invalid metadata to be written to the binary log when trying to replicate `BIT` columns. ([Bug#49618](#))
- **Disk Data:** Inserts of blob column values into a MySQL Cluster Disk Data table that exhausted the tablespace resulted in misleading `NO SUCH TUPLE` error messages rather than the expected error `TABLESPACE FULL`.

This issue appeared similar to [Bug#48113](#), but had a different underlying cause. ([Bug#52201](#))

- **Disk Data:** The error message returned after attempting to execute `ALTER LOGFILE GROUP` on a nonexistent logfile group did not indicate the reason for the failure. ([Bug#51111](#))
- **Cluster Replication:** The `--ndb-log-empty-epochs` option did not work correctly. ([Bug#49559](#))
- **Cluster Replication:** When `mysqld` was started with `--binlog-do-db` or `--binlog-ignore-db`, no `LOST_EVENTS` incident was written to the binary log. ([Bug#47096](#))
- **Cluster API:** When reading blob data with lock mode `LM_SimpleRead`, the lock was not upgraded as expected. ([Bug#51034](#))
- **Cluster API:** A number of issues were corrected in the NDB API coding examples found in the `storage/ndb/ndbapi-examples` directory in the MySQL Cluster source tree. These included possible endless recursion in `ndbapi_scan.cpp` as well as problems running some of the examples on systems using Windows or Mac OS due to the letter case used for some table names. ([Bug#30552](#), [Bug#30737](#))
- 1) In rare cases, if a thread was interrupted during a `FLUSH PRIVILEGES` operation, a debug assertion occurred later due to

improper diagnostics area setup. 2) A `KILL` operation could cause a console error message referring to a diagnostic area state without first ensuring that the state existed. ([Bug#33982](#))

### 17.7.3.7. Changes in MySQL Cluster NDB 6.3.32 (5.1.41-ndb-6.3.32) (04 March 2010)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.3 release.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.41 (see [Section C.1.12, “Changes in MySQL 5.1.41 \(05 November 2009\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- A new configuration parameter `HeartbeatThreadPriority` makes it possible to select between a first-in, first-out or round-round scheduling policy for management node and API node heartbeat threads, as well as to set the priority of these threads. See [Section 17.3.2.5, “Defining a MySQL Cluster Management Server”](#), or [Section 17.3.2.7, “Defining SQL and Other API Nodes in a MySQL Cluster”](#), for more information. ([Bug#49617](#))
- **Disk Data:** The `ndb_desc` utility can now show the extent space and free extent space for subordinate `BLOB` and `TEXT` columns (stored in hidden `BLOB` tables by NDB). A `--blob-info` option has been added for this program that causes `ndb_desc` to generate a report for each subordinate `BLOB` table. For more information, see [Section 17.4.9, “ndb\\_desc — Describe NDB Tables”](#). ([Bug#50599](#))

Bugs fixed:

- When one or more data nodes read their LCPs and applied undo logs significantly faster than others, this could lead to a race condition causing system restarts of data nodes to hang. This could most often occur when using both `ndbd` and `ndbmt` processes for the data nodes. ([Bug#51644](#))
- When deciding how to divide the REDO log, the `DBDIH` kernel block saved more than was needed to restore the previous local checkpoint, which could cause REDO log space to be exhausted prematurely (`NDB` error 410). ([Bug#51547](#))
- DML operations can fail with `NDB` error 1220 (`REDO LOG FILES OVERLOADED...`) if the opening and closing of REDO log files takes too much time. If this occurred as a GCI marker was being written in the REDO log while REDO log file 0 was being opened or closed, the error could persist until a GCP stop was encountered. This issue could be triggered when there was insufficient REDO log space (for example, with configuration parameter settings `NoOfFragmentLogFile = 6` and `FragmentLogFileSize = 6M`) with a load including a very high number of updates. ([Bug#51512](#))

See also [Bug#20904](#).

- During an online upgrade from MySQL Cluster NDB 6.2 to MySQL Cluster NDB 6.3, a sufficiently large amount of traffic with more than 1 DML operation per transaction could lead an NDB 6.3 data node to crash an NDB 6.2 data node with an internal error in the `DBLOQH` kernel block. ([Bug#51389](#))
- A side effect of the `ndb_restore --disable-indexes` and `--rebuild-indexes` options is to change the schema versions of indexes. When a `mysqld` later tried to drop a table that had been restored from backup using one or both of these options, the server failed to detect these changed indexes. This caused the table to be dropped, but the indexes to be left behind, leading to problems with subsequent backup and restore operations. ([Bug#51374](#))
- `ndb_restore` crashed while trying to restore a corrupted backup, due to missing error handling. ([Bug#51223](#))
- The `ndb_restore` message `Successfully created index `PRIMARY`...` was directed to `stderr` instead of `stdout`. ([Bug#51037](#))
- When using `NoOfReplicas` equal to 1 or 2, if data nodes from one node group were restarted 256 times and applications were running traffic such that it would encounter `NDB` error 1204 (`TEMPORARY FAILURE, DISTRIBUTION CHANGED`), the live node in the node group would crash, causing the cluster to crash as well. The crash occurred only when the error was encountered on the 256th restart; having the error on any previous or subsequent restart did not cause any problems. ([Bug#50930](#))
- A `SELECT` requiring a sort could fail with the error `CAN'T FIND RECORD IN 'TABLE'` when run concurrently with a `DELETE` from the same table. ([Bug#45687](#))

- **Cluster API:** An issue internal to `ndb_mgm` could cause problems when trying to start a large number of data nodes at the same time. ([Bug#51273](#))

### 17.7.3.8. Changes in MySQL Cluster NDB 6.3.31b (5.1.41-ndb-6.3.31b) (18 February 2010)

This is a replacement release for MySQL Cluster NDB 6.3.31a, fixing a critical issue in that version that was discovered shortly after its release ([Bug#51256](#)). MySQL Cluster NDB 6.3.31b is identical in all other respects to MySQL Cluster NDB 6.3.31a. Users of MySQL Cluster NDB 6.3.31 or MySQL Cluster NDB 6.3.31a should upgrade to the 6.3.31b release as soon as possible. Users of previous MySQL Cluster NDB 6.3 releases should bypass the 6.3.31 and 6.3.31a releases, and upgrade to 6.3.31b instead.

**Obtaining MySQL Cluster NDB 6.3.31b.** This is a source-only release. You can obtain the GPL source code for MySQL Cluster NDB 6.3.31b from [ftp://ftp.mysql.com/pub/mysql/download/cluster\\_telco/mysql-5.1.41-ndb-6.3.31b/](ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/mysql-5.1.41-ndb-6.3.31b/). You can also access the MySQL Cluster NDB 6.3 development source tree at <https://code.launchpad.net/~mysql/mysql-server/mysql-5.1-telco-6.3>.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.41 (see [Section C.1.12, “Changes in MySQL 5.1.41 \(05 November 2009\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- Setting `IndexMemory` greater than 2GB could cause data nodes to crash while starting. ([Bug#51256](#))

### 17.7.3.9. Changes in MySQL Cluster NDB 6.3.31a (5.1.41-ndb-6.3.31a) (15 February 2010)

#### Note

MySQL Cluster NDB 6.3.31a was withdrawn shortly after release, due to [Bug#51256](#). Users should upgrade to MySQL Cluster NDB 6.3.31b, which fixes this issue.

This is a replacement release for MySQL Cluster NDB 6.3.31, fixing a critical issue in that version that was discovered shortly after its release ([Bug#51027](#)). MySQL Cluster NDB 6.3.31a is identical in all other respects to MySQL Cluster NDB 6.3.31. Users of MySQL Cluster NDB 6.3.31 should upgrade to the 6.3.31a release as soon as possible. Users of previous MySQL Cluster NDB 6.3 releases should bypass the 6.3.31 release and upgrade to 6.3.31a instead.

**Obtaining MySQL Cluster NDB 6.3.31a.** This is a source-only release. You can obtain the GPL source code for MySQL Cluster NDB 6.3.31a from [ftp://ftp.mysql.com/pub/mysql/download/cluster\\_telco/mysql-5.1.41-ndb-6.3.31a/](ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/mysql-5.1.41-ndb-6.3.31a/). You can also access the MySQL Cluster NDB 6.3 development source tree at <https://code.launchpad.net/~mysql/mysql-server/mysql-5.1-telco-6.3>.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.41 (see [Section C.1.12, “Changes in MySQL 5.1.41 \(05 November 2009\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- An initial restart of a data node configured with a large amount of memory could fail with a `POINTER TOO LARGE` error. ([Bug#51027](#))

This regression was introduced by [Bug#47818](#).

### 17.7.3.10. Changes in MySQL Cluster NDB 6.3.31 (5.1.41-ndb-6.3.31) (02 February 2010)

#### Note

MySQL Cluster NDB 6.3.31 was withdrawn shortly after release, due to [Bug#51027](#). Users should upgrade to MySQL Cluster NDB 6.3.31a, which fixes this issue.

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.3 release.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.41 (see [Section C.1.12, “Changes in MySQL 5.1.41 \(05 November 2009\)”](#)).

### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **Important Change:** The maximum permitted value of the `ndb_autoincrement_prefetch_sz` system variable has been increased from 256 to 65536. ([Bug#50621](#))
- **Cluster Replication:** Due to the fact that no timestamp is available for delete operations, a delete using `NDB$MAX()` is actually processed as `NDB$OLD`. However, because this is not optimal for some use cases, `NDB$MAX_DELETE_WIN()` is added as a conflict resolution function; if the “timestamp” column value for a given row adding or updating an existing row coming from the master is higher than that on the slave, it is applied (as with `NDB$MAX()`); however, delete operations are treated as always having the higher value.

See `NDB$MAX_DELETE_WIN(column_name)`, for more information. ([Bug#50650](#))

- **Cluster Replication:** In circular replication, it was sometimes possible for an event to propagate such that it would be reapplied on all servers. This could occur when the originating server was removed from the replication circle and so could no longer act as the terminator of its own events, as normally happens in circular replication.

To prevent this from occurring, a new `IGNORE_SERVER_IDS` option is introduced for the `CHANGE MASTER TO` statement. This option takes a list of replication server IDs; events having a server ID which appears in this list are ignored and not applied. For more information, see [Section 12.5.2.1, “`CHANGE MASTER TO` Syntax”](#).

In conjunction with the introduction of `IGNORE_SERVER_IDS`, `SHOW SLAVE STATUS` has two new fields. `Replicate_Ignore_Server_Ids` displays information about ignored servers. `Master_Server_Id` displays the `server_id` value from the master. ([Bug#47037](#))

See also [Bug#25998](#), [Bug#27808](#).

Bugs fixed:

- Setting `BuildIndexThreads` greater than 1 with more than 31 ordered indexes caused node and system restarts to fail. ([Bug#50266](#))
- Dropping unique indexes in parallel while they were in use could cause node and cluster failures. ([Bug#50118](#))
- When setting the `LockPagesInMainMemory` configuration parameter failed, only the error `FAILED TO MEMLOCK PAGES...` was returned. Now in such cases the operating system's error code is also returned. ([Bug#49724](#))
- If a query on an `NDB` table compared a constant string value to a column, and the length of the string was greater than that of the column, condition pushdown did not work correctly. (The string was truncated to fit the column length before being pushed down.) Now in such cases, the condition is no longer pushed down. ([Bug#49459](#))
- Performing intensive inserts and deletes in parallel with a high scan load could a data node crashes due to a failure in the `DBACC` kernel block. This was because checking for when to perform bucket splits or merges considered the first 4 scans only. ([Bug#48700](#))
- During Start Phases 1 and 2, the `STATUS` command sometimes (falsely) returned `Not Connected` for data nodes running `ndbmttd`. ([Bug#47818](#))
- When performing a `DELETE` that included a left join from an `NDB` table, only the first matching row was deleted. ([Bug#47054](#))
- `mysqld` could sometimes crash during a commit while trying to handle NDB Error 4028 `NODE FAILURE CAUSED ABORT OF TRANSACTION`. ([Bug#38577](#))
- When setting `LockPagesInMainMemory`, the stated memory was not allocated when the node was started, but rather only when the memory was used by the data node process for other reasons. ([Bug#37430](#))
- Trying to insert more rows than would fit into an `NDB` table caused data nodes to crash. Now in such situations, the insert fails

gracefully with error 633 TABLE FRAGMENT HASH INDEX HAS REACHED MAXIMUM POSSIBLE SIZE. ([Bug#34348](#))

- **Disk Data:** When a crash occurs due to a problem in Disk Data code, the currently active page list is printed to `stdout` (that is, in one or more `ndb_nodeid_out.log` files). One of these lists could contain an endless loop; this caused a printout that was effectively never-ending. Now in such cases, a maximum of 512 entries is printed from each list. ([Bug#42431](#))
- On Mac OS X or Windows, sending a `SIGHUP` signal to the server or an asynchronous flush (triggered by `flush_time`) caused the server to crash. ([Bug#47525](#))
- The `ARCHIVE` storage engine lost records during a bulk insert. ([Bug#46961](#))
- When using the `ARCHIVE` storage engine, `SHOW TABLE STATUS` displayed incorrect information for `Max_data_length`, `Data_length` and `Avg_row_length`. ([Bug#29203](#))

### 17.7.3.11. Changes in MySQL Cluster NDB 6.3.30 (5.1.39-ndb-6.3.30) (15 December 2009)

This special-purpose evaluation release incorporates all bugfixes and feature changes from previous MySQL Cluster NDB 6.3 releases plus one new feature for evaluation. Most users of MySQL Cluster NDB 6.3 do not require this release; instead, you should use MySQL Cluster NDB 6.3.29 until MySQL Cluster NDB 6.3.31 is released.

This is a source-only release. You can obtain the GPL source code for MySQL Cluster NDB 6.3.30 from [ftp://ftp.mysql.com/pub/mysql/download/cluster\\_telco/mysql-5.1.39-ndb-6.3.30/](ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/mysql-5.1.39-ndb-6.3.30/).

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.39 (see [Section C.1.15, “Changes in MySQL 5.1.39 \(04 September 2009\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- Added multi-threaded ordered index building capability during system restarts or node restarts, controlled by the `BuildIndexThreads` data node configuration parameter (also introduced in this release).

### 17.7.3.12. Changes in MySQL Cluster NDB 6.3.29 (5.1.39-ndb-6.3.29) (15 December 2009)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.3 release.

This is a source-only release. You can obtain the GPL source code for MySQL Cluster NDB 6.3.29 from [ftp://ftp.mysql.com/pub/mysql/download/cluster\\_telco/mysql-5.1.39-ndb-6.3.29/](ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/mysql-5.1.39-ndb-6.3.29/).

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.39 (see [Section C.1.15, “Changes in MySQL 5.1.39 \(04 September 2009\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- This enhanced functionality is supported for upgrades to MySQL Cluster NDB 7.0 when the `NDB` engine version is 7.0.10 or later. ([Bug#48528](#), [Bug#49163](#))
- The output from `ndb_config --configinfo --xml` now indicates, for each configuration parameter, the following restart type information:
  - Whether a system restart or a node restart is required when resetting that parameter;
  - Whether cluster nodes need to be restarted using the `--initial` option when resetting the parameter.

([Bug#47366](#))

Bugs fixed:

- Node takeover during a system restart occurs when the REDO log for one or more data nodes is out of date, so that a node restart is invoked for that node or those nodes. If this happens while a `mysqld` process is attached to the cluster as an SQL node, the `mysqld` takes a global schema lock (a row lock), while trying to set up cluster-internal replication.

However, this setup process could fail, causing the global schema lock to be held for an excessive length of time, which made the node restart hang as well. As a result, the `mysqld` failed to set up cluster-internal replication, which led to tables being read only, and caused one node to hang during the restart.

### Note

This issue could actually occur in MySQL Cluster NDB 7.0 only, but the fix was also applied MySQL Cluster NDB 6.3, in order to keep the two codebases in alignment.

([Bug#49560](#))

- Sending `SIGHUP` to a `mysqld` running with the `--ndbcluster` and `--log-bin` options caused the process to crash instead of refreshing its log files. ([Bug#49515](#))
- If the master data node receiving a request from a newly-started API or data node for a node ID died before the request has been handled, the management server waited (and kept a mutex) until all handling of this node failure was complete before responding to any other connections, instead of responding to other connections as soon as it was informed of the node failure (that is, it waited until it had received a `NF_COMPLETEREP` signal rather than a `NODE_FAILREP` signal). On visible effect of this misbehavior was that it caused management client commands such as `SHOW` and `ALL STATUS` to respond with unnecessary slowness in such circumstances. ([Bug#49207](#))
- When evaluating the options `--include-databases`, `--include-tables`, `--exclude-databases`, and `--exclude-tables`, the `ndb_restore` program overwrote the result of the database-level options with the result of the table-level options rather than merging these results together, sometimes leading to unexpected and unpredictable results.

As part of the fix for this problem, the semantics of these options have been clarified; because of this, the rules governing their evaluation have changed slightly. These changes be summed up as follows:

- All `--include-*` and `--exclude-*` options are now evaluated from right to left in the order in which they are passed to `ndb_restore`.
- All `--include-*` and `--exclude-*` options are now cumulative.
- In the event of a conflict, the first (rightmost) option takes precedence.

For more detailed information and examples, see [Section 17.4.17, “ndb\\_restore — Restore a MySQL Cluster Backup”](#). ([Bug#48907](#))

- When performing tasks that generated large amounts of I/O (such as when using `ndb_restore`), an internal memory buffer could overflow, causing data nodes to fail with signal 6.

Subsequent analysis showed that this buffer was not actually required, so this fix removes it. ([Bug#48861](#))

- Exhaustion of send buffer memory or long signal memory caused data nodes to crash. Now an appropriate error message is provided instead when this situation occurs. ([Bug#48852](#))
- Under certain conditions, accounting of the number of free scan records in the local query handler could be incorrect, so that during node recovery or a local checkpoint operations, the LQH could find itself lacking a scan record that is expected to find, causing the node to crash. ([Bug#48697](#))

See also [Bug#48564](#).

- The creation of an ordered index on a table undergoing DDL operations could cause a data node crash under certain timing-dependent conditions. ([Bug#48604](#))
- During an LCP master takeover, when the newly elected master did not receive a `COPY_GCI` LCP protocol message but other nodes participating in the local checkpoint had received one, the new master could use an uninitialized variable, which caused it to crash. ([Bug#48584](#))
- When running many parallel scans, a local checkpoint (which performs a scan internally) could find itself not getting a scan record, which led to a data node crash. Now an extra scan record is reserved for this purpose, and a problem with obtaining the scan record returns an appropriate error (error code 489, `TOO MANY ACTIVE SCANS`). ([Bug#48564](#))
- During a node restart, logging was enabled on a per-fragment basis as the copying of each fragment was completed but local

checkpoints were not enabled until all fragments were copied, making it possible to run out of redo log file space (NDB error code 410) before the restart was complete. Now logging is enabled only after all fragments have been copied, just prior to enabling local checkpoints. ([Bug#48474](#))

- When employing NDB native backup to back up and restore an empty NDB table that used a non-sequential AUTO\_INCREMENT value, the AUTO\_INCREMENT value was not restored correctly. ([Bug#48005](#))
- `ndb_config --xml --configinfo` now indicates that parameters belonging in the [SCI], [SCI DEFAULT], [SHM], and [SHM DEFAULT] sections of the `config.ini` file are deprecated or experimental, as appropriate. ([Bug#47365](#))
- NDB stores blob column data in a separate, hidden table that is not accessible from MySQL. If this table was missing for some reason (such as accidental deletion of the file corresponding to the hidden table) when making a MySQL Cluster native backup, `ndb_restore` crashed when attempting to restore the backup. Now in such cases, `ndb_restore` fails with the error message TABLE `TABLE_NAME` HAS BLOB COLUMN (`COLUMN_NAME`) WITH MISSING PARTS TABLE IN BACKUP instead. ([Bug#47289](#))
- `DROP DATABASE` failed when there were stale temporary NDB tables in the database. This situation could occur if `mysqld` crashed during execution of a `DROP TABLE` statement after the table definition had been removed from `NDBCLUSTER` but before the corresponding `.ndb` file had been removed from the crashed SQL node's data directory. Now, when `mysqld` executes `DROP DATABASE`, it checks for these files and removes them if there are no corresponding table definitions for them found in `NDBCLUSTER`. ([Bug#44529](#))
- Creating an NDB table with an excessive number of large BIT columns caused the cluster to fail. Now, an attempt to create such a table is rejected with error 791 (TOO MANY TOTAL BITS IN BITFIELDS). ([Bug#42046](#))

See also [Bug#42047](#).

- When a long-running transaction lasting long enough to cause Error 410 (REDO LOG FILES OVERLOADED) was later committed or rolled back, it could happen that `NDBCLUSTER` was not able to release the space used for the REDO log, so that the error condition persisted indefinitely.

The most likely cause of such transactions is a bug in the application using MySQL Cluster. This fix should handle most cases where this might occur. ([Bug#36500](#))

- Deprecation and usage information obtained from `ndb_config --configinfo` regarding the `PortNumber` and `ServerPort` configuration parameters was improved. ([Bug#24584](#))
- Disk Data:** When running a write-intensive workload with a very large disk page buffer cache, CPU usage approached 100% during a local checkpoint of a cluster containing Disk Data tables. ([Bug#49532](#))
- Disk Data:** Repeatedly creating and then dropping Disk Data tables could eventually lead to data node failures. ([Bug#45794](#), [Bug#48910](#))
- Disk Data:** When the `FileSystemPathUndoFiles` configuration parameter was set to an non-existent path, the data nodes shut down with the generic error code 2341 (INTERNAL PROGRAM ERROR). Now in such cases, the error reported is error 2815 (FILE NOT FOUND).
- Cluster Replication:** When `expire_logs_days` was set, the thread performing the purge of the log files could deadlock, causing all binary log operations to stop. ([Bug#49536](#))
- Cluster API:** When a DML operation failed due to a uniqueness violation on an NDB table having more than one unique index, it was difficult to determine which constraint caused the failure; it was necessary to obtain an `NdbError` object, then decode its `details` property, which could lead to memory management issues in application code.

To help solve this problem, a new API method `Ndb::getNdbErrorDetail()` is added, providing a well-formatted string containing more precise information about the index that caused the unique constraint violation. The following additional changes are also made in the NDB API:

- Use of `NdbError.details` is now deprecated in favor of the new method.
- The `NdbDictionary::listObjects()` method has been modified to provide more information.

For more information, see `Ndb::getNdbErrorDetail()`, [The NdbError Structure](#), and `Dictionary::listObjects()`. ([Bug#48851](#))

- Cluster API:** When using blobs, calling `getBlobHandle()` requires the full key to have been set using `equal()`, because `getBlobHandle()` must access the key for adding blob table operations. However, if `getBlobHandle()` was called without first setting all parts of the primary key, the application using it crashed. Now, an appropriate error code is returned instead. ([Bug#28116](#), [Bug#48973](#))

### 17.7.3.13. Changes in MySQL Cluster NDB 6.3.28b (5.1.39-ndb-6.3.28b) (10 November 2009)

This release includes a fix for [Bug#48651](#), which was discovered in MySQL Cluster NDB 6.3.28a shortly after release. The MySQL Cluster NDB 6.3.28b release is identical in all other respects to MySQL Cluster NDB 6.3.28a. Users who have already installed MySQL Cluster NDB 6.3.28a should upgrade to MySQL Cluster NDB 6.3.28b as soon as possible; users seeking to upgrade from any other previous MySQL Cluster 6.3 release should upgrade to MySQL Cluster NDB 6.3.28b instead.

This is a source-only release. You can obtain the GPL source code for MySQL Cluster NDB 6.3.28b from <http://dev.mysql.com/downloads/cluster/>.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.39 (see [Section C.1.15, “Changes in MySQL 5.1.39 \(04 September 2009\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- When the combined length of all names of tables using the `NDB` storage engine was greater than or equal to 1024 bytes, issuing the `START BACKUP` command in the `ndb_mgm` client caused the cluster to crash. ([Bug#48531](#))

### 17.7.3.14. Changes in MySQL Cluster NDB 6.3.28a (5.1.39-ndb-6.3.28a) (05 November 2009)

#### Important

MySQL Cluster NDB 6.3.28a was pulled shortly after release due to [Bug#48651](#). Users seeking to upgrade from a previous MySQL Cluster NDB 6.3 release should instead use MySQL Cluster NDB 6.3.28b, which contains a fix for this bug, in addition to all bugfixes and improvements made in MySQL Cluster NDB 6.3.28a.

This release includes a fix for [Bug#48531](#), which was discovered in MySQL Cluster NDB 6.3.28 shortly after release. The MySQL Cluster NDB 6.3.28a release is identical in all other respects to MySQL Cluster NDB 6.3.28. Users who have already installed MySQL Cluster NDB 6.3.28 should upgrade to MySQL Cluster NDB 6.3.28a as soon as possible; users seeking to upgrade from any other previous MySQL Cluster 6.3 release should upgrade to MySQL Cluster NDB 6.3.28a instead.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.39 (see [Section C.1.15, “Changes in MySQL 5.1.39 \(04 September 2009\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- When the combined length of all names of tables using the `NDB` storage engine was greater than or equal to 1024 bytes, issuing the `START BACKUP` command in the `ndb_mgm` client caused the cluster to crash. ([Bug#48531](#))

### 17.7.3.15. Changes in MySQL Cluster NDB 6.3.28 (5.1.39-ndb-6.3.28) (31 October 2009)

#### Important

MySQL Cluster NDB 6.3.28 and 6.3.28a were pulled shortly after being released due to [Bug#48531](#) and [Bug#48651](#). Users seeking to upgrade from a previous MySQL Cluster NDB 6.3 release should instead use MySQL Cluster NDB 6.3.28b, which contains fixes for these critical bugs, in addition to all bugfixes and improvements made in MySQL Cluster NDB 6.3.28.

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.3 release.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.39 (see [Section C.1.15, “Changes in MySQL 5.1.39 \(04 September 2009\)”](#)).

### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **Performance:** Significant improvements in redo log handling and other filesystem operations can yield a considerable reduction in the time required for restarts. While actual restart times observed in a production setting will naturally vary according to database size, hardware, and other conditions, our own preliminary testing shows that these optimizations can yield startup times that are faster than those typical of previous MySQL Cluster releases by a factor of 50 or more.

Bugs fixed:

- **Important Change:** The `--with-ndb-port-base` option for `configure` did not function correctly, and has been deprecated. Attempting to use this option produces the warning `IGNORING DEPRECATED OPTION --WITH-NDB-PORT-BASE`.

Beginning with MySQL Cluster NDB 7.1.0, the deprecation warning itself is removed, and the `--with-ndb-port-base` option is simply handled as an unknown and invalid option if you try to use it. ([Bug#47941](#))

See also [Bug#38502](#).

- In certain cases, performing very large inserts on `NDB` tables when using `ndbmtd` caused the memory allocations for ordered or unique indexes (or both) to be exceeded. This could cause aborted transactions and possibly lead to data node failures. ([Bug#48037](#))

See also [Bug#48113](#).

- For `UPDATE IGNORE` statements, batching of updates is now disabled. This is because such statements failed when batching of updates was employed if any updates violated a unique constraint, to the fact a unique constraint violation could not be handled without aborting the transaction. ([Bug#48036](#))
- Starting a data node with a very large amount of `DataMemory` (approximately 90G or more) could lead to crash of the node due to job buffer congestion. ([Bug#47984](#))
- When an `UPDATE` statement was issued against an `NDB` table where an index was used to identify rows but no data was actually changed, the `NDB` storage returned zero found rows.

For example, consider the table created and populated using these statements:

```
CREATE TABLE t1
(
 c1 INT NOT NULL,
 c2 INT NOT NULL,
 PRIMARY KEY(c1),
 KEY(c2)
)
ENGINE = NDB;

INSERT INTO t1 VALUES(1, 1);
```

The following `UPDATE` statements, even though they did not change any rows, each still matched a row, but this was reported incorrectly in both cases, as shown here:

```
mysql> UPDATE t1 SET c2 = 1 WHERE c1 = 1;
Query OK, 0 rows affected (0.00 sec)
Rows matched: 0 Changed: 0 Warnings: 0

mysql> UPDATE t1 SET c1 = 1 WHERE c2 = 1;
Query OK, 0 rows affected (0.00 sec)
Rows matched: 0 Changed: 0 Warnings: 0
```

Now in such cases, the number of rows matched is correct. (In the case of each of the example `UPDATE` statements just shown, this is displayed as Rows matched: 1, as it should be.)

This issue could affect `UPDATE` statements involving any indexed columns in `NDB` tables, regardless of the type of index (including `KEY`, `UNIQUE KEY`, and `PRIMARY KEY`) or the number of columns covered by the index. ([Bug#47955](#))

- On Solaris, shutting down a management node failed when issuing the command to do so from a client connected to a different management node. ([Bug#47948](#))

- Setting `FragmentLogFile` to a value greater than 256 MB led to errors when trying to read the redo log file. ([Bug#47908](#))
- `SHOW CREATE TABLE` did not display the `AUTO_INCREMENT` value for `NDB` tables having `AUTO_INCREMENT` columns. ([Bug#47865](#))
- Under some circumstances, when a scan encountered an error early in processing by the `DBTC` kernel block (see [The DBTC Block](#)), a node could crash as a result. Such errors could be caused by applications sending incorrect data, or, more rarely, by a `DROP TABLE` operation executed in parallel with a scan. ([Bug#47831](#))
- When starting a node and synchronizing tables, memory pages were allocated even for empty fragments. In certain situations, this could lead to insufficient memory. ([Bug#47782](#))
- A very small race-condition between `NODE_FAILREP` and `LQH_TRANSREQ` signals when handling node failure could lead to operations (locks) not being taken over when they should have been, and subsequently becoming stale. This could lead to node restart failures, and applications getting into endless lock-conflicts with operations that were not released until the node was re-started. ([Bug#47715](#))

See also [Bug#41297](#).

- `configure` failed to honor the `--with-zlib-dir` option when trying to build MySQL Cluster from source. ([Bug#47223](#))
- `ndbd` was not built correctly when compiled using `gcc` 4.4.0. (The `ndbd` binary was built, but could not be started.) ([Bug#46113](#))
- If a node failed while sending a fragmented long signal, the receiving node did not free long signal assembly resources that it had allocated for the fragments of the long signal that had already been received. ([Bug#44607](#))
- When starting a cluster with a great many tables, it was possible for MySQL client connections as well as the slave SQL thread to issue DML statements against MySQL Cluster tables before `mysqld` had finished connecting to the cluster and making all tables writeable. This resulted in `TABLE ... IS READ ONLY` errors for clients and the Slave SQL thread.

This issue is fixed by introducing the `--ndb-wait-setup` option for the MySQL server. This provides a configurable maximum amount of time that `mysqld` waits for all `NDB` tables to become writeable, before enabling MySQL clients or the slave SQL thread to connect. ([Bug#40679](#))

See also [Bug#46955](#).

- When building MySQL Cluster, it was possible to configure the build using `--with-ndb-port` without supplying a port number. Now in such cases, `configure` fails with an error. ([Bug#38502](#))

See also [Bug#47941](#).

- When the MySQL server SQL mode included `STRICT_TRANS_TABLES`, storage engine warnings and error codes specific to `NDB` were returned when errors occurred, instead of the MySQL server errors and error codes expected by some programming APIs (such as Connector/J) and applications. ([Bug#35990](#))
- When a copying operation exhausted the available space on a data node while copying large `BLOB` columns, this could lead to failure of the data node and a `TABLE IS FULL` error on the SQL node which was executing the operation. Examples of such operations could include an `ALTER TABLE` that changed an `INT` column to a `BLOB` column, or a bulk insert of `BLOB` data that failed due to running out of space or to a duplicate key error. ([Bug#34583](#), [Bug#48040](#))

See also [Bug#41674](#), [Bug#45768](#).

- **Replication:** When `mysqlbinlog --verbose` was used to read a binary log that had been recorded using the row-based format, the output for events that updated some but not all columns of tables was not correct. ([Bug#47323](#))
- **Disk Data:** A local checkpoint of an empty fragment could cause a crash during a system restart which was based on that LCP. ([Bug#47832](#))

See also [Bug#41915](#).

- **Cluster Replication:** When using multiple active replication channels, it was sometimes possible that a node group would fail on the slave cluster, causing the slave cluster to shut down. ([Bug#47935](#))
- **Cluster Replication:** When recording a binary log using the `--ndb-log-update-as-write` and `--ndb-log-updated-only` options (both enabled by default) and later attempting to apply that binary log with `mysqlbinlog`, any operations that were played back from the log but which updated only some (but not all) columns caused any columns that were not updated to be reset to their default values. ([Bug#47674](#))

See also [Bug#47323](#), [Bug#46662](#).

- **Cluster Replication:** `mysqlbinlog` failed to apply correctly a binary log that had been recorded using `-ndb-log-update-as-write=1`. ([Bug#46662](#))  
See also [Bug#47323](#), [Bug#47674](#).
- **Cluster API:** If an NDB API program reads the same column more than once, it is possible exceed the maximum permissible message size, in which case the operation should be aborted due to NDB error 880 TRIED TO READ TOO MUCH - TOO MANY GETVALUE CALLS, however due to a change introduced in MySQL Cluster NDB 6.3.18, the check for this was not done correctly, which instead caused a data node crash. ([Bug#48266](#))
- **Cluster API:** The NDB API methods `Dictionary::listEvents()`, `Dictionary::listIndexes()`, `Dictionary::listObjects()`, and `NdbOperation::getErrorLine()` formerly had both `const` and non-`const` variants. The non-`const` versions of these methods have been removed. In addition, the `NdbOperation::getBlobHandle()` method has been re-implemented to provide consistent internal semantics. ([Bug#47798](#))
- **Cluster API:** A duplicate read of a column caused NDB API applications to crash. ([Bug#45282](#))
- **Cluster API:** The error handling shown in the example file `ndbapi_scan.cpp` included with the MySQL Cluster distribution was incorrect. ([Bug#39573](#))
- Installation of MySQL on Windows would fail to set the correct location for the character set files, which could lead to `mysqld` and `mysql` failing to initialize properly. ([Bug#17270](#))

### 17.7.3.16. Changes in MySQL Cluster NDB 6.3.27a (5.1.37-ndb-6.3.27a) (07 October 2009)

This release includes a fix for [Bug#47844](#), which was discovered in MySQL Cluster NDB 6.3.27 shortly after release. The MySQL Cluster NDB 6.3.27a release is identical in all other respects to MySQL Cluster NDB 6.3.27. Users who have already installed MySQL Cluster NDB 6.3.27 should upgrade to MySQL Cluster NDB 6.3.27a as soon as possible; users seeking to upgrade from MySQL Cluster NDB 6.3.26 or another previous MySQL Cluster 6.3 release should upgrade to MySQL Cluster NDB 6.3.27a instead.

This is a source-only release. You can obtain the GPL source code for MySQL Cluster NDB 6.3.27a from [ftp://ftp.mysql.com/pub/mysql/download/cluster\\_telco/mysql-5.1.37-ndb-6.3.27a/](ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/mysql-5.1.37-ndb-6.3.27a/).

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.37 (see [Section C.1.18, “Changes in MySQL 5.1.37 \(13 July 2009\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- The disconnection of an API or SQL node having a node ID greater than 49 caused a forced shutdown of the cluster. ([Bug#47844](#))
- The error message text for NDB error code 410 (REDO LOG FILES OVERLOADED...) was truncated. ([Bug#23662](#))

### 17.7.3.17. Changes in MySQL Cluster NDB 6.3.27 (5.1.37-ndb-6.3.27) (30 September 2009)

#### Important

MySQL Cluster NDB 6.3.27 was pulled shortly after release due to [Bug#47844](#). Users seeking to upgrade from a previous MySQL Cluster NDB 6.3 release should instead use MySQL Cluster NDB 6.3.27a, which contains a fix for this bug, in addition to all bugfixes and improvements made in MySQL Cluster NDB 6.3.27.

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.3 release.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.37 (see [Section C.1.18, “Changes in MySQL 5.1.37 \(13 July 2009\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this ver-

■ sion.

Functionality added or changed:

- **Disk Data:** Two new columns have been added to the output of `ndb_desc` to make it possible to determine how much of the disk space allocated to a given table or fragment remains free. (This information is not available from the `INFORMATION_SCHEMA.FILES` table, since the `FILES` table applies only to Disk Data files.) For more information, see [Section 17.4.9, “`ndb\_desc` — Describe NDB Tables”](#). ([Bug#47131](#))

Bugs fixed:

- **Cluster Replication: Important Change:** In a MySQL Cluster acting as a replication slave and having multiple SQL nodes, only the SQL node receiving events directly from the master recorded DDL statements in its binary logs unless this SQL node also had binary logging enabled; otherwise, other SQL nodes in the slave cluster failed to log DDL statements, regardless of their individual `--log-bin` settings.

The fix for this issue aligns binary logging of DDL statements with that of DML statements. In particular, you should take note of the following:

- DDL and DML statements on the master cluster are logged with the server ID of the server that actually writes the log.
- DDL and DML statements on the master cluster are logged by any attached `mysqld` that has binary logging enabled.
- Replicated DDL and DML statements on the slave are logged by any attached `mysqld` that has both `--log-bin` and `-log-slave-updates` enabled.
- Replicated DDL and DML statements are logged with the server ID of the original (master) MySQL server by any attached `mysqld` that has both `--log-bin` and `--log-slave-updates` enabled.

**Affect on upgrades.** When upgrading from a previous MySQL CLuster release, you should perform either one of the following:

- a. Upgrade servers that are performing binary logging before those that are not; do not perform any DDL on “old” SQL nodes until all SQL nodes have been upgraded.
- b. Make sure that `--log-slave-updates` is enabled on all SQL nodes performing binary logging prior to the upgrade, so that all DDL is captured.

## Note

■ Logging of DML statements was not affected by this issue.

([Bug#45756](#))

- `mysqld` allocated an excessively large buffer for handling `BLOB` values due to overestimating their size. (For each row, enough space was allocated to accommodate *every* `BLOB` or `TEXT` column value in the result set.) This could adversely affect performance when using tables containing `BLOB` or `TEXT` columns; in a few extreme cases, this issue could also cause the host system to run out of memory unexpectedly. ([Bug#47574](#))

See also [Bug#47572](#), [Bug#47573](#).

- `NDBCLUSTER` uses a dynamically-allocated buffer to store `BLOB` or `TEXT` column data that is read from rows in MySQL Cluster tables.

When an instance of the `NDBCLUSTER` table handler was recycled (this can happen due to table definition cache pressure or to operations such as `FLUSH TABLES` or `ALTER TABLE`), if the last row read contained blobs of zero length, the buffer was not freed, even though the reference to it was lost. This resulted in a memory leak.

For example, consider the table defined and populated as shown here:

```
CREATE TABLE t (a INT PRIMARY KEY, b LONGTEXT) ENGINE=NDB;
INSERT INTO t VALUES (1, REPEAT('F', 20000));
INSERT INTO t VALUES (2, ''');
```

Now execute repeatedly a `SELECT` on this table, such that the zero-length `LONGTEXT` row is last, followed by a `FLUSH TABLES` statement (which forces the handler object to be re-used), as shown here:

```
SELECT a, length(b) FROM bl ORDER BY a;
```

```
FLUSH TABLES;
```

Prior to the fix, this resulted in a memory leak proportional to the size of the stored `LONGTEXT` value each time these two statements were executed. ([Bug#47573](#))

See also [Bug#47572](#), [Bug#47574](#).

- Large transactions involving joins between tables containing `BLOB` columns used excessive memory. ([Bug#47572](#))

See also [Bug#47573](#), [Bug#47574](#).

- A variable was left uninitialized while a data node copied data from its peers as part of its startup routine; if the starting node died during this phase, this could lead a crash of the cluster when the node was later restarted. ([Bug#47505](#))
- When a data node restarts, it first runs the redo log until reaching the latest restorable global checkpoint; after this it scans the remainder of the redo log file, searching for entries that should be invalidated so they are not used in any subsequent restarts. (It is possible, for example, if restoring GCI number 25, that there might be entries belonging to GCI 26 in the redo log.) However, under certain rare conditions, during the invalidation process, the redo log files themselves were not always closed while scanning ahead in the redo log. In rare cases, this could lead to `MaxNoOfOpenFiles` being exceeded, causing the data node to crash. ([Bug#47171](#))
- For very large values of `MaxNoOfTables` + `MaxNoOfAttributes`, the calculation for `StringMemory` could overflow when creating large numbers of tables, leading to NDB error 773 (OUT OF STRING MEMORY, PLEASE MODIFY STRINGMEMORY CONFIG PARAMETER), even when `StringMemory` was set to 100 (100 percent). ([Bug#47170](#))
- The default value for the `StringMemory` configuration parameter, unlike other MySQL Cluster configuration parameters, was not set in `ndb/src/mgmsrv/ConfigInfo.cpp`. ([Bug#47166](#))
- Signals from a failed API node could be received after an `API_FAILREQ` signal (see [Operations and Signals](#)) has been received from that node, which could result in invalid states for processing subsequent signals. Now, all pending signals from a failing API node are processed before any `API_FAILREQ` signal is received. ([Bug#47039](#))

See also [Bug#44607](#).

- Using triggers on `NDB` tables caused `ndb_autoincrement_prefetch_sz` to be treated as having the NDB kernel's internal default value (32) and the value for this variable as set on the cluster's SQL nodes to be ignored. ([Bug#46712](#))
- Running an `ALTER TABLE` statement while an NDB backup was in progress caused `mysqld` to crash. ([Bug#44695](#))
- When performing auto-discovery of tables on individual SQL nodes, `NDBCLUSTER` attempted to overwrite existing `MyISAM.frm` files and corrupted them.

**Workaround.** In the `mysql` client, create a new table (`t2`) with same definition as the corrupted table (`t1`). Use your system shell or file manager to rename the old `.MYD` file to the new file name (for example, `mv t1.MYD t2.MYD`). In the `mysql` client, repair the new table, drop the old one, and rename the new table using the old file name (for example, `RENAME TABLE t2 TO t1`).

([Bug#42614](#))

- Running `ndb_restore` with the `--print` or `--print_log` option could cause it to crash. ([Bug#40428](#), [Bug#33040](#))
- An insert on an `NDB` table was not always flushed properly before performing a scan. One way in which this issue could manifest was that `LAST_INSERT_ID()` sometimes failed to return correct values when using a trigger on an `NDB` table. ([Bug#38034](#))
- When a data node received a `TAKE_OVERTCCONF` signal from the master before that node had received a `NODE_FAILREP`, a race condition could in theory result. ([Bug#37688](#))

See also [Bug#25364](#), [Bug#28717](#).

- Some joins on large `NDB` tables having `TEXT` or `BLOB` columns could cause `mysqld` processes to leak memory. The joins did not need to reference the `TEXT` or `BLOB` columns directly for this issue to occur. ([Bug#36701](#))
- On Mac OS X 10.5, commands entered in the management client failed and sometimes caused the client to hang, although management client commands invoked using the `--execute` (or `-e`) option from the system shell worked normally.

For example, the following command failed with an error and hung until killed manually, as shown here:

```
ndb_mgm> SHOW
WARNING, EVENT THREAD STARTUP FAILED, DEGRADED PRINTOUTS AS RESULT, ERRNO=36
^C
```

However, the same management client command, invoked from the system shell as shown here, worked correctly:

```
shell> ndb_mgm -e "SHOW"
```

(Bug#35751)

See also Bug#34438.

- **Replication:** In some cases, a `STOP SLAVE` statement could cause the replication slave to crash. This issue was specific to MySQL on Windows or Macintosh platforms. (Bug#45238, Bug#45242, Bug#45243, Bug#46013, Bug#46014, Bug#46030)  
See also Bug#40796.
- **Disk Data:** Calculation of free space for Disk Data table fragments was sometimes done incorrectly. This could lead to unnecessary allocation of new extents even when sufficient space was available in existing ones for inserted data. In some cases, this might also lead to crashes when restarting data nodes.

#### Note

This miscalculation was not reflected in the contents of the `INFORMATION_SCHEMA.FILES` table, as it applied to extents allocated to a fragment, and not to a file.

(Bug#47072)

- **Cluster API:** In some circumstances, if an API node encountered a data node failure between the creation of a transaction and the start of a scan using that transaction, then any subsequent calls to `startTransaction()` and `closeTransaction()` could cause the same transaction to be started and closed repeatedly. (Bug#47329)
- **Cluster API:** Performing multiple operations using the same primary key within the same `NdbTransaction::execute()` call could lead to a data node crash.

#### Note

This fix does not make change the fact that performing multiple operations using the same primary key within the same `execute()` is not supported; because there is no way to determine the order of such operations, the result of such combined operations remains undefined.

(Bug#44065)

See also Bug#44015.

- **API:** The fix for Bug#24507 could lead in some cases to client application failures due to a race condition. Now the server waits for the “dummy” thread to return before exiting, thus making sure that only one thread can initialize the POSIX threads library. (Bug#42850)

### 17.7.3.18. Changes in MySQL Cluster NDB 6.3.26 (5.1.35-ndb-6.3.26) (26 August 2009)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.3 release.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.35 (see Section C.1.20, “Changes in MySQL 5.1.35 (13 May 2009)”).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- On Solaris platforms, the MySQL Cluster management server and NDB API applications now use `CLOCK_REALTIME` as the default clock. (Bug#46183)
- A new option `--exclude-missing-columns` has been added for the `ndb_restore` program. In the event that any tables in the database or databases being restored to have fewer columns than the same-named tables in the backup, the extra columns in the backup's version of the tables are ignored. For more information, see Section 17.4.17, “`ndb_restore` — Re-

store a MySQL Cluster Backup". ([Bug#43139](#))

- **Note**

This issue, originally resolved in MySQL 5.1.16, re-occurred due to a later (unrelated) change. The fix has been re-applied.

([Bug#25984](#))

Bugs fixed:

- Restarting the cluster following a local checkpoint and an online `ALTER TABLE` on a non-empty table caused data nodes to crash. ([Bug#46651](#))
- Full table scans failed to execute when the cluster contained more than 21 table fragments.

- **Note**

The number of table fragments in the cluster can be calculated as the number of data nodes, times 8 (that is, times the value of the internal constant `MAX_FRAG_PER_NODE`), divided by the number of replicas. Thus, when `NoOfReplicas = 1` at least 3 data nodes were required to trigger this issue, and when `NoOfReplicas = 2` at least 4 data nodes were required to do so.

([Bug#46490](#))

- Killing MySQL Cluster nodes immediately following a local checkpoint could lead to a crash of the cluster when later attempting to perform a system restart.

The exact sequence of events causing this issue was as follows:

1. Local checkpoint occurs.
2. Immediately following the LCP, kill the master data node.
3. Kill the remaining data nodes within a few seconds of killing the master.
4. Attempt to restart the cluster.

([Bug#46412](#))

- Ending a line in the `config.ini` file with an extra semicolon character (`:`) caused reading the file to fail with a parsing error. ([Bug#46242](#))
- When combining an index scan and a delete with a primary key delete, the index scan and delete failed to initialize a flag properly. This could in rare circumstances cause a data node to crash. ([Bug#46069](#))
- `OPTIMIZE TABLE` on an `NDB` table could in some cases cause SQL and data nodes to crash. This issue was observed with both `ndbd` and `ndbmtd`. ([Bug#45971](#))
- The `AutoReconnect` configuration parameter for API nodes (including SQL nodes) has been added. This is intended to prevent API nodes from re-using allocated node IDs during cluster restarts. For more information, see [Section 17.3.2.7, “Defining SQL and Other API Nodes in a MySQL Cluster”](#).

This fix also introduces two new methods of the `Ndb_cluster_connection` class in the NDB API. For more information, see `Ndb_cluster_connection::set_auto_reconnect()`, and `Ndb_cluster_connection::get_auto_reconnect()`. ([Bug#45921](#))

- The signals used by `ndb_restore` to send progress information about backups to the cluster log accessed the cluster transporter without using any locks. Because of this, it was theoretically possible that these signals could be interfered with by heartbeat signals if both were sent at the same time, causing the `ndb_restore` messages to be corrupted. ([Bug#45646](#))
- Problems could arise when using `VARCHAR` columns whose size was greater than 341 characters and which used the `utf8_unicode_ci` collation. In some cases, this combination of conditions could cause certain queries and `OPTIMIZE TABLE` statements to crash `mysqld`. ([Bug#45053](#))
- An internal NDB API buffer was not properly initialized. ([Bug#44977](#))
- When a data node had written its GCI marker to the first page of a megabyte, and that node was later killed during restart after

having processed that page (marker) but before completing a LCP, the data node could fail with filesystem errors. ([Bug#44952](#))

See also [Bug#42564](#), [Bug#44291](#).

- The warning message `POSSIBLE BUG IN DBDIH::EXECBLOCK_COMMIT_ORD ...` could sometimes appear in the cluster log. This warning is obsolete, and has been removed. ([Bug#44563](#))
- In some cases, `OPTIMIZE TABLE` on an `NDB` table did not free any `DataMemory`. ([Bug#43683](#))
- If the cluster crashed during the execution of a `CREATE LOGFILE GROUP` statement, the cluster could not be restarted afterward. ([Bug#36702](#))

See also [Bug#34102](#).

- **Disk Data: Partitioning:** An `NDBCLUSTER` table created with a very large value for the `MAX_ROWS` option could—if this table was dropped and a new table with fewer partitions, but having the same table ID, was created—cause `ndbd` to crash when performing a system restart. This was because the server attempted to examine each partition whether or not it actually existed. ([Bug#45154](#))
- **Disk Data:** If the value set in the `config.ini` file for `FileSystemPathDD`, `FileSystemPathDataFiles`, or `FileSystemPathUndoFiles` was identical to the value set for `FileSystemPath`, that parameter was ignored when starting the data node with `--initial` option. As a result, the Disk Data files in the corresponding directory were not removed when performing an initial start of the affected data node or data nodes. ([Bug#46243](#))
- **Disk Data:** During a checkpoint, restore points are created for both the on-disk and in-memory parts of a Disk Data table. Under certain rare conditions, the in-memory restore point could include or exclude a row that should have been in the snapshot. This would later lead to a crash during or following recovery. ([Bug#41915](#))

See also [Bug#47832](#).

### 17.7.3.19. Changes in MySQL Cluster NDB 6.3.25 (5.1.34-ndb-6.3.25) (25 May 2009)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.3 release.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.34 (see [Section C.1.22, “Changes in MySQL 5.1.34 \(02 April 2009\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- Two new server status variables `Ndb_scan_count` and `Ndb_pruned_scan_count` have been introduced. `Ndb_scan_count` gives the number of scans executed since the cluster was last started. `Ndb_pruned_scan_count` gives the number of scans for which `NDBCLUSTER` was able to use partition pruning. Together, these variables can be used to help determine in the MySQL server whether table scans are pruned by `NDBCLUSTER`. ([Bug#44153](#))
- The `ndb_config` utility program can now provide an offline dump of all MySQL Cluster configuration parameters including information such as default and permitted values, brief description, and applicable section of the `config.ini` file. A dump in text format is produced when running `ndb_config` with the new `--configinfo` option, and in XML format when the options `--configinfo --xml` are used together. For more information and examples, see [Section 17.4.6, “ndb\\_config — Extract MySQL Cluster Configuration Information”](#).

Bugs fixed:

- **Important Change: Partitioning:** User-defined partitioning of an `NDBCLUSTER` table without any primary key sometimes failed, and could cause `mysqld` to crash.

Now, if you wish to create an `NDBCLUSTER` table with user-defined partitioning, the table must have an explicit primary key, and all columns listed in the partitioning expression must be part of the primary key. The hidden primary key used by the `NDBCLUSTER` storage engine is not sufficient for this purpose. However, if the list of columns is empty (that is, the table is defined using `PARTITION BY [LINEAR] KEY()`), then no explicit primary key is required.

This change does not effect the partitioning of tables using any storage engine other than `NDBCLUSTER`. ([Bug#40709](#))

- **Important Change:** Previously, the configuration parameter `NoOfReplicas` had no default value. Now the default for `NoOfReplicas` is 2, which is the recommended value in most settings. ([Bug#44746](#))
- **Packaging:** The `pkg` installer for MySQL Cluster on Solaris did not perform a complete installation due to an invalid directory reference in the post-install script. ([Bug#41998](#))
- When `ndb_config` could not find the file referenced by the `--config-file` option, it tried to read `my.cnf` instead, then failed with a misleading error message. ([Bug#44846](#))
- When a data node was down so long that its most recent local checkpoint depended on a global checkpoint that was no longer restorable, it was possible for it to be unable to use optimized node recovery when being restarted later. ([Bug#44844](#))

See also [Bug#26913](#).

- `ndb_config --xml` did not output any entries for the `HostName` parameter. In addition, the default listed for `MaxNoOfFiles` was outside the permitted range of values. ([Bug#44749](#))

See also [Bug#44685](#), [Bug#44746](#).

- The output of `ndb_config --xml` did not provide information about all sections of the configuration file. ([Bug#44685](#))

See also [Bug#44746](#), [Bug#44749](#).

- Inspection of the code revealed that several assignment operators (`=`) were used in place of comparison operators (`==`) in `Db-dihMain.cpp`. ([Bug#44567](#))

See also [Bug#44570](#).

- It was possible for NDB API applications to insert corrupt data into the database, which could subsequently lead to data node crashes. Now, stricter checking is enforced on input data for inserts and updates. ([Bug#44132](#))
- `ndb_restore` failed when trying to restore data on a big-endian machine from a backup file created on a little-endian machine. ([Bug#44069](#))
- The file `ndberror.c` contained a C++-style comment, which caused builds to fail with some C compilers. ([Bug#44036](#))
- When trying to use a data node with an older version of the management server, the data node crashed on startup. ([Bug#43699](#))
- In some cases, data node restarts during a system restart could fail due to insufficient redo log space. ([Bug#43156](#))
- `NDBCLUSTER` did not build correctly on Solaris 9 platforms. ([Bug#39080](#))

See also [Bug#39036](#), [Bug#39038](#).

- `ndb_restore --print_data` did not handle `DECIMAL` columns correctly. ([Bug#37171](#))
- The output of `ndbd --help` did not provide clear information about the program's `--initial` and `--initial-start` options. ([Bug#28905](#))
- It was theoretically possible for the value of a nonexistent column to be read as `NULL`, rather than causing an error. ([Bug#27843](#))
- **Disk Data:** This fix supercedes and improves on an earlier fix made for this bug in MySQL 5.1.18. ([Bug#24521](#))
- **Cluster Replication:** A failure when setting up replication events could lead to subsequent data node failures. ([Bug#44915](#))

### 17.7.3.20. Changes in MySQL Cluster NDB 6.3.24 (5.1.32-ndb-6.3.24) (09 April 2009)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.3 release.

This is a source-only release. You can obtain the GPL source code for MySQL Cluster NDB 6.3.24 from [ftp://ftp.mysql.com/pub/mysql/download/cluster\\_telco/mysql-5.1.32-ndb-6.3.24/](http://ftp.mysql.com/pub/mysql/download/cluster_telco/mysql-5.1.32-ndb-6.3.24/).

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.32 (see [Section C.1.24, “Changes in MySQL 5.1.32 \(14 February 2009\)](#)”).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this ver-

■ sion.

Bugs fixed:

- **Cluster Replication:** If data node failed during an event creation operation, there was a slight risk that a surviving data node could send an invalid table reference back to NDB, causing the operation to fail with a false Error 723 (`NO SUCH TABLE`). This could take place when a data node failed as a `mysqld` process was setting up MySQL Cluster Replication. ([Bug#43754](#))

- **Cluster API:** Partition pruning did not work correctly for queries involving multiple range scans.

As part of the fix for this issue, several improvements have been made in the NDB API, including the addition of a new `NdbScanOperation::getPruned()` method, a new variant of `NdbIndexScanOperation::setBound()`, and a new `Ndb::PartitionSpec` data structure. For more information about these changes, see `NdbScanOperation::getPruned()`, `NdbIndexScanOperation::setBound`, and [The PartitionSpec Structure](#). ([Bug#37934](#))

- `TransactionDeadlockDetectionTimeout` values less than 100 were treated as 100. This could cause scans to time out unexpectedly. ([Bug#44099](#))
- A race condition could occur when a data node failed to restart just before being included in the next global checkpoint. This could cause other data nodes to fail. ([Bug#43888](#))
- `TimeBetweenLocalCheckpoints` was measured from the end of one local checkpoint to the beginning of the next, rather than from the beginning of one LCP to the beginning of the next. This meant that the time spent performing the LCP was not taken into account when determining the `TimeBetweenLocalCheckpoints` interval, so that LCPs were not started often enough, possibly causing data nodes to run out of redo log space prematurely. ([Bug#43567](#))
- Using indexes containing variable-sized columns could lead to internal errors when the indexes were being built. ([Bug#43226](#))
- When a data node process had been killed after allocating a node ID, but before making contact with any other data node processes, it was not possible to restart it due to a node ID allocation failure.

This issue could effect either `ndbd` or `ndbmt` processes. ([Bug#43224](#))

This regression was introduced by [Bug#42973](#).

- Some queries using combinations of logical and comparison operators on an indexed column in the `WHERE` clause could fail with the error `GOT ERROR 4541 'INDEXBOUND HAS NO BOUND INFORMATION' FROM NDBCLUSTER`. ([Bug#42857](#))
- `ndb_restore` crashed when trying to restore a backup made to a MySQL Cluster running on a platform having different endianness from that on which the original backup was taken. ([Bug#39540](#))
- When aborting an operation involving both an insert and a delete, the insert and delete were aborted separately. This was because the transaction coordinator did not know that the operations affected on same row, and, in the case of a committed-read (tuple or index) scan, the abort of the insert was performed first, then the row was examined after the insert was aborted but before the delete was aborted. In some cases, this would leave the row in a inconsistent state. This could occur when a local checkpoint was performed during a backup. This issue did not affect primary key operations or scans that used locks (these are serialized).

After this fix, for ordered indexes, all operations that follow the operation to be aborted are now also aborted.

- **Disk Data:** When a log file group had an undo log file whose size was too small, restarting data nodes failed with `READ UNDERFLOW` errors.

As a result of this fix, the minimum permitted `INITIAL_SIZE` for an undo log file is now `1M` (1 megabyte). ([Bug#29574](#))

- **Cluster Replication:** When creating or altering a table an `NdbEventOperation` is created by the `mysqld` process to monitor the table for subsequent logging in the binlog. If this happened during a node restart there was a chance that the reference count on this event operation object could be incorrect, which could lead to an assert in debug MySQL Cluster builds. ([Bug#43752](#))
- **Cluster API:** If the largest offset of a `RecordSpecification` used for an `NdbRecord` object was for the `NULL` bits (and thus not a column), this offset was not taken into account when calculating the size used for the `RecordSpecification`. This meant that the space for the `NULL` bits could be overwritten by key or other information. ([Bug#43891](#))
- **Cluster API:** `BIT` columns created using the native NDB API format that were not created as nullable could still sometimes be overwritten, or cause other columns to be overwritten.

This issue did not effect tables having `BIT` columns created using the `mysqld` format (always used by MySQL Cluster SQL nodes). ([Bug#43802](#))

- **Cluster API:** The default `NdbRecord` structures created by `NdbDictionary` could have overlapping null bits and data

fields. ([Bug#43590](#))

- **Cluster API:** When performing insert or write operations, `NdbRecord` permits key columns to be specified in both the key record and in the attribute record. Only one key column value for each key column should be sent to the NDB kernel, but this was not guaranteed. This is now ensured as follows: For insert and write operations, key column values are taken from the key record; for scan takeover update operations, key column values are taken from the attribute record. ([Bug#42238](#))
- **Cluster API:** Ordered index scans using `NdbRecord` formerly expressed a `BoundEQ` range as separate lower and upper bounds, resulting in 2 copies of the column values being sent to the NDB kernel.

Now, when a range is specified by `NdbScanOperation::setBound()`, the passed pointers, key lengths, and inclusive bits are compared, and only one copy of the equal key columns is sent to the kernel. This makes such operations more efficient, as half the amount of `KeyInfo` is now sent for a `BoundEQ` range as before. ([Bug#38793](#))

### 17.7.3.21. Changes in MySQL Cluster NDB 6.3.23 (5.1.32-ndb-6.3.23) (24 February 2009)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.3 release.

This is a source-only release. You can obtain the GPL source code for MySQL Cluster NDB 6.3.23 from [ftp://ftp.mysql.com/pub/mysql/download/cluster\\_telco/mysql-5.1.32-ndb-6.3.23/](ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/mysql-5.1.32-ndb-6.3.23/).

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.32 (see [Section C.1.24, “Changes in MySQL 5.1.32 \(14 February 2009\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **Important Change: Replication:** `RESET MASTER` and `RESET SLAVE` now reset the values shown for `Last_IO_Error`, `Last_IO_Errno`, `Last_SQL_Error`, and `Last_SQL_Errno` in the output of `SHOW SLAVE STATUS`. ([Bug#34654](#))

See also [Bug#44270](#).

- A new data node configuration parameter `MaxLCPStartDelay` has been introduced to facilitate parallel node recovery by causing a local checkpoint to be delayed while recovering nodes are synchronizing data dictionaries and other meta-information. For more information about this parameter, see [Section 17.3.2.6, “Defining MySQL Cluster Data Nodes”](#). ([Bug#43053](#))

Bugs fixed:

- **Performance:** Updates of the `SYSTAB_0` system table to obtain a unique identifier did not use transaction hints for tables having no primary key. In such cases the NDB kernel used a cache size of 1. This meant that each insert into a table not having a primary key required an update of the corresponding `SYSTAB_0` entry, creating a potential performance bottleneck.

With this fix, inserts on `NDB` tables without primary keys can be under some conditions be performed up to 100% faster than previously. ([Bug#39268](#))

- **Packaging:** Packages for MySQL Cluster were missing the `libndbclient.so` and `libndbclient.a` files. ([Bug#42278](#))
- **Partitioning:** Executing `ALTER TABLE ... REORGANIZE PARTITION` on an `NDBCCLUSTER` table having only one partition caused `mysqld` to crash. ([Bug#41945](#))

See also [Bug#40389](#).

- Backup IDs greater than  $2^{31}$  were not handled correctly, causing negative values to be used in backup directory names and printouts. ([Bug#43042](#))
- When using `ndbmtd`, NDB kernel threads could hang while trying to start the data nodes with `LockPagesInMainMemory` set to 1. ([Bug#43021](#))
- When using multiple management servers and starting several API nodes (possibly including one or more SQL nodes) whose connectstrings listed the management servers in different order, it was possible for 2 API nodes to be assigned the same node ID. When this happened it was possible for an API node not to get fully connected, consequently producing a number of errors

whose cause was not easily recognizable. ([Bug#42973](#))

- `ndb_error_reporter` worked correctly only with GNU `tar`. (With other versions of `tar`, it produced empty archives.) ([Bug#42753](#))
- Triggers on `NDBCLUSTER` tables caused such tables to become locked. ([Bug#42751](#))

See also [Bug#16229](#), [Bug#18135](#).

- Given a MySQL Cluster containing no data (that is, whose data nodes had all been started using `--initial`, and into which no data had yet been imported) and having an empty backup directory, executing `START BACKUP` with a user-specified backup ID caused the data nodes to crash. ([Bug#41031](#))
- In some cases, `NDB` did not check correctly whether tables had changed before trying to use the query cache. This could result in a crash of the debug MySQL server. ([Bug#40464](#))
- **Disk Data:** It was not possible to add an in-memory column online to a table that used a table-level or column-level `STORAGE DISK` option. The same issue prevented `ALTER ONLINE TABLE ... REORGANIZE PARTITION` from working on Disk Data tables. ([Bug#42549](#))
- **Disk Data:** Creating a Disk Data tablespace with a very large extent size caused the data nodes to fail. The issue was observed when using extent sizes of 100 MB and larger. ([Bug#39096](#))
- **Disk Data:** Trying to execute a `CREATE LOGFILE GROUP` statement using a value greater than `150M` for `UNDO_BUFFER_SIZE` caused data nodes to crash.

As a result of this fix, the upper limit for `UNDO_BUFFER_SIZE` is now `600M`; attempting to set a higher value now fails gracefully with an error. ([Bug#34102](#))

See also [Bug#36702](#).

- **Disk Data:** When attempting to create a tablespace that already existed, the error message returned was `TABLE OR INDEX WITH GIVEN NAME ALREADY EXISTS`. ([Bug#32662](#))
- **Disk Data:** Using a path or filename longer than 128 characters for Disk Data undo log files and tablespace data files caused a number of issues, including failures of `CREATE LOGFILE GROUP`, `ALTER LOGFILE GROUP`, `CREATE TABLESPACE`, and `ALTER TABLESPACE` statements, as well as crashes of management nodes and data nodes.

With this fix, the maximum length for path and file names used for Disk Data undo log files and tablespace data files is now the same as the maximum for the operating system. ([Bug#31769](#), [Bug#31770](#), [Bug#31772](#))

- **Disk Data:** Attempting to perform a system restart of the cluster where there existed a logfile group without and undo log files caused the data nodes to crash.

### Note

While issuing a `CREATE LOGFILE GROUP` statement without an `ADD UNDOFILE` option fails with an error in the MySQL server, this situation could arise if an SQL node failed during the execution of a valid `CREATE LOGFILE GROUP` statement; it is also possible to create a logfile group without any undo log files using the NDB API.

([Bug#17614](#))

- **Cluster Replication:** Being disconnected from the cluster while setting up the binary log caused `mysqld` to hang or crash. ([Bug#43045](#))
- **Cluster Replication:** Primary key updates on `MyISAM` and `InnoDB` tables failed to replicate to `NDBCLUSTER` tables. ([Bug#42921](#))
- **Cluster API:** Some error messages from `ndb_mgmd` contained newline (`\n`) characters. This could break the MGM API protocol, which uses the newline as a line separator. ([Bug#43104](#))
- **Cluster API:** When using an ordered index scan without putting all key columns in the read mask, this invalid use of the NDB API went undetected, which resulted in the use of uninitialized memory. ([Bug#42591](#))

## 17.7.3.22. Changes in MySQL Cluster NDB 6.3.22 (5.1.31-ndb-6.3.22) (09 February 2009)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.3 release.

This is a source-only release. You can obtain the GPL source code for MySQL Cluster NDB 6.3.22 from [ftp://ftp.mysql.com/pub/mysql/download/cluster\\_telco/mysql-5.1.31-ndb-6.3.22/](http://ftp.mysql.com/pub/mysql/download/cluster_telco/mysql-5.1.31-ndb-6.3.22/).

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.31 (see [Section C.1.26, “Changes in MySQL 5.1.31 \(19 January 2009\)”](#)).

### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- New options are introduced for `ndb_restore` for determining which tables or databases should be restored:
  - `--include-tables` and `--include-databases` can be used to restore specific tables or databases.
  - `--exclude-tables` and `--exclude-databases` can be used to exclude the specified tables or databases from being restored.

For more information about these options, see [Section 17.4.17, “`ndb\_restore` — Restore a MySQL Cluster Backup”](#). ([Bug#40429](#))

Bugs fixed:

- When performing more than 32 index or tuple scans on a single fragment, the scans could be left hanging. This caused unnecessary timeouts, and in addition could possibly lead to a hang of an LCP. ([Bug#42559](#))
- A data node failure that occurred between calls to `NdbIndexScanOperation::readTuples(SF_OrderBy)` and `NdbTransaction::Execute()` was not correctly handled; a subsequent call to `nextResult()` caused a null pointer to be dereferenced, leading to a segfault in `mysqld`. ([Bug#42545](#))
- Issuing `SHOW GLOBAL STATUS LIKE 'NDB%'` before `mysqld` had connected to the cluster caused a segmentation fault. ([Bug#42458](#))
- Data node failures that occurred before all data nodes had connected to the cluster were not handled correctly, leading to additional data node failures. ([Bug#42422](#))
- When a cluster backup failed with Error 1304 (Node `node_id1`: Backup request from `node_id2` failed to start), no clear reason for the failure was provided.

As part of this fix, MySQL Cluster now retries backups in the event of sequence errors. ([Bug#42354](#))

See also [Bug#22698](#).

- Issuing `SHOW ENGINE NDBCLUSTER STATUS` on an SQL node before the management server had connected to the cluster caused `mysqld` to crash. ([Bug#42264](#))

## 17.7.3.23. Changes in MySQL Cluster NDB 6.3.21 (5.1.31-ndb-6.3.21) (19 January 2009)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.3 release.

### Note

MySQL Cluster NDB 6.3.21 was withdrawn due to issues discovered after its release.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.31 (see [Section C.1.26, “Changes in MySQL 5.1.31 \(19 January 2009\)”](#)).

### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **Important Change:** Formerly, when the management server failed to create a transporter for a data node connection,

`net_write_timeout` seconds elapsed before the data node was actually permitted to disconnect. Now in such cases the disconnection occurs immediately. ([Bug#41965](#))

See also [Bug#41713](#).

- It is now possible while in Single User Mode to restart all data nodes using `ALL RESTART` in the management client. Restarting of individual nodes while in Single User Mode remains not permitted. ([Bug#31056](#))
- Formerly, when using MySQL Cluster Replication, records for “empty” epochs—that is, epochs in which no changes to `NDB-CLUSTER` data or tables took place—were inserted into the `ndb_apply_status` and `ndb_binlog_index` tables on the slave even when `--log-slave-updates` was disabled. Beginning with MySQL Cluster NDB 6.2.16 and MySQL Cluster NDB 6.3.13 this was changed so that these “empty” epochs were no longer logged. However, it is now possible to re-enable the older behavior (and cause “empty” epochs to be logged) by using the `--ndb-log-empty-epochs` option. For more information, see [Section 16.1.3.3, “Replication Slave Options and Variables”](#).

See also [Bug#37472](#).

Bugs fixed:

- A maximum of 11 `TUP` scans were permitted in parallel. ([Bug#42084](#))
- Trying to execute an `ALTER ONLINE TABLE ... ADD COLUMN` statement while inserting rows into the table caused `mysqld` to crash. ([Bug#41905](#))
- If the master node failed during a global checkpoint, it was possible in some circumstances for the new master to use an incorrect value for the global checkpoint index. This could occur only when the cluster used more than one node group. ([Bug#41469](#))
- API nodes disconnected too aggressively from cluster when data nodes were being restarted. This could sometimes lead to the API node being unable to access the cluster at all during a rolling restart. ([Bug#41462](#))
- It was not possible to perform online upgrades from a MySQL Cluster NDB 6.2 release to MySQL Cluster NDB 6.3.8 or a later MySQL Cluster NDB 6.3 release. ([Bug#41435](#))
- Cluster log files were opened twice by internal log-handling code, resulting in a resource leak. ([Bug#41362](#))
- An abort path in the `DBLQH` kernel block failed to release a commit acknowledgment marker. This meant that, during node failure handling, the local query handler could be added multiple times to the marker record which could lead to additional node failures due to an array overflow. ([Bug#41296](#))
- During node failure handling (of a data node other than the master), there was a chance that the master was waiting for a `GCP_NODEFINISHED` signal from the failed node after having received it from all other data nodes. If this occurred while the failed node had a transaction that was still being committed in the current epoch, the master node could crash in the `DBTC` kernel block when discovering that a transaction actually belonged to an epoch which was already completed. ([Bug#41295](#))
- Issuing `EXIT` in the management client sometimes caused the client to hang. ([Bug#40922](#))
- In the event that a MySQL Cluster backup failed due to file permissions issues, conflicting reports were issued in the management client. ([Bug#34526](#))
- If all data nodes were shut down, MySQL clients were unable to access `NDBCLUSTER` tables and data even after the data nodes were restarted, unless the MySQL clients themselves were restarted. ([Bug#33626](#))
- **Disk Data:** Starting a cluster under load such that Disk Data tables used most of the undo buffer could cause data node failures. The fix for this bug also corrected an issue in the `LGMAN` kernel block where the amount of free space left in the undo buffer was miscalculated, causing buffer overruns. This could cause records in the buffer to be overwritten, leading to problems when restarting data nodes. ([Bug#28077](#))
- **Cluster Replication:** Sometimes, when using the `--ndb_log_orig` option, the `orig_epoch` and `orig_server_id` columns of the `ndb_binlog_index` table on the slave contained the ID and epoch of the local server instead. ([Bug#41601](#))
- **Cluster API:** `mgmapi.h` contained constructs which only worked in C++, but not in C. ([Bug#27004](#))

## 17.7.3.24. Changes in MySQL Cluster NDB 6.3.20 (5.1.30-ndb-6.3.20) (17 December 2008)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.3 release.

**Obtaining MySQL Cluster NDB 6.3.** You can download MySQL Cluster NDB 6.3.20 source code and binaries for supported platforms from <http://dev.mysql.com/downloads/cluster/>.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.30 (see [Section C.1.27, “Changes in MySQL 5.1.30 \(14 November 2008 General Availability\)”](#)).

### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **Cluster API:** Two new `Ndb_cluster_connection` methods have been added to help in diagnosing problems with NDB API client connections. The `get_latest_error()` method tells whether or not the latest connection attempt succeeded; if the attempt failed, `get_latest_error_msg()` provides an error message giving the reason. For more information, see `Ndb_cluster_connection::get_latest_error()`, and `Ndb_cluster_connection::get_latest_error_msg()`.

Bugs fixed:

- If a transaction was aborted during the handling of a data node failure, this could lead to the later handling of an API node failure not being completed. ([Bug#41214](#))
- Issuing `SHOW TABLES` repeatedly could cause `NDBCLUSTER` tables to be dropped. ([Bug#40854](#))
- Statements of the form `UPDATE ... ORDER BY ... LIMIT` run against `NDBCLUSTER` tables failed to update all matching rows, or failed with the error `CAN'T FIND RECORD IN 'TABLE_NAME'`. ([Bug#40081](#))
- Start phase reporting was inconsistent between the management client and the cluster log. ([Bug#39667](#))
- Status messages shown in the management client when restarting a management node were inappropriate and misleading. Now, when restarting a management node, the messages displayed are as follows, where `node_id` is the management node's node ID:
 

```
ndb_mgm> node_id RESTART
Shutting down MGM node node_id for restart
Node node_id is being restarted
ndb_mgm>
```

([Bug#29275](#))

- **Partitioning:** A query on a user-partitioned table caused MySQL to crash, where the query had the following characteristics:
  - The query's `WHERE` clause referenced an indexed column that was also in the partitioning key.
  - The query's `WHERE` clause included a value found in the partition.
  - The query's `WHERE` clause used the `<` or `<>` operators to compare with the indexed column's value with a constant.
  - The query used an `ORDER BY` clause, and the same indexed column was used in the `ORDER BY` clause.
  - The `ORDER BY` clause used an explicit or implicit `ASC` sort priority.

Two examples of such a query are given here, where `a` represents an indexed column used in the table's partitioning key:

1. 

```
SELECT * FROM table WHERE a < constant ORDER BY a;
```
2. 

```
SELECT * FROM table WHERE a <> constant ORDER BY a;
```

This bug was introduced in MySQL Cluster NDB 6.3.19. ([Bug#40954](#))

This regression was introduced by [Bug#30573](#), [Bug#33257](#), [Bug#33555](#).

- **Replication:** Issuing the statement `CHANGE MASTER TO ... MASTER_HEARTBEAT_PERIOD = period` using a value for `period` outside the permitted range caused the slave to crash. ([Bug#39077](#))
- **Disk Data:** This improves on a previous fix for this issue that was made in MySQL Cluster 6.3.8. ([Bug#37116](#))

See also [Bug#29186](#).

- **Cluster API:** When creating a scan using an `NdbScanFilter` object, it was possible to specify conditions against a `BIT` column, but the correct rows were not returned when the scan was executed.

As part of this fix, 4 new comparison operators have been implemented for use with scans on `BIT` columns:

- `COL_AND_MASK_EQ_MASK`
- `COL_AND_MASK_NE_MASK`
- `COL_AND_MASK_EQ_ZERO`
- `COL_AND_MASK_NE_ZERO`

For more information about these operators, see [The NdbScanFilter::BinaryCondition Type](#).

Equivalent methods are now also defined for `NdbInterpretedCode`; for more information, see [NdbInterpretedCode Bitwise Comparison Operations](#). ([Bug#40535](#))

### 17.7.3.25. Changes in MySQL Cluster NDB 6.3.19 (5.1.29-ndb-6.3.19) (21 November 2008)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.3 release.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.29 (see [Section C.1.28, “Changes in MySQL 5.1.29 \(11 October 2008\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **Cluster API: Important Change:** MGM API applications exited without raising any errors if the connection to the management server was lost. The fix for this issue includes two changes:
  1. The MGM API now provides its own `SIGPIPE` handler to catch the “broken pipe” error that occurs when writing to a closed or reset socket. This means that MGM API now behaves the same as NDB API in this regard.
  2. A new function `ndb_mgm_set_ignore_sigpipe()` has been added to the MGM API. This function makes it possible to bypass the `SIGPIPE` handler provided by the MGM API.  
([Bug#40498](#))
- **Cluster Replication: Important Note:** This release of MySQL Cluster derives in part from MySQL 5.1.29, where the default value for the `--binlog-format` option changed to `STATEMENT`. That change does *not* affect this or future MySQL Cluster NDB 6.x releases, where the default value for this option remains `MIXED`, since MySQL Cluster Replication does not work with the statement-based format. ([Bug#40586](#))
- When performing an initial start of a data node, fragment log files were always created sparsely—that is, not all bytes were written. Now it is possible to override this behavior using the new `InitFragmentLogFile` configuration parameter. ([Bug#40847](#))

Bugs fixed:

- **Cluster API:** Failed operations on `BLOB` and `TEXT` columns were not always reported correctly to the originating SQL node. Such errors were sometimes reported as being due to timeouts, when the actual problem was a transporter overload due to insufficient buffer space. ([Bug#39867](#), [Bug#39879](#))
- Undo logs and data files were created in 32K increments. Now these files are created in 512K increments, resulting in shorter creation times. ([Bug#40815](#))

- Redo log creation was very slow on some platforms, causing MySQL Cluster to start more slowly than necessary with some combinations of hardware and operating system. This was due to all write operations being synchronized to disk while creating a redo log file. Now this synchronization occurs only after the redo log has been created. ([Bug#40734](#))
- Transaction failures took longer to handle than was necessary.

When a data node acting as transaction coordinator (TC) failed, the surviving data nodes did not inform the API node initiating the transaction of this until the failure had been processed by all protocols. However, the API node needed only to know about failure handling by the transaction protocol—that is, it needed to be informed only about the TC takeover process. Now, API nodes (including MySQL servers acting as cluster SQL nodes) are informed as soon as the TC takeover is complete, so that it can carry on operating more quickly. ([Bug#40697](#))

- It was theoretically possible for stale data to be read from `NDBCLUSTER` tables when the transaction isolation level was set to `ReadCommitted`. ([Bug#40543](#))
- The `LockExecuteThreadToCPU` and `LockMaintThreadsToCPU` parameters did not work on Solaris. ([Bug#40521](#))
- `SET SESSION ndb_optimized_node_selection = 1` failed with an invalid warning message. ([Bug#40457](#))
- A restarting data node could fail with an error in the `DBDIH` kernel block when a local or global checkpoint was started or triggered just as the node made a request for data from another data node. ([Bug#40370](#))
- Restoring a MySQL Cluster from a dump made using `mysqldump` failed due to a spurious error: `CAN'T EXECUTE THE GIVEN COMMAND BECAUSE YOU HAVE ACTIVE LOCKED TABLES OR AN ACTIVE TRANSACTION`. ([Bug#40346](#))
- `O_DIRECT` was incorrectly disabled when making MySQL Cluster backups. ([Bug#40205](#))
- Heavy DDL usage caused the `mysqld` processes to hang due to a timeout error (NDB error code 266). ([Bug#39885](#))
- Executing `EXPLAIN SELECT` on an `NDBCLUSTER` table could cause `mysqld` to crash. ([Bug#39872](#))
- Events logged after setting `ALL CLUSTERLOG STATISTICS=15` in the management client did not always include the node ID of the reporting node. ([Bug#39839](#))
- The MySQL Query Cache did not function correctly with `NDBCLUSTER` tables containing `TEXT` columns. ([Bug#39295](#))
- A segfault in `Logger::Log` caused `ndbd` to hang indefinitely. This fix improves on an earlier one for this issue, first made in MySQL Cluster NDB 6.2.16 and MySQL Cluster NDB 6.3.17. ([Bug#39180](#))

See also [Bug#38609](#).

- Memory leaks could occur in handling of strings used for storing cluster metadata and providing output to users. ([Bug#38662](#))
- A duplicate key or other error raised when inserting into an `NDBCLUSTER` table caused the current transaction to abort, after which any SQL statement other than a `ROLLBACK` failed. With this fix, the `NDBCLUSTER` storage engine now performs an implicit rollback when a transaction is aborted in this way; it is no longer necessary to issue an explicit `ROLLBACK` statement, and the next statement that is issued automatically begins a new transaction.

## Note

It remains necessary in such cases to retry the complete transaction, regardless of which statement caused it to be aborted.

([Bug#32656](#))

See also [Bug#47654](#).

- Error messages for `NDBCLUSTER` error codes 1224 and 1227 were missing. ([Bug#28496](#))
- **Partitioning:** Dropping or creating an index on a partitioned table managed by the `InnoDB` Plugin locked the table. ([Bug#37453](#))
- **Disk Data:** Issuing concurrent `CREATE TABLESPACE`, `ALTER TABLESPACE`, `CREATE LOGFILE GROUP`, or `ALTER LOGFILE GROUP` statements on separate SQL nodes caused a resource leak that led to data node crashes when these statements were used again later. ([Bug#40921](#))
- **Disk Data:** Disk-based variable-length columns were not always handled like their memory-based equivalents, which could potentially lead to a crash of cluster data nodes. ([Bug#39645](#))
- **Disk Data:** `O_SYNC` was incorrectly disabled on platforms that do not support `O_DIRECT`. This issue was noted on Solaris but could have affected other platforms not having `O_DIRECT` capability. ([Bug#34638](#))

- **Cluster API:** The MGM API reset error codes on management server handles before checking them. This meant that calling an MGM API function with a null handle caused applications to crash. ([Bug#40455](#))
- **Cluster API:** It was not always possible to access parent objects directly from `NdbBlob`, `NdbOperation`, and `NdbScanOperation` objects. To alleviate this problem, a new `getNdbOperation()` method has been added to `NdbBlob` and new `getNdbTransaction()` methods have been added to `NdbOperation` and `NdbScanOperation`. In addition, a const variant of `NdbOperation::getErrorLine()` is now also available. ([Bug#40242](#))
- **Cluster API:** `NdbScanOperation::getBlobHandle()` failed when used with incorrect column names or numbers. ([Bug#40241](#))
- **Cluster API:** The MGM API function `ndb_mgm_listen_event()` ignored bind addresses.

As part of this fix, it is now possible to specify bind addresses in connectstrings. See [Section 17.3.2.3, “The MySQL Cluster Connectstring”](#), for more information. ([Bug#38473](#))
- **Cluster API:** The NDB API example programs included in MySQL Cluster source distributions failed to compile. ([Bug#37491](#))

See also [Bug#40238](#).

### 17.7.3.26. Changes in MySQL Cluster NDB 6.3.18 (5.1.28-ndb-6.3.18) (03 October 2008)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.3 release.

**Obtaining MySQL Cluster NDB 6.3.** You can download the latest MySQL Cluster NDB 6.3 source code and binaries for supported platforms from <http://dev.mysql.com/downloads/cluster/>.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.28 (see [Section C.1.29, “Changes in MySQL 5.1.28 \(28 August 2008\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- It is no longer a requirement for database autodiscovery that an SQL node already be connected to the cluster at the time that a database is created on another SQL node. It is no longer necessary to issue `CREATE DATABASE` (or `CREATE SCHEMA`) statements on an SQL node joining the cluster after a database is created for the new SQL node to see the database and any `NDCLUSTER` tables that it contains. ([Bug#39612](#))

Bugs fixed:

- When a transaction included a multi-row insert to an `NDCLUSTER` table that caused a constraint violation, the transaction failed to roll back. ([Bug#395638](#))
- Starting the MySQL Server with the `--ndbcluster` option plus an invalid command-line option (for example, using `mysqld --ndbcluster --foobar`) caused it to hang while shutting down the binlog thread. ([Bug#39635](#))
- Dropping and then re-creating a database on one SQL node caused other SQL nodes to hang. ([Bug#39613](#))
- Setting a low value of `MaxNoOfLocalScans` (< 100) and performing a large number of (certain) scans could cause the Transaction Coordinator to run out of scan fragment records, and then crash. Now when this resource is exhausted, the cluster returns Error 291 (`OUT OF SCANFRAG RECORDS IN TC (INCREASE MAXNOFLOCALSCANS)`) instead. ([Bug#39549](#))
- Creating a unique index on an `NDCLUSTER` table caused a memory leak in the `NDB` subscription manager (`SUMA`) which could lead to mysqld hanging, due to the fact that the resource shortage was not reported back to the `NDB` kernel correctly. ([Bug#39518](#))

See also [Bug#39450](#).

- Embedded `libmysqld` with `NDB` did not drop table events. ([Bug#39450](#))
- Unique identifiers in tables having no primary key were not cached. This fix has been observed to increase the efficiency of

`INSERT` operations on such tables by as much as 50%. ([Bug#39267](#))

- When restarting a data node, an excessively long shutdown message could cause the node process to crash. ([Bug#38580](#))
- After a forced shutdown and initial restart of the cluster, it was possible for SQL nodes to retain `.frm` files corresponding to `NDBCLUSTER` tables that had been dropped, and thus to be unaware that these tables no longer existed. In such cases, attempting to re-create the tables using `CREATE TABLE IF NOT EXISTS` could fail with a spurious `TABLE ... DOESN'T EXIST` error. ([Bug#37921](#))
- A statement of the form `DELETE FROM table WHERE primary_key=value` or `UPDATE table WHERE primary_key=value` where there was no row whose primary key column had the stated `value` appeared to succeed, with the server reporting that 1 row had been changed.

This issue was only known to affect MySQL Cluster NDB 6.3.11 and later NDB 6.3 versions. ([Bug#37153](#))

- Cluster Replication:** In some cases, dropping a database on the master could cause table logging to fail on the slave, or, when using a debug build, could cause the slave `mysqld` to fail completely. ([Bug#39404](#))
- Cluster API:** Passing a value greater than 65535 to `NdbInterpretedCode::add_val()` and `NdbInterpretedCode::sub_val()` caused these methods to have no effect. ([Bug#39536](#))

### 17.7.3.27. Changes in MySQL Cluster NDB 6.3.17 (5.1.27-ndb-6.3.17) (28 August 2008)

This is a new release, fixing recently discovered bugs in previous MySQL Cluster NDB 6.3 releases.

**Obtaining MySQL Cluster NDB 6.3.** Previously, MySQL Cluster NDB 6.3 releases were source-only releases which required compiling and installing using the instructions found in [Section 2.3, “Installing MySQL Using a Source Distribution”](#), and in [Section 17.2.1.1, “MySQL Cluster Multi-Computer Installation”](#). Beginning with MySQL Cluster NDB 6.3.17, binaries built from NDB 6.3 sources are also available. You can download the latest MySQL Cluster NDB 6.2 source code and binaries for supported platforms from <http://dev.mysql.com/downloads/cluster/>.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.3 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.27 (see [Section C.1.30, “Changes in MySQL 5.1.27 \(Not released\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- Packaging:** Support for the `InnoDB` storage engine was missing from the GPL source releases. An updated GPL source tarball `mysql-5.1.27-ndb-6.3.17-innodb.tar.gz` which includes code for building `InnoDB` can be found on [the MySQL FTP site](#).
- `MgmtSrvr::allocNodeId()` left a mutex locked following an `AMBIGUITY FOR NODE IF %D` error. ([Bug#39158](#))
- An invalid path specification caused `mysql-test-run.pl` to fail. ([Bug#39026](#))
- During transactional coordinator takeover (directly after node failure), the LQH finding an operation in the `LOG_COMMIT` state sent an `LQH_TRANS_CONF` signal twice, causing the TC to fail. ([Bug#38930](#))
- An invalid memory access caused the management server to crash on Solaris Sparc platforms. ([Bug#38628](#))
- A segfault in `Logger::Log` caused `ndbd` to hang indefinitely. ([Bug#38609](#))
- `ndb_mgmd` failed to start on older Linux distributions (2.4 kernels) that did not support e-polling. ([Bug#38592](#))
- `ndb_mgmd` sometimes performed unnecessary network I/O with the client. This in combination with other factors led to long-running threads that were attempting to write to clients that no longer existed. ([Bug#38563](#))
- `ndb_restore` failed with a floating point exception due to a division by zero error when trying to restore certain data files. ([Bug#38520](#))
- A failed connection to the management server could cause a resource leak in `ndb_mgmd`. ([Bug#38424](#))
- Failure to parse configuration parameters could cause a memory leak in the NDB log parser. ([Bug#38380](#))

- Renaming an `NDBCLUSTER` table on one SQL node, caused a trigger on this table to be deleted on another SQL node. ([Bug#36658](#))
- Attempting to add a `UNIQUE INDEX` twice to an `NDBCLUSTER` table, then deleting rows from the table could cause the MySQL Server to crash. ([Bug#35599](#))
- `ndb_restore` failed when a single table was specified. ([Bug#33801](#))
- `GCP_COMMIT` did not wait for transaction takeover during node failure. This could cause `GCP_SAVE_REQ` to be executed too early. This could also cause (very rarely) replication to skip rows. ([Bug#30780](#))
- **Cluster Replication:** During a parallel node restart, the starting nodes could (sometimes) incorrectly synchronize subscriptions among themselves. Instead, this synchronization now takes place only among nodes that have actually (completely) started. ([Bug#38767](#))
- **Cluster API:** Support for Multi-Range Read index scans using the old API (using, for example, `NdbIndexScanOperation::setBound()` or `NdbIndexScanOperation::end_of_bound()`) were dropped in MySQL Cluster NDB 6.2. This functionality is restored in MySQL Cluster NDB 6.3 beginning with 6.3.17, but remains unavailable in MySQL Cluster NDB 6.2. Both MySQL Cluster NDB 6.2 and 6.3 support Multi-Range Read scans through the `NdbRecord` API. ([Bug#38791](#))
- **Cluster API:** The `NdbScanOperation::readTuples()` method could be called multiple times without error. ([Bug#38717](#))
- **Cluster API:** Certain Multi-Range Read scans involving `IS NULL` and `IS NOT NULL` comparisons failed with an error in the `NDB` local query handler. ([Bug#38204](#))
- **Cluster API:** Problems with the public headers prevented `NDB` applications from being built with warnings turned on. ([Bug#38177](#))
- **Cluster API:** Creating an `NdbScanFilter` object using an `NdbScanOperation` object that had not yet had its `readTuples()` method called resulted in a crash when later attempting to use the `NdbScanFilter`. ([Bug#37986](#))
- **Cluster API:** Executing an `NdbRecord` interpreted delete created with an `ANYVALUE` option caused the transaction to abort. ([Bug#37672](#))

### 17.7.3.28. Changes in MySQL Cluster NDB 6.3.16 (5.1.24-ndb-6.3.16) (27 June 2008)

This is a new source release, fixing recently discovered bugs in previous MySQL Cluster NDB 6.3 releases.

**Obtaining MySQL Cluster NDB 6.3.** This is a source-only release, which you must compile and install using the instructions found in [Section 2.3, “Installing MySQL Using a Source Distribution”](#), and in [Section 17.2.1.1, “MySQL Cluster Multi-Computer Installation”](#). You can download the GPL source tarball from the MySQL FTP site at [ftp://ftp.mysql.com/pub/mysql/download/cluster\\_telco/](ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/).

This release incorporates all bugfixes and changes made in the previous MySQL Cluster NDB 6.3 release, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.24 (see [Section C.1.33, “Changes in MySQL 5.1.24 \(08 April 2008\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- Event buffer lag reports are now written to the cluster log. ([Bug#37427](#))
- Added the `--no-binlog` option for `ndb_restore`. When used, this option prevents information being written to SQL node binary logs from the restoration of a cluster backup. ([Bug#30452](#))

Bugs fixed:

- **Cluster API:** Changing the system time on data nodes could cause MGM API applications to hang and the data nodes to crash. ([Bug#35607](#))
- Failure of a data node could sometimes cause mysqld to crash. ([Bug#37628](#))

- `DELETE ... WHERE unique_index_column=value` deleted the wrong row from the table. ([Bug#37516](#))
- If subscription was terminated while a node was down, the epoch was not properly acknowledged by that node. ([Bug#37442](#))
- `libmysqld` failed to wait for the cluster binlog thread to terminate before exiting. ([Bug#37429](#))
- In rare circumstances, a connection followed by a disconnection could give rise to a “stale” connection where the connection still existed but was not seen by the transporter. ([Bug#37338](#))
- Queries against `NDBCLUSTER` tables were cached only if `autocommit` was in use. ([Bug#36692](#))
- **Cluster Replication:** Data was written to the binlog with `--log-slave-updates` disabled. ([Bug#37472](#))
- **Cluster API:** When some operations succeeded and some failed following a call to `NdbTransaction::execute(Commit, AO_IgnoreOnError)`, a race condition could cause spurious occurrences of NDB API Error 4011 (`INTERNAL_ERROR`). ([Bug#37158](#))
- **Cluster API:** Creating a table on an SQL node, then starting an NDB API application that listened for events from this table, then dropping the table from an SQL node, prevented data node restarts. ([Bug#32949](#), [Bug#37279](#))
- **Cluster API:** A buffer overrun in `NdbBlob::setValue()` caused erroneous results on Mac OS X. ([Bug#31284](#))

### 17.7.3.29. Changes in MySQL Cluster NDB 6.3.15 (5.1.24-ndb-6.3.15) (30 May 2008)

This is a new source release, fixing recently discovered bugs in previous MySQL Cluster NDB 6.3 releases.

**Obtaining MySQL Cluster NDB 6.3.** This is a source-only release, which you must compile and install using the instructions found in [Section 2.3, “Installing MySQL Using a Source Distribution”](#), and in [Section 17.2.1.1, “MySQL Cluster Multi-Computer Installation”](#). You can download the GPL source tarball from the MySQL FTP site at [ftp://ftp.mysql.com/pub/mysql/download/cluster\\_telco/](ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/).

This release incorporates all bugfixes and changes made in the previous MySQL Cluster NDB 6.3 release, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.24 (see [Section C.1.33, “Changes in MySQL 5.1.24 \(08 April 2008\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- In certain rare situations, `ndb_size.pl` could fail with the error `CAN'T USE STRING ("VALUE") AS A HASH REF WHILE "STRICT REFS" IN USE.` ([Bug#43022](#))
- Under some circumstances, a failed `CREATE TABLE` could mean that subsequent `CREATE TABLE` statements caused node failures. ([Bug#37092](#))
- A fail attempt to create an `NDB` table could in some cases lead to resource leaks or cluster failures. ([Bug#37072](#))
- Attempting to create a native backup of `NDB` tables having a large number of `NULL` columns and data could lead to node failures. ([Bug#37039](#))
- Checking of API node connections was not efficiently handled. ([Bug#36843](#))
- Attempting to delete a nonexistent row from a table containing a `TEXT` or `BLOB` column within a transaction caused the transaction to fail. ([Bug#36756](#))

See also [Bug#36851](#).

- If the combined total of tables and indexes in the cluster was greater than 4096, issuing `START BACKUP` caused data nodes to fail. ([Bug#36044](#))
- Where column values to be compared in a query were of the `VARCHAR` or `VARBINARY` types, `NDBCLUSTER` passed a value padded to the full size of the column, which caused unnecessary data to be sent to the data nodes. This also had the effect of wasting CPU and network bandwidth, and causing condition pushdown to be disabled where it could (and should) otherwise have been applied. ([Bug#35393](#))
- When dropping a table failed for any reason (such as when in single user mode) then the corresponding `.ndb` file was still re-

moved.

- **Replication:** When flushing tables, there was a slight chance that the flush occurred between the processing of one table map event and the next. Since the tables were opened one by one, subsequent locking of tables would cause the slave to crash. This problem was observed when replicating `NDBCLUSTER` or `InnoDB` tables, when executing multi-table updates, and when a trigger or a stored routine performed an (additional) insert on a table so that two tables were effectively being inserted into in the same statement. ([Bug#36197](#))
- **Cluster API:** Ordered index scans were not pruned correctly where a partitioning key was specified with an EQ-bound. ([Bug#36950](#))
- **Cluster API:** When an insert operation involving `BLOB` data was attempted on a row which already existed, no duplicate key error was correctly reported and the transaction is incorrectly aborted. In some cases, the existing row could also become corrupted. ([Bug#36851](#))

See also [Bug#26756](#).
- **Cluster API:** `NdbApi.hpp` depended on `ndb_global.h`, which was not actually installed, causing the compilation of programs that used `NdbApi.hpp` to fail. ([Bug#35853](#))

### 17.7.3.30. Changes in MySQL Cluster NDB 6.3.14 (5.1.24-ndb-6.3.14) (11 May 2008)

This is a new source release, fixing recently discovered bugs in previous MySQL Cluster NDB 6.3 releases.

**Obtaining MySQL Cluster NDB 6.3.** This is a source-only release, which you must compile and install using the instructions found in [Section 2.3, “Installing MySQL Using a Source Distribution”](#), and in [Section 17.2.1.1, “MySQL Cluster Multi-Computer Installation”](#). You can download the GPL source tarball from the MySQL FTP site at [ftp://ftp.mysql.com/pub/mysql/download/cluster\\_telco/](ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/).

This release incorporates all bugfixes and changes made in the previous MySQL Cluster NDB 6.3 release, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.24 (see [Section C.1.33, “Changes in MySQL 5.1.24 \(08 April 2008\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- `SET GLOBAL ndb_extra_logging` caused `mysqld` to crash. ([Bug#36547](#))
- A race condition caused by a failure in epoll handling could cause data nodes to fail. ([Bug#36537](#))
- Under certain rare circumstances, the failure of the new master node while attempting a node takeover would cause takeover errors to repeat without being resolved. ([Bug#36199](#), [Bug#36246](#), [Bug#36247](#), [Bug#36276](#))
- When more than one SQL node connected to the cluster at the same time, creation of the `mysql.ndb_schema` table failed on one of them with an explicit `TABLE EXISTS` error, which was not necessary. ([Bug#35943](#))
- `mysqld` failed to start after running `mysql_upgrade`. ([Bug#35708](#))
- Notification of a cascading master node failures could sometimes not be transmitted correctly (that is, transmission of the `NF_COMPLETEREP` signal could fail), leading to transactions hanging and timing out (`NDB` error 4012), scans hanging, and failure of the management server process. ([Bug#32645](#))
- If an API node disconnected and then reconnected during Start Phase 8, then the connection could be “blocked”—that is, the `QMGR` kernel block failed to detect that the API node was in fact connected to the cluster, causing issues with the `NDB` Subscription Manager (`SUMA`).
- `NDB` error 1427 (`API NODE DIED, WHEN SUB_START_REQ REACHED NODE`) was incorrectly classified as a schema error rather than a temporary error.
- **Cluster Replication:** Performing `SELECT ... FROM mysql.ndb_apply_status` before the `mysqld` process had connected to the cluster failed, and caused this table never to be created. ([Bug#36123](#))
- **Cluster API:** Accesing the debug version of `libndbcclient` using `dlopen()` resulted in a segmentation fault. ([Bug#35927](#))

- **Cluster API:** Attempting to pass a nonexistent column name to the `equal()` and `setValue()` methods of `NdbOperation` caused NDB API applications to crash. Now the column name is checked, and an error is returned in the event that the column is not found. ([Bug#33747](#))
- **Cluster API:** Relocation errors were encountered when trying to compile NDB API applications on a number of platforms, including 64-bit Linux. As a result, `libmysys`, `libmystrings`, and `libdbbug` have been changed from normal libraries to “noinst” `libtool` helper libraries. They are no longer installed as separate libraries; instead, all necessary symbols from these are added directly to `libndbclient`. This means that NDB API programs now need to be linked using only `-lndbclient`. ([Bug#29791](#))

### 17.7.3.31. Changes in MySQL Cluster NDB 6.3.13 (5.1.24-ndb-6.3.13) (10 April 2008)

This is a new source release, fixing recently discovered bugs in previous MySQL Cluster NDB 6.3 releases.

**Obtaining MySQL Cluster NDB 6.3.** This is a source-only release, which you must compile and install using the instructions found in [Section 2.3, “Installing MySQL Using a Source Distribution”](#), and in [Section 17.2.1.1, “MySQL Cluster Multi-Computer Installation”](#). You can download the GPL source tarball from the MySQL FTP site at [ftp://ftp.mysql.com/pub/mysql/download/cluster\\_telco/](ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/).

This release incorporates all bugfixes and changes made in the previous MySQL Cluster NDB 6.3 release, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.24 (see [Section C.1.33, “Changes in MySQL 5.1.24 \(08 April 2008\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- The `ndbd` and `ndb_mgmd` man pages have been reclassified from volume 1 to volume 8. ([Bug#34642](#))

Bugs fixed:

- **Important Change:** `mysqld_safe` now traps Signal 13 (`SIGPIPE`) so that this signal no longer kills the MySQL server process. ([Bug#33984](#))
- Node or system restarts could fail due an uninitialized variable in the `DTUP` kernel block. This issue was found in MySQL Cluster NDB 6.3.11. ([Bug#35797](#))
- If an error occurred while executing a statement involving a `BLOB` or `TEXT` column of an `NDB` table, a memory leak could result. ([Bug#35593](#))
- It was not possible to determine the value used for the `--ndb-cluster-connection-pool` option in the `mysql` client. Now this value is reported as a system status variable. ([Bug#35573](#))
- The `ndb_waiter` utility wrongly calculated timeouts. ([Bug#35435](#))
- A `SELECT` on a table with a nonindexed, large `VARCHAR` column which resulted in condition pushdown on this column could cause `mysqld` to crash. ([Bug#35413](#))
- `ndb_restore` incorrectly handled some data types when applying log files from backups. ([Bug#35343](#))
- In some circumstances, a stopped data node was handled incorrectly, leading to redo log space being exhausted following an initial restart of the node, or an initial or partial restart of the cluster (the wrong CGI might be used in such cases). This could happen, for example, when a node was stopped following the creation of a new table, but before a new LCP could be executed. ([Bug#35241](#))
- `SELECT ... LIKE ...` queries yielded incorrect results when used on `NDB` tables. As part of this fix, condition pushdown of such queries has been disabled; re-enabling it is expected to be done as part of a later, permanent fix for this issue. ([Bug#35185](#))
- `ndb_mgmd` reported errors to `STDOUT` rather than to `STDERR`. ([Bug#35169](#))
- Nested Multi-Range Read scans failed when the second Multi-Range Read released the first read's unprocessed operations, sometimes leading to an SQL node crash. ([Bug#35137](#))

- In some situations, a problem with synchronizing checkpoints between nodes could cause a system restart or a node restart to fail with `ERROR 630 DURING RESTORE OF TX.` ([Bug#34756](#))
- A node failure during an initial node restart followed by another node start could cause the master data node to fail, because it incorrectly gave the node permission to start even if the invalidated node's LCP was still running. ([Bug#34702](#))
- When a secondary index on a `DECIMAL` column was used to retrieve data from an `NDB` table, no results were returned even if the target table had a matched value in the column that was defined with the secondary index. ([Bug#34515](#))
- An `UPDATE` on an `NDB` table that set a new value for a unique key column could cause subsequent queries to fail. ([Bug#34208](#))
- If a data node in one node group was placed in the “not started” state (using `node_id RESTART -n`), it was not possible to stop a data node in a different node group. ([Bug#34201](#))
- Numerous `NDBCLUSTER` test failures occurred in builds compiled using `icc` on IA64 platforms. ([Bug#31239](#))
- If a `START BACKUP` command was issued while `ndb_restore` was running, the backup being restored could be overwritten. ([Bug#26498](#))
- `REPLACE` statements did not work correctly with `NDBCLUSTER` tables when all columns were not explicitly listed. ([Bug#22045](#))
- `CREATE TABLE` and `ALTER TABLE` statements using `ENGINE=NDB` or `ENGINE=NDBCLUSTER` caused `mysqld` to fail on Solaris 10 for x86 platforms. ([Bug#19911](#))
- **Replication:** A `CHANGE MASTER TO` statement with no `MASTER_HEARTBEAT_PERIOD` option failed to reset the heartbeat period to its default value. ([Bug#34686](#))
- **Cluster Replication:** In some cases, when updating only one or some columns in a table, the complete row was written to the binary log instead of only the updated column or columns, even when `ndb_log_updated_only` was set to 1. ([Bug#35208](#))
- **Cluster Replication:** Enabling the `ndb_wait_connected` system variable caused the server to wait for a partial connection plus an additional 3 seconds for a complete connection to the cluster. This could lead to issues with setting up the binary log. ([Bug#34757](#))
- **Cluster API:** Closing a scan before it was executed caused the application to segfault. ([Bug#36375](#))
- **Cluster API:** Using NDB API applications from older MySQL Cluster versions with `libndbclient` from newer ones caused the cluster to fail. ([Bug#36124](#))
- **Cluster API:** Some ordered index scans could return tuples out of order. ([Bug#35908](#))
- **Cluster API:** Scans having no bounds set were handled incorrectly. ([Bug#35876](#))
- **Cluster API:** `NdbScanFilter::getNdbOperation()`, which was inadvertently removed in MySQL Cluster NDB 6.3.11, has been restored. ([Bug#35854](#))
- Enabling the `read_only` system variable while `autocommit` mode was enabled caused `SELECT` statements for transactional storage engines to fail. ([Bug#35732](#))
- Executing a `FLUSH PRIVILEGES` statement after creating a temporary table in the `mysql` database with the same name as one of the MySQL system tables caused the server to crash.

#### **Note**

While it is possible to shadow a system table in this way, the temporary table exists only for the current user and connection, and does not effect any user privileges.  
([Bug#33275](#))

### **17.7.3.32. Changes in MySQL Cluster NDB 6.3.12 (5.1.23-ndb-6.3.12) (05 April 2008)**

MySQL Cluster NDB 6.3.12 was pulled due to issues discovered shortly after its release, and is no longer available. Users of MySQL Cluster NDB 6.3.10 and earlier MySQL Cluster NDB 6.3 releases should upgrade to MySQL Cluster NDB 6.3.13 or later.

For information about bugfixes and feature enhancements that were originally scheduled to appear for the first time in this release, see [Section 17.7.3.31, “Changes in MySQL Cluster NDB 6.3.13 \(5.1.24-ndb-6.3.13\) \(10 April 2008\)”](#).

### **17.7.3.33. Changes in MySQL Cluster NDB 6.3.11 (5.1.23-ndb-6.3.11) (28 March 2008)**

This release was pulled due to issues discovered shortly after its release, and is no longer available. Users of MySQL Cluster NDB 6.3.10 and earlier MySQL Cluster NDB 6.3 releases should upgrade to MySQL Cluster NDB 6.3.13 or later.

For information about bugfixes and feature enhancements that were originally scheduled to appear for the first time in this release, see [Section 17.7.3.31, “Changes in MySQL Cluster NDB 6.3.13 \(5.1.24-ndb-6.3.13\) \(10 April 2008\)”](#).

### 17.7.3.34. Changes in MySQL Cluster NDB 6.3.10 (5.1.23-ndb-6.3.10) (17 February 2008)

This is a new Beta development release, fixing recently discovered bugs in previous MySQL Cluster NDB 6.3 releases.

**Obtaining MySQL Cluster NDB 6.3.** This is a source-only release, which you must compile and install using the instructions found in [Section 2.3, “Installing MySQL Using a Source Distribution”](#), and in [Section 17.2.1.1, “MySQL Cluster Multi-Computer Installation”](#). You can download the GPL source tarball from the MySQL FTP site at [ftp://ftp.mysql.com/pub/mysql/download/cluster\\_telco/](ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/).

This Beta release incorporates all bugfixes and changes made in the previous MySQL Cluster NDB 6.3 release, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.23 (see [Section C.1.34, “Changes in MySQL 5.1.23 \(29 January 2008\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- Due to the reduction of the number of local checkpoints from 3 to 2 in MySQL Cluster NDB 6.3.8, a data node using ndbd from MySQL Cluster NDB 6.3.8 or later started using a file system from an earlier version could incorrectly invalidate local checkpoints too early during the startup process, causing the node to fail. ([Bug#34596](#))

### 17.7.3.35. Changes in MySQL Cluster NDB 6.3.9 (5.1.23-ndb-6.3.9) (12 February 2008)

This is a new Beta development release, fixing recently discovered bugs in previous MySQL Cluster NDB 6.3 releases.

**Obtaining MySQL Cluster NDB 6.3.** This is a source-only release, which you must compile and install using the instructions found in [Section 2.3, “Installing MySQL Using a Source Distribution”](#), and in [Section 17.2.1.1, “MySQL Cluster Multi-Computer Installation”](#). You can download the GPL source tarball from the MySQL FTP site at [ftp://ftp.mysql.com/pub/mysql/download/cluster\\_telco/](ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/).

This Beta release incorporates all bugfixes and changes made in the previous MySQL Cluster NDB 6.3 release, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.23 (see [Section C.1.34, “Changes in MySQL 5.1.23 \(29 January 2008\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- Beginning with this version, MySQL Cluster NDB 6.3.x releases once again include the [InnoDB](#) storage engine. To enable [InnoDB](#), you must configure the build using `--with-innodb`.

Bugs fixed:

- Cluster failures could sometimes occur when performing more than three parallel takeovers during node restarts or system restarts. This affected MySQL Cluster NDB 6.3.x releases only. ([Bug#34445](#))
- Upgrades of a cluster using while a [DataMemory](#) setting in excess of 16 GB caused data nodes to fail. ([Bug#34378](#))
- Performing many SQL statements on [NDB](#) tables while in [autocommit](#) mode caused a memory leak in [mysqld](#). ([Bug#34275](#))
- In certain rare circumstances, a race condition could occur between an aborted insert and a delete leading a data node crash. ([Bug#34260](#))

- Multi-table updates using ordered indexes during handling of node failures could cause other data nodes to fail. ([Bug#34216](#))
  - When configured with `NDB` support, MySQL failed to compile using `gcc` 4.3 on 64bit FreeBSD systems. ([Bug#34169](#))
  - The failure of a DDL statement could sometimes lead to node failures when attempting to execute subsequent DDL statements. ([Bug#34160](#))
  - Extremely long `SELECT` statements (where the text of the statement was in excess of 50000 characters) against `NDB` tables returned empty results. ([Bug#34107](#))
  - When configured with `NDB` support, MySQL failed to compile on 64bit FreeBSD systems. ([Bug#34046](#))
  - Statements executing multiple inserts performed poorly on `NDB` tables having `AUTO_INCREMENT` columns. ([Bug#33534](#))
  - The `ndb_waiter` utility polled `ndb_mgmd` excessively when obtaining the status of cluster data nodes. ([Bug#32025](#))
- See also [Bug#32023](#).
- Transaction atomicity was sometimes not preserved between reads and inserts under high loads. ([Bug#31477](#))
  - Having tables with a great many columns could cause Cluster backups to fail. ([Bug#30172](#))
  - **Cluster Replication: Disk Data:** Statements violating unique keys on Disk Data tables (such as attempting to insert `NULL` into a `NOT NULL` column) could cause data nodes to fail. When the statement was executed from the binlog, this could also result in failure of the slave cluster. ([Bug#34118](#))
  - **Disk Data:** Updating in-memory columns of one or more rows of Disk Data table, followed by deletion of these rows and re-insertion of them, caused data node failures. ([Bug#33619](#))
  - **Cluster Replication:** Setting `--replicate-ignore-db=mysql` caused the `mysql.ndb_apply_status` table not to be replicated, breaking Cluster Replication. ([Bug#28170](#))

### 17.7.3.36. Changes in MySQL Cluster NDB 6.3.8 (5.1.23-ndb-6.3.8) (29 January 2008 General Availability)

This is a new Beta development release, fixing recently discovered bugs in previous MySQL Cluster NDB 6.3 releases.

**Obtaining MySQL Cluster NDB 6.3.** This is a source-only release, which you must compile and install using the instructions found in [Section 2.3, “Installing MySQL Using a Source Distribution”](#), and in [Section 17.2.1.1, “MySQL Cluster Multi-Computer Installation”](#). You can download the GPL source tarball from the MySQL FTP site at [ftp://ftp.mysql.com/pub/mysql/download/cluster\\_telco/](ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/).

This Beta release incorporates all bugfixes and changes made in the previous MySQL Cluster NDB 6.3 release, as well as all bug-fixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.23 (see [Section C.1.34, “Changes in MySQL 5.1.23 \(29 January 2008\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **Cluster API: Important Change:** Because `NDB_LE_MemoryUsage.page_size_kb` shows memory page sizes in bytes rather than kilobytes, it has been renamed to `page_size_bytes`. The name `page_size_kb` is now deprecated and thus subject to removal in a future release, although it currently remains supported for reasons of backward compatibility. See [The Ndb\\_logevent\\_type Type](#), for more information about `NDB_LE_MemoryUsage`. ([Bug#30271](#))
- `ndb_restore` now supports basic *attribute promotion*; that is, data from a column of a given type can be restored to a column using a “larger” type. For example, Cluster backup data taken from a `SMALLINT` column can be restored to a `MEDIUMINT`, `INT`, or `BIGINT` column.

For more information, see [Section 17.4.17, “ndb\\_restore — Restore a MySQL Cluster Backup”](#).

- Now only 2 local checkpoints are stored, rather than 3 as in previous MySQL Cluster versions. This lowers disk space requirements and reduces the size and number of redo log files needed.
- The `mysqld` option `--ndb-batch-size` has been added. This enables control of the size of batches used for running trans-

actions.

- Node recovery can now be done in parallel, rather than sequentially, which can result in much faster recovery times.
- Persistence of `NDB` tables can now be controlled using the session variables `ndb_table_temporary` and `ndb_table_no_logging`. `ndb_table_no_logging` causes `NDB` tables not to be checkpointed to disk. `ndb_table_temporary` has the same effect; in addition, when `ndb_table_temporary` is used, no `NDB` table schema files are created.
- `OPTIMIZE TABLE` can now be interrupted. This can be done, for example, by killing the SQL thread performing the `OPTIMIZE` operation.

Bugs fixed:

- **Disk Data: Important Change:** It is no longer possible on 32-bit systems to issue statements appearing to create Disk Data log files or data files greater than 4 GB in size. (Trying to create log files or data files larger than 4 GB on 32-bit systems led to unrecoverable data node failures; such statements now fail with `NDB` error 1515.) ([Bug#29186](#))
- **Replication:** The code implementing heartbeats did not check for possible errors in some circumstances; this kept the dump thread hanging while waiting for heartbeats loop even though the slave was no longer connected. ([Bug#33332](#))
- High numbers of insert operations, delete operations, or both could cause `NDB` error 899 (`ROWID ALREADY ALLOCATED`) to occur unnecessarily. ([Bug#34033](#))
- A periodic failure to flush the send buffer by the `NDB` TCP transporter could cause an unnecessary delay of 10 ms between operations. ([Bug#34005](#))
- `DROP TABLE` did not free all data memory. This bug was observed in MySQL Cluster NDB 6.3.7 only. ([Bug#33802](#))
- A race condition could occur (very rarely) when the release of a GCI was followed by a data node failure. ([Bug#33793](#))
- Some tuple scans caused the wrong memory page to be accessed, leading to invalid results. This issue could affect both in-memory and Disk Data tables. ([Bug#33739](#))
- A failure to initialize an internal variable led to sporadic crashes during cluster testing. ([Bug#33715](#))
- The server failed to reject properly the creation of an `NDB` table having an unindexed `AUTO_INCREMENT` column. ([Bug#30417](#))
- Issuing an `INSERT ... ON DUPLICATE KEY UPDATE` concurrently with or following a `TRUNCATE TABLE` statement on an `NDB` table failed with `NDB` error 4350 `TRANSACTION ALREADY ABORTED`. ([Bug#29851](#))
- The Cluster backup process could not detect when there was no more disk space and instead continued to run until killed manually. Now the backup fails with an appropriate error when disk space is exhausted. ([Bug#28647](#))
- It was possible in `config.ini` to define cluster nodes having node IDs greater than the maximum permitted value. ([Bug#28298](#))
- Under some circumstances, a recovering data node did not use its own data, instead copying data from another node even when this was not required. This in effect bypassed the optimized node recovery protocol and caused recovery times to be unnecessarily long. ([Bug#26913](#))
- **Cluster Replication:** Consecutive DDL statements involving tables (`CREATE TABLE`, `ALTER TABLE`, and `DROP TABLE`) could be executed so quickly that previous DDL statements upon which they depended were not yet written in the binary log.

For example, if `DROP TABLE foo` was issued immediately following `CREATE TABLE foo`, the `DROP` statement could fail because the `CREATE` had not yet been recorded. ([Bug#34006](#))

- **Cluster Replication:** `ndb_restore -e` restored excessively large values to the `ndb_apply_status` table's `epoch` column when restoring to a MySQL Cluster version supporting Micro-GCPs from an older version that did not support these.

A workaround when restoring to MySQL Cluster releases supporting micro-GCPs previous to MySQL Cluster NDB 6.3.8 is to perform a 32-bit shift on the `epoch` column values to reduce them to their proper size. ([Bug#33406](#))

- **Cluster API:** Transactions containing inserts or reads would hang during `NdbTransaction::execute()` calls made from NDB API applications built against a MySQL Cluster version that did not support micro-GCPs accessing a later version that supported micro-GCPs. This issue was observed while upgrading from MySQL Cluster NDB 6.1.23 to MySQL Cluster NDB 6.2.10 when the API application built against the earlier version attempted to access a data node already running the later version, even after disabling micro-GCPs by setting `TimeBetweenEpochs` equal to 0. ([Bug#33895](#))

- **Cluster API:** When reading a `BIT(64)` value using `NdbOperation::getValue()`, 12 bytes were written to the buffer rather than the expected 8 bytes. ([Bug#33750](#))

### 17.7.3.37. Changes in MySQL Cluster NDB 6.3.7 (5.1.23-ndb-6.3.7) (19 December 2007)

This is a new Beta development release, fixing recently discovered bugs in previous MySQL Cluster NDB 6.3 releases.

**Obtaining MySQL Cluster NDB 6.3.** This is a source-only release, which you must compile and install using the instructions found in [Section 2.3, “Installing MySQL Using a Source Distribution”](#), and in [Section 17.2.1.1, “MySQL Cluster Multi-Computer Installation”](#). You can download the GPL source tarball from the MySQL FTP site at [ftp://ftp.mysql.com/pub/mysql/download/cluster\\_telco/](ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/).

This Beta release incorporates all bugfixes and changes made in the previous MySQL Cluster NDB 6.3 release, as well as all bug-fixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.23 (see [Section C.1.34, “Changes in MySQL 5.1.23 \(29 January 2008\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- Compressed local checkpoints and backups are now supported, resulting in a space savings of 50% or more over uncompressed LCPs and backups. Compression of these can be enabled in the `config.ini` file using the two new data node configuration parameters `CompressedLCP` and `CompressedBackup`, respectively.
- `OPTIMIZE TABLE` is now supported for `NDBCLUSTER` tables, subject to the following limitations:
  - Only in-memory tables are supported. `OPTIMIZE` still has no effect on Disk Data tables.
  - Only variable-length columns are supported. However, you can force columns defined using fixed-length data types to be dynamic using the `ROW_FORMAT` or `COLUMN_FORMAT` option with a `CREATE TABLE` or `ALTER TABLE` statement.

Memory reclaimed from an `NDB` table using `OPTIMIZE` is generally available to the cluster, and not confined to the table from which it was recovered, unlike the case with memory freed using `DELETE`.

The performance of `OPTIMIZE` on `NDB` tables can be regulated by adjusting the value of the `ndb_optimization_delay` system variable.

- It is now possible to cause statements occurring within the same transaction to be run as a batch by setting the session variable `transaction_allow_batching` to `1` or `ON`.

#### Note

To use this feature, `autocommit` must be disabled.

Bugs fixed:

- **Partitioning:** When partition pruning on an `NDB` table resulted in an ordered index scan spanning only one partition, any descending flag for the scan was wrongly discarded, causing `ORDER BY DESC` to be treated as `ORDER BY ASC, MAX()` to be handled incorrectly, and similar problems. ([Bug#33061](#))
- When all data and SQL nodes in the cluster were shut down abnormally (that is, other than by using `STOP` in the cluster management client), `ndb_mgm` used excessive amounts of CPU. ([Bug#33237](#))
- When using micro-GCPs, if a node failed while preparing for a global checkpoint, the master node would use the wrong GCI. ([Bug#32922](#))
- Under some conditions, performing an `ALTER TABLE` on an `NDBCLUSTER` table failed with a `TABLE IS FULL` error, even when only 25% of `DataMemory` was in use and the result should have been a table using less memory (for example, changing a `VARCHAR(100)` column to `VARCHAR(80)`). ([Bug#32670](#))
- **Cluster Replication: Replication:** Where a table being replicated had a `TEXT` or `BLOB` column, an `UPDATE` on the master that did not refer explicitly to this column in the `WHERE` clause stopped the SQL thread on the slave with `ERROR IN WRITE_ROWS EVENT: ROW APPLICATION FAILED. GOT ERROR 4288 'BLOB HANDLE FOR COLUMN NOT AVAILABLE' FROM NDB-CLUSTER.` ([Bug#30674](#))

- **Cluster Replication:** Creating the `mysql.ndb_replication` table with the wrong number of columns for the primary key caused `mysqld` to crash. Now a `CREATE TABLE [mysql.]ndb_replication` statement that is invalid for this reason fails with the error `BAD SCHEMA FOR MYSQL.NDB_REPLICATION TABLE. MESSAGE: WRONG NUMBER OF PRIMARY KEYS, EXPECTED NUMBER.` ([Bug#33159](#))

### 17.7.3.38. Changes in MySQL Cluster NDB 6.3.6 (5.1.22-ndb-6.3.6) (08 November 2007)

This is a new Beta development release, fixing recently discovered bugs in previous MySQL Cluster NDB 6.3 releases.

**Obtaining MySQL Cluster NDB 6.3.** This is a source-only release, which you must compile and install using the instructions found in [Section 2.3, “Installing MySQL Using a Source Distribution”](#), and in [Section 17.2.1.1, “MySQL Cluster Multi-Computer Installation”](#). You can download the GPL source tarball from the MySQL FTP site at [ftp://ftp.mysql.com/pub/mysql/download/cluster\\_telco/](ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/).

This Beta release incorporates all bugfixes and changes made in the previous MySQL Cluster NDB 6.3 release, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.22 (see [Section C.1.35, “Changes in MySQL 5.1.22 \(24 September 2007 Release Candidate\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **Important Note:** MySQL Cluster NDB 6.2 and 6.3 source archives are now available in separate commercial and GPL versions. Due to licensing concerns, previous MySQL Cluster NDB 6.2 and 6.3 source archives were removed from the FTP site.
- The output of the `ndb_mgm` client `SHOW` and `STATUS` commands now indicates when the cluster is in single user mode. ([Bug#27999](#))
- Unnecessary reads when performing a primary key or unique key update have been reduced, and in some cases, eliminated. (It is almost never necessary to read a record prior to an update, the lone exception to this being when a primary key is updated, since this requires a delete followed by an insert, which must be prepared by reading the record.) Depending on the number of primary key and unique key lookups that are performed per transaction, this can yield a considerable improvement in performance.
- Batched operations are now better supported for `DELETE` and `UPDATE`. (`UPDATE WHERE...` and multiple `DELETE`.)
- Introduced the `Ndb_execute_count` status variable, which measures the number of round trips made by queries to the `NDB` kernel.

Bugs fixed:

- An insert or update with combined range and equality constraints failed when run against an `NDB` table with the error `GOT UNKNOWN ERROR FROM NDB`. An example of such a statement would be `UPDATE t1 SET b = 5 WHERE a IN (7,8) OR a >= 10;`. ([Bug#31874](#))
- An error with an `if` statement in `sql/ha_ndbcluster.cc` could potentially lead to an infinite loop in case of failure when working with `AUTO_INCREMENT` columns in `NDB` tables. ([Bug#31810](#))
- The `NDB` storage engine code was not safe for strict-alias optimization in `gcc` 4.2.1. ([Bug#31761](#))
- `ndb_restore` displayed incorrect backup file version information. This meant (for example) that, when attempting to restore a backup made from a MySQL 5.1.22 cluster to a MySQL Cluster NDB 6.3.3 cluster, the restore process failed with the error `RESTORE PROGRAM OLDER THAN BACKUP VERSION. NOT SUPPORTED. USE NEW RESTORE PROGRAM.` ([Bug#31723](#))
- Following an upgrade, `ndb_mgmd` would fail with an `ArbitrationError`. ([Bug#31690](#))
- The `NDB` management client command `node_id REPORT MEMORY` provided no output when `node_id` was the node ID of a management or API node. Now, when this occurs, the management client responds with `Node node_id: is not a data node.` ([Bug#29485](#))
- Performing `DELETE` operations after a data node had been shut down could lead to inconsistent data following a restart of the node. ([Bug#26450](#))
- `UPDATE IGNORE` could sometimes fail on `NDB` tables due to the use of uninitialized data when checking for duplicate keys to

be ignored. ([Bug#25817](#))

- **Cluster Replication: Replication:** A node failure during replication could lead to buckets out of order; now active subscribers are checked for, rather than empty buckets. ([Bug#31701](#))
- **Cluster Replication:** Updates performed unnecessary writes to the primary keys of the rows being updated. ([Bug#31841](#))
- **Cluster Replication:** Slave batching did not work correctly with `UPDATE` statements. ([Bug#31787](#))
- **Cluster Replication:** When the master `mysqld` crashed or was restarted, no `LOST_EVENTS` entry was made in the binlog. ([Bug#31484](#))

See also [Bug#21494](#).

### 17.7.3.39. Changes in MySQL Cluster NDB 6.3.5 (5.1.22-ndb-6.3.5) (17 October 2007)

This is a new Beta development release, fixing recently discovered bugs in previous MySQL Cluster NDB 6.3 releases.

**Obtaining MySQL Cluster NDB 6.3.** This is a source-only release, which you must compile and install using the instructions found in [Section 2.3, “Installing MySQL Using a Source Distribution”](#), and in [Section 17.2.1.1, “MySQL Cluster Multi-Computer Installation”](#). You can download the GPL source tarball from the MySQL FTP site at [ftp://ftp.mysql.com/pub/mysql/download/cluster\\_telco/](ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/).

This Beta release incorporates all bugfixes and changes made in the previous MySQL Cluster NDB 6.3 release, as well as all bug-fixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.22 (see [Section C.1.35, “Changes in MySQL 5.1.22 \(24 September 2007 Release Candidate\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- A query against a table with `TEXT` or `BLOB` columns that would return more than a certain amount of data failed with `GOT_ER- ROR 4350 'TRANSACTION ALREADY ABORTED' FROM NDBCLUSTER.` ([Bug#31482](#))

This regression was introduced by [Bug#29102](#).

- **Cluster Replication:** In some cases, not all tables were properly initialized before the binary log thread was started. ([Bug#31618](#))

### 17.7.3.40. Changes in MySQL Cluster NDB 6.3.4 (5.1.22-ndb-6.3.4) (15 October 2007)

This is a new Beta development release, fixing recently discovered bugs in previous MySQL Cluster NDB 6.3 releases.

**Obtaining MySQL Cluster NDB 6.3.** This is a source-only release, which you must compile and install using the instructions found in [Section 2.3, “Installing MySQL Using a Source Distribution”](#), and in [Section 17.2.1.1, “MySQL Cluster Multi-Computer Installation”](#). You can download the GPL source tarball from the MySQL FTP site at [ftp://ftp.mysql.com/pub/mysql/download/cluster\\_telco/](ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/).

This Beta release incorporates all bugfixes and changes made in the previous MySQL Cluster NDB 6.3 release, as well as all bug-fixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.22 (see [Section C.1.35, “Changes in MySQL 5.1.22 \(24 September 2007 Release Candidate\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **Incompatible Change:** The `--ndb_optimized_node_selection` startup option for `mysqld` now permits a wider range of values and corresponding behaviors for SQL nodes when selecting a transaction coordinator.

You should be aware that the default value and behavior as well as the value type used for this option have changed, and that you may need to update the setting used for this option in your `my.cnf` file prior to upgrading `mysqld`. See [Section 5.1.4](#),

[“Server System Variables”](#), for more information.

- **Replication:** On MySQL replication slaves having multiple network interfaces, it is now possible to set which interface to use for connecting to the master. This can be done by using either the `mysqld` startup option `--master-bind` or the `MASTER_BIND='interface'` clause in a `CHANGE MASTER TO` statement. ([Bug#25939](#))
- **Cluster Replication:** A new configuration parameter `TimeBetweenEpochsTimeout` enables a timeout to be set for time between epochs. For more information, see [Section 17.3.2.6, “Defining MySQL Cluster Data Nodes”](#). ([Bug#31276](#))
- **Cluster Replication:** A replication heartbeat mechanism has been added to facilitate monitoring. This provides an alternative to checking log files, making it possible to detect in real time when a slave has failed.

Configuration of heartbeats is done using a new `MASTER_HEARTBEAT_PERIOD = interval` clause for the `CHANGE MASTER TO` statement (see [Section 12.5.2.1, “`CHANGE MASTER TO` Syntax”](#)); monitoring can be done by checking the values of the status variables `Slave_heartbeat_period` and `Slave_received_heartbeats` (see [Section 5.1.6, “Server Status Variables”](#)).

The addition of replication heartbeats addresses a number of issues:

- Relay logs were rotated every `slave_net_timeout` seconds even if no statements were being replicated.
- `SHOW SLAVE STATUS` displayed an incorrect value for `Seconds_Behind_Master` following a `FLUSH LOGS` statement.
- Replication master-slave connections used `slave_net_timeout` for connection timeouts. ([Bug#20435](#), [Bug#29309](#), [Bug#30932](#))
- **Cluster Replication:** Support for a new conflict resolution function `NDB$OLD()` has been added for handling simultaneous updates in multi-master and circular replication setups. A new status variable `Ndb_conflict_fn_old` tracks the number of times that updates are prevented from being applied due to this type of conflict resolution. See [Section 17.6.11, “MySQL Cluster Replication Conflict Resolution”](#), for more information.
- Additional checks were implemented to catch unsupported online `ALTER TABLE` operations. Currently it is not possible to re-order columns or to change the storage engine used for a table using online `ALTER TABLE`.

Some redundant checks made during online creation of indexes were removed.

- A `--bind-address` option has been added to a number of MySQL client programs: `mysql`, `mysqldump`, `mysqladmin`, `mysqlbinlog`, `mysqlcheck`, `mysqlimport`, and `mysqlshow`. This is for use on a computer having multiple network interfaces, and enables you to choose which interface is used to connect to the MySQL server.

Bugs fixed:

- It was possible in some cases for a node group to be “lost” due to missed local checkpoints following a system restart. ([Bug#31525](#))
- `NDB` tables having names containing nonalphanumeric characters (such as “\$”) were not discovered correctly. ([Bug#31470](#))
- A node failure during a local checkpoint could lead to a subsequent failure of the cluster during a system restart. ([Bug#31257](#))
- A cluster restart could sometimes fail due to an issue with table IDs. ([Bug#30975](#))
- Transaction timeouts were not handled well in some circumstances, leading to excessive number of transactions being aborted unnecessarily. ([Bug#30379](#))
- In some cases, the cluster management server logged entries multiple times following a restart of `mgmd`. ([Bug#29565](#))
- `ndb_mgm --help` did not display any information about the `-a` option. ([Bug#29509](#))
- An interpreted program of sufficient size and complexity could cause all cluster data nodes to shut down due to buffer overruns. ([Bug#29390](#))
- The cluster log was formatted inconsistently and contained extraneous newline characters. ([Bug#25064](#))
- A transaction was not aborted following the failure of statement. ([Bug#31320](#))
- Online `ALTER` operations involving a column whose data type has an implicit default value left behind temporary `.frm` files, causing subsequent `DROP DATABASE` statements to fail. ([Bug#31097](#))

- Errors could sometimes occur during an online `ADD COLUMN` under load. ([Bug#31082](#))
- Transactions were committed prematurely when `LOCK TABLE` and `SET autocommit = 0` were used together. ([Bug#30996](#))
- The `mysqld_safe` script contained a syntax error. ([Bug#30624](#))

### 17.7.3.41. Changes in MySQL Cluster NDB 6.3.3 (5.1.22-ndb-6.3.3) (20 September 2007)

This is a new Beta development release, fixing recently discovered bugs in previous MySQL Cluster NDB 6.3 releases.

**Obtaining MySQL Cluster NDB 6.3.** This is a source-only release, which you must compile and install using the instructions found in [Section 2.3, “Installing MySQL Using a Source Distribution”](#), and in [Section 17.2.1.1, “MySQL Cluster Multi-Computer Installation”](#). You can download the GPL source tarball from the MySQL FTP site at [ftp://ftp.mysql.com/pub/mysql/download/cluster\\_telco/](ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/).

This Beta release incorporates all bugfixes and changes made in the previous MySQL Cluster NDB 6.3 release, as well as all bug-fixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.22 (see [Section C.1.35, “Changes in MySQL 5.1.22 \(24 September 2007 Release Candidate\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- Mapping of `NDB` error codes to MySQL storage engine error codes has been improved. ([Bug#28423](#))
- **Cluster Replication: Replication:** A server status variable `ndb_conflict_fn_max` now provides a count of the number of times that conflict resolution for MySQL Cluster Replication has been applied.

See [Section 17.6.11, “MySQL Cluster Replication Conflict Resolution”](#), for more information.

Bugs fixed:

- **Partitioning:** `EXPLAIN PARTITIONS` reported partition usage by queries on `NDB` tables according to the standard MySQL hash function than the hash function used in the `NDB` storage engine. ([Bug#29550](#))
- Attempting to restore a backup made on a cluster host using one endian to a machine using the other endian could cause the cluster to fail. ([Bug#29674](#))
- The description of the `--print` option provided in the output from `ndb_restore --help` was incorrect. ([Bug#27683](#))
- Restoring a backup made on a cluster host using one endian to a machine using the other endian failed for `BLOB` and `DATE-TIME` columns. ([Bug#27543](#), [Bug#30024](#))
- Errors could sometimes occur during an online `ADD COLUMN` under load. ([Bug#31082](#))

### 17.7.3.42. Changes in MySQL Cluster NDB 6.3.2 (5.1.22-ndb-6.3.2) (07 September 2007)

This is a new Beta development release, fixing recently discovered bugs in previous MySQL Cluster NDB 6.3 releases.

**Obtaining MySQL Cluster NDB 6.3.** This is a source-only release, which you must compile and install using the instructions found in [Section 2.3, “Installing MySQL Using a Source Distribution”](#), and in [Section 17.2.1.1, “MySQL Cluster Multi-Computer Installation”](#). You can download the GPL source tarball from the MySQL FTP site at [ftp://ftp.mysql.com/pub/mysql/download/cluster\\_telco/](ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/).

This Beta release incorporates all bugfixes and changes made in the previous MySQL Cluster NDB 6.3 release, as well as all bug-fixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.22 (see [Section C.1.35, “Changes in MySQL 5.1.22 \(24 September 2007 Release Candidate\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- Online `ADD COLUMN`, `ADD INDEX`, and `DROP INDEX` operations can now be performed explicitly for `NDB` tables, as well as online renaming of tables and columns for `NDB` and `MyISAM` tables—that is, without copying or locking of the affected tables—using `ALTER ONLINE TABLE`.

Indexes can also be created and dropped online using `CREATE INDEX` and `DROP INDEX`, respectively, using the `ONLINE` keyword.

You can force operations that would otherwise be performed online to be done offline using the `OFFLINE` keyword.

See [Section 12.1.7, “`ALTER TABLE` Syntax”](#), [Section 12.1.13, “`CREATE INDEX` Syntax”](#), and [Section 12.1.24, “`DROP INDEX` Syntax”](#), for more information.

- It is now possible to control whether fixed-width or variable-width storage is used for a given column of an `NDB` table by means of the `COLUMN_FORMAT` specifier as part of the column's definition in a `CREATE TABLE` or `ALTER TABLE` statement.

It is also possible to control whether a given column of an `NDB` table is stored in memory or on disk, using the `STORAGE` specifier as part of the column's definition in a `CREATE TABLE` or `ALTER TABLE` statement.

For permitted values and other information about `COLUMN_FORMAT` and `STORAGE`, see [Section 12.1.17, “`CREATE TABLE` Syntax”](#).

- A new cluster management server startup option `--bind-address` makes it possible to restrict management client connections to `ndb_mgmd` to a single host and port. For more information, see [Section 17.4.4, “`ndb\_mgmd` — The MySQL Cluster Management Server Daemon”](#).
- **Cluster Replication:** Multi-way replication failover and recovery for `NDB` is facilitated with the introduction of the `-ndb-log-orig` option. When `mysqld` is started with this option, the originating server ID and epoch of each binlog event is recorded in the `mysql.ndb_binlog_index` table, which now contains two additional columns `orig_server_id` and `orig_epoch` for storing this information. In such cases, a single epoch on a slave may be represented by multiple rows in the slave's `ndb_binlog_index` table, one for each epoch as it originated from a master.
- **Cluster Replication:** The protocol for handling global checkpoints has been changed. It is now possible to control how often the GCI number is updated, and how often global checkpoints are written to disk, using the `TimeBetweenEpochs` configuration parameter. This improves the reliability and performance of MySQL Cluster Replication.

GCPs handled using the new protocol are sometimes referred to as “micro-GCPs”.

For more information, see [TimeBetweenEpochs](#).

Bugs fixed:

- When an `NDB` event was left behind but the corresponding table was later recreated and received a new table ID, the event could not be dropped. ([Bug#30877](#))
- When creating an `NDB` table with a column that has `COLUMN_FORMAT = DYNAMIC`, but the table itself uses `ROW_FORMAT=FIXED`, the table is considered dynamic, but any columns for which the row format is unspecified default to `FIXED`. Now in such cases the server issues the warning `ROW FORMAT FIXED INCOMPATIBLE WITH DYNAMIC ATTRIBUTE COLUMN_NAME`. ([Bug#30276](#))
- An insufficiently descriptive and potentially misleading Error 4006 (`CONNECT FAILURE - OUT OF CONNECTION OBJECTS...`) was produced when either of the following two conditions occurred:
  1. There were no more transaction records in the transaction coordinator
  2. An `NDB` object in the `NDB` API was initialized with insufficient parallelismSeparate error messages are now generated for each of these two cases. ([Bug#11313](#))
- For micro-GCPs, the assignment of “fake” CGI events no longer cause buckets to be sent out of order. Now, when assigning a GCI to a non-GCI event (that is, creating a pseudo-GCI or “fake” CGI), the GCI that is to arrive is always initiated, even if no known GCI exists, which could occur in the event of a node failure. ([Bug#30884](#))

### 17.7.3.43. Changes in MySQL Cluster NDB 6.3.1 (5.1.19-ndb-6.3.1) (04 July 2007)

This is a new Beta development release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.3 release.

**Obtaining MySQL Cluster NDB 6.3.** This is a source-only release, which you must compile and install using the instructions found in [Section 2.3, “Installing MySQL Using a Source Distribution”](#), and in [Section 17.2.1.1, “MySQL Cluster Multi-Computer Installation”](#). You can download the GPL source tarball from the MySQL FTP site at [ftp://ftp.mysql.com/pub/mysql/download/cluster\\_telco/](ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/).

This Beta release incorporates all bugfixes and changes made in the previous MySQL Cluster NDB 6.3 release, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.19 (see [Section C.1.38, “Changes in MySQL 5.1.19 \(25 May 2007\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- Batching of transactions was not handled correctly in some cases. ([Bug#29525](#))

### 17.7.3.44. Changes in MySQL Cluster NDB 6.3.0 (5.1.19-ndb-6.3.0) (02 July 2007 Beta)

This is the first development release for MySQL Cluster NDB 6.3, based on version 6.3 of the `NDBCLUSTER` storage engine.

**Obtaining MySQL Cluster NDB 6.3.** This is a source-only release, which you must compile and install using the instructions found in [Section 2.3, “Installing MySQL Using a Source Distribution”](#), and in [Section 17.2.1.1, “MySQL Cluster Multi-Computer Installation”](#). You can download the GPL source tarball from the MySQL FTP site at [ftp://ftp.mysql.com/pub/mysql/download/cluster\\_telco/](ftp://ftp.mysql.com/pub/mysql/download/cluster_telco/).

This Beta release incorporates all bugfixes and feature changes made in previous MySQL Cluster releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.19 (see [Section C.1.38, “Changes in MySQL 5.1.19 \(25 May 2007\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- Reporting functionality has been significantly enhanced in this release:
  - A new configuration parameter `BackupReportFrequency` now makes it possible to cause the management client to provide status reports at regular intervals as well as for such reports to be written to the cluster log (depending on cluster event logging levels). See [Section 17.3.2.6, “Defining MySQL Cluster Data Nodes”](#), for more information about this parameter.
  - A new `REPORT` command has been added in the cluster management client. `REPORT BackupStatus` enables you to obtain a backup status report at any time during a backup. `REPORT MemoryUsage` reports the current data memory and index memory used by each data node. For more about the `REPORT` command, see [Section 17.5.2, “Commands in the MySQL Cluster Management Client”](#).
  - `ndb_restore` now provides running reports of its progress when restoring a backup. In addition, a complete report status report on the backup is written to the cluster log.
- A new configuration parameter `ODirect` causes `NDB` to attempt using `O_DIRECT` writes for LCP, backups, and redo logs, often lowering CPU usage.
- **Cluster Replication:** This release implements conflict resolution, which makes it possible to determine on a per-table basis whether or not an update to a given row on the master should be applied on the slave. For more information, see [Section 17.6.11, “MySQL Cluster Replication Conflict Resolution”](#).

### 17.7.4. Changes in MySQL Cluster NDB 6.2

This section contains change history information for MySQL Cluster releases based on version 6.2 of the `NDBCLUSTER` storage engine.

For an overview of new features added in MySQL Cluster NDB 6.2, see [Section 17.1.4.4, “MySQL Cluster Development in](#)

MySQL Cluster NDB 6.2”.

### 17.7.4.1. Changes in MySQL Cluster NDB 6.2.19 (5.1.47-ndb-6.2.19) (Not yet released)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.2 release.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.2 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.47 (see [Section C.1.4, “Changes in MySQL 5.1.47 \(06 May 2010\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **Important Change:** More finely-grained control over restart-on-failure behavior is provided with two new data node configuration parameters `MaxStartFailRetries` and `StartFailRetryDelay`. `MaxStartFailRetries` limits the total number of retries made before giving up on starting the data node; `StartFailRetryDelay` sets the number of seconds between retry attempts.

These parameters are used only if `StopOnError` is set to 0.

For more information, see [Section 17.3.2.6, “Defining MySQL Cluster Data Nodes”](#). ([Bug#54341](#))

- **Cluster API:** It is now possible to determine, using the `ndb_desc` utility or the NDB API, which data nodes contain replicas of which partitions. For `ndb_desc`, a new `--extra-node-info` option is added to cause this information to be included in its output. A new method `NdbDictionary::Object::Table::getFragmentNodes()` is added to the NDB API for obtaining this information programmatically. ([Bug#51184](#))
- On Solaris platforms, the MySQL Cluster management server and NDB API applications now use `CLOCK_REALTIME` as the default clock. ([Bug#46183](#))

Bugs fixed:

- **Important Change:** The `--with-ndb-port-base` option for `configure` did not function correctly, and has been deprecated. Attempting to use this option produces the warning `IGNORING DEPRECATED OPTION --WITH-NDB-PORT-BASE`.

Beginning with MySQL Cluster NDB 7.1.0, the deprecation warning itself is removed, and the `--with-ndb-port-base` option is simply handled as an unknown and invalid option if you try to use it. ([Bug#47941](#))

See also [Bug#38502](#).

- **Cluster Replication: Important Change:** In a MySQL Cluster acting as a replication slave and having multiple SQL nodes, only the SQL node receiving events directly from the master recorded DDL statements in its binary logs unless this SQL node also had binary logging enabled; otherwise, other SQL nodes in the slave cluster failed to log DDL statements, regardless of their individual `--log-bin` settings.

The fix for this issue aligns binary logging of DDL statements with that of DML statements. In particular, you should take note of the following:

- DDL and DML statements on the master cluster are logged with the server ID of the server that actually writes the log.
- DDL and DML statements on the master cluster are logged by any attached `mysqld` that has binary logging enabled.
- Replicated DDL and DML statements on the slave are logged by any attached `mysqld` that has both `--log-bin` and `--log-slave-updates` enabled.
- Replicated DDL and DML statements are logged with the server ID of the original (master) MySQL server by any attached `mysqld` that has both `--log-bin` and `--log-slave-updates` enabled.

**Affect on upgrades.** When upgrading from a previous MySQL CLuster release, you should perform either one of the following:

- a. Upgrade servers that are performing binary logging before those that are not; do not perform any DDL on “old” SQL nodes until all SQL nodes have been upgraded.
- b. Make sure that `--log-slave-updates` is enabled on all SQL nodes performing binary logging prior to the upgrade,

so that all DDL is captured.

### Note

Logging of DML statements was not affected by this issue.

(Bug#45756)

- **Packaging:** The `pkg` installer for MySQL Cluster on Solaris did not perform a complete installation due to an invalid directory reference in the post-install script. (Bug#41998)
- It was possible for a `DROP DATABASE` statement to remove `NDB` hidden blob tables without removing the parent tables, with the result that the tables, although hidden to MySQL clients, were still visible in the output of `ndb_show_tables` but could not be dropped using `ndb_drop_table`. (Bug#54788)
- When performing an online alter table where 2 or more SQL nodes connected to the cluster were generating binary logs, an incorrect message could be sent from the data nodes, causing `mysqld` processes to crash. This problem was often difficult to detect, because restarting SQL node or data node processes could clear the error, and because the crash in `mysqld` did not occur until several minutes after the erroneous message was sent and received. (Bug#54168)
- A table having the maximum number of attributes permitted could not be backed up using the `ndb_mgm` client.

### Note

The maximum number of attributes supported per table is not the same for all MySQL Cluster releases. See [Section 17.1.5.5, “Limits Associated with Database Objects in MySQL Cluster”](#), to determine the maximum that applies in the release which you are using.

(Bug#54155)

- Creating a Disk Data table, dropping it, then creating an in-memory table and performing a restart, could cause data node processes to fail with errors in the `DBTUP` kernel block if the new table's internal ID was the same as that of the old Disk Data table. This could occur because undo log handling during the restart did not check that the table having this ID was now in-memory only. (Bug#53935)
- A table created while `ndb_table_no_logging` was enabled was not always stored to disk, which could lead to a data node crash with `ERROR OPENING DIH SCHEMA FILES FOR TABLE`. (Bug#53934)
- An internal buffer allocator used by `NDB` has the form `alloc(wanted, minimum)` and attempts to allocate `wanted` pages, but is permitted to allocate a smaller number of pages, between `wanted` and `minimum`. However, this allocator could sometimes allocate fewer than `minimum` pages, causing problems with multi-threaded building of ordered indexes. (Bug#53580)
- `NDB` truncated a column declared as `DECIMAL(65,0)` to a length of 64. Now such a column is accepted and handled correctly. In cases where the maximum length (65) is exceeded, `NDB` now raises an error instead of truncating. (Bug#53352)
- When a watchdog shutdown occurred due to an error, the process was not terminated quickly enough, sometimes resulting in a hang. (To correct this, the internal `_exit()` function is now called in such situations, rather than `exit()`.) (Bug#53246)
- Setting `DataMemory` higher than 4G on 32-bit platforms caused `ndbd` to crash, instead of failing gracefully with an error. (Bug#52536, Bug#50928)
- When running a `SELECT` on an `NDB` table with `BLOB` or `TEXT` columns, memory was allocated for the columns but was not freed until the end of the `SELECT`. This could cause problems with excessive memory usage when dumping (using for example `mysqldump`) tables with such columns and having many rows, large column values, or both. (Bug#52313)

See also Bug#56488, Bug#50310.

- When using `NoOfReplicas` equal to 1 or 2, if data nodes from one node group were restarted 256 times and applications were running traffic such that it would encounter `NDB` error 1204 (`TEMPORARY FAILURE, DISTRIBUTION CHANGED`), the live node in the node group would crash, causing the cluster to crash as well. The crash occurred only when the error was encountered on the 256th restart; having the error on any previous or subsequent restart did not cause any problems. (Bug#50930)
- If a query on an `NDB` table compared a constant string value to a column, and the length of the string was greater than that of the column, condition pushdown did not work correctly. (The string was truncated to fit the column length before being pushed down.) Now in such cases, the condition is no longer pushed down. (Bug#49459)
- When performing tasks that generated large amounts of I/O (such as when using `ndb_restore`), an internal memory buffer could overflow, causing data nodes to fail with signal 6.

Subsequent analysis showed that this buffer was not actually required, so this fix removes it. ([Bug#48861](#))

- Performing intensive inserts and deletes in parallel with a high scan load could cause a data node crash due to a failure in the **DBACC** kernel block. This was because checking for when to perform bucket splits or merges considered the first 4 scans only. ([Bug#48700](#))
- The creation of an ordered index on a table undergoing DDL operations could cause a data node crash under certain timing-dependent conditions. ([Bug#48604](#))
- In certain cases, performing very large inserts on **NDB** tables when using **ndbmtd** caused the memory allocations for ordered or unique indexes (or both) to be exceeded. This could cause aborted transactions and possibly lead to data node failures. ([Bug#48037](#))

See also [Bug#48113](#).

- When employing **NDB** native backup to back up and restore an empty **NDB** table that used a non-sequential **AUTO\_INCREMENT** value, the **AUTO\_INCREMENT** value was not restored correctly. ([Bug#48005](#))
- **SHOW CREATE TABLE** did not display the **AUTO\_INCREMENT** value for **NDB** tables having **AUTO\_INCREMENT** columns. ([Bug#47865](#))
- Under some circumstances, when a scan encountered an error early in processing by the **DBTC** kernel block (see [The DBTC Block](#)), a node could crash as a result. Such errors could be caused by applications sending incorrect data, or, more rarely, by a **DROP TABLE** operation executed in parallel with a scan. ([Bug#47831](#))
- When starting a node and synchronizing tables, memory pages were allocated even for empty fragments. In certain situations, this could lead to insufficient memory. ([Bug#47782](#))
- **mysqld** allocated an excessively large buffer for handling **BLOB** values due to overestimating their size. (For each row, enough space was allocated to accommodate *every* **BLOB** or **TEXT** column value in the result set.) This could adversely affect performance when using tables containing **BLOB** or **TEXT** columns; in a few extreme cases, this issue could also cause the host system to run out of memory unexpectedly. ([Bug#47574](#))

See also [Bug#47572](#), [Bug#47573](#).

- **NDBCLUSTER** uses a dynamically-allocated buffer to store **BLOB** or **TEXT** column data that is read from rows in MySQL Cluster tables.

When an instance of the **NDBCLUSTER** table handler was recycled (this can happen due to table definition cache pressure or to operations such as **FLUSH TABLES** or **ALTER TABLE**), if the last row read contained blobs of zero length, the buffer was not freed, even though the reference to it was lost. This resulted in a memory leak.

For example, consider the table defined and populated as shown here:

```
CREATE TABLE t (a INT PRIMARY KEY, b LONGTEXT) ENGINE=NDB;
INSERT INTO t VALUES (1, REPEAT('F', 20000));
INSERT INTO t VALUES (2, ''');
```

Now execute repeatedly a **SELECT** on this table, such that the zero-length **LONGTEXT** row is last, followed by a **FLUSH TABLES** statement (which forces the handler object to be re-used), as shown here:

```
SELECT a, length(b) FROM bl ORDER BY a;
FLUSH TABLES;
```

Prior to the fix, this resulted in a memory leak proportional to the size of the stored **LONGTEXT** value each time these two statements were executed. ([Bug#47573](#))

See also [Bug#47572](#), [Bug#47574](#).

- Large transactions involving joins between tables containing **BLOB** columns used excessive memory. ([Bug#47572](#))

See also [Bug#47573](#), [Bug#47574](#).

- A variable was left uninitialized while a data node copied data from its peers as part of its startup routine; if the starting node died during this phase, this could lead a crash of the cluster when the node was later restarted. ([Bug#47505](#))
- **NDB** stores blob column data in a separate, hidden table that is not accessible from MySQL. If this table was missing for some reason (such as accidental deletion of the file corresponding to the hidden table) when making a MySQL Cluster native backup, **ndb\_restore** crashed when attempting to restore the backup. Now in such cases, **ndb\_restore** fails with the error message **TABLE**

`TABLE_NAME` HAS BLOB COLUMN (`COLUMN_NAME`) WITH MISSING PARTS TABLE IN BACKUP instead. ([Bug#47289](#))

- For very large values of `MaxNoOfTables` + `MaxNoOfAttributes`, the calculation for `StringMemory` could overflow when creating large numbers of tables, leading to NDB error 773 (OUT OF STRING MEMORY, PLEASE MODIFY STRINGMEMORY CONFIG PARAMETER), even when `StringMemory` was set to 100 (100 percent). ([Bug#47170](#))
- The default value for the `StringMemory` configuration parameter, unlike other MySQL Cluster configuration parameters, was not set in `ndb/src/mgmsrv/ConfigInfo.cpp`. ([Bug#47166](#))
- Signals from a failed API node could be received after an `API_FAILREQ` signal (see [Operations and Signals](#)) has been received from that node, which could result in invalid states for processing subsequent signals. Now, all pending signals from a failing API node are processed before any `API_FAILREQ` signal is received. ([Bug#47039](#))

See also [Bug#44607](#).

- Using triggers on NDB tables caused `ndb_autoincrement_prefetch_sz` to be treated as having the NDB kernel's internal default value (32) and the value for this variable as set on the cluster's SQL nodes to be ignored. ([Bug#46712](#))
- Full table scans failed to execute when the cluster contained more than 21 table fragments.

### Note

The number of table fragments in the cluster can be calculated as the number of data nodes, times 8 (that is, times the value of the internal constant `MAX_FRAG_PER_NODE`), divided by the number of replicas. Thus, when `NoOfReplicas = 1` at least 3 data nodes were required to trigger this issue, and when `NoOfReplicas = 2` at least 4 data nodes were required to do so.

([Bug#46490](#))

- Ending a line in the `config.ini` file with an extra semicolon character (;) caused reading the file to fail with a parsing error. ([Bug#46242](#))
- When combining an index scan and a delete with a primary key delete, the index scan and delete failed to initialize a flag properly. This could in rare circumstances cause a data node to crash. ([Bug#46069](#))
- Problems could arise when using `VARCHAR` columns whose size was greater than 341 characters and which used the `utf8_unicode_ci` collation. In some cases, this combination of conditions could cause certain queries and `OPTIMIZE TABLE` statements to crash `mysqld`. ([Bug#45053](#))
- Running an `ALTER TABLE` statement while an NDB backup was in progress caused `mysqld` to crash. ([Bug#44695](#))
- If a node failed while sending a fragmented long signal, the receiving node did not free long signal assembly resources that it had allocated for the fragments of the long signal that had already been received. ([Bug#44607](#))
- When performing auto-discovery of tables on individual SQL nodes, `NDBCLUSTER` attempted to overwrite existing `MyISAM.frm` files and corrupted them.

**Workaround.** In the `mysql` client, create a new table (`t2`) with same definition as the corrupted table (`t1`). Use your system shell or file manager to rename the old `.MYD` file to the new file name (for example, `mv t1.MYD t2.MYD`). In the `mysql` client, repair the new table, drop the old one, and rename the new table using the old file name (for example, `RENAME TABLE t2 TO t1`).

([Bug#42614](#))

- When starting a cluster with a great many tables, it was possible for MySQL client connections as well as the slave SQL thread to issue DML statements against MySQL Cluster tables before `mysqld` had finished connecting to the cluster and making all tables writeable. This resulted in `TABLE ... IS READ ONLY` errors for clients and the Slave SQL thread.

This issue is fixed by introducing the `--ndb-wait-setup` option for the MySQL server. This provides a configurable maximum amount of time that `mysqld` waits for all NDB tables to become writeable, before enabling MySQL clients or the slave SQL thread to connect. ([Bug#40679](#))

See also [Bug#46955](#).

- Running `ndb_restore` with the `--print` or `--print_log` option could cause it to crash. ([Bug#40428](#), [Bug#33040](#))
- When building MySQL Cluster, it was possible to configure the build using `--with-ndb-port` without supplying a port number. Now in such cases, `configure` fails with an error. ([Bug#38502](#))

See also [Bug#47941](#).

- An insert on an **NDB** table was not always flushed properly before performing a scan. One way in which this issue could manifest was that `LAST_INSERT_ID()` sometimes failed to return correct values when using a trigger on an **NDB** table. ([Bug#38034](#))
- If the cluster crashed during the execution of a `CREATE LOGFILE GROUP` statement, the cluster could not be restarted afterward. ([Bug#36702](#))

See also [Bug#34102](#).

- Some joins on large **NDB** tables having `TEXT` or `BLOB` columns could cause `mysqld` processes to leak memory. The joins did not need to reference the `TEXT` or `BLOB` columns directly for this issue to occur. ([Bug#36701](#))
- When the MySQL server SQL mode included `STRICT_TRANS_TABLES`, storage engine warnings and error codes specific to **NDB** were returned when errors occurred, instead of the MySQL server errors and error codes expected by some programming APIs (such as Connector/J) and applications. ([Bug#35990](#))
- On Mac OS X 10.5, commands entered in the management client failed and sometimes caused the client to hang, although management client commands invoked using the `--execute` (or `-e`) option from the system shell worked normally.

For example, the following command failed with an error and hung until killed manually, as shown here:

```
ndb_mgm> SHOW
WARNING, EVENT THREAD STARTUP FAILED, DEGRADED PRINTOUTS AS RESULT, ERRNO=36
^C
```

However, the same management client command, invoked from the system shell as shown here, worked correctly:

```
shell> ndb_mgm -e "SHOW"
```

([Bug#35751](#))

See also [Bug#34438](#).

- When a copying operation exhausted the available space on a data node while copying large `BLOB` columns, this could lead to failure of the data node and a `TABLE IS FULL` error on the SQL node which was executing the operation. Examples of such operations could include an `ALTER TABLE` that changed an `INT` column to a `BLOB` column, or a bulk insert of `BLOB` data that failed due to running out of space or to a duplicate key error. ([Bug#34583](#), [Bug#48040](#))

See also [Bug#41674](#), [Bug#45768](#).

- Trying to insert more rows than would fit into an **NDB** table caused data nodes to crash. Now in such situations, the insert fails gracefully with error 633 `TABLE FRAGMENT HASH INDEX HAS REACHED MAXIMUM POSSIBLE SIZE`. ([Bug#34348](#))
- The error message text for **NDB** error code 410 (`REDO LOG FILES OVERLOADED...`) was truncated. ([Bug#23662](#))
- **Replication:** When `mysqlbinlog --verbose` was used to read a binary log that had been recorded using the row-based format, the output for events that updated some but not all columns of tables was not correct. ([Bug#47323](#))
- **Replication:** In some cases, a `STOP SLAVE` statement could cause the replication slave to crash. This issue was specific to MySQL on Windows or Macintosh platforms. ([Bug#45238](#), [Bug#45242](#), [Bug#45243](#), [Bug#46013](#), [Bug#46014](#), [Bug#46030](#))

See also [Bug#40796](#).

- **Disk Data:** As an optimization when inserting a row to an empty page, the page is not read, but rather simply initialized. However, this optimization was performed in all cases when an empty row was inserted, even though it should have been done only if it was the first time that the page had been used by a table or fragment. This is because, if the page had been in use, and then all records had been released from it, the page still needed to be read to learn its log sequence number (LSN).

This caused problems only if the page had been flushed using an incorrect LSN and the data node failed before any local checkpoint was completed—which would remove any need to apply the undo log, hence the incorrect LSN was ignored.

The user-visible result of the incorrect LSN was that it caused the data node to fail during a restart. It was perhaps also possible (although not conclusively proven) that this issue could lead to incorrect data. ([Bug#54986](#))

- **Disk Data:** Inserts of blob column values into a Disk Data table that exhausted the tablespace resulted in misleading error messages about rows not being found in the table rather than the expected error `OUT OF EXTENTS, TABLESPACE FULL`. ([Bug#48113](#))

See also [Bug#48037](#), [Bug#41674](#).

- **Disk Data:** A local checkpoint of an empty fragment could cause a crash during a system restart which was based on that LCP.

(Bug#47832)

See also Bug#41915.

- **Disk Data:** Calculation of free space for Disk Data table fragments was sometimes done incorrectly. This could lead to unnecessary allocation of new extents even when sufficient space was available in existing ones for inserted data. In some cases, this might also lead to crashes when restarting data nodes.

#### Note

This miscalculation was not reflected in the contents of the `INFORMATION_SCHEMA.FILES` table, as it applied to extents allocated to a fragment, and not to a file.

(Bug#47072)

- **Disk Data:** If the value set in the `config.ini` file for `FileSystemPathDD`, `FileSystemPathDataFiles`, or `FileSystemPathUndoFiles` was identical to the value set for `FileSystemPath`, that parameter was ignored when starting the data node with `--initial` option. As a result, the Disk Data files in the corresponding directory were not removed when performing an initial start of the affected data node or data nodes. (Bug#46243)
- **Disk Data:** Repeatedly creating and then dropping Disk Data tables could eventually lead to data node failures. (Bug#45794, Bug#48910)
- **Disk Data:** When a crash occurs due to a problem in Disk Data code, the currently active page list is printed to `stdout` (that is, in one or more `ndb_nodeid_out.log` files). One of these lists could contain an endless loop; this caused a printout that was effectively never-ending. Now in such cases, a maximum of 512 entries is printed from each list. (Bug#42431)
- **Cluster Replication:** When `expire_logs_days` was set, the thread performing the purge of the log files could deadlock, causing all binary log operations to stop. (Bug#49536)
- **Cluster Replication:** When using multiple active replication channels, it was sometimes possible that a node group would fail on the slave cluster, causing the slave cluster to shut down. (Bug#47935)
- **Cluster Replication:** When recording a binary log using the `--ndb-log-update-as-write` and `-ndb-log-updated-only` options (both enabled by default) and later attempting to apply that binary log with `mysql-binlog`, any operations that were played back from the log but which updated only some (but not all) columns caused any columns that were not updated to be reset to their default values. (Bug#47674)

See also Bug#47323, Bug#46662.

- **Cluster Replication:** `mysqlbinlog` failed to apply correctly a binary log that had been recorded using `--ndb-log-update-as-write=1`. (Bug#46662)

See also Bug#47323, Bug#47674.

- **Cluster Replication:** When inserting rows into the `mysql.ndb_binlog_index` table, duplicate key errors occurred when the size of the epoch number (a 64-bit integer) exceeded  $2^{53}$ . This happened because the `NDB` storage engine handler called the wrong overloaded variant of a MySQL Server internal API (the `Field::store()` method), which resulted in the epoch being mapped to a 64-bit double precision floating point number and a corresponding loss of accuracy for numbers greater than  $2^{53}$ . (Bug#35217)
- **Cluster API:** When reading blob data with lock mode `LM_SimpleRead`, the lock was not upgraded as expected. (Bug#51034)
- **Cluster API:** When a DML operation failed due to a uniqueness violation on an `NDB` table having more than one unique index, it was difficult to determine which constraint caused the failure; it was necessary to obtain an `NdbError` object, then decode its `details` property, which in could lead to memory management issues in application code.

To help solve this problem, a new API method `Ndb::getNdbErrorDetail()` is added, providing a well-formatted string containing more precise information about the index that caused the unique constraint violation. The following additional changes are also made in the NDB API:

- Use of `NdbError.details` is now deprecated in favor of the new method.
- The `NdbDictionary::listObjects()` method has been modified to provide more information.

For more information, see `Ndb::getNdbErrorDetail()`, [The NdbError Structure](#), and `Dictionary::listObjects()`. (Bug#48851)

- **Cluster API:** The NDB API methods `Dictionary::listEvents()`, `Dictionary::listIndexes()`, `Dictionary::listObjects()`, and `NdbOperation::getErrorLine()` formerly had both `const` and non-`const` variants.

The non-`const` versions of these methods have been removed. In addition, the `NdbOperation::getBlobHandle()` method has been re-implemented to provide consistent internal semantics. ([Bug#47798](#))

- **Cluster API:** In some circumstances, if an API node encountered a data node failure between the creation of a transaction and the start of a scan using that transaction, then any subsequent calls to `startTransaction()` and `closeTransaction()` could cause the same transaction to be started and closed repeatedly. ([Bug#47329](#))
- **Cluster API:** A duplicate read of a column caused NDB API applications to crash. ([Bug#45282](#))
- **Cluster API:** Performing multiple operations using the same primary key within the same `NdbTransaction::execute()` call could lead to a data node crash.

#### Note

This fix does not make change the fact that performing multiple operations using the same primary key within the same `execute()` is not supported; because there is no way to determine the order of such operations, the result of such combined operations remains undefined.

([Bug#44065](#))

See also [Bug#44015](#).

- **Cluster API:** The error handling shown in the example file `ndbapi_scan.cpp` included with the MySQL Cluster distribution was incorrect. ([Bug#39573](#))
- **Cluster API:** When using blobs, calling `getBlobHandle()` requires the full key to have been set using `equal()`, because `getBlobHandle()` must access the key for adding blob table operations. However, if `getBlobHandle()` was called without first setting all parts of the primary key, the application using it crashed. Now, an appropriate error code is returned instead. ([Bug#28116](#), [Bug#48973](#))
- **API:** The fix for [Bug#24507](#) could lead in some cases to client application failures due to a race condition. Now the server waits for the “dummy” thread to return before exiting, thus making sure that only one thread can initialize the POSIX threads library. ([Bug#42850](#))
- On some Unix/Linux platforms, an error during build from source could be produced, referring to a missing `LT_INIT` program. This is due to versions of `libtool` 2.1 and earlier. ([Bug#51009](#))
- On Mac OS X or Windows, sending a `SIGHUP` signal to the server or an asynchronous flush (triggered by `flush_time`) caused the server to crash. ([Bug#47525](#))
- 1) In rare cases, if a thread was interrupted during a `FLUSH PRIVILEGES` operation, a debug assertion occurred later due to improper diagnostics area setup. 2) A `KILL` operation could cause a console error message referring to a diagnostic area state without first ensuring that the state existed. ([Bug#33982](#))
- When using the `ARCHIVE` storage engine, `SHOW TABLE STATUS` displayed incorrect information for `Max_data_length`, `Data_length` and `Avg_row_length`. ([Bug#29203](#))
- Installation of MySQL on Windows would fail to set the correct location for the character set files, which could lead to `mysqld` and `mysql` failing to initialize properly. ([Bug#17270](#))

### 17.7.4.2. Changes in MySQL Cluster NDB 6.2.18 (5.1.34-ndb-6.2.18) (01 June 2009)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.2 release.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.2 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.34 (see [Section C.1.22, “Changes in MySQL 5.1.34 \(02 April 2009\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- **Important Change: Partitioning:** User-defined partitioning of an `NDBCLUSTER` table without any primary key sometimes failed, and could cause `mysqld` to crash.

Now, if you wish to create an `NDBCLUSTER` table with user-defined partitioning, the table must have an explicit primary key,

and all columns listed in the partitioning expression must be part of the primary key. The hidden primary key used by the `NDB-CLUSTER` storage engine is not sufficient for this purpose. However, if the list of columns is empty (that is, the table is defined using `PARTITION BY [LINEAR] KEY()`), then no explicit primary key is required.

This change does not effect the partitioning of tables using any storage engine other than `NDBCLUSTER`. ([Bug#40709](#))

- An internal NDB API buffer was not properly initialized. ([Bug#44977](#))
- When a data node had written its GCI marker to the first page of a megabyte, and that node was later killed during restart after having processed that page (marker) but before completing a LCP, the data node could fail with filesystem errors. ([Bug#44952](#))

See also [Bug#42564](#), [Bug#44291](#).

- Inspection of the code revealed that several assignment operators (`=`) were used in place of comparison operators (`==`) in `Db-dihMain.cpp`. ([Bug#44567](#))

See also [Bug#44570](#).

- It was possible for NDB API applications to insert corrupt data into the database, which could subsequently lead to data node crashes. Now, stricter checking is enforced on input data for inserts and updates. ([Bug#44132](#))
- `TransactionDeadlockDetectionTimeout` values less than 100 were treated as 100. This could cause scans to time out unexpectedly. ([Bug#44099](#))
- The file `ndberror.c` contained a C++-style comment, which caused builds to fail with some C compilers. ([Bug#44036](#))
- A race condition could occur when a data node failed to restart just before being included in the next global checkpoint. This could cause other data nodes to fail. ([Bug#43888](#))
- When trying to use a data node with an older version of the management server, the data node crashed on startup. ([Bug#43699](#))
- Using indexes containing variable-sized columns could lead to internal errors when the indexes were being built. ([Bug#43226](#))
- In some cases, data node restarts during a system restart could fail due to insufficient redo log space. ([Bug#43156](#))
- Some queries using combinations of logical and comparison operators on an indexed column in the `WHERE` clause could fail with the error `GOT ERROR 4541 'INDEXBOUND HAS NO BOUND INFORMATION'` from `NDBCLUSTER`. ([Bug#42857](#))
- `ndb_restore --print_data` did not handle `DECIMAL` columns correctly. ([Bug#37171](#))
- The output of `ndbd --help` did not provide clear information about the program's `--initial` and `--initial-start` options. ([Bug#28905](#))
- It was theoretically possible for the value of a nonexistent column to be read as `NULL`, rather than causing an error. ([Bug#27843](#))
- When aborting an operation involving both an insert and a delete, the insert and delete were aborted separately. This was because the transaction coordinator did not know that the operations affected same row, and, in the case of a committed-read (tuple or index) scan, the abort of the insert was performed first, then the row was examined after the insert was aborted but before the delete was aborted. In some cases, this would leave the row in a inconsistent state. This could occur when a local checkpoint was performed during a backup. This issue did not affect primary key operations or scans that used locks (these are serialized).

After this fix, for ordered indexes, all operations that follow the operation to be aborted are now also aborted.

- **Disk Data: Partitioning:** An `NDBCLUSTER` table created with a very large value for the `MAX_ROWS` option could—if this table was dropped and a new table with fewer partitions, but having the same table ID, was created—cause `ndbd` to crash when performing a system restart. This was because the server attempted to examine each partition whether or not it actually existed. ([Bug#45154](#))
- **Disk Data:** During a checkpoint, restore points are created for both the on-disk and in-memory parts of a Disk Data table. Under certain rare conditions, the in-memory restore point could include or exclude a row that should have been in the snapshot. This would later lead to a crash during or following recovery. ([Bug#41915](#))

See also [Bug#47832](#).

- **Disk Data:** When a log file group had an undo log file whose size was too small, restarting data nodes failed with `READ UNDERFLOW` errors.

As a result of this fix, the minimum permitted `INITIAL_SIZE` for an undo log file is now `1M` (1 megabyte). ([Bug#29574](#))

- **Disk Data:** This fix supercedes and improves on an earlier fix made for this bug in MySQL 5.1.18. ([Bug#24521](#))
- **Cluster Replication:** A failure when setting up replication events could lead to subsequent data node failures. ([Bug#44915](#))
- **Cluster API:** If the largest offset of a `RecordSpecification` used for an `NdbRecord` object was for the `NULL` bits (and thus not a column), this offset was not taken into account when calculating the size used for the `RecordSpecification`. This meant that the space for the `NULL` bits could be overwritten by key or other information. ([Bug#43891](#))
- **Cluster API:** The default `NdbRecord` structures created by `NdbDictionary` could have overlapping null bits and data fields. ([Bug#43590](#))
- **Cluster API:** When performing insert or write operations, `NdbRecord` permits key columns to be specified in both the key record and in the attribute record. Only one key column value for each key column should be sent to the NDB kernel, but this was not guaranteed. This is now ensured as follows: For insert and write operations, key column values are taken from the key record; for scan takeover update operations, key column values are taken from the attribute record. ([Bug#42238](#))
- **Cluster API:** Ordered index scans using `NdbRecord` formerly expressed a `BoundEQ` range as separate lower and upper bounds, resulting in 2 copies of the column values being sent to the NDB kernel.

Now, when a range is specified by `NdbScanOperation::setBound()`, the passed pointers, key lengths, and inclusive bits are compared, and only one copy of the equal key columns is sent to the kernel. This makes such operations more efficient, as half the amount of `KeyInfo` is now sent for a `BoundEQ` range as before. ([Bug#38793](#))

### 17.7.4.3. Changes in MySQL Cluster NDB 6.2.17 (5.1.32-ndb-6.2.17) (19 October 2008)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.2 release.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.2 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.32 (see [Section C.1.24, “Changes in MySQL 5.1.32 \(14 February 2009\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **Important Change:** Formerly, when the management server failed to create a transporter for a data node connection, `net_write_timeout` seconds elapsed before the data node was actually permitted to disconnect. Now in such cases the disconnection occurs immediately. ([Bug#41965](#))

See also [Bug#41713](#).

- **Important Change: Replication:** `RESET MASTER` and `RESET SLAVE` now reset the values shown for `Last_IO_Error`, `Last_IO_Errno`, `Last_SQL_Error`, and `Last_SQL_Errno` in the output of `SHOW SLAVE STATUS`. ([Bug#34654](#))

See also [Bug#44270](#).

- **Cluster Replication: Important Note:** This release of MySQL Cluster derives in part from MySQL 5.1.29, where the default value for the `--binlog-format` option changed to `STATEMENT`. That change does *not* affect this or future MySQL Cluster NDB 6.x releases, where the default value for this option remains `MIXED`, since MySQL Cluster Replication does not work with the statement-based format. ([Bug#40586](#))

- **Disk Data:** It is now possible to specify default locations for Disk Data data files and undo log files, either together or separately, using the data node configuration parameters `FileSystemPathDD`, `FileSystemPathDataFiles`, and `FileSystemPathUndoFiles`. For information about these configuration parameters, see [Disk Data filesystem parameters](#).

It is also now possible to specify a log file group, tablespace, or both, that is created when the cluster is started, using the `InitialLogFileGroup` and `InitialTablespace` data node configuration parameters. For information about these configuration parameters, see [Disk Data object creation parameters](#).

Bugs fixed:

- **Performance:** Updates of the `SYSTAB_0` system table to obtain a unique identifier did not use transaction hints for tables having no primary key. In such cases the NDB kernel used a cache size of 1. This meant that each insert into a table not having a primary key required an update of the corresponding `SYSTAB_0` entry, creating a potential performance bottleneck.

With this fix, inserts on `NDB` tables without primary keys can be under some conditions be performed up to 100% faster than previously. ([Bug#39268](#))

- **Packaging:** Packages for MySQL Cluster were missing the `libndbclient.so` and `libndbclient.a` files. ([Bug#42278](#))
- **Partitioning:** Executing `ALTER TABLE ... REORGANIZE PARTITION` on an `NDBCLUSTER` table having only one partition caused `mysqld` to crash. ([Bug#41945](#))

See also [Bug#40389](#).

- **Cluster API:** Failed operations on `BLOB` and `TEXT` columns were not always reported correctly to the originating SQL node. Such errors were sometimes reported as being due to timeouts, when the actual problem was a transporter overload due to insufficient buffer space. ([Bug#39867](#), [Bug#39879](#))
- Backup IDs greater than  $2^{31}$  were not handled correctly, causing negative values to be used in backup directory names and printouts. ([Bug#43042](#))
- When using `ndbmtd`, NDB kernel threads could hang while trying to start the data nodes with `LockPagesInMainMemory` set to 1. ([Bug#43021](#))
- When using multiple management servers and starting several API nodes (possibly including one or more SQL nodes) whose connectstrings listed the management servers in different order, it was possible for 2 API nodes to be assigned the same node ID. When this happened it was possible for an API node not to get fully connected, consequently producing a number of errors whose cause was not easily recognizable. ([Bug#42973](#))
- `ndb_error_reporter` worked correctly only with GNU `tar`. (With other versions of `tar`, it produced empty archives.) ([Bug#42753](#))
- Triggers on `NDBCLUSTER` tables caused such tables to become locked. ([Bug#42751](#))

See also [Bug#16229](#), [Bug#18135](#).

- When performing more than 32 index or tuple scans on a single fragment, the scans could be left hanging. This caused unnecessary timeouts, and in addition could possibly lead to a hang of an LCP. ([Bug#42559](#))
- A data node failure that occurred between calls to `NdbIndexScanOperation::readTuples(SF_OrderBy)` and `NdbTransaction::Execute()` was not correctly handled; a subsequent call to `nextResult()` caused a null pointer to be dereferenced, leading to a segfault in `mysqld`. ([Bug#42545](#))
- Issuing `SHOW GLOBAL STATUS LIKE 'NDB%'` before `mysqld` had connected to the cluster caused a segmentation fault. ([Bug#42458](#))
- Data node failures that occurred before all data nodes had connected to the cluster were not handled correctly, leading to additional data node failures. ([Bug#42422](#))
- When a cluster backup failed with Error 1304 (Node `node_id1`: Backup request from `node_id2` failed to start), no clear reason for the failure was provided.

As part of this fix, MySQL Cluster now retries backups in the event of sequence errors. ([Bug#42354](#))

See also [Bug#22698](#).

- Issuing `SHOW ENGINE NDBCLUSTER STATUS` on an SQL node before the management server had connected to the cluster caused `mysqld` to crash. ([Bug#42264](#))
- A maximum of 11 `TUP` scans were permitted in parallel. ([Bug#42084](#))
- Trying to execute an `ALTER ONLINE TABLE ... ADD COLUMN` statement while inserting rows into the table caused `mysqld` to crash. ([Bug#41905](#))
- If the master node failed during a global checkpoint, it was possible in some circumstances for the new master to use an incorrect value for the global checkpoint index. This could occur only when the cluster used more than one node group. ([Bug#41469](#))
- API nodes disconnected too aggressively from cluster when data nodes were being restarted. This could sometimes lead to the API node being unable to access the cluster at all during a rolling restart. ([Bug#41462](#))
- An abort path in the `DBLQH` kernel block failed to release a commit acknowledgment marker. This meant that, during node failure handling, the local query handler could be added multiple times to the marker record which could lead to additional node failures due to an array overflow. ([Bug#41296](#))

- During node failure handling (of a data node other than the master), there was a chance that the master was waiting for a `GCP_NODEFINISHED` signal from the failed node after having received it from all other data nodes. If this occurred while the failed node had a transaction that was still being committed in the current epoch, the master node could crash in the `DBTC` kernel block when discovering that a transaction actually belonged to an epoch which was already completed. ([Bug#41295](#))
- If a transaction was aborted during the handling of a data node failure, this could lead to the later handling of an API node failure not being completed. ([Bug#41214](#))
- Given a MySQL Cluster containing no data (that is, whose data nodes had all been started using `--initial`, and into which no data had yet been imported) and having an empty backup directory, executing `START BACKUP` with a user-specified backup ID caused the data nodes to crash. ([Bug#41031](#))
- Issuing `EXIT` in the management client sometimes caused the client to hang. ([Bug#40922](#))
- Redo log creation was very slow on some platforms, causing MySQL Cluster to start more slowly than necessary with some combinations of hardware and operating system. This was due to all write operations being synchronized to disk while creating a redo log file. Now this synchronization occurs only after the redo log has been created. ([Bug#40734](#))
- Transaction failures took longer to handle than was necessary.

When a data node acting as transaction coordinator (TC) failed, the surviving data nodes did not inform the API node initiating the transaction of this until the failure had been processed by all protocols. However, the API node needed only to know about failure handling by the transaction protocol—that is, it needed to be informed only about the TC takeover process. Now, API nodes (including MySQL servers acting as cluster SQL nodes) are informed as soon as the TC takeover is complete, so that it can carry on operating more quickly. ([Bug#40697](#))

- It was theoretically possible for stale data to be read from `NDBCLUSTER` tables when the transaction isolation level was set to `ReadCommitted`. ([Bug#40543](#))
- In some cases, `NDB` did not check correctly whether tables had changed before trying to use the query cache. This could result in a crash of the debug MySQL server. ([Bug#40464](#))
- Restoring a MySQL Cluster from a dump made using `mysqldump` failed due to a spurious error: `CAN'T EXECUTE THE GIVEN COMMAND BECAUSE YOU HAVE ACTIVE LOCKED TABLES OR AN ACTIVE TRANSACTION.` ([Bug#40346](#))
- `O_DIRECT` was incorrectly disabled when making MySQL Cluster backups. ([Bug#40205](#))
- Events logged after setting `ALL CLUSTERLOG STATISTICS=15` in the management client did not always include the node ID of the reporting node. ([Bug#39839](#))
- Start phase reporting was inconsistent between the management client and the cluster log. ([Bug#39667](#))
- The MySQL Query Cache did not function correctly with `NDBCLUSTER` tables containing `TEXT` columns. ([Bug#39295](#))
- A segfault in `Logger::Log` caused `ndbd` to hang indefinitely. This fix improves on an earlier one for this issue, first made in MySQL Cluster NDB 6.2.16 and MySQL Cluster NDB 6.3.17. ([Bug#39180](#))

See also [Bug#38609](#).

- Memory leaks could occur in handling of strings used for storing cluster metadata and providing output to users. ([Bug#38662](#))
- In the event that a MySQL Cluster backup failed due to file permissions issues, conflicting reports were issued in the management client. ([Bug#34526](#))
- A duplicate key or other error raised when inserting into an `NDBCLUSTER` table caused the current transaction to abort, after which any SQL statement other than a `ROLLBACK` failed. With this fix, the `NDBCLUSTER` storage engine now performs an implicit rollback when a transaction is aborted in this way; it is no longer necessary to issue an explicit `ROLLBACK` statement, and the next statement that is issued automatically begins a new transaction.

### Note

It remains necessary in such cases to retry the complete transaction, regardless of which statement caused it to be aborted.

([Bug#32656](#))

See also [Bug#47654](#).

- Error messages for `NDBCLUSTER` error codes 1224 and 1227 were missing. ([Bug#28496](#))
- **Partitioning:** A query on a user-partitioned table caused MySQL to crash, where the query had the following characteristics:

- The query's `WHERE` clause referenced an indexed column that was also in the partitioning key.
- The query's `WHERE` clause included a value found in the partition.
- The query's `WHERE` clause used the `<` or `<>` operators to compare with the indexed column's value with a constant.
- The query used an `ORDER BY` clause, and the same indexed column was used in the `ORDER BY` clause.
- The `ORDER BY` clause used an explicit or implicit `ASC` sort priority.

Two examples of such a query are given here, where `a` represents an indexed column used in the table's partitioning key:

1. 

```
SELECT * FROM table WHERE a < constant ORDER BY a;
```

2. 

```
SELECT * FROM table WHERE a <> constant ORDER BY a;
```

[\(Bug#40954\)](#)

This regression was introduced by [Bug#30573](#), [Bug#33257](#), [Bug#33555](#).

- **Partitioning:** Dropping or creating an index on a partitioned table managed by the `InnoDB` Plugin locked the table. ([Bug#37453](#))
  - **Disk Data:** It was not possible to add an in-memory column online to a table that used a table-level or column-level `STORAGE DISK` option. The same issue prevented `ALTER ONLINE TABLE ... REORGANIZE PARTITION` from working on Disk Data tables. ([Bug#42549](#))
  - **Disk Data:** Issuing concurrent `CREATE TABLESPACE`, `ALTER TABLESPACE`, `CREATE LOGFILE GROUP`, or `ALTER LOGFILE GROUP` statements on separate SQL nodes caused a resource leak that led to data node crashes when these statements were used again later. ([Bug#40921](#))
  - **Disk Data:** Disk-based variable-length columns were not always handled like their memory-based equivalents, which could potentially lead to a crash of cluster data nodes. ([Bug#39645](#))
  - **Disk Data:** Creating a Disk Data tablespace with a very large extent size caused the data nodes to fail. The issue was observed when using extent sizes of 100 MB and larger. ([Bug#39096](#))
  - **Disk Data:** Creation of a tablespace data file whose size was greater than 4 GB failed silently on 32-bit platforms. ([Bug#37116](#))
- See also [Bug#29186](#).
- **Disk Data:** `O_SYNC` was incorrectly disabled on platforms that do not support `O_DIRECT`. This issue was noted on Solaris but could have affected other platforms not having `O_DIRECT` capability. ([Bug#34638](#))
  - **Disk Data:** Trying to execute a `CREATE LOGFILE GROUP` statement using a value greater than `150M` for `UNDO_BUFFER_SIZE` caused data nodes to crash.

As a result of this fix, the upper limit for `UNDO_BUFFER_SIZE` is now `600M`; attempting to set a higher value now fails gracefully with an error. ([Bug#34102](#))

See also [Bug#36702](#).

- **Disk Data:** When attempting to create a tablespace that already existed, the error message returned was `TABLE OR INDEX WITH GIVEN NAME ALREADY EXISTS`. ([Bug#32662](#))
- **Disk Data:** Using a path or filename longer than 128 characters for Disk Data undo log files and tablespace data files caused a number of issues, including failures of `CREATE LOGFILE GROUP`, `ALTER LOGFILE GROUP`, `CREATE TABLESPACE`, and `ALTER TABLESPACE` statements, as well as crashes of management nodes and data nodes.

With this fix, the maximum length for path and file names used for Disk Data undo log files and tablespace data files is now the same as the maximum for the operating system. ([Bug#31769](#), [Bug#31770](#), [Bug#31772](#))

- **Disk Data:** Starting a cluster under load such that Disk Data tables used most of the undo buffer could cause data node failures.

The fix for this bug also corrected an issue in the `LGTMN` kernel block where the amount of free space left in the undo buffer was miscalculated, causing buffer overruns. This could cause records in the buffer to be overwritten, leading to problems when restarting data nodes. ([Bug#28077](#))

- **Disk Data:** Attempting to perform a system restart of the cluster where there existed a logfile group without and undo log files caused the data nodes to crash.

#### Note

While issuing a `CREATE LOGFILE GROUP` statement without an `ADD UNDOFILE` option fails with an error in the MySQL server, this situation could arise if an SQL node failed during the execution of a valid `CREATE LOGFILE GROUP` statement; it is also possible to create a logfile group without any undo log files using the NDB API.

(Bug#17614)

- **Cluster Replication:** Sometimes, when using the `--ndb_log_orig` option, the `orig_epoch` and `orig_server_id` columns of the `ndb_binlog_index` table on the slave contained the ID and epoch of the local server instead. (Bug#41601)
- **Cluster API:** Some error messages from `ndb_mgmd` contained newline (\n) characters. This could break the MGM API protocol, which uses the newline as a line separator. (Bug#43104)
- **Cluster API:** When using an ordered index scan without putting all key columns in the read mask, this invalid use of the NDB API went undetected, which resulted in the use of uninitialized memory. (Bug#42591)
- **Cluster API:** The MGM API reset error codes on management server handles before checking them. This meant that calling an MGM API function with a null handle caused applications to crash. (Bug#40455)
- **Cluster API:** It was not always possible to access parent objects directly from `NdbBlob`, `NdbOperation`, and `NdbScanOperation` objects. To alleviate this problem, a new `getNdbOperation()` method has been added to `NdbBlob` and new `getNdbTransaction()` methods have been added to `NdbOperation` and `NdbScanOperation`. In addition, a const variant of `NdbOperation::getErrorLine()` is now also available. (Bug#40242)
- **Cluster API:** `NdbScanOperation::getBlobHandle()` failed when used with incorrect column names or numbers. (Bug#40241)
- **Cluster API:** The NDB API example programs included in MySQL Cluster source distributions failed to compile. (Bug#37491)

See also Bug#40238.

- **Cluster API:** `mgmapi.h` contained constructs which only worked in C++, but not in C. (Bug#27004)

### 17.7.4.4. Changes in MySQL Cluster NDB 6.2.16 (5.1.28-ndb-6.2.16) (08 October 2008)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.2 release.

**Obtaining MySQL Cluster NDB 6.2.** You can download the latest MySQL Cluster NDB 6.2 source code and binaries for supported platforms from [ftp://ftp.mysql.com/pub/mysql/download/cluster\\_telco/mysql-5.1.28-ndb-6.2.16](http://ftp.mysql.com/pub/mysql/download/cluster_telco/mysql-5.1.28-ndb-6.2.16).

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.2 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.28 (see [Section C.1.29, “Changes in MySQL 5.1.28 \(28 August 2008\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- It is no longer a requirement for database autodiscovery that an SQL node already be connected to the cluster at the time that a database is created on another SQL node. It is no longer necessary to issue `CREATE DATABASE` (or `CREATE SCHEMA`) statements on an SQL node joining the cluster after a database is created for the new SQL node to see the database and any `NDCLUSTER` tables that it contains. (Bug#39612)

Bugs fixed:

- Heavy DDL usage caused the `mysqld` processes to hang due to a timeout error (NDB error code 266). (Bug#39885)
- Executing `EXPLAIN SELECT` on an `NDCLUSTER` table could cause `mysqld` to crash. (Bug#39872)

- Starting the MySQL Server with the `--ndbcluster` option plus an invalid command-line option (for example, using `mysqld --ndbcluster --foobar`) caused it to hang while shutting down the binlog thread. ([Bug#39635](#))
- Dropping and then re-creating a database on one SQL node caused other SQL nodes to hang. ([Bug#39613](#))
- Setting a low value of `MaxNoOfLocalScans` (< 100) and performing a large number of (certain) scans could cause the Transaction Coordinator to run out of scan fragment records, and then crash. Now when this resource is exhausted, the cluster returns Error 291 (OUT OF SCANFRAG RECORDS IN TC (INCREASE MAXNOOFLOCALSCANS)) instead. ([Bug#39549](#))
- Creating a unique index on an `NDBCLUSTER` table caused a memory leak in the `NDB` subscription manager (`SUMA`) which could lead to mysqld hanging, due to the fact that the resource shortage was not reported back to the `NDB` kernel correctly. ([Bug#39518](#))

See also [Bug#39450](#).

- Unique identifiers in tables having no primary key were not cached. This fix has been observed to increase the efficiency of `INSERT` operations on such tables by as much as 50%. ([Bug#39267](#))
- `MgmtSrvr::allocNodeId()` left a mutex locked following an AMBIGUITY FOR NODE IF %D error. ([Bug#39158](#))
- An invalid path specification caused `mysql-test-run.pl` to fail. ([Bug#39026](#))
- During transactional coordinator takeover (directly after node failure), the LQH finding an operation in the `LOG_COMMIT` state sent an `LQH_TRANS_CONF` signal twice, causing the TC to fail. ([Bug#38930](#))
- An invalid memory access caused the management server to crash on Solaris Sparc platforms. ([Bug#38628](#))
- A segfault in `Logger::Log` caused `ndbd` to hang indefinitely. ([Bug#38609](#))
- `ndb_mgmd` failed to start on older Linux distributions (2.4 kernels) that did not support e-polling. ([Bug#38592](#))
- When restarting a data node, an excessively long shutdown message could cause the node process to crash. ([Bug#38580](#))
- `ndb_mgmd` sometimes performed unnecessary network I/O with the client. This in combination with other factors led to long-running threads that were attempting to write to clients that no longer existed. ([Bug#38563](#))
- `ndb_restore` failed with a floating point exception due to a division by zero error when trying to restore certain data files. ([Bug#38520](#))
- A failed connection to the management server could cause a resource leak in `ndb_mgmd`. ([Bug#38424](#))
- Failure to parse configuration parameters could cause a memory leak in the `NDB` log parser. ([Bug#38380](#))
- After a forced shutdown and initial restart of the cluster, it was possible for SQL nodes to retain `.frm` files corresponding to `NDBCLUSTER` tables that had been dropped, and thus to be unaware that these tables no longer existed. In such cases, attempting to re-create the tables using `CREATE TABLE IF NOT EXISTS` could fail with a spurious TABLE ... DOESN'T EXIST error. ([Bug#37921](#))
- Renaming an `NDBCLUSTER` table on one SQL node, caused a trigger on this table to be deleted on another SQL node. ([Bug#36658](#))
- Attempting to add a `UNIQUE INDEX` twice to an `NDBCLUSTER` table, then deleting rows from the table could cause the MySQL Server to crash. ([Bug#35599](#))
- `ndb_restore` failed when a single table was specified. ([Bug#33801](#))
- `GCP_COMMIT` did not wait for transaction takeover during node failure. This could cause `GCP_SAVE_REQ` to be executed too early. This could also cause (very rarely) replication to skip rows. ([Bug#30780](#))
- **Cluster Replication:** In some cases, dropping a database on the master could cause table logging to fail on the slave, or, when using a debug build, could cause the slave `mysqld` to fail completely. ([Bug#39404](#))
- **Cluster Replication:** During a parallel node restart, the starting nodes could (sometimes) incorrectly synchronize subscriptions among themselves. Instead, this synchronization now takes place only among nodes that have actually (completely) started. ([Bug#38767](#))
- **Cluster Replication:** Data was written to the binlog with `--log-slave-updates` disabled. ([Bug#37472](#))
- **Cluster API:** Passing a value greater than 65535 to `NdbInterpretedCode::add_val()` and `NdbInterpretedCode::sub_val()` caused these methods to have no effect. ([Bug#39536](#))

- **Cluster API:** The `NdbScanOperation::readTuples()` method could be called multiple times without error. ([Bug#38717](#))
- **Cluster API:** Certain Multi-Range Read scans involving `IS NULL` and `IS NOT NULL` comparisons failed with an error in the `NDB` local query handler. ([Bug#38204](#))
- **Cluster API:** Problems with the public headers prevented `NDB` applications from being built with warnings turned on. ([Bug#38177](#))
- **Cluster API:** Creating an `NdbScanFilter` object using an `NdbScanOperation` object that had not yet had its `readTuples()` method called resulted in a crash when later attempting to use the `NdbScanFilter`. ([Bug#37986](#))
- **Cluster API:** Executing an `NdbRecord` interpreted delete created with an `ANYVALUE` option caused the transaction to abort. ([Bug#37672](#))
- **Cluster API:** Accessing the debug version of `libndbclient` using `dlopen()` resulted in a segmentation fault. ([Bug#35927](#))

#### 17.7.4.5. Changes in MySQL Cluster NDB 6.2.15 (5.1.23-ndb-6.2.15) (22 May 2008)

This is re-release of MySQL Cluster NDB 6.2.14 providing binaries for supported platforms. For more information, see [Section 17.7.4.6, “Changes in MySQL Cluster NDB 6.2.14 \(5.1.23-ndb-6.2.14\) \(05 March 2008\)](#)”.

**Obtaining MySQL Cluster NDB 6.2.** You can download the latest MySQL Cluster NDB 6.2 source code and binaries for supported platforms from <http://dev.mysql.com/downloads/cluster/>.

#### 17.7.4.6. Changes in MySQL Cluster NDB 6.2.14 (5.1.23-ndb-6.2.14) (05 March 2008)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.2 release.

**Obtaining MySQL Cluster NDB 6.2.** You can download the latest MySQL Cluster NDB 6.2 source code and binaries for supported platforms from <http://dev.mysql.com/downloads/cluster/>.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.2 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.23 (see [Section C.1.34, “Changes in MySQL 5.1.23 \(29 January 2008\)”](#)).

##### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- Added the `MaxBufferedEpochs` data node configuration parameter, which controls the maximum number of unprocessed epochs by which a subscribing node can lag. Subscribers which exceed this number are disconnected and forced to reconnect. See [Section 17.3.2.6, “Defining MySQL Cluster Data Nodes”](#), for more information.
- **Replication:** Introduced the `slave_exec_mode` system variable to control whether idempotent or strict mode is used for replication conflict resolution. Idempotent mode suppresses duplicate-key, no-key-found, and some other errors, and is needed for circular replication, multi-master replication, and some other complex replication setups when using MySQL Cluster, where idempotent mode is the default. However, strict mode is the default for storage engines other than `NDB`. ([Bug#31609](#))
- **Cluster Replication:** `RESET MASTER` now uses `TRUNCATE TABLE` rather than `DELETE` to clear the `mysql.ndb_binlog_index` table. This improves the performance of the statement and is less likely to leave the table in a fragmented state. ([Bug#34356](#))
- Formerly, when the MySQL server crashed, the generated stack dump was numeric and required external tools to properly resolve the names of functions. This is not very helpful to users having a limited knowledge of debugging techniques. In addition, the generated stack trace contained only the names of functions and was formatted differently for each platform due to different stack layouts.

Now it is possible to take advantage of newer versions of the GNU C Library provide a set of functions to obtain and manipulate stack traces from within the program. On systems that use the ELF binary format, the stack trace contains important information such as the shared object where the call was generated, an offset into the function, and the actual return address. Having the function name also makes possible the name demangling of C++ functions.

The library generates meaningful stack traces on the following platforms: i386, x86\_64, PowerPC, IA64, Alpha, and S390. On other platforms, a numeric stack trace is still produced, and the use of the `resolve_stack_dump` utility is still required. ([Bug#31891](#))

- `mysqltest` now has `mkdir` and `rmdir` commands for creating and removing directories. ([Bug#31004](#))
- Added the `Uptime_since_flush_status` status variable, which indicates the number of seconds since the most recent `FLUSH STATUS` statement. (Community contribution by Jeremy Cole) ([Bug#24822](#))

Bugs fixed:

- **Performance:** `InnoDB` exhibited thread thrashing with more than 50 concurrent connections under an update-intensive workload. ([Bug#22868](#))
- **Incompatible Change:** The `UPDATE` statement permitted `NULL` to be assigned to `NOT NULL` columns (the implicit default value for the column data type was assigned). This was changed so that an error occurs.

This change was reverted, because the original report was determined not to be a bug: Assigning `NULL` to a `NOT NULL` column in an `UPDATE` statement should produce an error only in strict SQL mode and set the column to the implicit default with a warning otherwise, which was the original behavior. See [Section 10.1.4, “Data Type Default Values”](#), and [Bug#39265](#). ([Bug#33699](#))

- **Important Change: Replication:** When the master crashed during an update on a transactional table while in `autocommit` mode, the slave failed. This fix causes every transaction (including `autocommit` transactions) to be recorded in the binlog as starting with a `BEGIN` and ending with a `COMMIT` or `ROLLBACK`. ([Bug#26395](#))
- **Replication: Important Note:** Network timeouts between the master and the slave could result in corruption of the relay log. This fix rectifies a long-standing replication issue when using unreliable networks, including replication over wide area networks such as the Internet. If you experience reliability issues and see many `YOU HAVE AN ERROR IN YOUR SQL SYNTAX` errors on replication slaves, we strongly recommend that you upgrade to a MySQL version which includes this fix. ([Bug#26489](#))
- **Replication:** When the Windows version of `mysqlbinlog` read 4.1 binlogs containing `LOAD DATA INFILE` statements, it output backslashes as path separators, causing problems for client programs expecting forward slashes. In such cases, it now converts `\\"` to `/` in directory paths. ([Bug#34355](#))
- **Replication:** `SHOW SLAVE STATUS` failed when slave I/O was about to terminate. ([Bug#34305](#))
- **Replication:** `mysqlbinlog` from a 5.1 or later MySQL distribution could not read binary logs generated by a 4.1 server when the logs contained `LOAD DATA INFILE` statements. ([Bug#34141](#))

This regression was introduced by [Bug#32407](#).

- **Replication:** A `CREATE USER`, `DROP USER`, or `RENAME USER` statement that fails on the master, or that is a duplicate of any of these statements, is no longer written to the binlog; previously, either of these occurrences could cause the slave to fail. ([Bug#33862](#))

See also [Bug#29749](#).

- **Replication:** `mysqlbinlog` failed to release all of its memory after terminating abnormally. ([Bug#33247](#))
- **Replication:** The error message generated due to lack of a default value for an extra column was not sufficiently informative. ([Bug#32971](#))
- **Replication:** When a user variable was used inside an `INSERT` statement, the corresponding binlog event was not written to the binlog correctly. ([Bug#32580](#))
- **Replication:** When using row-based replication, deletes from a table with a foreign key constraint failed on the slave. ([Bug#32468](#))
- **Replication:** SQL statements containing comments using `--` syntax were not replayable by `mysqlbinlog`, even though such statements replicated correctly. ([Bug#32205](#))
- **Replication:** When using row-based replication from a master running MySQL 5.1.21 or earlier to a slave running 5.1.22 or later, updates of integer columns failed on the slave with `ERROR IN UNKNOWN EVENT: ROW APPLICATION FAILED`. ([Bug#31583](#))

This regression was introduced by [Bug#21842](#).

- **Replication:** Replicating write, update, or delete events from a master running MySQL 5.1.15 or earlier to a slave running 5.1.16 or later caused the slave to crash. ([Bug#31581](#))
- **Replication:** When using row-based replication, the slave stopped when attempting to delete nonexistent rows from a slave table without a primary key. In addition, no error was reported when this occurred. ([Bug#31552](#))
- **Replication:** Issuing a `DROP VIEW` statement caused replication to fail if the view did not actually exist. ([Bug#30998](#))
- **Replication:** Replication of `LOAD DATA INFILE` could fail when `read_buffer_size` was larger than `max_allowed_packet`. ([Bug#30435](#))
- **Replication:** Replication crashed with the `NDB` storage engine when `mysqld` was started with `-character-set-server=ucs2`. ([Bug#29562](#))
- **Replication:** Setting `server_id` did not update its value for the current session. ([Bug#28908](#))
- **Replication:** Some older servers wrote events to the binary log using different numbering from what is currently used, even though the file format number in the file is the same. Slaves running MySQL 5.1.18 and later could not read these binary logs properly. Binary logs from these older versions now are recognized and event numbers are mapped to the current numbering so that they can be interpreted properly. ([Bug#27779](#), [Bug#32434](#))

This regression was introduced by [Bug#22583](#).

- **Cluster Replication:** Enabling the `ndb_wait_connected` system variable caused the server to wait for a partial connection plus an additional 3 seconds for a complete connection to the cluster. This could lead to issues with setting up the binary log. ([Bug#34757](#))
- **Cluster API:** Closing a scan before it was executed caused the application to segfault. ([Bug#36375](#))
- **Cluster API:** Using NDB API applications from older MySQL Cluster versions with `libndbclient` from newer ones caused the cluster to fail. ([Bug#36124](#))
- **Cluster API:** Scans having no bounds set were handled incorrectly. ([Bug#35876](#))
- Use of stored functions in the `WHERE` clause for `SHOW OPEN TABLES` caused a server crash. ([Bug#34166](#))
- Large unsigned integers were improperly handled for prepared statements, resulting in truncation or conversion to negative numbers. ([Bug#33798](#))
- The server crashed when executing a query that had a subquery containing an equality `X=Y` where `Y` referred to a named select list expression from the parent select. The server crashed when trying to use the `X=Y` equality for `ref`-based access. ([Bug#33794](#))
- `ORDER BY ... DESC` sorts could produce misordered results. ([Bug#33697](#))
- The server could crash when `REPEAT` or another control instruction was used in conjunction with labels and a `LEAVE` instruction. ([Bug#33618](#))
- `SET GLOBAL myisam_max_sort_file_size=DEFAULT` set `myisam_max_sort_file_size` to an incorrect value. ([Bug#33382](#))

See also [Bug#31177](#).

- Granting the `UPDATE` privilege on one column of a view caused the server to crash. ([Bug#33201](#))
- For `DECIMAL` columns used with the `ROUND(X,D)` or `TRUNCATE(X,D)` function with a nonconstant value of `D`, adding an `ORDER BY` for the function result produced misordered output. ([Bug#32143](#))

See also [Bug#33402](#), [Bug#30617](#).

- The `SHOW ENGINE INNODB STATUS` and `SHOW ENGINE INNODB MUTEX` statements incorrectly required the `SUPER` privilege rather than the `PROCESS` privilege. ([Bug#32710](#))
- Tables in the `mysql` database that stored the current `sql_mode` value as part of stored program definitions were not updated with newer mode values (`NO_ENGINE_SUBSTITUTION`, `PAD_CHAR_TO_FULL_LENGTH`). This causes various problems defining stored programs if those modes were included in the current `sql_mode` value. ([Bug#32633](#))
- `ROUND(X,D)` or `TRUNCATE(X,D)` for nonconstant values of `D` could crash the server if these functions were used in an `ORDER BY` that was resolved using `filesort`. ([Bug#30889](#))
- Resetting the query cache by issuing a `SET GLOBAL query_cache_size=0` statement caused the server to crash if it con-

currently was saving a new result set to the query cache. ([Bug#30887](#))

- The `Table_locks_waited` waited variable was not incremented in the cases that a lock had to be waited for but the waiting thread was killed or the request was aborted. ([Bug#30331](#))
- The `Com_create_function` status variable was not incremented properly. ([Bug#30252](#))
- `mysqld` displayed the `--enable-pstack` option in its help message even if MySQL was configured without `--with-pstack`. ([Bug#29836](#))
- Views were treated as insertable even if some base table columns with no default value were omitted from the view definition. (This is contrary to the condition for insertability that a view must contain all columns in the base table that do not have a default value.) ([Bug#29477](#))
- Previously, the parser accepted the ODBC `{ OJ ... LEFT OUTER JOIN ... }` syntax for writing left outer joins. The parser now permits `{ OJ ... }` to be used to write other types of joins, such as `INNER JOIN` or `RIGHT OUTER JOIN`. This helps with compatibility with some third-party applications, but is not official ODBC syntax. ([Bug#28317](#))
- The parser rules for the `SHOW PROFILE` statement were revised to work with older versions of `bison`. ([Bug#27433](#))
- `resolveip` failed to produce correct results for host names that begin with a digit. ([Bug#27427](#))
- `mysqlcheck -A -r` did not correctly identify all tables that needed repairing. ([Bug#25347](#))
- Warnings for deprecated syntax constructs used in stored routines make sense to report only when the routine is being created, but they were also being reported when the routine was parsed for loading into the execution cache. Now they are reported only at routine creation time. ([Bug#21801](#))
- `CREATE ... SELECT` did not always set `DEFAULT` column values in the new table. ([Bug#21380](#))
- If a `SELECT` calls a stored function in a transaction, and a statement within the function fails, that statement should roll back. Furthermore, if `ROLLBACK` is executed after that, the entire transaction should be rolled back. Before this fix, the failed statement did not roll back when it failed (even though it might ultimately get rolled back by a `ROLLBACK` later that rolls back the entire transaction). ([Bug#12713](#))

See also [Bug#34655](#).

#### 17.7.4.7. Changes in MySQL Cluster NDB 6.2.13 (5.1.23-ndb-6.2.13) (22 February 2008)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.2 release.

**Obtaining MySQL Cluster NDB 6.2.** You can download the latest MySQL Cluster NDB 6.2 source code and binaries for supported platforms from <http://dev.mysql.com/downloads/cluster/>.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.2 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.23 (see [Section C.1.34, “Changes in MySQL 5.1.23 \(29 January 2008\)”](#)).

##### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- A node failure during an initial node restart followed by another node start could cause the master data node to fail, because it incorrectly gave the node permission to start even if the invalidated node's LCP was still running. ([Bug#34702](#))

#### 17.7.4.8. Changes in MySQL Cluster NDB 6.2.12 (5.1.23-ndb-6.2.12) (12 February 2008)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.2 release.

**Obtaining MySQL Cluster NDB 6.2.** You can download the latest MySQL Cluster NDB 6.2 source code and binaries for supported platforms from <http://dev.mysql.com/downloads/cluster/>.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.2 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.23 (see [Section C.1.34, “Changes in MySQL 5.1.23 \(29 January 2008\)”](#)).

**Note**

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- Beginning with this version, MySQL Cluster NDB 6.3.x releases once again include the `InnoDB` storage engine. To enable `InnoDB`, you must configure the build using `--with-innodb`.

Bugs fixed:

- Upgrades of a cluster using while a `DataMemory` setting in excess of 16 GB caused data nodes to fail. ([Bug#34378](#))
- Performing many SQL statements on `NDB` tables while in `autocommit` mode caused a memory leak in `mysqld`. ([Bug#34275](#))
- In certain rare circumstances, a race condition could occur between an aborted insert and a delete leading a data node crash. ([Bug#34260](#))
- Multi-table updates using ordered indexes during handling of node failures could cause other data nodes to fail. ([Bug#34216](#))
- When configured with `NDB` support, MySQL failed to compile using `gcc` 4.3 on 64bit FreeBSD systems. ([Bug#34169](#))
- The failure of a DDL statement could sometimes lead to node failures when attempting to execute subsequent DDL statements. ([Bug#34160](#))
- Extremely long `SELECT` statements (where the text of the statement was in excess of 50000 characters) against `NDB` tables returned empty results. ([Bug#34107](#))
- Statements executing multiple inserts performed poorly on `NDB` tables having `AUTO_INCREMENT` columns. ([Bug#33534](#))
- The `ndb_warter` utility polled `ndb_mgmd` excessively when obtaining the status of cluster data nodes. ([Bug#32025](#))

See also [Bug#32023](#).

- Transaction atomicity was sometimes not preserved between reads and inserts under high loads. ([Bug#31477](#))
- Having tables with a great many columns could cause Cluster backups to fail. ([Bug#30172](#))
- **Cluster Replication: Disk Data:** Statements violating unique keys on Disk Data tables (such as attempting to insert `NULL` into a `NOT NULL` column) could cause data nodes to fail. When the statement was executed from the binlog, this could also result in failure of the slave cluster. ([Bug#34118](#))
- **Disk Data:** Updating in-memory columns of one or more rows of Disk Data table, followed by deletion of these rows and re-insertion of them, caused data node failures. ([Bug#33619](#))
- **Cluster Replication:** Setting `--replicate-ignore-db=mysql` caused the `mysql.ndb_apply_status` table not to be replicated, breaking Cluster Replication. ([Bug#28170](#))

## 17.7.4.9. Changes in MySQL Cluster NDB 6.2.11 (5.1.23-ndb-6.2.11) (28 January 2008)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.2 release.

**Obtaining MySQL Cluster NDB 6.2.** You can download the latest MySQL Cluster NDB 6.2 source code and binaries for supported platforms from <http://dev.mysql.com/downloads/cluster/>.

This release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.2 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.23 (see [Section C.1.34, “Changes in MySQL 5.1.23 \(29 January 2008\)”](#)).

**Note**

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **Cluster API: Important Change:** Because `NDB_LE_MemoryUsage.page_size_kb` shows memory page sizes in bytes rather than kilobytes, it has been renamed to `page_size_bytes`. The name `page_size_kb` is now deprecated and thus subject to removal in a future release, although it currently remains supported for reasons of backward compatibility. See [The `Ndb\_logevent\_type` Type](#), for more information about `NDB_LE_MemoryUsage`. ([Bug#30271](#))

Bugs fixed:

- High numbers of insert operations, delete operations, or both could cause `NDB` error 899 (`ROWID ALREADY ALLOCATED`) to occur unnecessarily. ([Bug#34033](#))
- A periodic failure to flush the send buffer by the `NDB` TCP transporter could cause an unnecessary delay of 10 ms between operations. ([Bug#34005](#))
- A race condition could occur (very rarely) when the release of a GCI was followed by a data node failure. ([Bug#33793](#))
- Some tuple scans caused the wrong memory page to be accessed, leading to invalid results. This issue could affect both in-memory and Disk Data tables. ([Bug#33739](#))
- The server failed to reject properly the creation of an `NDB` table having an unindexed `AUTO_INCREMENT` column. ([Bug#30417](#))
- Issuing an `INSERT ... ON DUPLICATE KEY UPDATE` concurrently with or following a `TRUNCATE TABLE` statement on an `NDB` table failed with `NDB` error 4350 `TRANSACTION ALREADY ABORTED`. ([Bug#29851](#))
- The Cluster backup process could not detect when there was no more disk space and instead continued to run until killed manually. Now the backup fails with an appropriate error when disk space is exhausted. ([Bug#28647](#))
- It was possible in `config.ini` to define cluster nodes having node IDs greater than the maximum permitted value. ([Bug#28298](#))
- **Cluster Replication:** `ndb_restore -e` restored excessively large values to the `ndb_apply_status` table's `epoch` column when restoring to a MySQL Cluster version supporting Micro-GCPs from an older version that did not support these.

A workaround when restoring to MySQL Cluster releases supporting micro-GCPs previous to MySQL Cluster NDB 6.3.8 is to perform a 32-bit shift on the `epoch` column values to reduce them to their proper size. ([Bug#33406](#))

- **Cluster API:** Transactions containing inserts or reads would hang during `NdbTransaction::execute()` calls made from NDB API applications built against a MySQL Cluster version that did not support micro-GCPs accessing a later version that supported micro-GCPs. This issue was observed while upgrading from MySQL Cluster NDB 6.1.23 to MySQL Cluster NDB 6.2.10 when the API application built against the earlier version attempted to access a data node already running the later version, even after disabling micro-GCPs by setting `TimeBetweenEpochs` equal to 0. ([Bug#33895](#))
- **Cluster API:** When reading a `BIT(64)` value using `NdbOperation::getValue()`, 12 bytes were written to the buffer rather than the expected 8 bytes. ([Bug#33750](#))

#### 17.7.4.10. Changes in MySQL Cluster NDB 6.2.10 (5.1.23-ndb-6.2.10) (19 December 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.2 release.

**Obtaining MySQL Cluster NDB 6.2.** You can download the latest MySQL Cluster NDB 6.2 source code and binaries for supported platforms from <http://dev.mysql.com/downloads/cluster/>.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.2 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.23 (see [Section C.1.34, “Changes in MySQL 5.1.23 \(29 January 2008\)”](#)).

##### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- **Partitioning:** When partition pruning on an `NDB` table resulted in an ordered index scan spanning only one partition, any descending flag for the scan was wrongly discarded, causing `ORDER BY DESC` to be treated as `ORDER BY ASC, MAX()` to be handled incorrectly, and similar problems. ([Bug#33061](#))

- When all data and SQL nodes in the cluster were shut down abnormally (that is, other than by using `STOP` in the cluster management client), `ndb_mgm` used excessive amounts of CPU. ([Bug#33237](#))
- When using micro-GCPs, if a node failed while preparing for a global checkpoint, the master node would use the wrong GCI. ([Bug#32922](#))
- Under some conditions, performing an `ALTER TABLE` on an `NDBCLUSTER` table failed with a `TABLE IS FULL` error, even when only 25% of `DataMemory` was in use and the result should have been a table using less memory (for example, changing a `VARCHAR(100)` column to `VARCHAR(80)`). ([Bug#32670](#))

### 17.7.4.11. Changes in MySQL Cluster NDB 6.2.9 (5.1.22-ndb-6.2.9) (22 November 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.2 release.

**Obtaining MySQL Cluster NDB 6.2.** You can download the latest MySQL Cluster NDB 6.2 source code and binaries for supported platforms from <http://dev.mysql.com/downloads/cluster/>.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.2 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.22 (see [Section C.1.35, “Changes in MySQL 5.1.22 \(24 September 2007 Release Candidate\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- Added the `ndb_mgm` client command `DUMP 8011`, which dumps all subscribers to the cluster log. See [DUMP 8011](#), for more information.

Bugs fixed:

- A local checkpoint could sometimes be started before the previous LCP was restorable from a global checkpoint. ([Bug#32519](#))
- High numbers of API nodes on a slow or congested network could cause connection negotiation to time out prematurely, leading to the following issues:
  - Excessive retries
  - Excessive CPU usage
  - Partially connected API nodes ([Bug#32359](#))
- The failure of a master node could lead to subsequent failures in local checkpointing. ([Bug#32160](#))
- Adding a new `TINYTEXT` column to an `NDB` table which used `COLUMN_FORMAT = DYNAMIC`, and when binary logging was enabled, caused all cluster `mysqld` processes to crash. ([Bug#30213](#))
- After adding a new column of one of the `TEXT` or `BLOB` types to an `NDB` table which used `COLUMN_FORMAT = DYNAMIC`, it was no longer possible to access or drop the table using SQL. ([Bug#30205](#))
- A restart of the cluster failed when more than 1 REDO phase was in use. ([Bug#22696](#))
- **Cluster Replication: Replication:** Where a table being replicated had a `TEXT` or `BLOB` column, an `UPDATE` on the master that did not refer explicitly to this column in the `WHERE` clause stopped the SQL thread on the slave with `ERROR IN WRITE_ROWS EVENT: ROW APPLICATION FAILED. GOT ERROR 4288 'BLOB HANDLE FOR COLUMN NOT AVAILABLE' FROM NDB-CLUSTER.` ([Bug#30674](#))
- **Cluster Replication:** Under certain conditions, the slave stopped processing relay logs. This resulted in the logs never being cleared and the slave eventually running out of disk space. ([Bug#31958](#))

### 17.7.4.12. Changes in MySQL Cluster NDB 6.2.8 (5.1.22-ndb-6.2.8) (08 November 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.2 release.

**Obtaining MySQL Cluster NDB 6.2.** You can download the latest MySQL Cluster NDB 6.2 source code and binaries for supported platforms from <http://dev.mysql.com/downloads/cluster/>.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.2 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.22 (see [Section C.1.35, “Changes in MySQL 5.1.22 \(24 September 2007 Release Candidate\)”](#)).

### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **Important Note:** MySQL Cluster NDB 6.2 and 6.3 source archives are now available in separate commercial and GPL versions. Due to licensing concerns, previous MySQL Cluster NDB 6.2 and 6.3 source archives were removed from the FTP site.
- The output of the `ndb_mgm` client `SHOW` and `STATUS` commands now indicates when the cluster is in single user mode. ([Bug#27999](#))

Bugs fixed:

- In a cluster running in diskless mode and with arbitration disabled, the failure of a data node during an insert operation caused other data node to fail. ([Bug#31980](#))
- An insert or update with combined range and equality constraints failed when run against an `NDB` table with the error `GOT UNKNOWN_ERROR FROM NDB`. An example of such a statement would be `UPDATE t1 SET b = 5 WHERE a IN (7,8) OR a >= 10;`. ([Bug#31874](#))
- An error with an `if` statement in `sql/ha_ndbcluster.cc` could potentially lead to an infinite loop in case of failure when working with `AUTO_INCREMENT` columns in `NDB` tables. ([Bug#31810](#))
- The `NDB` storage engine code was not safe for strict-alias optimization in `gcc` 4.2.1. ([Bug#31761](#))
- Following an upgrade, `ndb_mgmd` would fail with an `ArbitrationError`. ([Bug#31690](#))
- The `NDB` management client command `node_id REPORT MEMORY` provided no output when `node_id` was the node ID of a management or API node. Now, when this occurs, the management client responds with `Node node_id: is not a data node.` ([Bug#29485](#))
- Performing `DELETE` operations after a data node had been shut down could lead to inconsistent data following a restart of the node. ([Bug#26450](#))
- `UPDATE IGNORE` could sometimes fail on `NDB` tables due to the use of uninitialized data when checking for duplicate keys to be ignored. ([Bug#25817](#))
- **Cluster Replication: Replication:** A node failure during replication could lead to buckets out of order; now active subscribers are checked for, rather than empty buckets. ([Bug#31701](#))
- **Cluster Replication:** When the master `mysqld` crashed or was restarted, no `LOST_EVENTS` entry was made in the binlog. ([Bug#31484](#))

See also [Bug#21494](#).

## 17.7.4.13. Changes in MySQL Cluster NDB 6.2.7 (5.1.22-ndb-6.2.7) (10 October 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.2 release.

**Obtaining MySQL Cluster NDB 6.2.** You can download the latest MySQL Cluster NDB 6.2 source code and binaries for supported platforms from <http://dev.mysql.com/downloads/cluster/>.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.2 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.22 (see [Section C.1.35, “Changes in MySQL 5.1.22 \(24 September 2007 Release Candidate\)”](#)).

### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **Cluster Replication:** A new configuration parameter `TimeBetweenEpochsTimeout` enables a timeout to be set for time between epochs. For more information, see [Section 17.3.2.6, “Defining MySQL Cluster Data Nodes”](#). ([Bug#31276](#))
- Additional checks were implemented to catch unsupported online `ALTER TABLE` operations. Currently it is not possible to re-order columns or to change the storage engine used for a table using online `ALTER TABLE`.

Some redundant checks made during online creation of indexes were removed.

Bugs fixed:

- It was possible in some cases for a node group to be “lost” due to missed local checkpoints following a system restart. ([Bug#31525](#))
- `NDB` tables having names containing nonalphanumeric characters (such as “\$”) were not discovered correctly. ([Bug#31470](#))
- A node failure during a local checkpoint could lead to a subsequent failure of the cluster during a system restart. ([Bug#31257](#))
- A cluster restart could sometimes fail due to an issue with table IDs. ([Bug#30975](#))
- Transaction timeouts were not handled well in some circumstances, leading to excessive number of transactions being aborted unnecessarily. ([Bug#30379](#))
- In some cases, the cluster management server logged entries multiple times following a restart of `mgmd`. ([Bug#29565](#))
- `ndb_mgm --help` did not display any information about the `-a` option. ([Bug#29509](#))
- The cluster log was formatted inconsistently and contained extraneous newline characters. ([Bug#25064](#))
- Online `ALTER` operations involving a column whose data type has an implicit default value left behind temporary `.frm` files, causing subsequent `DROP DATABASE` statements to fail. ([Bug#31097](#))
- Transactions were committed prematurely when `LOCK TABLE` and `SET autocommit = 0` were used together. ([Bug#30996](#))
- The `mysqld_safe` script contained a syntax error. ([Bug#30624](#))

#### 17.7.4.14. Changes in MySQL Cluster NDB 6.2.6 (5.1.22-ndb-6.2.6) (20 September 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.2 release.

**Obtaining MySQL Cluster NDB 6.2.** You can download the latest MySQL Cluster NDB 6.2 source code and binaries for supported platforms from <http://dev.mysql.com/downloads/cluster/>.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.2 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.22 (see [Section C.1.35, “Changes in MySQL 5.1.22 \(24 September 2007 Release Candidate\)”](#)).

##### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- Mapping of `NDB` error codes to MySQL storage engine error codes has been improved. ([Bug#28423](#))

Bugs fixed:

- **Partitioning:** `EXPLAIN PARTITIONS` reported partition usage by queries on `NDB` tables according to the standard MySQL

hash function than the hash function used in the `NDB` storage engine. ([Bug#29550](#))

- When an `NDB` event was left behind but the corresponding table was later recreated and received a new table ID, the event could not be dropped. ([Bug#30877](#))
- Attempting to restore a backup made on a cluster host using one endian to a machine using the other endian could cause the cluster to fail. ([Bug#29674](#))
- The description of the `--print` option provided in the output from `ndb_restore --help` was incorrect. ([Bug#27683](#))
- Restoring a backup made on a cluster host using one endian to a machine using the other endian failed for `BLOB` and `DATE-TIME` columns. ([Bug#27543](#), [Bug#30024](#))
- An insufficiently descriptive and potentially misleading Error 4006 (`CONNECT FAILURE - OUT OF CONNECTION OBJECTS...`) was produced when either of the following two conditions occurred:
  1. There were no more transaction records in the transaction coordinator
  2. An `NDB` object in the `NDB` API was initialized with insufficient parallelismSeparate error messages are now generated for each of these two cases. ([Bug#11313](#))
- For micro-GCPs, the assignment of “fake” CGI events no longer cause buckets to be sent out of order. Now, when assigning a GCI to a non-GCI event (that is, creating a pseudo-GCI or “fake” CGI), the GCI that is to arrive is always initiated, even if no known GCI exists, which could occur in the event of a node failure. ([Bug#30884](#))

#### 17.7.4.15. Changes in MySQL Cluster NDB 6.2.5 (5.1.22-ndb-6.2.5) (06 September 2007 General Availability)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.2 release.

**Obtaining MySQL Cluster NDB 6.2.** You can download the latest MySQL Cluster NDB 6.2 source code and binaries for supported platforms from <http://dev.mysql.com/downloads/cluster/>.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.2 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.22 (see [Section C.1.35, “Changes in MySQL 5.1.22 \(24 September 2007 Release Candidate\)”](#)).

##### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- The following improvements have been made in the `ndb_size.pl` utility:
  - The script can now be used with multiple databases; lists of databases and tables can also be excluded from analysis.
  - Schema name information has been added to index table calculations.
  - The database name is now an optional parameter, the exclusion of which causes all databases to be examined.
  - If selecting from `INFORMATION_SCHEMA` fails, the script now attempts to fall back to `SHOW TABLES`.
  - A `--real_table_name` option has been added; this designates a table to handle unique index size calculations.
  - The report title has been amended to cover cases where more than one database is being analyzed.

Support for a `--socket` option was also added.

For more information, see [Section 17.4.21, “`ndb\_size.pl` — NDBCLOUD Size Requirement Estimator”](#). ([Bug#28683](#), [Bug#28253](#))

- Online `ADD COLUMN`, `ADD INDEX`, and `DROP INDEX` operations can now be performed explicitly for `NDB` tables, as well as online renaming of tables and columns for `NDB` and `MyISAM` tables—that is, without copying or locking of the affected tables—using `ALTER ONLINE TABLE`.

Indexes can also be created and dropped online using `CREATE INDEX` and `DROP INDEX`, respectively, using the `ONLINE` keyword.

You can force operations that would otherwise be performed online to be done offline using the `OFFLINE` keyword.

See [Section 12.1.7, “ALTER TABLE Syntax”](#), [Section 12.1.13, “CREATE INDEX Syntax”](#), and [Section 12.1.24, “DROP INDEX Syntax”](#), for more information.

- It is now possible to control whether fixed-width or variable-width storage is used for a given column of an `NDB` table by means of the `COLUMN_FORMAT` specifier as part of the column's definition in a `CREATE TABLE` or `ALTER TABLE` statement.

It is also possible to control whether a given column of an `NDB` table is stored in memory or on disk, using the `STORAGE` specifier as part of the column's definition in a `CREATE TABLE` or `ALTER TABLE` statement.

For permitted values and other information about `COLUMN_FORMAT` and `STORAGE`, see [Section 12.1.17, “CREATE TABLE Syntax”](#).

- A new cluster management server startup option `--bind-address` makes it possible to restrict management client connections to `ndb_mgmd` to a single host and port. For more information, see [Section 17.4.4, “`ndb\_mgmd` — The MySQL Cluster Management Server Daemon”](#).
- **Cluster Replication:** The protocol for handling global checkpoints has been changed. It is now possible to control how often the GCI number is updated, and how often global checkpoints are written to disk, using the `TimeBetweenEpochs` configuration parameter. This improves the reliability and performance of MySQL Cluster Replication.

GCPs handled using the new protocol are sometimes referred to as “micro-GCPs”.

For more information, see [TimeBetweenEpochs](#).

Bugs fixed:

- When handling `BLOB` columns, the addition of read locks to the lock queue was not handled correctly. ([Bug#30764](#))
- Discovery of `NDB` tables did not work correctly with `INFORMATION_SCHEMA`. ([Bug#30667](#))
- A file system close operation could fail during a node or system restart. ([Bug#30646](#))
- Using the `--ndb-cluster-connection-pool` option for `mysqld` caused DDL statements to be executed twice. ([Bug#30598](#))
- When creating an `NDB` table with a column that has `COLUMN_FORMAT = DYNAMIC`, but the table itself uses `ROW_FORMAT=FIXED`, the table is considered dynamic, but any columns for which the row format is unspecified default to `FIXED`. Now in such cases the server issues the warning `ROW FORMAT FIXED INCOMPATIBLE WITH DYNAMIC ATTRIBUTE COLUMN_NAME`. ([Bug#30276](#))
- `ndb_size.pl` failed on tables with `FLOAT` columns whose definitions included commas (for example, `FLOAT(6,2)`). ([Bug#29228](#))
- Reads on `BLOB` columns were not locked when they needed to be to guarantee consistency. ([Bug#29102](#))

See also [Bug#31482](#).

- A query using joins between several large tables and requiring unique index lookups failed to complete, eventually returning `UNKNOWN_ERROR` after a very long period of time. This occurred due to inadequate handling of instances where the Transaction Coordinator ran out of `TransactionBufferMemory`, when the cluster should have returned NDB error code 4012 (`REQUEST_NDBD_TIME-OUT`). ([Bug#28804](#))
- An attempt to perform a `SELECT ... FROM INFORMATION_SCHEMA.TABLES` whose result included information about `NDB` tables for which the user had no privileges crashed the MySQL Server on which the query was performed. ([Bug#26793](#))
- **Cluster Replication:** Cluster replication did not handle large `VARCHAR` columns correctly. ([Bug#29904](#))
- **Cluster Replication:** An issue with the `mysql.ndb_apply_status` table could cause `NDB` schema autodiscovery to fail in certain rare circumstances. ([Bug#20872](#))
- **Cluster API:** A call to `CHECK_TIMEDOUT_RET()` in `mgmapi.cpp` should have been a call to `DBG_CHECK_TIMEDOUT_RET()`. ([Bug#30681](#))

## 17.7.4.16. Changes in MySQL Cluster NDB 6.2.4 (5.1.19-ndb-6.2.4) (04 July 2007)

---

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.2 release.

**Obtaining MySQL Cluster NDB 6.2.** You can download the latest MySQL Cluster NDB 6.2 source code and binaries for supported platforms from <http://dev.mysql.com/downloads/cluster/>.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.2 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.19 (see [Section C.1.38, “Changes in MySQL 5.1.19 \(25 May 2007\)”,](#)).

#### **Note**

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- When restarting a data node, queries could hang during that node's start phase 5, and continue only after the node had entered phase 6. ([Bug#29364](#))
- Replica redo logs were inconsistently handled during a system restart. ([Bug#29354](#))
- **Disk Data:** Performing Disk Data schema operations during a node restart could cause forced shutdowns of other data nodes. ([Bug#29501](#))
- **Disk Data:** Disk data meta-information that existed in `ndbd` might not be visible to `mysqld`. ([Bug#28720](#))
- **Disk Data:** The number of free extents was incorrectly reported for some tablespaces. ([Bug#28642](#))
- Batching of transactions was not handled correctly in some cases. ([Bug#29525](#))

### **17.7.4.17. Changes in MySQL Cluster NDB 6.2.3 (5.1.19-ndb-6.2.3) (02 July 2007)**

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.2 release.

**Obtaining MySQL Cluster NDB 6.2.** You can download the latest MySQL Cluster NDB 6.2 source code and binaries for supported platforms from <http://dev.mysql.com/downloads/cluster/>.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.2 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.18 (see [Section C.1.39, “Changes in MySQL 5.1.18 \(08 May 2007\)”,](#)).

#### **Note**

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- When restarting a data node, queries could hang during that node's start phase 5, and continue only after the node had entered phase 6. ([Bug#29364](#))
- Replica redo logs were inconsistently handled during a system restart. ([Bug#29354](#))
- **Disk Data:** Performing Disk Data schema operations during a node restart could cause forced shutdowns of other data nodes. ([Bug#29501](#))
- **Disk Data:** Disk data meta-information that existed in `ndbd` might not be visible to `mysqld`. ([Bug#28720](#))
- **Disk Data:** The number of free extents was incorrectly reported for some tablespaces. ([Bug#28642](#))
- Batching of transactions was not handled correctly in some cases. ([Bug#29525](#))

### **17.7.4.18. Changes in MySQL Cluster NDB 6.2.2 (5.1.18-ndb-6.2.2) (07 May 2007)**

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.2 release.

**Obtaining MySQL Cluster NDB 6.2.** You can download the latest MySQL Cluster NDB 6.2 source code and binaries for suppor-

ted platforms from <http://dev.mysql.com/downloads/cluster/>.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.2 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.18 (see [Section C.1.39, “Changes in MySQL 5.1.18 \(08 May 2007\)”\).](#)

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- New cluster management client `DUMP` commands were added to aid in tracking transactions, scan operations, and locks. See [DUMP 2350](#), [DUMP 2352](#), and [DUMP 2550](#), for more information.
- Added the `mysqld` option `--ndb-cluster-connection-pool` that enables a single MySQL server to use multiple connections to the cluster. This enables scaling out using multiple MySQL clients per SQL node instead of or in addition to using multiple SQL nodes with the cluster.

For more information about this option, see [Section 17.3.4, “MySQL Server Options and Variables for MySQL Cluster”](#).

### 17.7.4.19. Changes in MySQL Cluster NDB 6.2.1 (5.1.18-ndb-6.2.1) (30 April 2007)

This is a Beta development release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.2 release.

**Obtaining MySQL Cluster NDB 6.2.** You can download the latest MySQL Cluster NDB 6.2 source code and binaries for supported platforms from <http://dev.mysql.com/downloads/cluster/>.

This Beta release incorporates all bugfixes and changes made in the previous MySQL Cluster NDB 6.2 release, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.18 (see [Section C.1.39, “Changes in MySQL 5.1.18 \(08 May 2007\)”\).](#)

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- Multiple operations involving deletes followed by reads were not handled correctly.

#### Note

This issue could also affect MySQL Cluster Replication.

([Bug#28276](#))

- **Cluster API:** Using `NdbBlob::writeData()` to write data in the middle of an existing blob value (that is, updating the value) could overwrite some data past the end of the data to be changed. ([Bug#27018](#))
- Incorrect handling of fragmentation in a node takeover during a restart could cause stale data to be copied to the starting node, leading eventually to failure of the node. ([Bug#27434](#))
- An incorrect assertion was made when sending a `TCKEYFAILREF` or `TCKEYCONF` message to a failed data node. ([Bug#26814](#))

### 17.7.4.20. Changes in MySQL Cluster NDB 6.2.0 (5.1.16-ndb-6.2.0) (03 March 2007 Beta)

This is the first MySQL Cluster NDB 6.2 development release, based on version 6.2 of the `NDBCLUSTER` storage engine.

**Obtaining MySQL Cluster NDB 6.2.** You can download the latest MySQL Cluster NDB 6.2 source code and binaries for supported platforms from <http://dev.mysql.com/downloads/cluster/>.

This Beta release incorporates bugfixes and changes made in previous MySQL Cluster releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.16 (see [Section C.1.41, “Changes in MySQL 5.1.16 \(26 February 2007\)”\).](#)

**Note**

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- An `ndb_wait_connected` system variable has been added for `mysqld`. It causes `mysqld` wait a specified amount of time to be connected to the cluster before accepting client connections. For more information, see [Section 17.3.4.3, “MySQL Cluster System Variables”](#).
- **Cluster API:** The `Ndb::startTransaction()` method now provides an alternative interface for starting a transaction. See `Ndb::startTransaction()`, for more information.
- **Cluster API:** Methods were added to the `Ndb_cluster_connection` class to facilitate iterating over existing `NDB` objects. See `ndb_cluster_connection::get_next_ndb_object()`, for more information.
- It is now possible to disable arbitration by setting `ArbitrationRank` equal to `0` on all nodes.
- A new `TcpBind_INADDR_ANY` configuration parameter enables data nodes node to bind `INADDR_ANY` instead of a host name or IP address in the `config.ini` file.
- Memory allocation has been improved on 32-bit architectures that enables using close to 3GB for `DataMemory` and `In-dexMemory` combined.

## 17.7.5. Changes in MySQL Cluster NDB 6.1

This section contains change history information for MySQL Cluster releases based on version 6.1 of the `NDBCLUSTER` storage engine.

For an overview of features that were added added in MySQL Cluster NDB 6.1, see [Section 17.1.4.5, “MySQL Cluster Development in MySQL Cluster NDB 6.1”](#).

**Note**

MySQL Cluster NDB 6.1 is no longer being developed or maintained, and the information presented in the next few sections should be considered to be of historical interest only. If you are using MySQL Cluster NDB 6.1, you should upgrade as soon as possible to the most recent version of MySQL Cluster NDB 6.2 or later MySQL Cluster release series.

### 17.7.5.1. Changes in MySQL Cluster NDB 6.1.23 (5.1.15-ndb-6.1.23) (20 November 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

**MySQL Cluster NDB 6.1 no longer in development.** MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see [Section C.1.42, “Changes in MySQL 5.1.15 \(25 January 2007\)”](#)).

**Note**

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- The `NDB` storage engine code was not safe for strict-alias optimization in `gcc` 4.2.1. ([Bug#31761](#))
- **Cluster Replication:** Under certain conditions, the slave stopped processing relay logs. This resulted in the logs never being cleared and the slave eventually running out of disk space. ([Bug#31958](#))

### 17.7.5.2. Changes in MySQL Cluster NDB 6.1.22 (5.1.15-ndb-6.1.22) (19 October 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

**MySQL Cluster NDB 6.1 no longer in development.** MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see [Section C.1.42, “Changes in MySQL 5.1.15 \(25 January 2007\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- It was possible in some cases for a node group to be “lost” due to missed local checkpoints following a system restart. ([Bug#31525](#))
- **Cluster Replication: Replication:** A node failure during replication could lead to buckets out of order; now active subscribers are checked for, rather than empty buckets. ([Bug#31701](#))

### 17.7.5.3. Changes in MySQL Cluster NDB 6.1.21 (5.1.15-ndb-6.1.21) (01 October 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

**MySQL Cluster NDB 6.1 no longer in development.** MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see [Section C.1.42, “Changes in MySQL 5.1.15 \(25 January 2007\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- A node failure during a local checkpoint could lead to a subsequent failure of the cluster during a system restart. ([Bug#31257](#))
- A cluster restart could sometimes fail due to an issue with table IDs. ([Bug#30975](#))

### 17.7.5.4. Changes in MySQL Cluster NDB 6.1.20 (5.1.15-ndb-6.1.20) (14 September 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

**MySQL Cluster NDB 6.1 no longer in development.** MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see [Section C.1.42, “Changes in MySQL 5.1.15 \(25 January 2007\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- **Cluster Replication: Replication:** Incorrect handling of `INSERT` plus `DELETE` operations with regard to local checkpoints caused data node failures in multi-master replication setups. ([Bug#30914](#))

### 17.7.5.5. Changes in MySQL Cluster NDB 6.1.19 (5.1.15-ndb-6.1.19) (01 August 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

**MySQL Cluster NDB 6.1 no longer in development.** MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see [Section C.1.42, “Changes in MySQL 5.1.15 \(25 January 2007\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- Whenever a TCP send buffer is over 80% full, temporary error 1218 (`SEND BUFFERS OVERLOADED IN NDB KERNEL`) is now returned. See [SendBufferMemory](#) for more information.
- An `INFO` event is now sent if the time between global checkpoints is excessive, or if `DUMP 7901` is issued in the management client.

### 17.7.5.6. Changes in MySQL Cluster NDB 6.1.18 (5.1.15-ndb-6.1.18) (Not released)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

**MySQL Cluster NDB 6.1 no longer in development.** MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see [Section C.1.42, “Changes in MySQL 5.1.15 \(25 January 2007\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- When restarting a data node, queries could hang during that node's start phase 5, and continue only after the node had entered phase 6. ([Bug#29364](#))
- **Replication:** Storage engine error conditions in row-based replication were not correctly reported to the user. ([Bug#29570](#))
- **Disk Data:** Disk data meta-information that existed in `ndbd` might not be visible to `mysqld`. ([Bug#28720](#))
- **Disk Data:** The number of free extents was incorrectly reported for some tablespaces. ([Bug#28642](#))

### 17.7.5.7. Changes in MySQL Cluster NDB 6.1.17 (5.1.15-ndb-6.1.17) (03 July 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

**MySQL Cluster NDB 6.1 no longer in development.** MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes

and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see [Section C.1.42, “Changes in MySQL 5.1.15 \(25 January 2007\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **Cluster Replication: Replication:** Batching of updates on cluster replication slaves, enabled using the `-slave-allow-batching` option for `mysqld`.

Bugs fixed:

- Replica redo logs were inconsistently handled during a system restart. ([Bug#29354](#))

### 17.7.5.8. Changes in MySQL Cluster NDB 6.1.16 (5.1.15-ndb-6.1.16) (29 June 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

**MySQL Cluster NDB 6.1 no longer in development.** MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see [Section C.1.42, “Changes in MySQL 5.1.15 \(25 January 2007\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- When a node failed to respond to a `COPY_GCI` signal as part of a global checkpoint, the master node was killed instead of the node that actually failed. ([Bug#29331](#))
- An invalid comparison made during `REDO` validation that could lead to an `ERROR WHILE READING REDO LOG` condition. ([Bug#29118](#))
- The wrong data pages were sometimes invalidated following a global checkpoint. ([Bug#29067](#))
- If at least 2 files were involved in `REDO` invalidation, then file 0 of page 0 was not updated and so pointed to an invalid part of the redo log. ([Bug#29057](#))
- **Disk Data:** When dropping a page, the stack’s bottom entry could sometime be left “cold” rather than “hot”, violating the rules for stack pruning. ([Bug#29176](#))

### 17.7.5.9. Changes in MySQL Cluster NDB 6.1.15 (5.1.15-ndb-6.1.15) (20 June 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

**MySQL Cluster NDB 6.1 no longer in development.** MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see [Section C.1.42, “Changes in MySQL 5.1.15 \(25 January 2007\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this ver-

■ sion.

Bugs fixed:

- Memory corruption could occur due to a problem in the `DBTUP` kernel block. ([Bug#29229](#))

## 17.7.5.10. Changes in MySQL Cluster NDB 6.1.14 (5.1.15-ndb-6.1.14) (19 June 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

**MySQL Cluster NDB 6.1 no longer in development.** MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see [Section C.1.42, “Changes in MySQL 5.1.15 \(25 January 2007\)”](#)).

### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- In the event that two data nodes in the same node group and participating in a GCP crashed before they had written their respective `P0.sysfile` files, `QMGR` could refuse to start, issuing an invalid `INSUFFICIENT NODES FOR RESTART` error instead. ([Bug#29167](#))

## 17.7.5.11. Changes in MySQL Cluster NDB 6.1.13 (5.1.15-ndb-6.1.13) (15 June 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

**MySQL Cluster NDB 6.1 no longer in development.** MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see [Section C.1.42, “Changes in MySQL 5.1.15 \(25 January 2007\)”](#)).

### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- Read ahead was implemented for backups of Disk Data tables, resulting in a 10 to 15% increase in backup speed of Disk Data tables. ([Bug#29099](#))

Bugs fixed:

- **Cluster API:** `NdbApi.hpp` depended on `ndb_global.h`, which was not actually installed, causing the compilation of programs that used `NdbApi.hpp` to fail. ([Bug#35853](#))

## 17.7.5.12. Changes in MySQL Cluster NDB 6.1.12 (5.1.15-ndb-6.1.12) (13 June 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

**MySQL Cluster NDB 6.1 no longer in development.** MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see [Section C.1.42, “Changes in MySQL 5.1.15 \(25 January 2007\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- New cluster management client `DUMP` commands were added to aid in tracking transactions, scan operations, and locks. See [DUMP 2350](#), [DUMP 2352](#), and [DUMP 2550](#).
- Backup dump output was extended to provide more information.

Bugs fixed:

- It is now possible to set the maximum size of the allocation unit for table memory using the `MaxAllocate` configuration parameter. ([Bug#29044](#))

### 17.7.5.13. Changes in MySQL Cluster NDB 6.1.11 (5.1.15-ndb-6.1.11) (06 June 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

**MySQL Cluster NDB 6.1 no longer in development.** MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see [Section C.1.42, “Changes in MySQL 5.1.15 \(25 January 2007\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **Important Change:** The `TimeBetweenWatchdogCheckInitial` configuration parameter was added to enable setting of a separate watchdog timeout for memory allocation during startup of the data nodes. See [Section 17.3.2.6, “Defining MySQL Cluster Data Nodes”](#), for more information. ([Bug#28899](#))
- A new configuration parameter `ODirect` causes `NDB` to attempt using `O_DIRECT` writes for LCP, backups, and redo logs, often lowering CPU usage.
- It is now possible to set the size of redo log files (fragment log files) using the `FragmentLogFileSize` configuration parameter.

Bugs fixed:

- Having large amounts of memory locked caused swapping to disk. ([Bug#28751](#))
- LCP files were not removed following an initial system restart. ([Bug#28726](#))
- **Disk Data:** Repeated `INSERT` and `DELETE` operations on a Disk Data table having one or more large `VARCHAR` columns could cause data nodes to fail. ([Bug#20612](#))

### 17.7.5.14. Changes in MySQL Cluster NDB 6.1.10 (5.1.15-ndb-6.1.10) (30 May 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

**MySQL Cluster NDB 6.1 no longer in development.** MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see Section C.1.42, “Changes in MySQL 5.1.15 (25 January 2007)”).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- A new `times` printout was added in the `ndbd` watchdog thread.
- Some unneeded printouts in the `ndbd` out file were removed.
- The names of some log and other files were changed to avoid issues with the `tar` command's 99-character file name limit.

Bugs fixed:

- A regression in the heartbeat monitoring code could lead to node failure under high load. This issue affected MySQL 5.1.19 and MySQL Cluster NDB 6.1.10 only. ([Bug#28783](#))
- A corrupt schema file could cause a `FILE ALREADY OPEN` error. ([Bug#28770](#))
- Setting `InitialNoOpenFiles` equal to `MaxNoOfOpenFiles` caused an error. This was due to the fact that the actual value of `MaxNoOfOpenFiles` as used by the cluster was offset by 1 from the value set in `config.ini`. ([Bug#28749](#))
- A race condition could result when nonmaster nodes (in addition to the master node) tried to update active status due to a local checkpoint (that is, between `NODE_FAILURE` and `COPY_GCIREQ` events). Now only the master updates the active status. ([Bug#28717](#))
- A fast global checkpoint under high load with high usage of the redo buffer caused data nodes to fail. ([Bug#28653](#))
- **Disk Data:** When loading data into a cluster following a version upgrade, the data nodes could forcibly shut down due to page and buffer management failures (that is, `ndbrequire` failures in `PGMAN`). ([Bug#28525](#))

### 17.7.5.15. Changes in MySQL Cluster NDB 6.1.9 (5.1.15-ndb-6.1.9) (24 May 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

**MySQL Cluster NDB 6.1 no longer in development.** MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see Section C.1.42, “Changes in MySQL 5.1.15 (25 January 2007)”).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- When an API node sent more than 1024 signals in a single batch, `NDB` would process only the first 1024 of these, and then hang. ([Bug#28443](#))
- **Disk Data:** The cluster backup process scanned in `ACC` index order, which had bad effects for disk data. ([Bug#28593](#))

### 17.7.5.16. Changes in MySQL Cluster NDB 6.1.8 (5.1.15-ndb-6.1.8) (05 May 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

**MySQL Cluster NDB 6.1 no longer in development.** MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see [Section C.1.42, “Changes in MySQL 5.1.15 \(25 January 2007\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- Local checkpoint files relating to dropped `NDB` tables were not removed. ([Bug#28348](#))
- Repeated insertion of data generated by `mysqldump` into `NDB` tables could eventually lead to failure of the cluster. ([Bug#27437](#))
- **Disk Data:** Extremely large inserts into Disk Data tables could lead to data node failure in some circumstances. ([Bug#27942](#))
- **Cluster API:** In a multi-operation transaction, a delete operation followed by the insertion of an implicit `NULL` failed to overwrite an existing value. ([Bug#20535](#))
- Setting `MaxNoOfTables` very low and relative to `DataMemory` caused `OUT OF MEMORY IN NDB KERNEL` errors when inserting relatively small amounts of data into NDB tables. ([Bug#24173](#))

### 17.7.5.17. Changes in MySQL Cluster NDB 6.1.7 (5.1.15-ndb-6.1.7) (05 May 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

**MySQL Cluster NDB 6.1 no longer in development.** MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see [Section C.1.42, “Changes in MySQL 5.1.15 \(25 January 2007\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **Cluster Replication: Incompatible Change:** The schema for the `ndb_apply_status` table in the `mysql` system database has changed. When upgrading to this release from a previous MySQL Cluster NDB 6.x or mainline MySQL 5.1 release, you must drop the `mysql.ndb_apply_status` table, then restart the server for the table to be re-created with the new schema.

See [Section 17.6.4, “MySQL Cluster Replication Schema and Tables”](#), for additional information.

Bugs fixed:

- The cluster waited 30 seconds instead of 30 milliseconds before reading table statistics. ([Bug#28093](#))
- Under certain rare circumstances, `ndbd` could get caught in an infinite loop when one transaction took a read lock and then a second transaction attempted to obtain a write lock on the same tuple in the lock queue. ([Bug#28073](#))
- Under some circumstances, a node restart could fail to update the Global Checkpoint Index (GCI). ([Bug#28023](#))
- An `INSERT` followed by a delete `DELETE` on the same `NDB` table caused a memory leak. ([Bug#27756](#))

This regression was introduced by [Bug#20612](#).

- Under certain rare circumstances performing a `DROP TABLE` or `TRUNCATE TABLE` on an `NDB` table could cause a node failure or forced cluster shutdown. ([Bug#27581](#))
- Memory usage of a `mysqld` process grew even while idle. ([Bug#27560](#))
- Performing a delete followed by an insert during a local checkpoint could cause a `ROWID ALREADY ALLOCATED` error. ([Bug#27205](#))
- **Cluster Replication: Disk Data:** An issue with replication of Disk Data tables could in some cases lead to node failure. ([Bug#28161](#))
- **Disk Data:** Changes to a Disk Data table made as part of a transaction could not be seen by the client performing the changes until the transaction had been committed. ([Bug#27757](#))
- **Disk Data:** When restarting a data node following the creation of a large number of Disk Data objects (approximately 200 such objects), the cluster could not assign a node ID to the restarting node. ([Bug#25741](#))
- **Disk Data:** Changing a column specification or issuing a `TRUNCATE TABLE` statement on a Disk Data table caused the table to become an in-memory table.

This fix supersedes an incomplete fix that was made for this issue in MySQL 5.1.15. ([Bug#24667](#), [Bug#25296](#))

- **Cluster Replication:** Some queries that updated multiple tables were not backed up correctly. ([Bug#27748](#))
- **Cluster Replication:** It was possible for API nodes to begin interacting with the cluster subscription manager before they were fully connected to the cluster. ([Bug#27728](#))
- **Cluster Replication:** Under very high loads, checkpoints could be read or written with checkpoint indexes out of order. ([Bug#27651](#))
- **Cluster API:** An issue with the way in which the `NdbDictionary::Dictionary::listEvents()` method freed resources could sometimes lead to memory corruption. ([Bug#27663](#))
- `mysqldump` could not dump log tables. ([Bug#26121](#))
- The `--with-readline` option for `configure` did not work for commercial source packages, but no error message was printed to that effect. Now a message is printed. ([Bug#25530](#))

## 17.7.5.18. Changes in MySQL Cluster NDB 6.1.6 (5.1.15-ndb-6.1.6) (Not released)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

**MySQL Cluster NDB 6.1 no longer in development.** MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see [Section C.1.42, “Changes in MySQL 5.1.15 \(25 January 2007\)”](#)).

### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **Cluster Replication: Incompatible Change:** The schema for the `ndb_apply_status` table in the `mysql` system database has changed. When upgrading to this release from a previous MySQL Cluster NDB 6.x or mainline MySQL 5.1 release, you must drop the `mysql.ndb_apply_status` table, then restart the server for the table to be re-created with the new schema.

See [Section 17.6.4, “MySQL Cluster Replication Schema and Tables”](#), for additional information.

Bugs fixed:

- A data node failing while another data node was restarting could leave the cluster in an inconsistent state. In certain rare cases, this could lead to a race condition and the eventual forced shutdown of the cluster. ([Bug#27466](#))
- It was not possible to set `LockPagesInMainMemory` equal to 0. ([Bug#27291](#))
- A race condition could sometimes occur if the node acting as master failed while node IDs were still being allocated during startup. ([Bug#27286](#))
- When a data node was taking over as the master node, a race condition could sometimes occur as the node was assuming responsibility for handling of global checkpoints. ([Bug#27283](#))
- `mysqld` could crash shortly after a data node failure following certain DML operations. ([Bug#27169](#))
- The same failed request from an API node could be handled by the cluster multiple times, resulting in reduced performance. ([Bug#27087](#))
- The failure of a data node while restarting could cause other data nodes to hang or crash. ([Bug#27003](#))
- `mysqld` processes would sometimes crash under high load.

#### Note

This fix improves on and replaces a fix for this bug that was made in MySQL Cluster NDB 6.1.5.

([Bug#26825](#))

- **Disk Data:** `DROP INDEX` on a Disk Data table did not always move data from memory into the tablespace. ([Bug#25877](#))
- **Cluster Replication:** Trying to replicate a large number of frequent updates with a relatively small relay log (`max-relay-log-size` set to 1M or less) could cause the slave to crash. ([Bug#27529](#))
- **Cluster API:** An issue with the way in which the `NdbDictionary::Dictionary::listEvents()` method freed resources could sometimes lead to memory corruption. ([Bug#27663](#))
- **Cluster API:** A delete operation using a scan followed by an insert using a scan could cause a data node to fail. ([Bug#27203](#))

### 17.7.5.19. Changes in MySQL Cluster NDB 6.1.5 (5.1.15-ndb-6.1.5) (15 March 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

**MySQL Cluster NDB 6.1 no longer in development.** MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see [Section C.1.42, “Changes in MySQL 5.1.15 \(25 January 2007\)”](#)).

#### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- **Cluster Replication: Incompatible Change:** The schema for the `ndb_apply_status` table in the `mysql` system database has changed. When upgrading to this release from a previous MySQL Cluster NDB 6.x or mainline MySQL 5.1 release, you must drop the `mysql.ndb_apply_status` table, then restart the server for the table to be re-created with the new schema.

See [Section 17.6.4, “MySQL Cluster Replication Schema and Tables”](#), for additional information.

Bugs fixed:

- Creating a table on one SQL node while in single user mode caused other SQL nodes to crash. ([Bug#26997](#))
- `mysqld` processes would sometimes crash under high load.

**Note**

This fix was reverted in MySQL Cluster NDB 6.1.6.

([Bug#26825](#))

- An infinite loop in an internal logging function could cause trace logs to fill up with `UNKNOWN SIGNAL TYPE` error messages and thus grow to unreasonable sizes. ([Bug#26720](#))
- **Disk Data:** When creating a log file group, setting `INITIAL_SIZE` to less than `UNDO_BUFFER_SIZE` caused data nodes to crash. ([Bug#25743](#))

## 17.7.5.20. Changes in MySQL Cluster NDB 6.1.4 (5.1.15-ndb-6.1.4) (09 March 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

**MySQL Cluster NDB 6.1 no longer in development.** MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see [Section C.1.42, “Changes in MySQL 5.1.15 \(25 January 2007\)”](#)).

**Note**

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- An `ndb_wait_connected` system variable has been added for `mysqld`. It causes `mysqld` wait a specified amount of time to be connected to the cluster before accepting client connections. For more information, see [Section 17.3.4.3, “MySQL Cluster System Variables”](#).
- **Cluster API:** It is now possible to specify the transaction coordinator when starting a transaction. See `Ndb::startTransaction()`, for more information.
- **Cluster API:** It is now possible to iterate over all existing `NDB` objects using three new methods of the `Ndb_cluster_connection` class:
  - `lock_ndb_objects()`
  - `get_next_ndb_object()`
  - `unlock_ndb_objects()`For more information about these methods and their use, see `ndb_cluster_connection::get_next_ndb_object()`, in the MySQL Cluster API Guide.
- Data node memory allocation has been improved. On 32-bit platforms, it should now be possible to use close to 3GB RAM for `IndexMemory` and `DataMemory` combined.

Bugs fixed:

- Using only the `--print_data` option (and no other options) with `ndb_restore` caused `ndb_restore` to fail. ([Bug#26741](#))

This regression was introduced by [Bug#14612](#).

- An inadvertent use of unaligned data caused `ndb_restore` to fail on some 64-bit platforms, including Sparc and Itanium-2. ([Bug#26739](#))
- Assigning a node ID greater than 63 to an SQL node caused an out of bounds error in `mysqld`. It should now be possible to assign to SQL nodes node IDs up to 255. ([Bug#26663](#))

## 17.7.5.21. Changes in MySQL Cluster NDB 6.1.3 (5.1.15-ndb-6.1.3) (25 February 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

**MySQL Cluster NDB 6.1 no longer in development.** MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see [Section C.1.42, “Changes in MySQL 5.1.15 \(25 January 2007\)”](#)).

### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- The `ndbd_redo_log_reader` utility is now part of the default build. For more information, see [Section 17.4.16, “ndbd\\_redo\\_log\\_reader — Check and Print Content of Cluster Redo Log”](#).
- The `ndb_show_tables` utility now displays information about table events. See [Section 17.4.20, “ndb\\_show\\_tables — Display List of NDB Tables”](#), for more information.
- **Cluster API:** A new `listEvents()` method has been added to the `Dictionary` class. See [Dictionary::listEvents\(\)](#), for more information.
- It is now possible to disable arbitration by setting `ArbitrationRank = 0` on all management and SQL nodes.

Bugs fixed:

- An invalid pointer was returned following a `FSCLOSECONF` signal when accessing the REDO logs during a node restart or system restart. ([Bug#26515](#))
- The `InvalidUndoBufferSize` error used the same error code ([763](#)) as the `IncompatibleVersions` error. `InvalidUndoBufferSize` now uses its own error code ([779](#)). ([Bug#26490](#))
- The failure of a data node when restarting it with `--initial` could lead to failures of subsequent data node restarts. ([Bug#26481](#))
- Takeover for local checkpointing due to multiple failures of master nodes was sometimes incorrectly handled. ([Bug#26457](#))
- The `LockPagesInMainMemory` parameter was not read until after distributed communication had already started between cluster nodes. When the value of this parameter was `1`, this could sometimes result in data node failure due to missed heartbeats. ([Bug#26454](#))
- Under some circumstances, following the restart of a management node, all data nodes would connect to it normally, but some of them subsequently failed to log any events to the management node. ([Bug#26293](#))
- No appropriate error message was provided when there was insufficient REDO log file space for the cluster to start. ([Bug#25801](#))
- A memory allocation failure in `SUMA` (the cluster Subscription Manager) could cause the cluster to crash. ([Bug#25239](#))
- The message `ERROR 0 IN READAUTOINCREMENTVALUE(): NO ERROR` was written to the error log whenever `SHOW TABLE STATUS` was performed on a Cluster table that did not have an `AUTO_INCREMENT` column.

### Note

This improves on and supersedes an earlier fix that was made for this issue in MySQL 5.1.12.

([Bug#21033](#))

- **Disk Data:** A memory overflow could occur with tables having a large amount of data stored on disk, or with queries using a very high degree of parallelism on Disk Data tables. ([Bug#26514](#))
- **Disk Data:** Use of a tablespace whose `INITIAL_SIZE` was greater than 1 GB could cause the cluster to crash. ([Bug#26487](#))

## 17.7.5.22. Changes in MySQL Cluster NDB 6.1.2 (5.1.15-ndb-6.1.2) (07 February 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

**MySQL Cluster NDB 6.1 no longer in development.** MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in previous MySQL Cluster NDB 6.1 releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see [Section C.1.42, “Changes in MySQL 5.1.15 \(25 January 2007\)”](#)).

### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Bugs fixed:

- Using node IDs greater than 48 could sometimes lead to incorrect memory access and a subsequent forced shutdown of the cluster. ([Bug#26267](#))

## 17.7.5.23. Changes in MySQL Cluster NDB 6.1.1 (5.1.15-ndb-6.1.1) (01 February 2007)

This is a bugfix release, fixing recently discovered bugs in the previous MySQL Cluster NDB 6.1 release.

**MySQL Cluster NDB 6.1 no longer in development.** MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

This Beta release incorporates all bugfixes and changes made in the previous MySQL Cluster NDB 6.1 release, as well as all bugfixes and feature changes which were added in mainline MySQL 5.1 through MySQL 5.1.15 (see [Section C.1.42, “Changes in MySQL 5.1.15 \(25 January 2007\)”](#)).

### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- A single cluster can now support up to 255 API nodes, including MySQL servers acting as SQL nodes. See [Section 17.1.5.8, “Issues Exclusive to MySQL Cluster”](#), for more information.

Bugs fixed:

- A memory leak could cause problems during a node or cluster shutdown or failure. ([Bug#25997](#))
- **Cluster API: Disk Data:** A delete and a read performed in the same operation could cause one or more data nodes to crash. This could occur when the operation affected more than 5 columns concurrently, or when one or more of the columns was of the `VARCHAR` type and was stored on disk. ([Bug#25794](#))
- An element could sometimes be inserted twice into the hash table, causing a data node to crash. ([Bug#25286](#))

## 17.7.5.24. Changes in MySQL Cluster NDB 6.1.0 (5.1.14-ndb-6.1.0) (20 December 2006)

This is the first MySQL Cluster NDB 6.1 release, incorporating new features and bugfixes made for the `NDBCLUSTER` storage engine made since branching from MySQL 5.1.14 standard (see [Section C.1.43, “Changes in MySQL 5.1.14 \(05 December 2006\)”](#)).

**MySQL Cluster NDB 6.1 no longer in development.** MySQL Cluster NDB 6.1 (formerly known as “MySQL Cluster Carrier Grade Edition 6.1.x”) is no longer being developed or maintained; if you are using a MySQL Cluster NDB 6.1 release, you should consider upgrading to MySQL Cluster NDB 6.2 or 6.3.

### Note

Please refer to our bug database at <http://bugs.mysql.com/> for more details about the individual bugs fixed in this version.

Functionality added or changed:

- A new configuration parameter `MemReportFrequency` enables additional control of data node memory usage. Previously, only warnings at predetermined percentages of memory allocation were given; setting this parameter enables that behavior to be overridden. For more information, see [Section 17.3.2.6, “Defining MySQL Cluster Data Nodes”](#).

Bugs fixed:

- When a data node was shut down using the management client `STOP` command, a connection event (`NDB_LE_Connected`) was logged instead of a disconnection event (`NDB_LE_Disconnected`). ([Bug#22773](#))
- `SELECT` statements with a `BLOB` or `TEXT` column in the selected column list and a `WHERE` condition including a primary key lookup on a `VARCHAR` primary key produced empty result sets. ([Bug#19956](#))
- **Disk Data:** `MEDIUMTEXT` columns of Disk Data tables were stored in memory rather than on disk, even if the columns were not indexed. ([Bug#25001](#))
- **Disk Data:** Performing a node restart with a newly dropped Disk Data table could lead to failure of the node during the restart. ([Bug#24917](#))
- **Disk Data:** When restoring from backup a cluster containing any Disk Data tables with hidden primary keys, a node failure resulted which could lead to a crash of the cluster. ([Bug#24166](#))
- **Disk Data:** Repeated `CREATE`, `DROP`, or `TRUNCATE TABLE` in various combinations with system restarts between these operations could lead to the eventual failure of a system restart. ([Bug#21948](#))
- **Disk Data:** Extents that should have been available for re-use following a `DROP TABLE` operation were not actually made available again until after the cluster had performed a local checkpoint. ([Bug#17605](#))
- **Cluster API:** Invoking the `NdbTransaction::execute()` method using execution type `Commit` and abort option `AO_IgnoreError` could lead to a crash of the transaction coordinator (`DBTC`). ([Bug#25090](#))
- **Cluster API:** A unique index lookup on a nonexistent tuple could lead to a data node timeout (error 4012). ([Bug#25059](#))
- **Cluster API:** When using the `NdbTransaction::execute()` method, a very long timeout (greater than 5 minutes) could result if the last data node being polled was disconnected from the cluster. ([Bug#24949](#))
- **Cluster API:** Due to an error in the computation of table fragment arrays, some transactions were not executed from the correct starting point. ([Bug#24914](#))
- Under certain rare circumstances, local checkpoints were not performed properly, leading to an inability to restart one or more data nodes. ([Bug#24664](#))

## 17.7.6. Release Series Changelogs: MySQL Cluster NDB 6.X and 7.X

This section contains unified changelog information for each MySQL Cluster release series (NDB 6.1, NDB 6.2, NDB 6.3, and NDB 7.0).

For changelogs covering individual MySQL Cluster NDB 6.X and MySQL Cluster NDB 7.X releases, see [Section 17.7, “Changes in MySQL Cluster NDB 6.X and 7.X”](#).

For general information about features added in MySQL Cluster NDB 6.X and 7.X, see [Section 17.1.4, “MySQL Cluster Development History”](#).

An overview of features added in MySQL 5.1 not specific to MySQL Cluster can be found here: [Section 1.5, “What Is New in MySQL 5.1”](#). For a complete list of all bugfixes and features changes made in MySQL 5.1 that are not specific to MySQL Cluster, see [Section C.1, “Changes in Release 5.1.x \(Production\)”](#).

### 17.7.6.1. Changes in the MySQL Cluster NDB 7.1 Series

This section contains unified change history highlights for all MySQL Cluster releases based on version 7.1 of the `NDBCLUSTER` storage engine through MySQL Cluster NDB 7.1.8. Included are all changelog entries in the categories *MySQL Cluster*, *Disk Data*, and *Cluster API*.

For an overview of features that were added in MySQL Cluster NDB 7.1, see [Section 17.1.4.1, “MySQL Cluster Development in MySQL Cluster NDB 7.1”](#).

- [Changes in MySQL Cluster NDB 7.1.8 \(5.1.47-ndb-7.1.8\)](#)
- [Changes in MySQL Cluster NDB 7.1.7 \(5.1.47-ndb-7.1.7\)](#)
- [Changes in MySQL Cluster NDB 7.1.6 \(5.1.47-ndb-7.1.6\)](#)
- [Changes in MySQL Cluster NDB 7.1.5 \(5.1.47-ndb-7.1.5\)](#)
- [Changes in MySQL Cluster NDB 7.1.4 \(5.1.44-ndb-7.1.4\)](#)
- [Changes in MySQL Cluster NDB 7.1.3 \(5.1.44-ndb-7.1.3\)](#)
- [Changes in MySQL Cluster NDB 7.1.2 \(5.1.41-ndb-7.1.2\)](#)
- [Changes in MySQL Cluster NDB 7.1.1 \(5.1.41-ndb-7.1.1\)](#)
- [Changes in MySQL Cluster NDB 7.1.0 \(5.1.39-ndb-7.1.0\)](#)

### **Changes in MySQL Cluster NDB 7.1.8 (5.1.47-ndb-7.1.8)**

Functionality added or changed:

- `mysqldump` as supplied with MySQL Cluster now has an `--add-drop-trigger` option which adds a `DROP TRIGGER IF EXISTS` statement before each dumped trigger definition. ([Bug#55691](#))

See also [Bug#34325](#).

Bugs fixed:

- Under certain rare conditions, attempting to start more than one `ndb_mgmd` process simultaneously using the `--reload` option caused a race condition such that none of the `ndb_mgmd` processes could start. ([Bug#56844](#))
- When distributing `CREATE TABLE` and `DROP TABLE` operations among several SQL nodes attached to a MySQL Cluster, the `LOCK_OPEN` lock normally protecting `mysqld`'s internal table list is released so that other queries or DML statements are not blocked. However, to make sure that other DDL is not executed simultaneously, a global schema lock (implemented as a row-level lock by `NDB`) is used, such that all operations that can modify the state of the `mysqld` internal table list also need to acquire this global schema lock. The `SHOW TABLE STATUS` statement did not acquire this lock. ([Bug#56841](#))
- MySQL Cluster stores, for each row in each `NDB` table, a Global Checkpoint Index (GCI) which identifies the last committed transaction that modified the row. As such, a GCI can be thought of as a coarse-grained row version.

Due to changes in the format used by `NDB` to store local checkpoints (LCPs) in MySQL Cluster NDB 6.3.11, it could happen that, following cluster shutdown and subsequent recovery, the GCI values for some rows could be changed unnecessarily; this could possibly, over the course of many node or system restarts (or both), lead to an inconsistent database. ([Bug#56770](#))

- When multiple SQL nodes were connected to the cluster and one of them stopped in the middle of a DDL operation, the `mysqld` process issuing the DDL timed out with the error `DISTRIBUTING TBL_NAME TIMED OUT. IGNORING.` ([Bug#56763](#))
- An online `ALTER TABLE ... ADD COLUMN` operation that changed the table schema such that the number of 32-bit words used for the bitmask allocated to each DML operation increased during a transaction in DML which was performed prior to DDL which was followed by either another DML operation or—if using replication—a commit, led to data node failure.

This was because the data node did not take into account that the bitmask for the before-image was smaller than the current bitmask, which caused the node to crash. ([Bug#56524](#))

- On Windows, a data node refused to start in some cases unless the `ndbd.exe` executable was invoked using an absolute rather than a relative path. ([Bug#56257](#))
- The failure of a data node during some scans could cause other data nodes to fail. ([Bug#54945](#))
- Exhausting the number of available commit-ack markers (controlled by the `MaxNoOfConcurrentTransactions` parameter) led to a data node crash. ([Bug#54944](#))
- When running a `SELECT` on an `NDB` table with `BLOB` or `TEXT` columns, memory was allocated for the columns but was not

freed until the end of the `SELECT`. This could cause problems with excessive memory usage when dumping (using for example `mysqldump`) tables with such columns and having many rows, large column values, or both. ([Bug#52313](#))

See also [Bug#56488](#), [Bug#50310](#).

### Changes in MySQL Cluster NDB 7.1.7 (5.1.47-ndb-7.1.7)

Functionality added or changed:

- **Important Change:** More finely-grained control over restart-on-failure behavior is provided with two new data node configuration parameters `MaxStartFailRetries` and `StartFailRetryDelay`. `MaxStartFailRetries` limits the total number of retries made before giving up on starting the data node; `StartFailRetryDelay` sets the number of seconds between retry attempts.

These parameters are used only if `StopOnError` is set to 0.

For more information, see [Section 17.3.2.6, “Defining MySQL Cluster Data Nodes”](#). ([Bug#54341](#))

Bugs fixed:

- **Important Change:** It is no longer possible to make a dump of the `ndbinfo` database using `mysqldump`. ([Bug#54316](#))
- `ndb_restore` always reported 0 for the `GCPStop` (end point of the backup). Now it provides useful binary log position and epoch information. ([Bug#56298](#))
- The `LockExecuteThreadToCPU` configuration parameter was not handled correctly for CPU ID values greater than 255. ([Bug#56185](#))
- Following a failure of the master data node, the new master sometimes experienced a race condition which caused the node to terminate with a `GcpStop` error. ([Bug#56044](#))
- Trying to create a table having a `BLOB` or `TEXT` column with `DEFAULT ''` failed with the error `ILLEGAL NULL ATTRIBUTE`. (An empty default is allowed and ignored by `MyISAM`; `NDB` should do the same.) ([Bug#55121](#))
- `ndb_mgmd --nodaemon` logged to the console in addition to the configured log destination. ([Bug#54779](#))
- The warning `MAXNOOFEEXECUTIONTHREADS (#) > LOCKEXECUTETHREADTOCPU COUNT (#), THIS COULD CAUSE CONTE`NTION could be logged when running `ndbd`, even though the condition described can occur only when using `ndbmt`. ([Bug#54342](#))
- Startup messages previously written by `ndb_mgmd` to `stdout` are now written to the cluster log instead when `LogDestination` is set. ([Bug#47595](#))
- The graceful shutdown of a data node could sometimes cause transactions to be aborted unnecessarily. ([Bug#18538](#))

See also [Bug#55641](#).

### Changes in MySQL Cluster NDB 7.1.6 (5.1.47-ndb-7.1.6)

Functionality added or changed:

- Added the `DictTrace` data node configuration parameter, for use in debugging NDB code. For more information, see [Section 17.3.2.6, “Defining MySQL Cluster Data Nodes”](#). ([Bug#55963](#))
- Added the `--server-id-bits` option for `mysqld` and `mysqlbinlog`.

For `mysqld`, the `--server-id-bits` option indicates the number of least significant bits within the 32-bit server ID which actually identify the server. Indicating that the server ID uses less than 32 bits permits the remaining bits to be used for other purposes by NDB API applications using the Event API and `NdbOperation::OperationOptions::AnyValue`.

For `mysqlbinlog`, the `--server-id-bits` option tells `mysqlbinlog` how to interpret the server IDs in the binary log when the binary log was written by a `mysqld` having its `server_id_bits` set to less than the maximum (32). ([Bug#52305](#))

Bugs fixed:

- **Cluster API: Important Change:** The poll and select calls made by the MGM API were not interrupt-safe; that is, a signal caught by the process while waiting for an event on one or more sockets returned error -1 with `errno` set to `EINTR`. This caused problems with MGM API functions such as `ndb_mgm_logevent_get_next()` and `ndb_mgm_get_status2()`.

To fix this problem, the internal `ndb_socket_poller::poll()` function has been made `EINTR`-safe.

The old version of this function has been retained as `poll_unsafe()`, for use by those parts of NDB that do not need the `EINTR`-safe version of the function. ([Bug#55906](#))

- The TCP configuration parameters `HostName1` and `HostName2` were not displayed in the output of `ndb_config -configinfo`. ([Bug#55839](#))
- When another data node failed, a given data node `DBTC` kernel block could time out while waiting for `DBDIH` to signal commits of pending transactions, leading to a crash. Now in such cases the timeout generates a prinout, and the data node continues to operate. ([Bug#55715](#))
- Using the `--disable-config-cache` option with `ndb_mgmd` caused a memory leak. ([Bug#55205](#))
- The `configure.js` option `WITHOUT_DYNAMIC_PLUGINS=TRUE` was ignored when building MySQL Cluster for Windows using `CMake`. Among the effects of this issue was that `CMake` attempted to build the `InnoDB` storage engine as a plugin (`.DLL` file) even though the `InnoDB Plugin` is not currently supported by MySQL Cluster. ([Bug#54913](#))
- It was possible for a `DROP DATABASE` statement to remove `NDB` hidden blob tables without removing the parent tables, with the result that the tables, although hidden to MySQL clients, were still visible in the output of `ndb_show_tables` but could not be dropped using `ndb_drop_table`. ([Bug#54788](#))
- An excessive number of timeout warnings (normally used only for debugging) were written to the data node logs. ([Bug#53987](#))
- **Disk Data:** As an optimization when inserting a row to an empty page, the page is not read, but rather simply initialized. However, this optimization was performed in all cases when an empty row was inserted, even though it should have been done only if it was the first time that the page had been used by a table or fragment. This is because, if the page had been in use, and then all records had been released from it, the page still needed to be read to learn its log sequence number (LSN).

This caused problems only if the page had been flushed using an incorrect LSN and the data node failed before any local checkpoint was completed—which would removed any need to apply the undo log, hence the incorrect LSN was ignored.

The user-visible result of the incorrect LSN was that it caused the data node to fail during a restart. It was perhaps also possible (although not conclusively proven) that this issue could lead to incorrect data. ([Bug#54986](#))

- **Cluster API:** Calling `NdbTransaction::refresh()` did not update the timer for `TransactionInactiveTimeout`. ([Bug#54724](#))

## Changes in MySQL Cluster NDB 7.1.5 (5.1.47-ndb-7.1.5)

Functionality added or changed:

- Restrictions on some types of mismatches in column definitions when restoring data using `ndb_restore` have been relaxed. These include the following types of mismatches:
  - Different `COLUMN_FORMAT` settings (`FIXED`, `DYNAMIC`, `DEFAULT`)
  - Different `STORAGE` settings (`MEMORY`, `DISK`)
  - Different default values
  - Different distribution key settings

Now, when one of these types of mismatches in column definitions is encountered, `ndb_restore` no longer stops with an error; instead, it accepts the data and inserts it into the target table, while issuing a warning to the user.

For more information, see [Section 17.4.17, “`ndb\_restore` — Restore a MySQL Cluster Backup”](#). ([Bug#54423](#))

See also [Bug#53810](#), [Bug#54178](#), [Bug#54242](#), [Bug#54279](#).

- It is now possible to install management node and data node processes as Windows services. (See [Section 17.2.2.4, “Installing MySQL Cluster Processes as Windows Services”](#), for more information.) In addition, data node processes on Windows are now maintained by angel processes, just as they are on other platforms supported by MySQL Cluster.

Bugs fixed:

- The disconnection of all API nodes (including SQL nodes) during an `ALTER TABLE` caused a memory leak. ([Bug#54685](#))
- If a node shutdown (either in isolation or as part of a system shutdown) occurred directly following a local checkpoint, it was possible that this local checkpoint would not be used when restoring the cluster. ([Bug#54611](#))
- The setting for `BuildIndexThreads` was ignored by `ndbmtd`, which made it impossible to use more than 4 cores for re-building indexes. ([Bug#54521](#))
- When adding multiple new node groups to a MySQL Cluster, it was necessary for each new node group to add only the nodes to be assigned to the new node group, create that node group using `CREATE NODEGROUP`, then repeat this process for each new node group to be added to the cluster. The fix for this issue makes it possible to add all of the new nodes at one time, and then issue several `CREATE NODEGROUP` commands in succession. ([Bug#54497](#))
- When performing an online alter table where 2 or more SQL nodes connected to the cluster were generating binary logs, an incorrect message could be sent from the data nodes, causing `mysqld` processes to crash. This problem was often difficult to detect, because restarting SQL node or data node processes could clear the error, and because the crash in `mysqld` did not occur until several minutes after the erroneous message was sent and received. ([Bug#54168](#))
- A table having the maximum number of attributes permitted could not be backed up using the `ndb_mgm` client.

#### Note

The maximum number of attributes supported per table is not the same for all MySQL Cluster releases. See [Section 17.1.5.5, “Limits Associated with Database Objects in MySQL Cluster”](#), to determine the maximum that applies in the release which you are using.

([Bug#54155](#))

- The presence of duplicate `[tcp]` sections in the `config.ini` file caused the management server to crash. Now in such cases, `ndb_mgmd` fails gracefully with an appropriate error message. ([Bug#49400](#))
- The two MySQL Server options, `--ndb-wait-connected` and `--ndb-wait-setup`, did not set the corresponding system variables. ([Bug#48402](#))
- **Cluster API:** When using the NDB API, it was possible to rename a table with the same name as that of an existing table.

#### Note

This issue did not affect table renames executed using SQL on MySQL servers acting as MySQL Cluster API nodes.

([Bug#54651](#))

- **Cluster API:** An excessive number of client connections, such that more than 1024 file descriptors, sockets, or both were open, caused NDB API applications to crash. ([Bug#34303](#))

## Changes in MySQL Cluster NDB 7.1.4 (5.1.44-ndb-7.1.4)

Functionality added or changed:

- **Important Change:** The maximum number of attributes (columns plus indexes) per table has increased to 512.
- A `--wait-nodes` option has been added for `ndb_waiter`. When this option is used, the program waits only for the nodes having the listed IDs to reach the desired state. For more information, see [Section 17.4.22, “ndb\\_waiter — Wait for MySQL Cluster to Reach a Given Status”](#). ([Bug#52323](#))
- As part of this change, new methods relating to default values have been added to the `Column` and `Table` classes in the NDB API. For more information, see `Column::getDefaultValue()`, `Column::setDefaultValue()`, and `Table::hasDefaultValues()`. ([Bug#30529](#))
- Added the MySQL Cluster management server option `--config-cache`, which makes it possible to enable and disable configuration caching. This option is turned on by default; to disable configuration caching, start `ndb_mgmd` with `--config-cache=0`, or with `--skip-config-cache`. See [Section 17.4.4, “ndb\\_mgmd — The MySQL Cluster Management Server Daemon”](#), for more information.
- Added the `--skip-unknown-objects` option for `ndb_restore`. This option causes `ndb_restore` to ignore any schema objects which it does not recognize. Currently, this is useful chiefly for restoring native backups made from a cluster

running MySQL Cluster NDB 7.0 to a cluster running MySQL Cluster NDB 6.3.

Bugs fixed:

- **Cluster API: Incompatible Change:** The default behavior of the NDB API Event API has changed as follows:

Previously, when creating an `NdbDictionary::Event`, DDL operations (alter and drop operations on tables) were automatically reported on any event operation that used this event, but as a result of this change, this is no longer the case. Instead, you must now invoke the event's `setReport()` method, with the new `EventReport` value `ER_DDL`, to get this behavior.

For existing NDB API applications where you wish to retain the old behavior, you must update the code as indicated previously, then recompile, following an upgrade. Otherwise, DDL operations are no longer reported after upgrading `libndbclient`.

For more information, see [The Event::EventReport Type](#), and `Event::setReport()`. ([Bug#53308](#))

- **Cluster API: Incompatible Change:** The default behavior of the NDB API Event API has changed as follows:

Previously, when creating an `NdbDictionary::Event`, DDL operations (alter and drop operations on tables) were automatically reported on any event operation that used this event, but as a result of this change, this is no longer the case. Instead, you must now invoke the event's `setReport()` method, with the new `EventReport` value `ER_DDL`, to get this behavior.

For existing NDB API applications where you wish to retain the old behavior, you must update the code as indicated previously, then recompile, following an upgrade. Otherwise, DDL operations are no longer reported after upgrading `libndbclient`.

For more information, see [The Event::EventReport Type](#), and `Event::setReport()`. ([Bug#53308](#))

- After creating `NDB` tables until creation of a table failed due to `NDB` error `905 OUT OF ATTRIBUTE RECORDS ( INCREASE MAXNOOFATTRIBUTES )`, then increasing `MaxNoOfAttributes` and restarting all management node and data node processes, attempting to drop and re-create one of the tables failed with the error `OUT OF TABLE RECORDS . . .`, even when sufficient table records were available. ([Bug#53944](#))

See also [Bug#52055](#).

- Creating a Disk Data table, dropping it, then creating an in-memory table and performing a restart, could cause data node processes to fail with errors in the `DBTUP` kernel block if the new table's internal ID was the same as that of the old Disk Data table. This could occur because undo log handling during the restart did not check that the table having this ID was now in-memory only. ([Bug#53935](#))
- A table created while `ndb_table_no_logging` was enabled was not always stored to disk, which could lead to a data node crash with `ERROR OPENING DIH SCHEMA FILES FOR TABLE`. ([Bug#53934](#))
- An internal buffer allocator used by `NDB` has the form `alloc(wanted, minimum)` and attempts to allocate `wanted` pages, but is permitted to allocate a smaller number of pages, between `wanted` and `minimum`. However, this allocator could sometimes allocate fewer than `minimum` pages, causing problems with multi-threaded building of ordered indexes. ([Bug#53580](#))
- When compiled with support for `epoll` but this functionality is not available at runtime, MySQL Cluster tries to fall back to use the `select()` function in its place. However, an extra `ndbout_c()` call in the transporter registry code caused `ndbd` to fail instead. ([Bug#53482](#))
- The value set for the `ndb_mgmd` option `--ndb-nodeid` was not verified prior to use as being within the permitted range (1 to 255, inclusive), leading to a crash of the management server. ([Bug#53412](#))
- `NDB` truncated a column declared as `DECIMAL(65, 0)` to a length of 64. Now such a column is accepted and handled correctly. In cases where the maximum length (65) is exceeded, `NDB` now raises an error instead of truncating. ([Bug#53352](#))
- When an `NDB` log handler failed, the memory allocated to it was freed twice. ([Bug#53200](#))
- Setting `DataMemory` higher than 4G on 32-bit platforms caused `ndbd` to crash, instead of failing gracefully with an error. ([Bug#52536](#), [Bug#50928](#))
- When the `LogDestination` parameter was set using with a relative path, the management server failed to store its value unless started with `--initial` or `--reload`. ([Bug#52268](#))
- When creating an index, `NDB` failed to check whether the internal ID allocated to the index was within the permissible range, leading to an assertion. This issue could manifest itself as a data node failure with `NDB` error `707 (NO MORE TABLE METADATA RECORDS ( INCREASE MAXNOOFTABLES ))`, when creating tables in rapid succession (for example, by a script, or when importing

from `mysqldump`), even with a relatively high value for `MaxNoOfTables` and a relatively low number of tables. ([Bug#52055](#))

- `ndb_restore` did not raise any errors if hashmap creation failed during execution. ([Bug#51434](#))
- Specifying the node ID as part of the `--ndb-connectstring` option to `mysqld` was not handled correctly.

The fix for this issue includes the following changes:

- Multiple occurrences of any of the `mysqld` options `--ndb-connectstring`, `--ndb-mgmd-host`, and `--ndb-nodeid` are now handled in the same way as with other MySQL server options, in that the value set in the last occurrence of the option is the value that is used by `mysqld`.

Now, if `--ndb-nodeid` is used, its value overrides that of any `nodeid` setting used in `--ndb-connectstring`. For example, starting `mysqld` with `--ndb-connectstring=nodeid=1,10.100.1.100 --ndb-nodeid=3` now produces the same result as starting it with `--ndb-connectstring=nodeid=3,10.100.1.100`.

- The 1024-character limit on the length of the connectstring is removed, and `--ndb-connectstring` is now handled in this regard in the same way as other `mysqld` options.
- In the NDB API, a new constructor for `Ndb_cluster_connection` is added which takes as arguments a connectstring and the node ID to force the API node to use. See [Ndb\\_cluster\\_connection Class Constructor](#), for more information.

([Bug#44299](#))

- NDB did not distinguish correctly between table names differing only by lettercase when `lower_case_table_names` was set to 0. ([Bug#33158](#))
- `ndb_mgm -e "ALL STATUS"` erroneously reported that data nodes remained in start phase 0 until they had actually started.

### Changes in MySQL Cluster NDB 7.1.3 (5.1.44-ndb-7.1.3)

Functionality added or changed:

- **Incompatible Change:** The schema for the `memoryusage` table of the `ndbinfo` information database has changed, as detailed in the following list:
  - The `max` column has been renamed to `total`.
  - The `used` and `total` (formerly `max`) columns now display values in bytes rather than memory pages.
  - Added the columns `used_pages` and `total_pages` to show the amount of a resource used and total amount available in pages.
  - The size of the memory pages used for calculating data memory (`used_pages` and `total_pages` columns) is now 32K rather than 16K.

For more information, see [Section 17.5.8.6, “The ndbinfo memoryusage Table”](#).

- **Incompatible Change:** The schema for the `memoryusage` table of the `ndbinfo` information database has changed, as detailed in the following list:
  - The `max` column has been renamed to `total`.
  - The `used` and `total` (formerly `max`) columns now display values in bytes rather than memory pages.
  - Added the columns `used_pages` and `total_pages` to show the amount of a resource used and total amount available in pages.
  - The size of the memory pages used for calculating data memory (`used_pages` and `total_pages` columns) is now 32K rather than 16K.

For more information, see [Section 17.5.8.6, “The ndbinfo memoryusage Table”](#).

- **Important Change:** The experimental `ndbinfo.pools` table has been removed. Information useful to MySQL Cluster administration that was contained in this table should be available from other `ndbinfo` tables. See [Section 17.5.8, “The ndbinfo MySQL Cluster Information Database”](#), for additional information.
- **Important Note:** MySQL Cluster 7.1 is now supported for production use on Windows platforms.

## Important

Some limitations specific to Windows remain; the most important of these are given in the following list:

- There is not yet any Windows installer for MySQL Cluster; you must extract, place, configure, and start the necessary MySQL Cluster executables manually.
- MySQL Cluster processes cannot yet be installed as Windows services. This means that each process executable must be run from a command prompt, and cannot be backgrounded. If you close the command prompt window in which you started the process, the process terminates.
- There is as yet no “angel” process for data nodes; if a data node process quits, it must be restarted manually.
- `ndb_error_reporter` is not yet available on Windows.
- The multi-threaded data node process (`ndbmtd`) is not yet included in the binary distribution. However, it should be built automatically if you build MySQL Cluster from source.

As with MySQL Cluster on other supported platforms, you cannot build MySQL Cluster for Windows from the MySQL Server 5.1 sources; you must use the source code from the MySQL Cluster NDB 7.1 tree.

Bugs fixed:

- If a node or cluster failure occurred while `mysqld` was scanning the `ndb.ndb_schema` table (which it does when attempting to connect to the cluster), insufficient error handling could lead to a crash by `mysqld` in certain cases. This could happen in a MySQL Cluster with a great many tables, when trying to restart data nodes while one or more `mysqld` processes were restarting. ([Bug#52325](#))
- In MySQL Cluster NDB 7.0 and later, DDL operations are performed within schema transactions; the NDB kernel code for starting a schema transaction checks that all data nodes are at the same version before permitting a schema transaction to start. However, when a version mismatch was detected, the client was not actually informed of this problem, which caused the client to hang. ([Bug#52228](#))
- After running a mixed series of node and system restarts, a system restart could hang or fail altogether. This was caused by setting the value of the newest completed global checkpoint too low for a data node performing a node restart, which led to the node reporting incorrect GCI intervals for its first local checkpoint. ([Bug#52217](#))
- When performing a complex mix of node restarts and system restarts, the node that was elected as master sometimes required optimized node recovery due to missing `REDO` information. When this happened, the node crashed with `FAILURE TO RECREATE OBJECT ... DURING RESTART, ERROR 721` (because the `DBDICT` restart code was run twice). Now when this occurs, node takeover is executed immediately, rather than being made to wait until the remaining data nodes have started. ([Bug#52135](#))

See also [Bug#48436](#).

- The internal variable `ndb_new_handler`, which is no longer used, has been removed. ([Bug#51858](#))
- `ha_ndbcluster.cc` was not compiled with the same `SAFEMALLOC` and `SAFE_MUTEX` flags as the MySQL Server. ([Bug#51857](#))
- When debug compiling MySQL Cluster on Windows, the mysys library was not compiled with `-DSAFEMALLOC` and `-DSAFE_MUTEX`, due to the fact that `my_socket.c` was misnamed as `my_socket.cc`. ([Bug#51856](#))
- Some values shown in the `ndbinfo.memoryusage` table did not match corresponding values shown by the `ndb_mgm` client `ALL REPORT MEMORYUSAGE` command. ([Bug#51735](#))
- The redo log protects itself from being filled up by periodically checking how much space remains free. If insufficient redo log space is available, it sets the state `TAIL_PROBLEM` which results in transactions being aborted with error code 410 (`OUT OF REDO LOG`). However, this state was not set following a node restart, which meant that if a data node had insufficient redo log space following a node restart, it could crash a short time later with `FATAL ERROR DUE TO END OF REDO LOG`. Now, this space is checked during node restarts. ([Bug#51723](#))
- Restoring a MySQL Cluster backup between platforms having different endianness failed when also restoring metadata and the backup contained a hashmap not already present in the database being restored to. This issue was discovered when trying to restore a backup made on Solaris/SPARC to a MySQL Cluster running on Solaris/x86, but could conceivably occur in other cases where the endianness of the platform on which the backup was taken differed from that of the platform being restored to. ([Bug#51432](#))
- A `mysqld`, when attempting to access the `ndbinfo` database, crashed if could not contact the management server.

**Bug#51067)**

- The `mysql` client `system` command did not work properly. This issue was only known to affect the version of the `mysql` client that was included with MySQL Cluster NDB 7.0 and MySQL Cluster NDB 7.1 releases. ([Bug#48574](#))
- **Cluster API: Packaging:** The file `META-INF/services/org.apache.openjpa.lib.conf.ProductDerivation` was missing from the `clusterjpa` JAR file. This could cause setting `openjpa.BrokerFactory` to “`ndb`” to be rejected. ([Bug#52106](#))
- **Disk Data:** Inserts of blob column values into a MySQL Cluster Disk Data table that exhausted the tablespace resulted in misleading `NO SUCH TUPLE` error messages rather than the expected error `TABLESPACE FULL`.  
This issue appeared similar to [Bug#48113](#), but had a different underlying cause. ([Bug#52201](#))
- **Disk Data:** DDL operations on Disk Data tables having a relatively small `UNDO_BUFFER_SIZE` could fail unexpectedly.
- **Cluster API:** A number of issues were corrected in the NDB API coding examples found in the `storage/ndb/ndbapi-examples` directory in the MySQL Cluster source tree. These included possible endless recursion in `ndbapi_scan.cpp` as well as problems running some of the examples on systems using Windows or Mac OS due to the letter case used for some table names. ([Bug#30552](#), [Bug#30737](#))

**Changes in MySQL Cluster NDB 7.1.2 (5.1.41-ndb-7.1.2)**

Functionality added or changed:

- **Cluster API:** It is now possible to determine, using the `ndb_desc` utility or the NDB API, which data nodes contain replicas of which partitions. For `ndb_desc`, a new `--extra-node-info` option is added to cause this information to be included in its output. A new method `NdbDictionary::Object::Table::getFragmentNodes()` is added to the NDB API for obtaining this information programmatically. ([Bug#51184](#))
- **Cluster API:** It is now possible to determine, using the `ndb_desc` utility or the NDB API, which data nodes contain replicas of which partitions. For `ndb_desc`, a new `--extra-node-info` option is added to cause this information to be included in its output. A new method `NdbDictionary::Object::Table::getFragmentNodes()` is added to the NDB API for obtaining this information programmatically. ([Bug#51184](#))
- Numeric codes used in management server status update messages in the cluster logs have been replaced with text descriptions. ([Bug#49627](#))

See also [Bug#44248](#).

- A new configuration parameter `HeartbeatThreadPriority` makes it possible to select between a first-in, first-out or round-round scheduling policy for management node and API node heartbeat threads, as well as to set the priority of these threads. See [Section 17.3.2.5, “Defining a MySQL Cluster Management Server”](#), or [Section 17.3.2.7, “Defining SQL and Other API Nodes in a MySQL Cluster”](#), for more information. ([Bug#49617](#))
- Start phases are now written to the data node logs. ([Bug#49158](#))
- Formerly, the `REPORT` and `DUMP` commands returned output to all `ndb_mgm` clients connected to the same MySQL Cluster. Now, these commands return their output only to the `ndb_mgm` client that actually issued the command. ([Bug#40865](#))
- **Disk Data:** The `ndb_desc` utility can now show the extent space and free extent space for subordinate `BLOB` and `TEXT` columns (stored in hidden `BLOB` tables by NDB). A `--blob-info` option has been added for this program that causes `ndb_desc` to generate a report for each subordinate `BLOB` table. For more information, see [Section 17.4.9, “ndb\\_desc — Describe NDB Tables”](#). ([Bug#50599](#))

Bugs fixed:

- **Important Change:** The `DATA_MEMORY` column of the `ndbinfo.memoryusage` table was renamed to `memory_type`. ([Bug#50926](#))
- When deciding how to divide the REDO log, the `DBDIH` kernel block saved more than was needed to restore the previous local checkpoint, which could cause REDO log space to be exhausted prematurely (NDB error 410). ([Bug#51547](#))
- DML operations can fail with NDB error 1220 (`REDO LOG FILES OVERLOADED...`) if the opening and closing of REDO log files takes too much time. If this occurred as a GCI marker was being written in the REDO log while REDO log file 0 was being opened or closed, the error could persist until a GCP stop was encountered. This issue could be triggered when there was insufficient REDO log space (for example, with configuration parameter settings `NoOfFragmentLogFile = 6` and `Frag-`

`mentLogFileSize = 6M`) with a load including a very high number of updates. ([Bug#51512](#))

See also [Bug#20904](#).

- An attempted online upgrade from a MySQL Cluster NDB 6.3 or 7.0 release to a MySQL Cluster NDB 7.1 release failed, as the first upgraded data node rejected the remaining data nodes as using incompatible versions. ([Bug#51429](#))
- A side effect of the `ndb_restore --disable-indexes` and `--rebuild-indexes` options is to change the schema versions of indexes. When a `mysqld` later tried to drop a table that had been restored from backup using one or both of these options, the server failed to detect these changed indexes. This caused the table to be dropped, but the indexes to be left behind, leading to problems with subsequent backup and restore operations. ([Bug#51374](#))
- The output of the `ndb_mgm` client `REPORT BACKUPSTATUS` command could sometimes contain errors due to uninitialized data. ([Bug#51316](#))
- Setting `IndexMemory` greater than 2GB could cause data nodes to crash while starting. ([Bug#51256](#))
- `ndb_restore` crashed while trying to restore a corrupted backup, due to missing error handling. ([Bug#51223](#))
- The `ndb_restore` message `Successfully created index `PRIMARY`...` was directed to `stderr` instead of `stdout`. ([Bug#51037](#))
- An initial restart of a data node configured with a large amount of memory could fail with a `POINTER TOO LARGE` error. ([Bug#51027](#))

This regression was introduced by [Bug#47818](#).

- When using `NoOfReplicas` equal to 1 or 2, if data nodes from one node group were restarted 256 times and applications were running traffic such that it would encounter NDB error 1204 (`TEMPORARY FAILURE, DISTRIBUTION CHANGED`), the live node in the node group would crash, causing the cluster to crash as well. The crash occurred only when the error was encountered on the 256th restart; having the error on any previous or subsequent restart did not cause any problems. ([Bug#50930](#))
  - A `GROUP BY` query against NDB tables sometimes did not use any indexes unless the query included a `FORCE INDEX` option. With this fix, indexes are used by such queries (where otherwise possible) even when `FORCE INDEX` is not specified. ([Bug#50736](#))
  - `ndbmtd` started on a single-core machine could sometimes fail with a `JOB BUFFER FULL` error when `MaxNoOfExecution-Threads` was set greater than `LockExecuteThreadToCPU`. Now a warning is logged when this occurs. ([Bug#50582](#))
  - The following issues were fixed in the `ndb_mgm` client `REPORT MEMORYUSAGE` command:
    - The client sometimes inserted extra `ndb_mgm>` prompts within the output.
    - For data nodes running `ndbmtd`, `IndexMemory` was reported before `DataMemory`.
    - Also for data nodes running `ndbmtd`, there were multiple `IndexMemory` entries listed in the output.
- ([Bug#50196](#))
- Issuing a command in the `ndb_mgm` client after it had lost its connection to the management server could cause the client to crash. ([Bug#49219](#))
  - Replication of a MySQL Cluster using multi-threaded data nodes could fail with forced shutdown of some data nodes due to the fact that `ndbmtd` exhausted `LongMessageBuffer` much more quickly than `ndbd`. After this fix, passing of replication data between the `DBTUP` and `SUMA` NDB kernel blocks is done using `DataMemory` rather than `LongMessageBuffer`.

Until you can upgrade, you may be able to work around this issue by increasing the `LongMessageBuffer` setting; doubling the default should be sufficient in most cases. ([Bug#46914](#))

- Information about several management client commands was missing from (that is, truncated in) the output of the `HELP` command. ([Bug#46114](#))
- A `SELECT` requiring a sort could fail with the error `CAN'T FIND RECORD IN 'TABLE'` when run concurrently with a `DELETE` from the same table. ([Bug#45687](#))
- When the `MemReportFrequency` configuration parameter was set in `config.ini`, the `ndb_mgm` client `REPORT MEMORYUSAGE` command printed its output multiple times. ([Bug#37632](#))
- `ndb_mgm -e "..." REPORT ...` did not write any output to `stdout`.

The fix for this issue also prevents the cluster log from being flooded with `INFO` messages when `DataMemory` usage reaches

100%, and insures that when the usage is decreased, an appropriate message is written to the cluster log. ([Bug#31542](#), [Bug#44183](#), [Bug#49782](#))

- **Disk Data:** The error message returned after attempting to execute `ALTER LOGFILE GROUP` on an nonexistent logfile group did not indicate the reason for the failure. ([Bug#51111](#))
- **Cluster API:** An issue internal to `ndb_mgm` could cause problems when trying to start a large number of data nodes at the same time. ([Bug#51273](#))
- **Cluster API:** When reading blob data with lock mode `LM_SimpleRead`, the lock was not upgraded as expected. ([Bug#51034](#))

### Changes in MySQL Cluster NDB 7.1.1 (5.1.41-ndb-7.1.1)

Functionality added or changed:

- The `ndbinfo` database is added to provide MySQL Cluster metadata in real time. The tables making up this database contain information about memory, buffer, and other resource usage, as well as configuration parameters and settings, event counts, and other useful data. Access to `ndbinfo` is done by executing standard SQL queries on its tables using the `mysql` command-line client or other MySQL client application. No special setup procedures are required; `ndbinfo` is created automatically and visible in the output of `SHOW DATABASES` when the MySQL Server is connected to a MySQL Cluster.

For more information about `ndbinfo`, see [Section 17.5.8, “The ndbinfo MySQL Cluster Information Database”](#).

- **Cluster API:** ClusterJ 1.0 and ClusterJPA 1.0 are now available for programming Java applications with MySQL Cluster. ClusterJ is a Java connector providing an object-relational API for performing high-speed operations such as primary key lookups on a MySQL Cluster database, but does not require the use of the MySQL Server or JDBC (Connector/J). ClusterJ uses a new library NdbJTie which enables direct access from Java to the NDB API and thus to the `NDBCLUSTER` storage engine. ClusterJPA is a new implementation of [OpenJPA](#), and can use either a JDBC connection to a MySQL Cluster SQL node (MySQL Server) or a direct connection to MySQL Cluster using NdbJTie, depending on availability and operational performance.

ClusterJ, ClusterJPA, and NdbJTie require Java 1.5 or 1.6, and MySQL Cluster NDB 7.0 or later.

All necessary libraries and other files for ClusterJ, ClusterJPA, and NdbJTie can be found in the MySQL Cluster NDB 7.1.1 or later distribution.

Bugs fixed:

- When a primary key lookup on an `NDB` table containing one or more `BLOB` columns was executed in a transaction, a shared lock on any blob tables used by the `NDB` table was held for the duration of the transaction. (This did not occur for indexed or non-indexed `WHERE` conditions.)

Now in such cases, the lock is released after all `BLOB` data has been read. ([Bug#49190](#))

### Changes in MySQL Cluster NDB 7.1.0 (5.1.39-ndb-7.1.0)

Functionality added or changed:

- **Important Change:** The default value of the `DiskIOThreadPool` data node configuration parameter has changed from 8 to 2.

Bugs fixed:

- **Important Change:** The `--with-ndb-port-base` option for `configure` has been removed. It is now handled as an unknown and invalid option if you attempt to use it when configuring a build of MySQL Cluster. ([Bug#47941](#))

See also [Bug#38502](#).

- The value set by the `--ndb-cluster-connection-pool` option was not shown in the output of `SHOW STATUS LIKE 'NDB%'`. ([Bug#44118](#))

## 17.7.6.2. Changes in the MySQL Cluster NDB 7.0 Series

This section contains unified change history highlights for all MySQL Cluster releases based on version 7.0 of the `NDBCLUSTER` storage engine through MySQL Cluster NDB 7.0.19. Included are all changelog entries in the categories *MySQL Cluster*, *Disk Data*, and *Cluster API*.

Early MySQL Cluster NDB 7.0 releases tagged “NDB 6.4.x” are also included in this listing.

For an overview of features that were added in MySQL Cluster NDB 7.0, see [Section 17.1.4.2, “MySQL Cluster Development in MySQL Cluster NDB 7.0”](#).

- [Changes in MySQL Cluster NDB 7.0.19 \(5.1.47-ndb-7.0.19\)](#)
- [Changes in MySQL Cluster NDB 7.0.18 \(5.1.47-ndb-7.0.18\)](#)
- [Changes in MySQL Cluster NDB 7.0.17 \(5.1.47-ndb-7.0.17\)](#)
- [Changes in MySQL Cluster NDB 7.0.16 \(5.1.47-ndb-7.0.16\)](#)

### Changes in MySQL Cluster NDB 7.0.19 (5.1.47-ndb-7.0.19)

Functionality added or changed:

- `mysqldump` as supplied with MySQL Cluster now has an `--add-drop-trigger` option which adds a `DROP TRIGGER IF EXISTS` statement before each dumped trigger definition. ([Bug#55691](#))

See also [Bug#34325](#).

Bugs fixed:

- Under certain rare conditions, attempting to start more than one `ndb_mgmd` process simultaneously using the `--reload` option caused a race condition such that none of the `ndb_mgmd` processes could start. ([Bug#56844](#))
- When distributing `CREATE TABLE` and `DROP TABLE` operations among several SQL nodes attached to a MySQL Cluster, the `LOCK_OPEN` lock normally protecting `mysql`'s internal table list is released so that other queries or DML statements are

not blocked. However, to make sure that other DDL is not executed simultaneously, a global schema lock (implemented as a row-level lock by `NDB`) is used, such that all operations that can modify the state of the `mysqld` internal table list also need to acquire this global schema lock. The `SHOW TABLE STATUS` statement did not acquire this lock. ([Bug#56841](#))

- MySQL Cluster stores, for each row in each `NDB` table, a Global Checkpoint Index (GCI) which identifies the last committed transaction that modified the row. As such, a GCI can be thought of as a coarse-grained row version.

Due to changes in the format used by `NDB` to store local checkpoints (LCPs) in MySQL Cluster NDB 6.3.11, it could happen that, following cluster shutdown and subsequent recovery, the GCI values for some rows could be changed unnecessarily; this could possibly, over the course of many node or system restarts (or both), lead to an inconsistent database. ([Bug#56770](#))

- When multiple SQL nodes were connected to the cluster and one of them stopped in the middle of a DDL operation, the `mysqld` process issuing the DDL timed out with the error `DISTRIBUTING TBL_NAME TIMED OUT. IGNORING.` ([Bug#56763](#))
- An online `ALTER TABLE ... ADD COLUMN` operation that changed the table schema such that the number of 32-bit words used for the bitmask allocated to each DML operation increased during a transaction in DML which was performed prior to DDL which was followed by either another DML operation or—if using replication—a commit, led to data node failure.

This was because the data node did not take into account that the bitmask for the before-image was smaller than the current bitmask, which caused the node to crash. ([Bug#56524](#))

- On Windows, a data node refused to start in some cases unless the `ndbd.exe` executable was invoked using an absolute rather than a relative path. ([Bug#56257](#))
- The failure of a data node during some scans could cause other data nodes to fail. ([Bug#54945](#))
- Exhausting the number of available commit-ack markers (controlled by the `MaxNoOfConcurrentTransactions` parameter) led to a data node crash. ([Bug#54944](#))
- When running a `SELECT` on an `NDB` table with `BLOB` or `TEXT` columns, memory was allocated for the columns but was not freed until the end of the `SELECT`. This could cause problems with excessive memory usage when dumping (using for example `mysqldump`) tables with such columns and having many rows, large column values, or both. ([Bug#52313](#))

See also [Bug#56488](#), [Bug#50310](#).

## Changes in MySQL Cluster NDB 7.0.18 (5.1.47-ndb-7.0.18)

Functionality added or changed:

- Important Change:** More finely-grained control over restart-on-failure behavior is provided with two new data node configuration parameters `MaxStartFailRetries` and `StartFailRetryDelay`. `MaxStartFailRetries` limits the total number of retries made before giving up on starting the data node; `StartFailRetryDelay` sets the number of seconds between retry attempts.

These parameters are used only if `StopOnError` is set to 0.

For more information, see [Section 17.3.2.6, “Defining MySQL Cluster Data Nodes”](#). ([Bug#54341](#))

Bugs fixed:

- `ndb_restore` always reported 0 for the `GCPStop` (end point of the backup). Now it provides useful binary log position and epoch information. ([Bug#56298](#))
- The `LockExecuteThreadToCPU` configuration parameter was not handled correctly for CPU ID values greater than 255. ([Bug#56185](#))
- Following a failure of the master data node, the new master sometimes experienced a race condition which caused the node to terminate with a `GcpStop` error. ([Bug#56044](#))
- Trying to create a table having a `BLOB` or `TEXT` column with `DEFAULT ''` failed with the error `ILLEGAL NULL ATTRIBUTE`. (An empty default is allowed and ignored by `MyISAM`; `NDB` should do the same.) ([Bug#55121](#))
- `ndb_mgmd --nodaemon` logged to the console in addition to the configured log destination. ([Bug#54779](#))
- The warning `MAXNOFEXECUTIONTHREADS (#) > LOCKEXECUTETHREADTOCPU COUNT (#), THIS COULD CAUSE CONTENTION` could be logged when running `ndbd`, even though the condition described can occur only when using `ndbmtd`. ([Bug#54342](#))

- Startup messages previously written by `ndb_mgmd` to `stdout` are now written to the cluster log instead when `LogDestination` is set. ([Bug#47595](#))
- The graceful shutdown of a data node could sometimes cause transactions to be aborted unnecessarily. ([Bug#18538](#))  
See also [Bug#55641](#).

### Changes in MySQL Cluster NDB 7.0.17 (5.1.47-ndb-7.0.17)

Functionality added or changed:

- Added the `DictTrace` data node configuration parameter, for use in debugging NDB code. For more information, see [Section 17.3.2.6, “Defining MySQL Cluster Data Nodes”](#). ([Bug#55963](#))
- Added the `--server-id-bits` option for `mysqld` and `mysqlbinlog`.

For `mysqld`, the `--server-id-bits` option indicates the number of least significant bits within the 32-bit server ID which actually identify the server. Indicating that the server ID uses less than 32 bits permits the remaining bits to be used for other purposes by NDB API applications using the Event API and `NdbOperation::OperationOptions::AnyValue`.

For `mysqlbinlog`, the `--server-id-bits` option tells `mysqlbinlog` how to interpret the server IDs in the binary log when the binary log was written by a `mysqld` having its `server_id_bits` set to less than the maximum (32). ([Bug#52305](#))

Bugs fixed:

- **Cluster API: Important Change:** The poll and select calls made by the MGM API were not interrupt-safe; that is, a signal caught by the process while waiting for an event on one or more sockets returned error -1 with `errno` set to `EINTR`. This caused problems with MGM API functions such as `ndb_mgm_logevent_get_next()` and `ndb_mgm_get_status2()`.

To fix this problem, the internal `ndb_socket_poller::poll()` function has been made `EINTR`-safe.

The old version of this function has been retained as `poll_unsafe()`, for use by those parts of NDB that do not need the `EINTR`-safe version of the function. ([Bug#55906](#))

- The TCP configuration parameters `HostName1` and `HostName2` were not displayed in the output of `ndb_config -configinfo`. ([Bug#55839](#))
- When another data node failed, a given data node `DBTC` kernel block could time out while waiting for `DBDIH` to signal commits of pending transactions, leading to a crash. Now in such cases the timeout generates a prinout, and the data node continues to operate. ([Bug#55715](#))
- Using the `--disable-config-cache` option with `ndb_mgmd` caused a memory leak. ([Bug#55205](#))
- The `configure.js` option `WITHOUT_DYNAMIC_PLUGINS=TRUE` was ignored when building MySQL Cluster for Windows using `CMake`. Among the effects of this issue was that `CMake` attempted to build the `InnoDB` storage engine as a plugin (`.DLL` file) even though the `InnoDB Plugin` is not currently supported by MySQL Cluster. ([Bug#54913](#))
- It was possible for a `DROP DATABASE` statement to remove `NDB` hidden blob tables without removing the parent tables, with the result that the tables, although hidden to MySQL clients, were still visible in the output of `ndb_show_tables` but could not be dropped using `ndb_drop_table`. ([Bug#54788](#))
- An excessive number of timeout warnings (normally used only for debugging) were written to the data node logs. ([Bug#53987](#))
- **Disk Data:** As an optimization when inserting a row to an empty page, the page is not read, but rather simply initialized. However, this optimization was performed in all cases when an empty row was inserted, even though it should have been done only if it was the first time that the page had been used by a table or fragment. This is because, if the page had been in use, and then all records had been released from it, the page still needed to be read to learn its log sequence number (LSN).

This caused problems only if the page had been flushed using an incorrect LSN and the data node failed before any local checkpoint was completed—which would removed any need to apply the undo log, hence the incorrect LSN was ignored.

The user-visible result of the incorrect LSN was that it caused the data node to fail during a restart. It was perhaps also possible (although not conclusively proven) that this issue could lead to incorrect data. ([Bug#54986](#))

- **Cluster API:** Calling `NdbTransaction::refresh()` did not update the timer for `TransactionInactiveTimeout`. ([Bug#54724](#))

## Changes in MySQL Cluster NDB 7.0.16 (5.1.47-ndb-7.0.16)

Functionality added or changed:

- Restrictions on some types of mismatches in column definitions when restoring data using `ndb_restore` have been relaxed. These include the following types of mismatches:
  - Different `COLUMN_FORMAT` settings (`FIXED`, `DYNAMIC`, `DEFAULT`)
  - Different `STORAGE` settings (`MEMORY`, `DISK`)
  - Different default values
  - Different distribution key settings

Now, when one of these types of mismatches in column definitions is encountered, `ndb_restore` no longer stops with an error; instead, it accepts the data and inserts it into the target table, while issuing a warning to the user.

For more information, see [Section 17.4.17, “`ndb\_restore` — Restore a MySQL Cluster Backup”](#). (Bug#54423)

See also Bug#53810, Bug#54178, Bug#54242, Bug#54279.

- Introduced the `HeartbeatOrder` data node configuration parameter, which can be used to set the order in which heartbeats are transmitted between data nodes. This parameter can be useful in situations where multiple data nodes are running on the same host and a temporary disruption in connectivity between hosts would otherwise cause the loss of a node group, leading to failure of the cluster. (Bug#52182)
- It is now possible to install management node and data node processes as Windows services. (See [Section 17.2.2.4, “Installing MySQL Cluster Processes as Windows Services”](#), for more information.) In addition, data node processes on Windows are now maintained by angel processes, just as they are on other platforms supported by MySQL Cluster.

Bugs fixed:

- The disconnection of all API nodes (including SQL nodes) during an `ALTER TABLE` caused a memory leak. (Bug#54685)
- If a node shutdown (either in isolation or as part of a system shutdown) occurred directly following a local checkpoint, it was possible that this local checkpoint would not be used when restoring the cluster. (Bug#54611)
- The setting for `BuildIndexThreads` was ignored by `ndbmtd`, which made it impossible to use more than 4 cores for re-building indexes. (Bug#54521)
- When adding multiple new node groups to a MySQL Cluster, it was necessary for each new node group to add only the nodes to be assigned to the new node group, create that node group using `CREATE NODEGROUP`, then repeat this process for each new node group to be added to the cluster. The fix for this issue makes it possible to add all of the new nodes at one time, and then issue several `CREATE NODEGROUP` commands in succession. (Bug#54497)
- When performing an online alter table where 2 or more SQL nodes connected to the cluster were generating binary logs, an incorrect message could be sent from the data nodes, causing `mysqld` processes to crash. This problem was often difficult to detect, because restarting SQL node or data node processes could clear the error, and because the crash in `mysqld` did not occur until several minutes after the erroneous message was sent and received. (Bug#54168)
- A table having the maximum number of attributes permitted could not be backed up using the `ndb_mgm` client. (Bug#54155)

### Note

The maximum number of attributes supported per table is not the same for all MySQL Cluster releases. See [Section 17.1.5.5, “Limits Associated with Database Objects in MySQL Cluster”](#), to determine the maximum that applies in the release which you are using.

(Bug#54155)

- During initial node restarts, initialization of the REDO log was always performed 1 node at a time, during start phase 4. Now this is done during start phase 2, so that the initialization can be performed in parallel, thus decreasing the time required for initial restarts involving multiple nodes. (Bug#50062)
- The presence of duplicate `[tcp]` sections in the `config.ini` file caused the management server to crash. Now in such cases, `ndb_mgmd` fails gracefully with an appropriate error message. (Bug#49400)

- The two MySQL Server options, `--ndb-wait-connected` and `--ndb-wait-setup`, did not set the corresponding system variables. ([Bug#48402](#))
- **Cluster API:** When using the NDB API, it was possible to rename a table with the same name as that of an existing table.

### Note

This issue did not affect table renames executed using SQL on MySQL servers acting as MySQL Cluster API nodes. ([Bug#54651](#))

- **Cluster API:** An excessive number of client connections, such that more than 1024 file descriptors, sockets, or both were open, caused NDB API applications to crash. ([Bug#34303](#))

## Changes in MySQL Cluster NDB 7.0.15b (5.1.44-ndb-7.0.15b)

Bugs fixed:

- **Cluster API:** The value of an internal constant used in the implementation of the `NdbOperation` and `NdbScanOperation` classes, causing MySQL Cluster NDB 7.0 NDB API applications compiled against MySQL Cluster NDB 7.0.14 or earlier to fail when run with MySQL Cluster 7.0.15, and MySQL Cluster NDB 7.1 NDB API applications compiled against MySQL Cluster NDB 7.1.3 or earlier to break when used with MySQL Cluster 7.1.4. ([Bug#54516](#))

## Changes in MySQL Cluster NDB 7.0.14 (5.1.44-ndb-7.0.14)

Functionality added or changed:

- **Cluster API:** It is now possible to determine, using the `ndb_desc` utility or the NDB API, which data nodes contain replicas of which partitions. For `ndb_desc`, a new `--extra-node-info` option is added to cause this information to be included in its output. A new method `NdbDictionary::Object::Table::getFragmentNodes()` is added to the NDB API for obtaining this information programmatically. ([Bug#51184](#))
- **Cluster API:** It is now possible to determine, using the `ndb_desc` utility or the NDB API, which data nodes contain replicas of which partitions. For `ndb_desc`, a new `--extra-node-info` option is added to cause this information to be included in its output. A new method `NdbDictionary::Object::Table::getFragmentNodes()` is added to the NDB API for obtaining this information programmatically. ([Bug#51184](#))
- Formerly, the `REPORT` and `DUMP` commands returned output to all `ndb_mgm` clients connected to the same MySQL Cluster. Now, these commands return their output only to the `ndb_mgm` client that actually issued the command. ([Bug#40865](#))

Bugs fixed:

- **Cluster API: Incompatible Change:** The default behavior of the NDB API Event API has changed as follows:

Previously, when creating an `NdbDictionary::Event`, DDL operations (alter and drop operations on tables) were automatically reported on any event operation that used this event, but as a result of this change, this is no longer the case. Instead, you must now invoke the event's `setReport()` method, with the new `EventReport` value `ER_DDL`, to get this behavior.

For existing NDB API applications where you wish to retain the old behavior, you must update the code as indicated previously, then recompile, following an upgrade. Otherwise, DDL operations are no longer reported after upgrading `libndbclient`.

For more information, see [The Event::EventReport Type](#), and `Event::setReport()`. ([Bug#53308](#))

- **Cluster API: Incompatible Change:** The default behavior of the NDB API Event API has changed as follows:

Previously, when creating an `NdbDictionary::Event`, DDL operations (alter and drop operations on tables) were automatically reported on any event operation that used this event, but as a result of this change, this is no longer the case. Instead, you must now invoke the event's `setReport()` method, with the new `EventReport` value `ER_DDL`, to get this behavior.

For existing NDB API applications where you wish to retain the old behavior, you must update the code as indicated previously, then recompile, following an upgrade. Otherwise, DDL operations are no longer reported after upgrading `libndbclient`.

For more information, see [The Event::EventReport Type](#), and `Event::setReport()`. ([Bug#53308](#))

- If a node or cluster failure occurred while `mysqld` was scanning the `ndb.ndb_schema` table (which it does when attempting to connect to the cluster), insufficient error handling could lead to a crash by `mysqld` in certain cases. This could happen in a MySQL Cluster with a great many tables, when trying to restart data nodes while one or more `mysqld` processes were restarting. ([Bug#52325](#))
- In MySQL Cluster NDB 7.0 and later, DDL operations are performed within schema transactions; the NDB kernel code for starting a schema transaction checks that all data nodes are at the same version before permitting a schema transaction to start. However, when a version mismatch was detected, the client was not actually informed of this problem, which caused the client to hang. ([Bug#52228](#))
- After running a mixed series of node and system restarts, a system restart could hang or fail altogether. This was caused by setting the value of the newest completed global checkpoint too low for a data node performing a node restart, which led to the node reporting incorrect GCI intervals for its first local checkpoint. ([Bug#52217](#))
- When performing a complex mix of node restarts and system restarts, the node that was elected as master sometimes required optimized node recovery due to missing `REDO` information. When this happened, the node crashed with `FAILURE TO RECREATE OBJECT ... DURING RESTART, ERROR 721` (because the `DBDICT` restart code was run twice). Now when this occurs, node takeover is executed immediately, rather than being made to wait until the remaining data nodes have started. ([Bug#52135](#))

See also [Bug#48436](#).

- The internal variable `ndb_new_handler`, which is no longer used, has been removed. ([Bug#51858](#))
- `ha_ndbcluster.cc` was not compiled with the same `SAFEMALLOC` and `SAFE_MUTEX` flags as the MySQL Server. ([Bug#51857](#))
- When debug compiling MySQL Cluster on Windows, the mysys library was not compiled with `-DSAFEMALLOC` and `-DSAFE_MUTEX`, due to the fact that `my_socket.c` was misnamed as `my_socket.cc`. ([Bug#51856](#))
- The redo log protects itself from being filled up by periodically checking how much space remains free. If insufficient redo log space is available, it sets the state `TAIL_PROBLEM` which results in transactions being aborted with error code 410 (`OUT OF REDO LOG`). However, this state was not set following a node restart, which meant that if a data node had insufficient redo log space following a node restart, it could crash a short time later with `FATAL ERROR DUE TO END OF REDO LOG`. Now, this space is checked during node restarts. ([Bug#51723](#))
- Restoring a MySQL Cluster backup between platforms having different endianness failed when also restoring metadata and the backup contained a hashmap not already present in the database being restored to. This issue was discovered when trying to restore a backup made on Solaris/SPARC to a MySQL Cluster running on Solaris/x86, but could conceivably occur in other cases where the endianness of the platform on which the backup was taken differed from that of the platform being restored to. ([Bug#51432](#))
- The output of the `ndb_mgm` client `REPORT BACKUPSTATUS` command could sometimes contain errors due to uninitialized data. ([Bug#51316](#))
- A `GROUP BY` query against `NDB` tables sometimes did not use any indexes unless the query included a `FORCE INDEX` option. With this fix, indexes are used by such queries (where otherwise possible) even when `FORCE INDEX` is not specified. ([Bug#50736](#))
- The following issues were fixed in the `ndb_mgm` client `REPORT MEMORYUSAGE` command:
  - The client sometimes inserted extra `ndb_mgm>` prompts within the output.
  - For data nodes running `ndbmtd`, `IndexMemory` was reported before `DataMemory`.
  - Also for data nodes running `ndbmtd`, there were multiple `IndexMemory` entries listed in the output.

([Bug#50196](#))
- Issuing a command in the `ndb_mgm` client after it had lost its connection to the management server could cause the client to crash. ([Bug#49219](#))
- The `mysql` client `system` command did not work properly. This issue was only known to affect the version of the `mysql` client that was included with MySQL Cluster NDB 7.0 and MySQL Cluster NDB 7.1 releases. ([Bug#48574](#))
- The internal `ErrorReporter::formatMessage()` method could in some cases cause a buffer overflow. ([Bug#47120](#))
- Information about several management client commands was missing from (that is, truncated in) the output of the `HELP` command. ([Bug#46114](#))
- The `ndb_print_backup_file` utility failed to function, due to a previous internal change in the NDB code. ([Bug#41512](#), [Bug#48673](#))

- When the `MemReportFrequency` configuration parameter was set in `config.ini`, the `ndb_mgm` client `REPORT MEMORYUSAGE` command printed its output multiple times. ([Bug#37632](#))
- `ndb_mgm -e ".... REPORT ..."` did not write any output to `stdout`.

The fix for this issue also prevents the cluster log from being flooded with `INFO` messages when `DataMemory` usage reaches 100%, and insures that when the usage is decreased, an appropriate message is written to the cluster log. ([Bug#31542](#), [Bug#44183](#), [Bug#49782](#))

- **Disk Data:** Inserts of blob column values into a MySQL Cluster Disk Data table that exhausted the tablespace resulted in misleading `NO SUCH TUPLE` error messages rather than the expected error `TABLESPACE FULL`.

This issue appeared similar to [Bug#48113](#), but had a different underlying cause. ([Bug#52201](#))

- **Disk Data:** The error message returned after attempting to execute `ALTER LOGFILE GROUP` on an nonexistent logfile group did not indicate the reason for the failure. ([Bug#51111](#))
- **Disk Data:** DDL operations on Disk Data tables having a relatively small `UNDO_BUFFER_SIZE` could fail unexpectedly.
- **Cluster API:** When reading blob data with lock mode `LM_SimpleRead`, the lock was not upgraded as expected. ([Bug#51034](#))
- **Cluster API:** A number of issues were corrected in the NDB API coding examples found in the `storage/ndb/ndbapi-examples` directory in the MySQL Cluster source tree. These included possible endless recursion in `ndb-bapi-scan.cpp` as well as problems running some of the examples on systems using Windows or Mac OS due to the letter case used for some table names. ([Bug#30552](#), [Bug#30737](#))

### Changes in MySQL Cluster NDB 7.0.13 (5.1.41-ndb-7.0.13)

Functionality added or changed:

- A new configuration parameter `HeartbeatThreadPriority` makes it possible to select between a first-in, first-out or round-round scheduling policy for management node and API node heartbeat threads, as well as to set the priority of these threads. See [Section 17.3.2.5, “Defining a MySQL Cluster Management Server”](#), or [Section 17.3.2.7, “Defining SQL and Other API Nodes in a MySQL Cluster”](#), for more information. ([Bug#49617](#))
- Start phases are now written to the data node logs. ([Bug#49158](#))
- **Disk Data:** The `ndb_desc` utility can now show the extent space and free extent space for subordinate `BLOB` and `TEXT` columns (stored in hidden `BLOB` tables by NDB). A `--blob-info` option has been added for this program that causes `ndb_desc` to generate a report for each subordinate `BLOB` table. For more information, see [Section 17.4.9, “ndb\\_desc — Describe NDB Tables”](#). ([Bug#50599](#))

Bugs fixed:

- When performing a system restart of a MySQL Cluster where multi-threaded data nodes were in use, there was a slight risk that the restart would hang due to incorrect serialization of signals passed between LQH instances and proxies; some signals were sent using a proxy, and others directly, which meant that the order in which they were sent and received could not be guaranteed. If signals arrived in the wrong order, this could cause one or more data nodes to hang. Now all signals that need to be sent and received in the same order are sent using the same path. ([Bug#51645](#))
- When one or more data nodes read their LCPs and applied undo logs significantly faster than others, this could lead to a race condition causing system restarts of data nodes to hang. This could most often occur when using both `ndbd` and `ndbmt` processes for the data nodes. ([Bug#51644](#))
- When deciding how to divide the REDO log, the `DBDIH` kernel block saved more than was needed to restore the previous local checkpoint, which could cause REDO log space to be exhausted prematurely (NDB error 410). ([Bug#51547](#))
- DML operations can fail with NDB error 1220 (`REDO LOG FILES OVERLOADED...`) if the opening and closing of REDO log files takes too much time. If this occurred as a GCI marker was being written in the REDO log while REDO log file 0 was being opened or closed, the error could persist until a GCP stop was encountered. This issue could be triggered when there was insufficient REDO log space (for example, with configuration parameter settings `NoOfFragmentLogFile = 6` and `FragmentLogFileSize = 6M`) with a load including a very high number of updates. ([Bug#51512](#))

See also [Bug#20904](#).

- A side effect of the `ndb_restore --disable-indexes` and `--rebuild-indexes` options is to change the schema

versions of indexes. When a `mysqld` later tried to drop a table that had been restored from backup using one or both of these options, the server failed to detect these changed indexes. This caused the table to be dropped, but the indexes to be left behind, leading to problems with subsequent backup and restore operations. ([Bug#51374](#))

- `ndb_restore` crashed while trying to restore a corrupted backup, due to missing error handling. ([Bug#51223](#))
- The `ndb_restore` message `Successfully created index `PRIMARY`...` was directed to `stderr` instead of `stdout`. ([Bug#51037](#))
- When using `NoOfReplicas` equal to 1 or 2, if data nodes from one node group were restarted 256 times and applications were running traffic such that it would encounter `NDB` error 1204 (`TEMPORARY FAILURE, DISTRIBUTION CHANGED`), the live node in the node group would crash, causing the cluster to crash as well. The crash occurred only when the error was encountered on the 256th restart; having the error on any previous or subsequent restart did not cause any problems. ([Bug#50930](#))
- Replication of a MySQL Cluster using multi-threaded data nodes could fail with forced shutdown of some data nodes due to the fact that `ndbmtd` exhausted `LongMessageBuffer` much more quickly than `ndbd`. After this fix, passing of replication data between the `DBTUP` and `SUMA` NDB kernel blocks is done using `DataMemory` rather than `LongMessageBuffer`.

Until you can upgrade, you may be able to work around this issue by increasing the `LongMessageBuffer` setting; doubling the default should be sufficient in most cases. ([Bug#46914](#))

- A `SELECT` requiring a sort could fail with the error `CAN'T FIND RECORD IN 'TABLE'` when run concurrently with a `DELETE` from the same table. ([Bug#45687](#))
- **Cluster API:** An issue internal to `ndb_mgm` could cause problems when trying to start a large number of data nodes at the same time. ([Bug#51273](#))

### Changes in MySQL Cluster NDB 7.0.12 (5.1.41-ndb-7.0.12)

Functionality added or changed:

- Numeric codes used in management server status update messages in the cluster logs have been replaced with text descriptions. ([Bug#49627](#))

See also [Bug#44248](#).

Bugs fixed:

- `ndbmtd` started on a single-core machine could sometimes fail with a `JOB BUFFER FULL` error when `MaxNoOfExecution-Threads` was set greater than `LockExecuteThreadToCPU`. Now a warning is logged when this occurs. ([Bug#50582](#))
- When a primary key lookup on an `NDB` table containing one or more `BLOB` columns was executed in a transaction, a shared lock on any blob tables used by the `NDB` table was held for the duration of the transaction. (This did not occur for indexed or non-indexed `WHERE` conditions.)

Now in such cases, the lock is released after all `BLOB` data has been read. ([Bug#49190](#))

### Changes in MySQL Cluster NDB 7.0.11 (5.1.41-ndb-7.0.11)

Functionality added or changed:

- **Important Change:** The maximum permitted value of the `ndb_autoincrement_prefetch_sz` system variable has been increased from 256 to 65536. ([Bug#50621](#))
- Added multi-threaded ordered index building capability during system restarts or node restarts, controlled by the `BuildIndexThreads` data node configuration parameter (also introduced in this release).

Bugs fixed:

- Initial start of partitioned nodes did not work correctly. This issue was observed in MySQL Cluster NDB 7.0 only. ([Bug#50661](#))
- The `CREATE NODEGROUP` client command in `ndb_mgm` could sometimes cause the forced shutdown of a data node. ([Bug#50594](#))

- Local query handler information was not reported or written to the cluster log correctly. This issue is thought to have been introduced in MySQL Cluster NDB 7.0.10. ([Bug#50467](#))
- Online upgrades from MySQL Cluster NDB 7.0.9b to MySQL Cluster NDB 7.0.10 did not work correctly. Current MySQL Cluster NDB 7.0 users should upgrade directly to MySQL Cluster NDB 7.0.11 or later.

This issue is not known to have affected MySQL Cluster NDB 6.3, and it should be possible to upgrade from MySQL Cluster NDB 6.3 to MySQL Cluster NDB 7.0.10 without problems. See [Section 17.2.5.2, “MySQL Cluster 5.1 and MySQL Cluster NDB 6.x/7.x Upgrade and Downgrade Compatibility”](#), for more information. ([Bug#50433](#))

- Dropping unique indexes in parallel while they were in use could cause node and cluster failures. ([Bug#50118](#))
- When attempting to join a running cluster whose management server had been started with the `--nowait-nodes` option and having SQL nodes with dynamically allocated node IDs, a second management server failed with spurious `INTERNAL EROR: FOUND DYNAMIC PORTS WITH VALUE IN CONFIG...` error messages. ([Bug#49807](#))
- When setting the `LockPagesInMainMemory` configuration parameter failed, only the error `FAILED TO MEMLOCK PAGES...` was returned. Now in such cases the operating system's error code is also returned. ([Bug#49724](#))
- If a query on an `NDB` table compared a constant string value to a column, and the length of the string was greater than that of the column, condition pushdown did not work correctly. (The string was truncated to fit the column length before being pushed down.) Now in such cases, the condition is no longer pushed down. ([Bug#49459](#))
- `ndbmted` was not built on Windows (`CMake` did not provide a build target for it). ([Bug#49325](#))
- Performing intensive inserts and deletes in parallel with a high scan load could cause a data node crashes due to a failure in the `DBACC` kernel block. This was because checking for when to perform bucket splits or merges considered the first 4 scans only. ([Bug#48700](#))
- During Start Phases 1 and 2, the `STATUS` command sometimes (falsely) returned `Not Connected` for data nodes running `ndbmted`. ([Bug#47818](#))
- When performing a `DELETE` that included a left join from an `NDB` table, only the first matching row was deleted. ([Bug#47054](#))
- Under some circumstances, the `DBTC` kernel block could send an excessive number of commit and completion messages which could lead to a the job buffer filling up and node failure. This was especially likely to occur when using `ndbmted` with a single data node. ([Bug#45989](#))
- `mysqld` could sometimes crash during a commit while trying to handle NDB Error 4028 `NODE FAILURE CAUSED ABORT OF TRANSACTION`. ([Bug#38577](#))
- When setting `LockPagesInMainMemory`, the stated memory was not allocated when the node was started, but rather only when the memory was used by the data node process for other reasons. ([Bug#37430](#))
- Trying to insert more rows than would fit into an `NDB` table caused data nodes to crash. Now in such situations, the insert fails gracefully with error 633 `TABLE FRAGMENT HASH INDEX HAS REACHED MAXIMUM POSSIBLE SIZE`. ([Bug#34348](#))

## Changes in MySQL Cluster NDB 7.0.10 (5.1.39-ndb-7.0.10)

Functionality added or changed:

- Added the `ndb_mgmd --nowait-nodes` option, which permits a cluster that is configured to use multiple management servers to be started using fewer than the number configured. This is most likely to be useful when a cluster is configured with two management servers and you wish to start the cluster using only one of them.

See [Section 17.4.4, “`ndb\_mgmd` — The MySQL Cluster Management Server Daemon”](#), for more information. ([Bug#48669](#))

- This enhanced functionality is supported for upgrades from MySQL Cluster NDB 6.3 when the `NDB` engine version is 6.3.29 or later. ([Bug#48528](#), [Bug#49163](#))
- The output from `ndb_config --configinfo --xml` now indicates, for each configuration parameter, the following restart type information:
  - Whether a system restart or a node restart is required when resetting that parameter;
  - Whether cluster nodes need to be restarted using the `--initial` option when resetting the parameter.

([Bug#47366](#))

Bugs fixed:

- Node takeover during a system restart occurs when the REDO log for one or more data nodes is out of date, so that a node restart is invoked for that node or those nodes. If this happens while a `mysqld` process is attached to the cluster as an SQL node, the `mysqld` takes a global schema lock (a row lock), while trying to set up cluster-internal replication.

However, this setup process could fail, causing the global schema lock to be held for an excessive length of time, which made the node restart hang as well. As a result, the `mysqld` failed to set up cluster-internal replication, which led to tables being read only, and caused one node to hang during the restart.

### Note

This issue could actually occur in MySQL Cluster NDB 7.0 only, but the fix was also applied MySQL Cluster NDB 6.3, in order to keep the two codebases in alignment.

([Bug#49560](#))

- Sending `SIGHUP` to a `mysqld` running with the `--ndbcluster` and `--log-bin` options caused the process to crash instead of refreshing its log files. ([Bug#49515](#))
- If the master data node receiving a request from a newly-started API or data node for a node ID died before the request has been handled, the management server waited (and kept a mutex) until all handling of this node failure was complete before responding to any other connections, instead of responding to other connections as soon as it was informed of the node failure (that is, it waited until it had received a `NF_COMPLETEREP` signal rather than a `NODE_FAILREP` signal). On visible effect of this misbehavior was that it caused management client commands such as `SHOW` and `ALL STATUS` to respond with unnecessary slowness in such circumstances. ([Bug#49207](#))
- Attempting to create more than 11435 tables failed with Error 306 (OUT OF FRAGMENT RECORDS IN DIH). ([Bug#49156](#))
- When evaluating the options `--include-databases`, `--include-tables`, `--exclude-databases`, and `--exclude-tables`, the `ndb_restore` program overwrote the result of the database-level options with the result of the table-level options rather than merging these results together, sometimes leading to unexpected and unpredictable results.

As part of the fix for this problem, the semantics of these options have been clarified; because of this, the rules governing their evaluation have changed slightly. These changes be summed up as follows:

- All `--include-*` and `--exclude-*` options are now evaluated from right to left in the order in which they are passed to `ndb_restore`.
- All `--include-*` and `--exclude-*` options are now cumulative.
- In the event of a conflict, the first (rightmost) option takes precedence.

For more detailed information and examples, see [Section 17.4.17, “ndb\\_restore — Restore a MySQL Cluster Backup”](#). ([Bug#48907](#))

- When performing tasks that generated large amounts of I/O (such as when using `ndb_restore`), an internal memory buffer could overflow, causing data nodes to fail with signal 6.  
Subsequent analysis showed that this buffer was not actually required, so this fix removes it. ([Bug#48861](#))
- Exhaustion of send buffer memory or long signal memory caused data nodes to crash. Now an appropriate error message is provided instead when this situation occurs. ([Bug#48852](#))
- In some situations, when it was not possible for an SQL node to start a schema transaction (necessary, for instance, as part of an online `ALTER TABLE`), `NDBCLUSTER` did not correctly indicate the error to the MySQL server, which led `mysqld` to crash. ([Bug#48841](#))
- Under certain conditions, accounting of the number of free scan records in the local query handler could be incorrect, so that during node recovery or a local checkpoint operations, the LQH could find itself lacking a scan record that is expected to find, causing the node to crash. ([Bug#48697](#))

See also [Bug#48564](#).

- The creation of an ordered index on a table undergoing DDL operations could cause a data node crash under certain timing-dependent conditions. ([Bug#48604](#))
- During an LCP master takeover, when the newly elected master did not receive a `COPY_GCI` LCP protocol message but other nodes participating in the local checkpoint had received one, the new master could use an uninitialized variable, which caused it to crash. ([Bug#48584](#))

- When running many parallel scans, a local checkpoint (which performs a scan internally) could find itself not getting a scan record, which led to a data node crash. Now an extra scan record is reserved for this purpose, and a problem with obtaining the scan record returns an appropriate error (error code 489, `TOO MANY ACTIVE SCANS`). ([Bug#48564](#))
- During a node restart, logging was enabled on a per-fragment basis as the copying of each fragment was completed but local checkpoints were not enabled until all fragments were copied, making it possible to run out of redo log file space (NDB error code 410) before the restart was complete. Now logging is enabled only after all fragments have been copied, just prior to enabling local checkpoints. ([Bug#48474](#))
- When using very large transactions containing many inserts, `ndbmtd` could fail with `Signal 11` without an easily detectable reason, due to an internal variable being uninitialized in the event that the `LongMessageBuffer` was overloaded. Now, the variable is initialized in such cases, avoiding the crash, and an appropriate error message is generated. ([Bug#48441](#))

See also [Bug#46914](#).

- A data node crashing while restarting, followed by a system restart could lead to incorrect handling of redo log metadata, causing the system restart to fail with `ERROR WHILE READING REDO LOG`. ([Bug#48436](#))
- Starting a `mysqld` process with `--ndb-nodeid` (either as a command-line option or by assigning it a value in `my.cnf`) caused the `mysqld` to get only the corresponding connection from the `[mysqld]` section in the `config.ini` file having the matching ID, even when connection pooling was enabled (that is, when the `mysqld` process was started with `-ndb-cluster-connection-pool` set greater than 1). ([Bug#48405](#))

See also [Bug#27644](#), [Bug#38590](#), [Bug#41592](#).

- The configuration check that each management server runs to verify that all connected `ndb_mgmd` processes have the same configuration could fail when a configuration change took place while this check was in progress. Now in such cases, the configuration check is rescheduled for a later time, after the change is complete. ([Bug#48143](#))
- When employing NDB native backup to back up and restore an empty NDB table that used a non-sequential `AUTO_INCREMENT` value, the `AUTO_INCREMENT` value was not restored correctly. ([Bug#48005](#))
- `ndb_config --xml --configinfo` now indicates that parameters belonging in the `[SCI]`, `[SCI DEFAULT]`, `[SHM]`, and `[SHM DEFAULT]` sections of the `config.ini` file are deprecated or experimental, as appropriate. ([Bug#47365](#))
- NDB stores blob column data in a separate, hidden table that is not accessible from MySQL. If this table was missing for some reason (such as accidental deletion of the file corresponding to the hidden table) when making a MySQL Cluster native backup, `ndb_restore` crashed when attempting to restore the backup. Now in such cases, `ndb_restore` fails with the error message `TABLE TABLE_NAME HAS BLOB COLUMN (COLUMN_NAME) WITH MISSING PARTS TABLE IN BACKUP` instead. ([Bug#47289](#))
- In MySQL Cluster NDB 7.0, `ndb_config` and `ndb_error_reporter` were printing warnings about management and data nodes running on the same host to `stdout` instead of `stderr`, as was the case in earlier MySQL Cluster release series. ([Bug#44689](#), [Bug#49160](#))

See also [Bug#25941](#).

- `DROP DATABASE` failed when there were stale temporary NDB tables in the database. This situation could occur if `mysqld` crashed during execution of a `DROP TABLE` statement after the table definition had been removed from `NDBCLUSTER` but before the corresponding `.ndb` file had been removed from the crashed SQL node's data directory. Now, when `mysqld` executes `DROP DATABASE`, it checks for these files and removes them if there are no corresponding table definitions for them found in `NDBCLUSTER`. ([Bug#44529](#))
- Creating an NDB table with an excessive number of large `BIT` columns caused the cluster to fail. Now, an attempt to create such a table is rejected with error 791 (`TOO MANY TOTAL BITS IN BITFIELDS`). ([Bug#42046](#))

See also [Bug#42047](#).

- When a long-running transaction lasting long enough to cause Error 410 (`REDO LOG FILES OVERLOADED`) was later committed or rolled back, it could happen that `NDBCLUSTER` was not able to release the space used for the REDO log, so that the error condition persisted indefinitely.

The most likely cause of such transactions is a bug in the application using MySQL Cluster. This fix should handle most cases where this might occur. ([Bug#36500](#))

- Deprecation and usage information obtained from `ndb_config --configinfo` regarding the `PortNumber` and `ServerPort` configuration parameters was improved. ([Bug#24584](#))
- **Disk Data:** When running a write-intensive workload with a very large disk page buffer cache, CPU usage approached 100% during a local checkpoint of a cluster containing Disk Data tables. ([Bug#49532](#))

- **Disk Data:** `NDBCLUSTER` failed to provide a valid error message if it failed to commit schema transactions during an initial start if the cluster was configured using the `InitialLogFileGroup` parameter. ([Bug#48517](#))
  - **Disk Data:** In certain limited cases, it was possible when the cluster contained Disk Data tables for `ndbmtd` to crash during a system restart. ([Bug#48498](#))
- See also [Bug#47832](#).
- **Disk Data:** Repeatedly creating and then dropping Disk Data tables could eventually lead to data node failures. ([Bug#45794](#), [Bug#48910](#))
  - **Disk Data:** When a crash occurs due to a problem in Disk Data code, the currently active page list is printed to `stdout` (that is, in one or more `ndb_nodeid_out.log` files). One of these lists could contain an endless loop; this caused a printout that was effectively never-ending. Now in such cases, a maximum of 512 entries is printed from each list. ([Bug#42431](#))
  - **Disk Data:** When the `FileSystemPathUndoFiles` configuration parameter was set to an non-existent path, the data nodes shut down with the generic error code 2341 (`INTERNAL PROGRAM ERROR`). Now in such cases, the error reported is error 2815 (`FILE NOT FOUND`).
  - **Cluster API:** When a DML operation failed due to a uniqueness violation on an `NDB` table having more than one unique index, it was difficult to determine which constraint caused the failure; it was necessary to obtain an `NdbError` object, then decode its `details` property, which could lead to memory management issues in application code.

To help solve this problem, a new API method `Ndb::getNdbErrorDetail()` is added, providing a well-formatted string containing more precise information about the index that caused the unique constraint violation. The following additional changes are also made in the NDB API:

- Use of `NdbError.details` is now deprecated in favor of the new method.
- The `NdbDictionary::listObjects()` method has been modified to provide more information.

For more information, see `Ndb::getNdbErrorDetail()`, [The NdbError Structure](#), and `Dictionary::listObjects()`. ([Bug#48851](#))

- **Cluster API:** When using blobs, calling `getBlobHandle()` requires the full key to have been set using `equal()`, because `getBlobHandle()` must access the key for adding blob table operations. However, if `getBlobHandle()` was called without first setting all parts of the primary key, the application using it crashed. Now, an appropriate error code is returned instead. ([Bug#28116](#), [Bug#48973](#))

### Changes in MySQL Cluster NDB 7.0.9a (5.1.39-ndb-7.0.9a)

Bugs fixed:

- When the combined length of all names of tables using the `NDB` storage engine was greater than or equal to 1024 bytes, issuing the `START BACKUP` command in the `ndb_mgm` client caused the cluster to crash. ([Bug#48531](#))

### Changes in MySQL Cluster NDB 7.0.8a (5.1.37-ndb-7.0.8a)

Bugs fixed:

- The disconnection of an API or SQL node having a node ID greater than 49 caused a forced shutdown of the cluster. ([Bug#47844](#))
- The error message text for `NDB` error code 410 (`REDO LOG FILES OVERLOADED...`) was truncated. ([Bug#23662](#))

### Changes in MySQL Cluster NDB 7.0.7 (5.1.35-ndb-7.0.7)

Functionality added or changed:

- **Important Change:** The default value of the `DiskIOThreadPool` data node configuration parameter has changed from 8 to 2.
- On Solaris platforms, the MySQL Cluster management server and NDB API applications now use `CLOCK_REALTIME` as the default clock. ([Bug#46183](#))
- Formerly, node IDs were represented in the cluster log using a complex hexadecimal/binary encoding scheme. Now, node IDs

are reported in the cluster log using numbers in standard decimal notation. ([Bug#44248](#))

- A new option `--exclude-missing-columns` has been added for the `ndb_restore` program. In the event that any tables in the database or databases being restored to have fewer columns than the same-named tables in the backup, the extra columns in the backup's version of the tables are ignored. For more information, see [Section 17.4.17, “ndb\\_restore — Restore a MySQL Cluster Backup”](#). ([Bug#43139](#))

• **Note**

This issue, originally resolved in MySQL 5.1.16, re-occurred due to a later (unrelated) change. The fix has been re-applied.

([Bug#25984](#))

- Previously, it was possible to disable arbitration only by setting `ArbitrationRank` to 0 on all management and API nodes. A new data node configuration parameter `Arbitration` simplifies this task; to disable arbitration, you can now use `Arbitration = Disabled` in the `[ndbd default]` section of the `config.ini` file.

It is now also possible to configure arbitration in such a way that the cluster waits until the time determined by `ArbitrationTimeout` passes for an external manager to perform arbitration instead of handling it internally. This can be done by setting `Arbitration = WaitExternal` in the `[ndbd default]` section of the `config.ini` file.

The default value for the Arbitration parameter is `Default`, which permits arbitration to proceed normally, as determined by the `ArbitrationRank` settings for the management and API nodes.

For more information, see [Section 17.3.2.6, “Defining MySQL Cluster Data Nodes”](#).

Bugs fixed:

- **Packaging:** The `pkg` installer for MySQL Cluster on Solaris did not perform a complete installation due to an invalid directory reference in the post-install script. ([Bug#41998](#))
- The output from `ndb_config --configinfo --xml` contained quote characters (") within quoted XML attributes, causing it to be not well-formed. ([Bug#46891](#))
- When using multi-threaded data node processes (`ndbmtd`), it was possible for LQH threads to continue running even after all `NDB` tables had been dropped. This meant that dropping the last remaining `NDB` table during a local checkpoint could cause multi-threaded data nodes to fail. ([Bug#46890](#))
- During a global checkpoint, LQH threads could run unevenly, causing a circular buffer overflow by the Subscription Manager, which led to data node failure. ([Bug#46782](#))

See also [Bug#46123](#), [Bug#46723](#), [Bug#45612](#).

- Restarting the cluster following a local checkpoint and an online `ALTER TABLE` on a non-empty table caused data nodes to crash. ([Bug#46651](#))
- A combination of index creation and drop operations (or creating and dropping tables having indexes) with node and system restarts could lead to a crash. ([Bug#46552](#))
- Following an upgrade from MySQL Cluster NDB 6.3.x to MySQL Cluster NDB 7.0.6, DDL and backup operations failed. ([Bug#46494](#), [Bug#46563](#))
- Full table scans failed to execute when the cluster contained more than 21 table fragments.

• **Note**

The number of table fragments in the cluster can be calculated as the number of data nodes, times 8 (that is, times the value of the internal constant `MAX_FRAG_PER_NODE`), divided by the number of replicas. Thus, when `NoOfReplicas = 1` at least 3 data nodes were required to trigger this issue, and when `NoOfReplicas = 2` at least 4 data nodes were required to do so.

([Bug#46490](#))

- Killing MySQL Cluster nodes immediately following a local checkpoint could lead to a crash of the cluster when later attempting to perform a system restart.

The exact sequence of events causing this issue was as follows:

1. Local checkpoint occurs.
2. Immediately following the LCP, kill the master data node.
3. Kill the remaining data nodes within a few seconds of killing the master.
4. Attempt to restart the cluster.

([Bug#46412](#))

- Creating an index when the cluster had run out of table records could cause data nodes to crash. ([Bug#46295](#))
- Ending a line in the `config.ini` file with an extra semicolon character (`:`) caused reading the file to fail with a parsing error. ([Bug#46242](#))
- When combining an index scan and a delete with a primary key delete, the index scan and delete failed to initialize a flag properly. This could in rare circumstances cause a data node to crash. ([Bug#46069](#))
- `OPTIMIZE TABLE` on an `NDB` table could in some cases cause SQL and data nodes to crash. This issue was observed with both `ndbd` and `ndbmtd`. ([Bug#45971](#))
- The `AutoReconnect` configuration parameter for API nodes (including SQL nodes) has been added. This is intended to prevent API nodes from re-using allocated node IDs during cluster restarts. For more information, see [Section 17.3.2.7, “Defining SQL and Other API Nodes in a MySQL Cluster”](#).

This fix also introduces two new methods of the `Ndb_cluster_connection` class in the NDB API. For more information, see `Ndb_cluster_connection::set_auto_reconnect()`, and `Ndb_cluster_connection::get_auto_reconnect()`. ([Bug#45921](#))

- DML statements run during an upgrade from MySQL Cluster NDB 6.3 to NDB 7.0 were not handled correctly. ([Bug#45917](#))
- On Windows, the internal `basestring_vsprintf()` function did not return a POSIX-compliant value as expected, causing the management server to crash when trying to start a MySQL Cluster with more than 4 data nodes. ([Bug#45733](#))
- The signals used by `ndb_restore` to send progress information about backups to the cluster log accessed the cluster transporter without using any locks. Because of this, it was theoretically possible that these signals could be interfered with by heartbeat signals if both were sent at the same time, causing the `ndb_restore` messages to be corrupted. ([Bug#45646](#))
- Due to changes in the way that `NDBCLUSTER` handles schema changes (implementation of schema transactions) in MySQL Cluster NDB 7.0, it was not possible to create MySQL Cluster tables having more than 16 indexes using a single `CREATE TABLE` statement.

This issue occurs only in MySQL Cluster NDB 7.0 releases prior to 7.0.7 (including releases numbered NDB 6.4.x).

If you are not yet able to upgrade from an earlier MySQL Cluster NDB 7.0 release, you can work around this problem by creating the table without any indexes, then adding the indexes using a separate `CREATE INDEX` statement for each index. ([Bug#45525](#))

- `storage/ndb/src/common/util/CMakeLists.txt` did not build the `BaseString-t` test program for Windows as the equivalent `storage/ndb/src/common/util/Makefile.am` does when building MySQL Cluster on Unix platforms. ([Bug#45099](#))
- Problems could arise when using `VARCHAR` columns whose size was greater than 341 characters and which used the `utf8_unicode_ci` collation. In some cases, this combination of conditions could cause certain queries and `OPTIMIZE TABLE` statements to crash `mysqld`. ([Bug#45053](#))
- The warning message `POSSIBLE BUG IN DBDIH::EXECBLOCK_COMMIT_ORD ...` could sometimes appear in the cluster log. This warning is obsolete, and has been removed. ([Bug#44563](#))
- Debugging code causing `ndbd` to use file compression on NTFS filesystems failed with an error. (The code was removed.) This issue affected debug builds of MySQL Cluster on Windows platforms only. ([Bug#44418](#))
- `ALTER TABLE REORGANIZE PARTITION` could fail with Error 741 (`UNSUPPORTED ALTER TABLE`) if the appropriate hash-map was not present. This could occur when adding nodes online; for example, when going from 2 data nodes to 3 data nodes with `NoOfReplicas=1`, or from 4 data nodes to 6 data nodes with `NoOfReplicas=2`. ([Bug#44301](#))
- Previously, a `GCP_STOP` event was written to the cluster log as an `INFO` event. Now it is logged as a `WARNING` event instead. ([Bug#43853](#))
- In some cases, `OPTIMIZE TABLE` on an `NDB` table did not free any `DataMemory`. ([Bug#43683](#))

- If the cluster crashed during the execution of a `CREATE LOGFILE GROUP` statement, the cluster could not be restarted afterward. ([Bug#36702](#))

See also [Bug#34102](#).

- **Disk Data: Partitioning:** An `NDBCLUSTER` table created with a very large value for the `MAX_ROWS` option could—if this table was dropped and a new table with fewer partitions, but having the same table ID, was created—cause `ndbd` to crash when performing a system restart. This was because the server attempted to examine each partition whether or not it actually existed. ([Bug#45154](#))
- **Disk Data:** If the value set in the `config.ini` file for `FileSystemPathDD`, `FileSystemPathDataFiles`, or `FileSystemPathUndoFiles` was identical to the value set for `FileSystemPath`, that parameter was ignored when starting the data node with `--initial` option. As a result, the Disk Data files in the corresponding directory were not removed when performing an initial start of the affected data node or data nodes. ([Bug#46243](#))

### Changes in MySQL Cluster NDB 7.0.6 (5.1.34-ndb-7.0.6)

Functionality added or changed:

- The `ndb_config` utility program can now provide an offline dump of all MySQL Cluster configuration parameters including information such as default and permitted values, brief description, and applicable section of the `config.ini` file. A dump in text format is produced when running `ndb_config` with the new `--configinfo` option, and in XML format when the options `--configinfo --xml` are used together. For more information and examples, see [Section 17.4.6, “`ndb\_config` — Extract MySQL Cluster Configuration Information”](#).

Bugs fixed:

- **Important Change: Partitioning:** User-defined partitioning of an `NDBCLUSTER` table without any primary key sometimes failed, and could cause `mysqld` to crash.

Now, if you wish to create an `NDBCLUSTER` table with user-defined partitioning, the table must have an explicit primary key, and all columns listed in the partitioning expression must be part of the primary key. The hidden primary key used by the `NDBCLUSTER` storage engine is not sufficient for this purpose. However, if the list of columns is empty (that is, the table is defined using `PARTITION BY [LINEAR] KEY()`), then no explicit primary key is required.

This change does not effect the partitioning of tables using any storage engine other than `NDBCLUSTER`. ([Bug#40709](#))

- **Important Change:** Previously, the configuration parameter `NoOfReplicas` had no default value. Now the default for `NoOfReplicas` is 2, which is the recommended value in most settings. ([Bug#44746](#))
- **Important Note:** It was not possible to perform an online upgrade from any MySQL Cluster NDB 6.x release to MySQL Cluster NDB 7.0.5 or any to earlier MySQL Cluster NDB 7.0 release.

With this fix, it is possible in MySQL Cluster NDB 7.0.6 and later to perform online upgrades from MySQL Cluster NDB 6.3.8 and later MySQL Cluster NDB 6.3 releases, or from MySQL Cluster NDB 7.0.5 or later MySQL Cluster NDB 7.0 releases. Online upgrades to MySQL Cluster NDB 7.0 releases previous to MySQL Cluster NDB 7.0.6 from earlier MySQL Cluster releases remain unsupported; online upgrades from MySQL Cluster NDB 7.0 releases previous to MySQL Cluster NDB 7.0.5 (including NDB 6.4.x beta releases) to later MySQL Cluster NDB 7.0 releases also remain unsupported. ([Bug#4294](#))

- An internal NDB API buffer was not properly initialized. ([Bug#44977](#))
- When a data node had written its GCI marker to the first page of a megabyte, and that node was later killed during restart after having processed that page (marker) but before completing a LCP, the data node could fail with filesystem errors. ([Bug#44952](#))

See also [Bug#42564](#), [Bug#44291](#).

- When restarting a data nodes, management and API nodes reconnecting to it failed to re-use existing ports that had already been dynamically allocated for communications with that data node. ([Bug#44866](#))
- When `ndb_config` could not find the file referenced by the `--config-file` option, it tried to read `my.cnf` instead, then failed with a misleading error message. ([Bug#44846](#))
- When a data node was down so long that its most recent local checkpoint depended on a global checkpoint that was no longer restorable, it was possible for it to be unable to use optimized node recovery when being restarted later. ([Bug#44844](#))

See also [Bug#26913](#).

- Online upgrades to MySQL Cluster NDB 7.0 from a MySQL Cluster NDB 6.3 release could fail due to changes in the handling of key lengths and unique indexes during node recovery. ([Bug#44827](#))
- `ndb_config --xml` did not output any entries for the `HostName` parameter. In addition, the default listed for `MaxNoOfFiles` was outside the permitted range of values. ([Bug#44749](#))

See also [Bug#44685](#), [Bug#44746](#).

- The output of `ndb_config --xml` did not provide information about all sections of the configuration file. ([Bug#44685](#))

See also [Bug#44746](#), [Bug#44749](#).

- Use of `__builtin_expect()` had the side effect that compiler warnings about misuse of `=` (assignment) instead of `==` in comparisons were lost when building in debug mode. This is no longer employed when configuring the build with the `-with-debug` option. ([Bug#44570](#))

See also [Bug#44567](#).

- Inspection of the code revealed that several assignment operators (`=`) were used in place of comparison operators (`==`) in `Db-dihMain.cpp`. ([Bug#44567](#))

See also [Bug#44570](#).

- When using large numbers of configuration parameters, the management server took an excessive amount of time (several minutes or more) to load these from the configuration cache when starting. This problem occurred when there were more than 32 configuration parameters specified, and became progressively worse with each additional multiple of 32 configuration parameters. ([Bug#44488](#))
- Building the MySQL Cluster NDB 7.0 tree failed when using the `icc` compiler. ([Bug#44310](#))
- SSL connections to SQL nodes failed on big-endian platforms. ([Bug#44295](#))
- Signals providing node state information (`NODE_STATE REP` and `CHANGE_NODE_STATE REQ`) were not propagated to all blocks of `ndbmtld`. This could cause the following problems:
  - Inconsistent redo logs when performing a graceful shutdown;
  - Data nodes crashing when later restarting the cluster, data nodes needing to perform node recovery during the system restart, or both.

([Bug#44291](#))

See also [Bug#42564](#).

- An NDB internal timing function did not work correctly on Windows and could cause `mysqld` to fail on some AMD processors, or when running inside a virtual machine. ([Bug#44276](#))
- It was possible for NDB API applications to insert corrupt data into the database, which could subsequently lead to data node crashes. Now, stricter checking is enforced on input data for inserts and updates. ([Bug#44132](#))
- `ndb_restore` failed when trying to restore data on a big-endian machine from a backup file created on a little-endian machine. ([Bug#44069](#))
- Repeated starting and stopping of data nodes could cause `ndb_mgmd` to fail. This issue was observed on Solaris/SPARC. ([Bug#43974](#))
- A number of incorrectly formatted output strings in the source code caused compiler warnings. ([Bug#43878](#))
- When trying to use a data node with an older version of the management server, the data node crashed on startup. ([Bug#43699](#))
- In some cases, data node restarts during a system restart could fail due to insufficient redo log space. ([Bug#43156](#))
- `NDBCLUSTER` did not build correctly on Solaris 9 platforms. ([Bug#39080](#))

See also [Bug#39036](#), [Bug#39038](#).

- The output of `ndbd --help` did not provide clear information about the program's `--initial` and `--initial-start` options. ([Bug#28905](#))
- It was theoretically possible for the value of a nonexistent column to be read as `NULL`, rather than causing an error. ([Bug#27843](#))

- **Disk Data:** During a checkpoint, restore points are created for both the on-disk and in-memory parts of a Disk Data table. Under certain rare conditions, the in-memory restore point could include or exclude a row that should have been in the snapshot. This would later lead to a crash during or following recovery.

This issue was somewhat more likely to be encountered when using `ndbmtd`. ([Bug#41915](#))

See also [Bug#47832](#).

- **Disk Data:** This fix supercedes and improves on an earlier fix made for this bug in MySQL 5.1.18. ([Bug#24521](#))

### Changes in MySQL Cluster NDB 7.0.5 (5.1.32-ndb-7.0.5)

Functionality added or changed:

- Two new server status variables `Ndb_scan_count` and `Ndb_pruned_scan_count` have been introduced. `Ndb_scan_count` gives the number of scans executed since the cluster was last started. `Ndb_pruned_scan_count` gives the number of scans for which `NDBCLUSTER` was able to use partition pruning. Together, these variables can be used to help determine in the MySQL server whether table scans are pruned by `NDBCLUSTER`. ([Bug#44153](#))

Bugs fixed:

- **Important Note:** Due to problem discovered after the code freeze for this release, it is not possible to perform an online upgrade from any MySQL Cluster NDB 6.x release to MySQL Cluster NDB 7.0.5 or any earlier MySQL Cluster NDB 7.0 release.

This issue is fixed in MySQL Cluster NDB 7.0.6 and later for upgrades from MySQL Cluster NDB 6.3.8 and later MySQL Cluster NDB 6.3 releases, or from MySQL Cluster NDB 7.0.5. ([Bug#44294](#))

- **Cluster Replication:** If data node failed during an event creation operation, there was a slight risk that a surviving data node could send an invalid table reference back to NDB, causing the operation to fail with a false Error 723 (`NO SUCH TABLE`). This could take place when a data node failed as a `mysqld` process was setting up MySQL Cluster Replication. ([Bug#43754](#))
- **Cluster API:** The following issues occurred when performing an online (rolling) upgrade of a cluster to a version of MySQL Cluster that supports configuration caching from a version that does not:
  1. When using multiple management servers, after upgrading and restarting one `ndb_mgmd`, any remaining management servers using the previous version of `ndb_mgmd` could not synchronize their configuration data.
  2. The MGM API `ndb_mgm_get_configuration()` function failed to obtain configuration data.  
([Bug#43641](#))
- **Cluster API:** The following issues occurred when performing an online (rolling) upgrade of a cluster to a version of MySQL Cluster that supports configuration caching from a version that does not:
  1. When using multiple management servers, after upgrading and restarting one `ndb_mgmd`, any remaining management servers using the previous version of `ndb_mgmd` could not synchronize their configuration data.
  2. The MGM API `ndb_mgm_get_configuration()` function failed to obtain configuration data.  
([Bug#43641](#))

If the number of fragments per table rises above a certain threshold, the `DBDIH` kernel block's on-disk table-definition grows large enough to occupy 2 pages. However, in MySQL Cluster NDB 7.0 (including MySQL Cluster NDB 6.4 releases), only 1 page was actually written, causing table definitions stored on disk to be incomplete.

This issue was not observed in MySQL Cluster release series prior to MySQL Cluster NDB 7.0. ([Bug#44135](#))

- `TransactionDeadlockDetectionTimeout` values less than 100 were treated as 100. This could cause scans to time out unexpectedly. ([Bug#44099](#))
- The file `ndberror.c` contained a C++-style comment, which caused builds to fail with some C compilers. ([Bug#44036](#))
- A race condition could occur when a data node failed to restart just before being included in the next global checkpoint. This could cause other data nodes to fail. ([Bug#43888](#))
- The setting for `ndb_use_transactions` was ignored. This issue was only known to occur in MySQL Cluster NDB 6.4.3 and MySQL Cluster NDB 7.0.4. ([Bug#43236](#))

- When a data node process had been killed after allocating a node ID, but before making contact with any other data node processes, it was not possible to restart it due to a node ID allocation failure.

This issue could effect either `ndbd` or `ndbmt` processes. ([Bug#43224](#))

This regression was introduced by [Bug#42973](#).

- `ndb_restore` crashed when trying to restore a backup made to a MySQL Cluster running on a platform having different endianness from that on which the original backup was taken. ([Bug#39540](#))
- PID files for the data and management node daemons were not removed following a normal shutdown. ([Bug#37225](#))
- `ndb_restore --print_data` did not handle `DECIMAL` columns correctly. ([Bug#37171](#))
- Invoking the management client `START BACKUP` command from the system shell (for example, as `ndb_mgm -e "START BACKUP"`) did not work correctly, unless the backup ID was included when the command was invoked.

Now, the backup ID is no longer required in such cases, and the backup ID that is automatically generated is printed to stdout, similar to how this is done when invoking `START BACKUP` within the management client. ([Bug#31754](#))

- When aborting an operation involving both an insert and a delete, the insert and delete were aborted separately. This was because the transaction coordinator did not know that the operations affected on same row, and, in the case of a committed-read (tuple or index) scan, the abort of the insert was performed first, then the row was examined after the insert was aborted but before the delete was aborted. In some cases, this would leave the row in a inconsistent state. This could occur when a local checkpoint was performed during a backup. This issue did not affect primary key operations or scans that used locks (these are serialized).

After this fix, for ordered indexes, all operations that follow the operation to be aborted are now also aborted.

- **Disk Data:** When using multi-threaded data nodes, `DROP TABLE` statements on Disk Data tables could hang. ([Bug#43825](#))
- **Disk Data:** This fix completes one that was made for this issue in MySQL Cluster NDB-7.0.4, which did not rectify the problem in all cases. ([Bug#43632](#))
- **Cluster API:** If the largest offset of a `RecordSpecification` used for an `NdbRecord` object was for the `NULL` bits (and thus not a column), this offset was not taken into account when calculating the size used for the `RecordSpecification`. This meant that the space for the `NULL` bits could be overwritten by key or other information. ([Bug#43891](#))
- **Cluster API:** `BIT` columns created using the native NDB API format that were not created as nullable could still sometimes be overwritten, or cause other columns to be overwritten.

This issue did not effect tables having `BIT` columns created using the mysqld format (always used by MySQL Cluster SQL nodes). ([Bug#43802](#))

## Changes in MySQL Cluster NDB 7.0.4 (5.1.32-ndb-7.0.4)

Functionality added or changed:

- **Important Change:** The default values for a number of MySQL Cluster configuration parameters relating to memory usage and buffering have changed. These parameters include `RedoBuffer`, `LongMessageBuffer`, `BackupMemory`, `BackupDataBufferSize`, `BackupLogBufferSize`, `BackupWriteSize`, `BackupMaxWriteSize`, `SendBufferMemory` (when applied to TCP transporters), and `ReceiveBufferMemory`.

For more information, see [Section 17.3, “MySQL Cluster Configuration”](#).

- When restoring from backup, `ndb_restore` now reports the last global checkpoint reached when the backup was taken. ([Bug#37384](#))

Bugs fixed:

- **Cluster API:** Partition pruning did not work correctly for queries involving multiple range scans.

As part of the fix for this issue, several improvements have been made in the NDB API, including the addition of a new `NdbScanOperation::getPruned()` method, a new variant of `NdbIndexScanOperation::setBound()`, and a new `Ndb::PartitionSpec` data structure. For more information about these changes, see `NdbScanOperation::getPruned()`, `NdbIndexScanOperation::setBound`, and [The PartitionSpec Structure](#). ([Bug#37934](#))

- **Cluster API:** Partition pruning did not work correctly for queries involving multiple range scans.

As part of the fix for this issue, several improvements have been made in the NDB API, including the addition of a new `NdbScanOperation::getPruned()` method, a new variant of `NdbIndexScanOperation::setBound()`, and a new `Ndb::PartitionSpec` data structure. For more information about these changes, see `NdbScanOperation::getPruned()`, `NdbIndexScanOperation::setBound`, and `The PartitionSpec Structure`. ([Bug#37934](#))

- `TimeBetweenLocalCheckpoints` was measured from the end of one local checkpoint to the beginning of the next, rather than from the beginning of one LCP to the beginning of the next. This meant that the time spent performing the LCP was not taken into account when determining the `TimeBetweenLocalCheckpoints` interval, so that LCPs were not started often enough, possibly causing data nodes to run out of redo log space prematurely. ([Bug#43567](#))
- The management server failed to start correctly in daemon mode. ([Bug#43559](#))
- Following a `DROP NODEGROUP` command, the output of `SHOW` in the `ndb_mgm` client was not updated to reflect the fact that the data nodes affected by this command were no longer part of a node group. ([Bug#43413](#))
- Using indexes containing variable-sized columns could lead to internal errors when the indexes were being built. ([Bug#43226](#))
- When using `ndbmtd`, multiple data node failures caused the remaining data nodes to fail as well. ([Bug#43109](#))
- It was not possible to add new data nodes to the cluster online using multi-threaded data node processes (`ndbmtd`). ([Bug#43108](#))
- Some queries using combinations of logical and comparison operators on an indexed column in the `WHERE` clause could fail with the error `GOT ERROR 4541 'INDEXBOUND HAS NO BOUND INFORMATION' FROM NDBCLUSTER`. ([Bug#42857](#))
- **Disk Data:** When using multi-threaded data nodes, dropping a Disk Data table followed by a data node restart led to a crash. ([Bug#43632](#))
- **Disk Data:** When using `ndbmtd`, repeated high-volume inserts (on the order of 10000 rows inserted at a time) on a Disk Data table would eventually lead to a data node crash. ([Bug#41398](#))
- **Disk Data:** When a log file group had an undo log file whose size was too small, restarting data nodes failed with `READ UNDERFLOW` errors.

As a result of this fix, the minimum permitted `INITIAL_SIZE` for an undo log file is now `1M` (1 megabyte). ([Bug#29574](#))

- **Cluster API:** The default `NdbRecord` structures created by `NdbDictionary` could have overlapping null bits and data fields. ([Bug#43590](#))
- **Cluster API:** When performing insert or write operations, `NdbRecord` permits key columns to be specified in both the key record and in the attribute record. Only one key column value for each key column should be sent to the NDB kernel, but this was not guaranteed. This is now ensured as follows: For insert and write operations, key column values are taken from the key record; for scan takeover update operations, key column values are taken from the attribute record. ([Bug#42238](#))
- **Cluster API:** Ordered index scans using `NdbRecord` formerly expressed a `BoundEQ` range as separate lower and upper bounds, resulting in 2 copies of the column values being sent to the NDB kernel.

Now, when a range is specified by `NdbScanOperation::setBound()`, the passed pointers, key lengths, and inclusive bits are compared, and only one copy of the equal key columns is sent to the kernel. This makes such operations more efficient, as half the amount of `KeyInfo` is now sent for a `BoundEQ` range as before. ([Bug#38793](#))

## Changes in MySQL Cluster NDB 6.4.3 (5.1.32-ndb-6.4.3)

Functionality added or changed:

- A new data node configuration parameter `MaxLCPStartDelay` has been introduced to facilitate parallel node recovery by causing a local checkpoint to be delayed while recovering nodes are synchronizing data dictionaries and other meta-information. For more information about this parameter, see [Section 17.3.2.6, “Defining MySQL Cluster Data Nodes”](#). ([Bug#43053](#))
- New options are introduced for `ndb_restore` for determining which tables or databases should be restored:
  - `--include-tables` and `--include-databases` can be used to restore specific tables or databases.
  - `--exclude-tables` and `--exclude-databases` can be used to exclude the specified tables or databases from being restored.

For more information about these options, see [Section 17.4.17, “`ndb\_restore` — Restore a MySQL Cluster Backup”](#). ([Bug#40429](#))

- **Disk Data:** It is now possible to specify default locations for Disk Data data files and undo log files, either together or separately, using the data node configuration parameters `FileSystemPathDD`, `FileSystemPathDataFiles`, and `FileSystemPathUndoFiles`. For information about these configuration parameters, see [Disk Data filesystem parameters](#).

It is also now possible to specify a log file group, tablespace, or both, that is created when the cluster is started, using the `InitialLogFileGroup` and `InitialTablespace` data node configuration parameters. For information about these configuration parameters, see [Disk Data object creation parameters](#).

Bugs fixed:

- **Performance:** Updates of the `SYSTAB_0` system table to obtain a unique identifier did not use transaction hints for tables having no primary key. In such cases the NDB kernel used a cache size of 1. This meant that each insert into a table not having a primary key required an update of the corresponding `SYSTAB_0` entry, creating a potential performance bottleneck.

With this fix, inserts on `NDB` tables without primary keys can be under some conditions be performed up to 100% faster than previously. ([Bug#39268](#))

- **Important Note:** It is not possible in this release to install the `InnoDB` plugin if `InnoDB` support has been compiled into `mysqld`. ([Bug#42610](#))

This regression was introduced by [Bug#29263](#).

- **Packaging:** Packages for MySQL Cluster were missing the `libndbclient.so` and `libndbclient.a` files. ([Bug#42278](#))
- **Partitioning:** Executing `ALTER TABLE ... REORGANIZE PARTITION` on an `NDBCLUSTER` table having only one partition caused `mysqld` to crash. ([Bug#41945](#))

See also [Bug#40389](#).

- Backup IDs greater than  $2^{31}$  were not handled correctly, causing negative values to be used in backup directory names and printouts. ([Bug#43042](#))
- When using `ndbmtd`, NDB kernel threads could hang while trying to start the data nodes with `LockPagesInMainMemory` set to 1. ([Bug#43021](#))
- When using multiple management servers and starting several API nodes (possibly including one or more SQL nodes) whose connectstrings listed the management servers in different order, it was possible for 2 API nodes to be assigned the same node ID. When this happened it was possible for an API node not to get fully connected, consequently producing a number of errors whose cause was not easily recognizable. ([Bug#42973](#))
- When using multi-threaded data nodes, `IndexMemory`, `MaxNoOfLocalOperations`, and `MaxNoOfLocalScans` were effectively multiplied by the number of local query handlers in use by each `ndbmtd` instance. ([Bug#42765](#))

See also [Bug#42215](#).

- `ndb_error_reporter` worked correctly only with GNU `tar`. (With other versions of `tar`, it produced empty archives.) ([Bug#42753](#))
- Triggers on `NDBCLUSTER` tables caused such tables to become locked. ([Bug#42751](#))

See also [Bug#16229](#), [Bug#18135](#).

- When performing more than 32 index or tuple scans on a single fragment, the scans could be left hanging. This caused unnecessary timeouts, and in addition could possibly lead to a hang of an LCP. ([Bug#42559](#))
- A data node failure that occurred between calls to `NdbIndexScanOperation::readTuples(SF_OrderBy)` and `NdbTransaction::Execute()` was not correctly handled; a subsequent call to `nextResult()` caused a null pointer to be dereferenced, leading to a segfault in `mysqld`. ([Bug#42545](#))
- If the cluster configuration cache file was larger than 32K, the management server would not start. ([Bug#42543](#))
- Issuing `SHOW GLOBAL STATUS LIKE 'NDB%'` before `mysqld` had connected to the cluster caused a segmentation fault. ([Bug#42458](#))
- When using `ndbmtd` for all data nodes, repeated failures of one data node during DML operations caused other data nodes to

fail. ([Bug#42450](#))

- Data node failures that occurred before all data nodes had connected to the cluster were not handled correctly, leading to additional data node failures. ([Bug#42422](#))
- When using multi-threaded data nodes, their `DataMemory` and `IndexMemory` usage as reported was multiplied by the number of local query handlers (worker threads), making it appear that much more memory was being used than was actually the case. ([Bug#42215](#))

See also [Bug#42765](#).

- Given a MySQL Cluster containing no data (that is, whose data nodes had all been started using `--initial`, and into which no data had yet been imported) and having an empty backup directory, executing `START BACKUP` with a user-specified backup ID caused the data nodes to crash. ([Bug#41031](#))
- In some cases, `NDB` did not check correctly whether tables had changed before trying to use the query cache. This could result in a crash of the debug MySQL server. ([Bug#40464](#))
- **Disk Data:** It was not possible to add an in-memory column online to a table that used a table-level or column-level `STORAGE DISK` option. The same issue prevented `ALTER ONLINE TABLE ... REORGANIZE PARTITION` from working on Disk Data tables. ([Bug#42549](#))
- **Disk Data:** Repeated insert and delete operations on disk-based tables could lead to failures in the NDB Tablespace Manager (`TSMAN` kernel block). ([Bug#40344](#))
- **Disk Data:** Creating a Disk Data tablespace with a very large extent size caused the data nodes to fail. The issue was observed when using extent sizes of 100 MB and larger. ([Bug#39096](#))
- **Disk Data:** Trying to execute a `CREATE LOGFILE GROUP` statement using a value greater than `150M` for `UNDO_BUFFER_SIZE` caused data nodes to crash.

As a result of this fix, the upper limit for `UNDO_BUFFER_SIZE` is now `600M`; attempting to set a higher value now fails gracefully with an error. ([Bug#34102](#))

See also [Bug#36702](#).

- **Disk Data:** When attempting to create a tablespace that already existed, the error message returned was `TABLE OR INDEX WITH GIVEN NAME ALREADY EXISTS.` ([Bug#32662](#))
- **Disk Data:** Using a path or filename longer than 128 characters for Disk Data undo log files and tablespace data files caused a number of issues, including failures of `CREATE LOGFILE GROUP`, `ALTER LOGFILE GROUP`, `CREATE TABLESPACE`, and `ALTER TABLESPACE` statements, as well as crashes of management nodes and data nodes.

With this fix, the maximum length for path and file names used for Disk Data undo log files and tablespace data files is now the same as the maximum for the operating system. ([Bug#31769](#), [Bug#31770](#), [Bug#31772](#))

- **Disk Data:** Attempting to perform a system restart of the cluster where there existed a logfile group without and undo log files caused the data nodes to crash.

### Note

While issuing a `CREATE LOGFILE GROUP` statement without an `ADD UNDOFILE` option fails with an error in the MySQL server, this situation could arise if an SQL node failed during the execution of a valid `CREATE LOGFILE GROUP` statement; it is also possible to create a logfile group without any undo log files using the NDB API.

([Bug#17614](#))

- **Cluster API:** Some error messages from `ndb_mgmd` contained newline (`\n`) characters. This could break the MGM API protocol, which uses the newline as a line separator. ([Bug#43104](#))
- **Cluster API:** When using an ordered index scan without putting all key columns in the read mask, this invalid use of the NDB API went undetected, which resulted in the use of uninitialized memory. ([Bug#42591](#))

### Changes in MySQL Cluster NDB 6.4.2 (5.1.31-ndb-6.4.2)

Bugs fixed:

- Connections using IPv6 were not handled correctly by `mysqld`. ([Bug#42413](#))

See also [Bug#42412](#), [Bug#38247](#).

- When a cluster backup failed with Error 1304 (Node `node_id1`: Backup request from `node_id2` failed to start), no clear reason for the failure was provided.

As part of this fix, MySQL Cluster now retries backups in the event of sequence errors. ([Bug#42354](#))

See also [Bug#22698](#).

- Issuing `SHOW ENGINE NDBCLUSTER STATUS` on an SQL node before the management server had connected to the cluster caused `mysqld` to crash. ([Bug#42264](#))
- When using `ndbmt`, setting `MaxNoOfThreads` to a value higher than the actual number of cores available and with insufficient `SharedGlobalMemory` caused the data nodes to crash.

The fix for this issue changes the behavior of `ndbmt` such that its internal job buffers no longer rely on `SharedGlobalMemory`. ([Bug#42254](#))

## Changes in MySQL Cluster NDB 6.4.1 (5.1.31-ndb-6.4.1)

Functionality added or changed:

- **Important Change:** Formerly, when the management server failed to create a transporter for a data node connection, `net_write_timeout` seconds elapsed before the data node was actually permitted to disconnect. Now in such cases the disconnection occurs immediately. ([Bug#41965](#))

See also [Bug#41713](#).

- Formerly, when using MySQL Cluster Replication, records for “empty” epochs—that is, epochs in which no changes to `NDB-CLUSTER` data or tables took place—were inserted into the `ndb_apply_status` and `ndb_binlog_index` tables on the slave even when `--log-slave-updates` was disabled. Beginning with MySQL Cluster NDB 6.2.16 and MySQL Cluster NDB 6.3.13 this was changed so that these “empty” epochs were no longer logged. However, it is now possible to re-enable the older behavior (and cause “empty” epochs to be logged) by using the `--ndb-log-empty-epochs` option. For more information, see [Section 16.1.3.3, “Replication Slave Options and Variables”](#).

See also [Bug#37472](#).

Bugs fixed:

- A maximum of 11 `TUP` scans were permitted in parallel. ([Bug#42084](#))
- The management server could hang after attempting to halt it with the `STOP` command in the management client. ([Bug#42056](#))

See also [Bug#40922](#).

- When using `ndbmt`, one thread could flood another thread, which would cause the system to stop with a `JOB BUFFER FULL` condition (currently implemented as an abort). This could be caused by committing or aborting a large transaction (50000 rows or more) on a single data node running `ndbmt`. To prevent this from happening, the number of signals that can be accepted by the system threads is calculated before executing them, and only executing them if sufficient space is found. ([Bug#42052](#))
- MySQL Cluster would not compile when using `libwrap`. This issue was known to occur only in MySQL Cluster NDB 6.4.0. ([Bug#41918](#))
- Trying to execute an `ALTER ONLINE TABLE ... ADD COLUMN` statement while inserting rows into the table caused `mysqld` to crash. ([Bug#41905](#))
- When a data node connects to the management server, the node sends its node ID and transporter type; the management server then verifies that there is a transporter set up for that node and that it is in the correct state, and then sends back an acknowledgement to the connecting node. If the transporter was not in the correct state, no reply was sent back to the connecting node, which would then hang until a read timeout occurred (60 seconds). Now, if the transporter is not in the correct state, the management server acknowledges this promptly, and the node immediately disconnects. ([Bug#41713](#))

See also [Bug#41965](#).

- Issuing `EXIT` in the management client sometimes caused the client to hang. ([Bug#40922](#))
- In the event that a MySQL Cluster backup failed due to file permissions issues, conflicting reports were issued in the manage-

ment client. ([Bug#34526](#))

- If all data nodes were shut down, MySQL clients were unable to access `NDBCLUSTER` tables and data even after the data nodes were restarted, unless the MySQL clients themselves were restarted. ([Bug#33626](#))

## Changes in MySQL Cluster NDB 6.4.0 (5.1.30-ndb-6.4.0)

Functionality added or changed:

- **Important Change:** MySQL Cluster now caches its configuration data. This means that, by default, the management server only reads the global configuration file (usually named `config.ini`) the first time that it is started, and does not automatically re-read the this file when restarted. This behavior can be controlled using new management server options (`--config-dir`, `--initial`, and `--reload`) that have been added for this purpose. For more information, see [Section 17.3.2, “MySQL Cluster Configuration Files”](#), and [Section 17.4.4, “`ndb\_mgmd` — The MySQL Cluster Management Server Daemon”](#).
- It is now possible while in Single User Mode to restart all data nodes using `ALL RESTART` in the management client. Restarting of individual nodes while in Single User Mode remains not permitted. ([Bug#31056](#))
- It is now possible to add data nodes to a MySQL Cluster online—that is, to a running MySQL Cluster without shutting it down. For information about the procedure for adding data nodes online, see [Section 17.5.11, “Adding MySQL Cluster Data Nodes Online”](#).
- A multi-threaded version of the MySQL Cluster data node daemon is now available. The multi-threaded `ndbmtd` binary is similar to `ndbd` and functions in much the same way, but is intended for use on machines with multiple CPU cores. For more information, see [Section 17.4.3, “`ndbmtd` — The MySQL Cluster Data Node Daemon \(Multi-Threaded\)”](#).
- It is now possible when performing a cluster backup to determine whether the backup matches the state of the data when the backup began or when it ended, using the new `START BACKUP` options `SNAPSHOTSTART` and `SNAPSHOTEND` in the management client. See [Section 17.5.3.2, “Using The MySQL Cluster Management Client to Create a Backup”](#), for more information.
- **Cluster API:** Two new `Ndb_cluster_connection` methods have been added to help in diagnosing problems with NDB API client connections. The `get_latest_error()` method tells whether or not the latest connection attempt succeeded; if the attempt failed, `get_latest_error_msg()` provides an error message giving the reason. For more information, see `Ndb_cluster_connection::get_latest_error()`, and `Ndb_cluster_connection::get_latest_error_msg()`.

Bugs fixed:

- API nodes disconnected too aggressively from cluster when data nodes were being restarted. This could sometimes lead to the API node being unable to access the cluster at all during a rolling restart. ([Bug#41462](#))
- When long signal buffer exhaustion in the `ndbd` process resulted in a signal being dropped, the usual handling mechanism did not take fragmented signals into account. This could result in a crash of the data node because the fragmented signal handling mechanism was not able to work with the missing fragments. ([Bug#39235](#))
- The failure of a master node during a DDL operation caused the cluster to be unavailable for further DDL operations until it was restarted; failures of nonmaster nodes during DLL operations caused the cluster to become completely inaccessible. ([Bug#36718](#))
- Status messages shown in the management client when restarting a management node were inappropriate and misleading. Now, when restarting a management node, the messages displayed are as follows, where `node_id` is the management node's node ID:

```
ndb_mgm> node_id RESTART
Shutting down MGM node node_id for restart
Node node_id is being restarted
ndb_mgm>
```

([Bug#29275](#))

- A data node failure when `NoOfReplicas` was greater than 2 caused all cluster SQL nodes to crash. ([Bug#18621](#))

### 17.7.6.3. Changes in the MySQL Cluster NDB 6.3 Series

This section contains unified change history highlights for all MySQL Cluster releases based on version 6.3 of the `NDBCLUSTER` storage engine through MySQL Cluster NDB 6.3.38. Included are all changelog entries in the categories *MySQL Cluster*, *Disk Data*, and *Cluster API*.

For an overview of features that were added in MySQL Cluster NDB 6.3, see [Section 17.1.4.3, “MySQL Cluster Development in MySQL Cluster NDB 6.3”](#).

### Changes in MySQL Cluster NDB 6.3.38 (5.1.47-ndb-6.3.38)

Functionality added or changed:

- `mysqldump` as supplied with MySQL Cluster now has an `--add-drop-trigger` option which adds a `DROP TRIGGER IF EXISTS` statement before each dumped trigger definition. ([Bug#55691](#))

See also [Bug#34325](#).

Bugs fixed:

- When distributing `CREATE TABLE` and `DROP TABLE` operations among several SQL nodes attached to a MySQL Cluster, the `LOCK_OPEN` lock normally protecting `mysqld`'s internal table list is released so that other queries or DML statements are not blocked. However, to make sure that other DDL is not executed simultaneously, a global schema lock (implemented as a row-level lock by `NDB`) is used, such that all operations that can modify the state of the `mysqld` internal table list also need to acquire this global schema lock. The `SHOW TABLE STATUS` statement did not acquire this lock. ([Bug#56841](#))
- MySQL Cluster stores, for each row in each `NDB` table, a Global Checkpoint Index (GCI) which identifies the last committed transaction that modified the row. As such, a GCI can be thought of as a coarse-grained row version.

Due to changes in the format used by `NDB` to store local checkpoints (LCPs) in MySQL Cluster NDB 6.3.11, it could happen that, following cluster shutdown and subsequent recovery, the GCI values for some rows could be changed unnecessarily; this could possibly, over the course of many node or system restarts (or both), lead to an inconsistent database. ([Bug#56770](#))

- When multiple SQL nodes were connected to the cluster and one of them stopped in the middle of a DDL operation, the `mysqld` process issuing the DDL timed out with the error `DISTRIBUTING TBL_NAME TIMED OUT. IGNORING.` ([Bug#56763](#))
- An online `ALTER TABLE ... ADD COLUMN` operation that changed the table schema such that the number of 32-bit words used for the bitmask allocated to each DML operation increased during a transaction in DML which was performed prior to DDL which was followed by either another DML operation or—if using replication—a commit, led to data node failure.

This was because the data node did not take into account that the bitmask for the before-image was smaller than the current bitmask, which caused the node to crash. ([Bug#56524](#))

- The failure of a data node during some scans could cause other data nodes to fail. ([Bug#54945](#))
- Exhausting the number of available commit-ack markers (controlled by the `MaxNoOfConcurrentTransactions` parameter) led to a data node crash. ([Bug#54944](#))
- When running a `SELECT` on an `NDB` table with `BLOB` or `TEXT` columns, memory was allocated for the columns but was not freed until the end of the `SELECT`. This could cause problems with excessive memory usage when dumping (using for example `mysqldump`) tables with such columns and having many rows, large column values, or both. ([Bug#52313](#))

See also [Bug#56488](#), [Bug#50310](#).

### Changes in MySQL Cluster NDB 6.3.37 (5.1.47-ndb-6.3.37)

Functionality added or changed:

- **Important Change:** More finely-grained control over restart-on-failure behavior is provided with two new data node configuration parameters `MaxStartFailRetries` and `StartFailRetryDelay`. `MaxStartFailRetries` limits the total number of retries made before giving up on starting the data node; `StartFailRetryDelay` sets the number of seconds between retry attempts.

These parameters are used only if `StopOnError` is set to 0.

For more information, see [Section 17.3.2.6, “Defining MySQL Cluster Data Nodes”](#). ([Bug#54341](#))

Bugs fixed:

- Following a failure of the master data node, the new master sometimes experienced a race condition which caused the node to terminate with a `GcpStop` error. ([Bug#56044](#))
- The warning `MAXNOOFEVENTS (#) > LOCKEXECUTETHREADTOCPU COUNT (#), THIS COULD CAUSE CONTE-N-TION` could be logged when running `ndbd`, even though the condition described can occur only when using `ndbmtd`. ([Bug#54342](#))
- The graceful shutdown of a data node could sometimes cause transactions to be aborted unnecessarily. ([Bug#18538](#))

See also [Bug#55641](#).

### Changes in MySQL Cluster NDB 6.3.36 (5.1.47-ndb-6.3.36)

Functionality added or changed:

- Added the `DictTrace` data node configuration parameter, for use in debugging NDB code. For more information, see [Section 17.3.2.6, “Defining MySQL Cluster Data Nodes”](#). ([Bug#55963](#))

Bugs fixed:

- **Cluster API: Important Change:** The poll and select calls made by the MGM API were not interrupt-safe; that is, a signal caught by the process while waiting for an event on one or more sockets returned error -1 with `errno` set to `EINTR`. This caused problems with MGM API functions such as `ndb_mgm_logevent_get_next()` and `ndb_mgm_get_status2()`.

To fix this problem, the internal `ndb_socket_poller::poll()` function has been made `EINTR`-safe.

The old version of this function has been retained as `poll_unsafe()`, for use by those parts of NDB that do not need the `EINTR`-safe version of the function. ([Bug#55906](#))

- When another data node failed, a given data node `DBTC` kernel block could time out while waiting for `DBDIH` to signal commits of pending transactions, leading to a crash. Now in such cases the timeout generates a prinout, and the data node continues to operate. ([Bug#55715](#))
- The `configure.js` option `WITHOUT_DYNAMIC_PLUGINS=TRUE` was ignored when building MySQL Cluster for Windows using `CMake`. Among the effects of this issue was that `CMake` attempted to build the `InnoDB` storage engine as a plugin (`.DLL` file) even though the `InnoDB Plugin` is not currently supported by MySQL Cluster. ([Bug#54913](#))
- It was possible for a `DROP DATABASE` statement to remove `NDB` hidden blob tables without removing the parent tables, with the result that the tables, although hidden to MySQL clients, were still visible in the output of `ndb_show_tables` but could not be dropped using `ndb_drop_table`. ([Bug#54788](#))
- An excessive number of timeout warnings (normally used only for debugging) were written to the data node logs. ([Bug#53987](#))
- **Disk Data:** As an optimization when inserting a row to an empty page, the page is not read, but rather simply initialized. However, this optimization was performed in all cases when an empty row was inserted, even though it should have been done only if it was the first time that the page had been used by a table or fragment. This is because, if the page had been in use, and then all records had been released from it, the page still needed to be read to learn its log sequence number (LSN).

This caused problems only if the page had been flushed using an incorrect LSN and the data node failed before any local checkpoint was completed—which would removed any need to apply the undo log, hence the incorrect LSN was ignored.

The user-visible result of the incorrect LSN was that it caused the data node to fail during a restart. It was perhaps also possible (although not conclusively proven) that this issue could lead to incorrect data. ([Bug#54986](#))

- **Cluster API:** Calling `NdbTransaction::refresh()` did not update the timer for `TransactionInactiveTimeout`. ([Bug#54724](#))

### Changes in MySQL Cluster NDB 6.3.35 (5.1.47-ndb-6.3.35)

Functionality added or changed:

- Restrictions on some types of mismatches in column definitions when restoring data using `ndb_restore` have been relaxed. These include the following types of mismatches:
  - Different `COLUMN_FORMAT` settings (`FIXED`, `DYNAMIC`, `DEFAULT`)
  - Different `STORAGE` settings (`MEMORY`, `DISK`)
  - Different default values
  - Different distribution key settings

Now, when one of these types of mismatches in column definitions is encountered, `ndb_restore` no longer stops with an error; instead, it accepts the data and inserts it into the target table, while issuing a warning to the user.

For more information, see [Section 17.4.17, “`ndb\_restore` — Restore a MySQL Cluster Backup”](#). ([Bug#54423](#))

See also [Bug#53810](#), [Bug#54178](#), [Bug#54242](#), [Bug#54279](#).

- Introduced the `HeartbeatOrder` data node configuration parameter, which can be used to set the order in which heartbeats are transmitted between data nodes. This parameter can be useful in situations where multiple data nodes are running on the same host and a temporary disruption in connectivity between hosts would otherwise cause the loss of a node group, leading to failure of the cluster. ([Bug#52182](#))

Bugs fixed:

- The disconnection of all API nodes (including SQL nodes) during an `ALTER TABLE` caused a memory leak. ([Bug#54685](#))
- If a node shutdown (either in isolation or as part of a system shutdown) occurred directly following a local checkpoint, it was possible that this local checkpoint would not be used when restoring the cluster. ([Bug#54611](#))
- When performing an online alter table where 2 or more SQL nodes connected to the cluster were generating binary logs, an incorrect message could be sent from the data nodes, causing `mysqld` processes to crash. This problem was often difficult to detect, because restarting SQL node or data node processes could clear the error, and because the crash in `mysqld` did not occur until several minutes after the erroneous message was sent and received. ([Bug#54168](#))
- A table having the maximum number of attributes permitted could not be backed up using the `ndb_mgm` client.

### Note

The maximum number of attributes supported per table is not the same for all MySQL Cluster releases. See [Section 17.1.5.5, “Limits Associated with Database Objects in MySQL Cluster”](#), to determine the maximum that applies in the release which you are using.

([Bug#54155](#))

- During initial node restarts, initialization of the REDO log was always performed 1 node at a time, during start phase 4. Now this is done during start phase 2, so that the initialization can be performed in parallel, thus decreasing the time required for initial restarts involving multiple nodes. ([Bug#50062](#))
- **Cluster API:** When using the NDB API, it was possible to rename a table with the same name as that of an existing table.

### Note

This issue did not affect table renames executed using SQL on MySQL servers acting as MySQL Cluster API nodes.

([Bug#54651](#))

- **Cluster API:** An excessive number of client connections, such that more than 1024 file descriptors, sockets, or both were open, caused NDB API applications to crash. ([Bug#34303](#))

## Changes in MySQL Cluster NDB 6.3.34 (5.1.44-ndb-6.3.34)

Functionality added or changed:

- A `--wait-nodes` option has been added for `ndb_waiter`. When this option is used, the program waits only for the nodes

having the listed IDs to reach the desired state. For more information, see [Section 17.4.22, “`ndb\_waiter` — Wait for MySQL Cluster to Reach a Given Status”](#). ([Bug#52323](#))

- Added the `--skip-unknown-objects` option for `ndb_restore`. This option causes `ndb_restore` to ignore any schema objects which it does not recognize. Currently, this is useful chiefly for restoring native backups made from a cluster running MySQL Cluster NDB 7.0 to a cluster running MySQL Cluster NDB 6.3.

Bugs fixed:

- Cluster API: Incompatible Change:** The default behavior of the NDB API Event API has changed as follows:

Previously, when creating an `NdbDictionary::Event`, DDL operations (alter and drop operations on tables) were automatically reported on any event operation that used this event, but as a result of this change, this is no longer the case. Instead, you must now invoke the event's `setReport()` method, with the new `EventReport` value `ER_DDL`, to get this behavior.

For existing NDB API applications where you wish to retain the old behavior, you must update the code as indicated previously, then recompile, following an upgrade. Otherwise, DDL operations are no longer reported after upgrading `libndbclient`.

For more information, see [The `Event::EventReport` Type](#), and [Event::setReport\(\)](#). ([Bug#53308](#))

- Cluster API: Incompatible Change:** The default behavior of the NDB API Event API has changed as follows:

Previously, when creating an `NdbDictionary::Event`, DDL operations (alter and drop operations on tables) were automatically reported on any event operation that used this event, but as a result of this change, this is no longer the case. Instead, you must now invoke the event's `setReport()` method, with the new `EventReport` value `ER_DDL`, to get this behavior.

For existing NDB API applications where you wish to retain the old behavior, you must update the code as indicated previously, then recompile, following an upgrade. Otherwise, DDL operations are no longer reported after upgrading `libndbclient`.

For more information, see [The `Event::EventReport` Type](#), and [Event::setReport\(\)](#). ([Bug#53308](#))

- Creating a Disk Data table, dropping it, then creating an in-memory table and performing a restart, could cause data node processes to fail with errors in the `DBTUP` kernel block if the new table's internal ID was the same as that of the old Disk Data table. This could occur because undo log handling during the restart did not check that the table having this ID was now in-memory only. ([Bug#53935](#))
- A table created while `ndb_table_no_logging` was enabled was not always stored to disk, which could lead to a data node crash with `ERROR OPENING DIH SCHEMA FILES FOR TABLE`. ([Bug#53934](#))
- An internal buffer allocator used by `NDB` has the form `alloc(wanted, minimum)` and attempts to allocate `wanted` pages, but is permitted to allocate a smaller number of pages, between `wanted` and `minimum`. However, this allocator could sometimes allocate fewer than `minimum` pages, causing problems with multi-threaded building of ordered indexes. ([Bug#53580](#))
- When compiled with support for `epoll` but this functionality is not available at runtime, MySQL Cluster tries to fall back to use the `select()` function in its place. However, an extra `ndbout_c()` call in the transporter registry code caused `ndbd` to fail instead. ([Bug#53482](#))
- `NDB` truncated a column declared as `DECIMAL(65, 0)` to a length of 64. Now such a column is accepted and handled correctly. In cases where the maximum length (65) is exceeded, `NDB` now raises an error instead of truncating. ([Bug#53352](#))
- When a watchdog shutdown occurred due to an error, the process was not terminated quickly enough, sometimes resulting in a hang. (To correct this, the internal `_exit()` function is now called in such situations, rather than `exit()`.) ([Bug#53246](#))
- Setting `DataMemory` higher than 4G on 32-bit platforms caused `ndbd` to crash, instead of failing gracefully with an error. ([Bug#52536](#), [Bug#50928](#))
- `NDB` did not distinguish correctly between table names differing only by lettercase when `lower_case_table_names` was set to 0. ([Bug#33158](#))
- `ndb_mgm -e "ALL STATUS"` erroneously reported that data nodes remained in start phase 0 until they had actually started.

## Changes in MySQL Cluster NDB 6.3.33 (5.1.44-ndb-6.3.33)

Functionality added or changed:

- **Cluster API:** It is now possible to determine, using the `ndb_desc` utility or the NDB API, which data nodes contain replicas of which partitions. For `ndb_desc`, a new `--extra-node-info` option is added to cause this information to be included in its output. A new method `NdbDictionary::Object::Table::getFragmentNodes()` is added to the NDB API for obtaining this information programmatically. ([Bug#51184](#))
- **Cluster API:** It is now possible to determine, using the `ndb_desc` utility or the NDB API, which data nodes contain replicas of which partitions. For `ndb_desc`, a new `--extra-node-info` option is added to cause this information to be included in its output. A new method `NdbDictionary::Object::Table::getFragmentNodes()` is added to the NDB API for obtaining this information programmatically. ([Bug#51184](#))
- Formerly, the `REPORT` and `DUMP` commands returned output to all `ndb_mgm` clients connected to the same MySQL Cluster. Now, these commands return their output only to the `ndb_mgm` client that actually issued the command. ([Bug#40865](#))

Bugs fixed:

- If a node or cluster failure occurred while `mysqld` was scanning the `ndb.ndb_schema` table (which it does when attempting to connect to the cluster), insufficient error handling could lead to a crash by `mysqld` in certain cases. This could happen in a MySQL Cluster with a great many tables, when trying to restart data nodes while one or more `mysqld` processes were restarting. ([Bug#52325](#))
- After running a mixed series of node and system restarts, a system restart could hang or fail altogether. This was caused by setting the value of the newest completed global checkpoint too low for a data node performing a node restart, which led to the node reporting incorrect GCI intervals for its first local checkpoint. ([Bug#52217](#))
- When performing a complex mix of node restarts and system restarts, the node that was elected as master sometimes required optimized node recovery due to missing `REDO` information. When this happened, the node crashed with `FAILURE TO RECREATE OBJECT ... DURING RESTART, ERROR 721` (because the `DBDICT` restart code was run twice). Now when this occurs, node takeover is executed immediately, rather than being made to wait until the remaining data nodes have started. ([Bug#52135](#))

See also [Bug#48436](#).

- The redo log protects itself from being filled up by periodically checking how much space remains free. If insufficient redo log space is available, it sets the state `TAIL_PROBLEM` which results in transactions being aborted with error code 410 (`OUT OF REDO LOG`). However, this state was not set following a node restart, which meant that if a data node had insufficient redo log space following a node restart, it could crash a short time later with `FATAL ERROR DUE TO END OF REDO LOG`. Now, this space is checked during node restarts. ([Bug#51723](#))
- The output of the `ndb_mgm` client `REPORT BACKUPSTATUS` command could sometimes contain errors due to uninitialized data. ([Bug#51316](#))
- A `GROUP BY` query against `NDB` tables sometimes did not use any indexes unless the query included a `FORCE INDEX` option. With this fix, indexes are used by such queries (where otherwise possible) even when `FORCE INDEX` is not specified. ([Bug#50736](#))
- The `ndb_mgm` client sometimes inserted extra prompts within the output of the `REPORT MEMORYUSAGE` command. ([Bug#50196](#))
- Issuing a command in the `ndb_mgm` client after it had lost its connection to the management server could cause the client to crash. ([Bug#49219](#))
- The `ndb_print_backup_file` utility failed to function, due to a previous internal change in the NDB code. ([Bug#41512](#), [Bug#48673](#))
- When the `MemReportFrequency` configuration parameter was set in `config.ini`, the `ndb_mgm` client `REPORT MEMORYUSAGE` command printed its output multiple times. ([Bug#37632](#))
- `ndb_mgm -e ".... REPORT ..."` did not write any output to `stdout`.

The fix for this issue also prevents the cluster log from being flooded with `INFO` messages when `DataMemory` usage reaches 100%, and insures that when the usage is decreased, an appropriate message is written to the cluster log. ([Bug#31542](#), [Bug#44183](#), [Bug#49782](#))

- **Disk Data:** Inserts of blob column values into a MySQL Cluster Disk Data table that exhausted the tablespace resulted in misleading `NO SUCH TUPLE` error messages rather than the expected error `TABLESPACE FULL`.

This issue appeared similar to [Bug#48113](#), but had a different underlying cause. ([Bug#52201](#))

- **Disk Data:** The error message returned after attempting to execute `ALTER LOGFILE GROUP` on a nonexistent logfile group did not indicate the reason for the failure. ([Bug#51111](#))

- **Cluster API:** When reading blob data with lock mode `LM_SimpleRead`, the lock was not upgraded as expected. ([Bug#51034](#))
- **Cluster API:** A number of issues were corrected in the NDB API coding examples found in the `storage/ndb/ndbapi-examples` directory in the MySQL Cluster source tree. These included possible endless recursion in `ndbapi_scan.cpp` as well as problems running some of the examples on systems using Windows or Mac OS due to the letter case used for some table names. ([Bug#30552](#), [Bug#30737](#))

### Changes in MySQL Cluster NDB 6.3.32 (5.1.41-ndb-6.3.32)

Functionality added or changed:

- A new configuration parameter `HeartbeatThreadPriority` makes it possible to select between a first-in, first-out or round-round scheduling policy for management node and API node heartbeat threads, as well as to set the priority of these threads. See [Section 17.3.2.5, “Defining a MySQL Cluster Management Server”](#), or [Section 17.3.2.7, “Defining SQL and Other API Nodes in a MySQL Cluster”](#), for more information. ([Bug#49617](#))
- **Disk Data:** The `ndb_desc` utility can now show the extent space and free extent space for subordinate `BLOB` and `TEXT` columns (stored in hidden `BLOB` tables by NDB). A `--blob-info` option has been added for this program that causes `ndb_desc` to generate a report for each subordinate `BLOB` table. For more information, see [Section 17.4.9, “ndb\\_desc — Describe NDB Tables”](#). ([Bug#50599](#))

Bugs fixed:

- When one or more data nodes read their LCPs and applied undo logs significantly faster than others, this could lead to a race condition causing system restarts of data nodes to hang. This could most often occur when using both `ndbd` and `ndbmttd` processes for the data nodes. ([Bug#51644](#))
- When deciding how to divide the REDO log, the `DBDIH` kernel block saved more than was needed to restore the previous local checkpoint, which could cause REDO log space to be exhausted prematurely (NDB error 410). ([Bug#51547](#))
- DML operations can fail with NDB error 1220 (`REDO LOG FILES OVERLOADED...`) if the opening and closing of REDO log files takes too much time. If this occurred as a GCI marker was being written in the REDO log while REDO log file 0 was being opened or closed, the error could persist until a GCP stop was encountered. This issue could be triggered when there was insufficient REDO log space (for example, with configuration parameter settings `NoOfFragmentLogFile = 6` and `FragmentLogFileSize = 6M`) with a load including a very high number of updates. ([Bug#51512](#))

See also [Bug#20904](#).

- During an online upgrade from MySQL Cluster NDB 6.2 to MySQL Cluster NDB 6.3, a sufficiently large amount of traffic with more than 1 DML operation per transaction could lead an NDB 6.3 data node to crash an NDB 6.2 data node with an internal error in the `DBLOQH` kernel block. ([Bug#51389](#))
- A side effect of the `ndb_restore --disable-indexes` and `--rebuild-indexes` options is to change the schema versions of indexes. When a `mysqld` later tried to drop a table that had been restored from backup using one or both of these options, the server failed to detect these changed indexes. This caused the table to be dropped, but the indexes to be left behind, leading to problems with subsequent backup and restore operations. ([Bug#51374](#))
- `ndb_restore` crashed while trying to restore a corrupted backup, due to missing error handling. ([Bug#51223](#))
- The `ndb_restore` message `Successfully created index `PRIMARY`...` was directed to `stderr` instead of `stdout`. ([Bug#51037](#))
- When using `NoOfReplicas` equal to 1 or 2, if data nodes from one node group were restarted 256 times and applications were running traffic such that it would encounter NDB error 1204 (`TEMPORARY FAILURE, DISTRIBUTION CHANGED`), the live node in the node group would crash, causing the cluster to crash as well. The crash occurred only when the error was encountered on the 256th restart; having the error on any previous or subsequent restart did not cause any problems. ([Bug#50930](#))
- A `SELECT` requiring a sort could fail with the error `CAN'T FIND RECORD IN 'TABLE'` when run concurrently with a `DELETE` from the same table. ([Bug#45687](#))
- **Cluster API:** An issue internal to `ndb_mgm` could cause problems when trying to start a large number of data nodes at the same time. ([Bug#51273](#))

### Changes in MySQL Cluster NDB 6.3.31a (5.1.41-ndb-6.3.31a)

Bugs fixed:

- An initial restart of a data node configured with a large amount of memory could fail with a `POINTER TOO LARGE` error. ([Bug#51027](#))

This regression was introduced by [Bug#47818](#).

### Changes in MySQL Cluster NDB 6.3.30 (5.1.39-ndb-6.3.30)

Functionality added or changed:

- Added multi-threaded ordered index building capability during system restarts or node restarts, controlled by the `BuildIndexThreads` data node configuration parameter (also introduced in this release).

### Changes in MySQL Cluster NDB 6.3.29 (5.1.39-ndb-6.3.29)

Functionality added or changed:

- This enhanced functionality is supported for upgrades to MySQL Cluster NDB 7.0 when the `NDB` engine version is 7.0.10 or later. ([Bug#48528](#), [Bug#49163](#))
- The output from `ndb_config --configinfo --xml` now indicates, for each configuration parameter, the following restart type information:
  - Whether a system restart or a node restart is required when resetting that parameter;
  - Whether cluster nodes need to be restarted using the `--initial` option when resetting the parameter.

([Bug#47366](#))

Bugs fixed:

- Node takeover during a system restart occurs when the REDO log for one or more data nodes is out of date, so that a node restart is invoked for that node or those nodes. If this happens while a `mysqld` process is attached to the cluster as an SQL node, the `mysqld` takes a global schema lock (a row lock), while trying to set up cluster-internal replication.

However, this setup process could fail, causing the global schema lock to be held for an excessive length of time, which made the node restart hang as well. As a result, the `mysqld` failed to set up cluster-internal replication, which led to tables being read only, and caused one node to hang during the restart.

#### Note

This issue could actually occur in MySQL Cluster NDB 7.0 only, but the fix was also applied MySQL Cluster NDB 6.3, in order to keep the two codebases in alignment.

([Bug#49560](#))

- Sending `SIGHUP` to a `mysqld` running with the `--ndbcluster` and `--log-bin` options caused the process to crash instead of refreshing its log files. ([Bug#49515](#))
- If the master data node receiving a request from a newly-started API or data node for a node ID died before the request has been handled, the management server waited (and kept a mutex) until all handling of this node failure was complete before responding to any other connections, instead of responding to other connections as soon as it was informed of the node failure (that is, it waited until it had received a `NF_COMPLETEREP` signal rather than a `NODE_FAILREP` signal). On visible effect of this misbehavior was that it caused management client commands such as `SHOW` and `ALL STATUS` to respond with unnecessary slowness in such circumstances. ([Bug#49207](#))
- When evaluating the options `--include-databases`, `--include-tables`, `--exclude-databases`, and `--exclude-tables`, the `ndb_restore` program overwrote the result of the database-level options with the result of the table-level options rather than merging these results together, sometimes leading to unexpected and unpredictable results.

As part of the fix for this problem, the semantics of these options have been clarified; because of this, the rules governing their evaluation have changed slightly. These changes be summed up as follows:

- All `--include-*` and `--exclude-*` options are now evaluated from right to left in the order in which they are passed

to `ndb_restore`.

- All `--include-*` and `--exclude-*` options are now cumulative.
- In the event of a conflict, the first (rightmost) option takes precedence.

For more detailed information and examples, see [Section 17.4.17, “`ndb\_restore` — Restore a MySQL Cluster Backup”](#). ([Bug#48907](#))

- When performing tasks that generated large amounts of I/O (such as when using `ndb_restore`), an internal memory buffer could overflow, causing data nodes to fail with signal 6.

Subsequent analysis showed that this buffer was not actually required, so this fix removes it. ([Bug#48861](#))

- Exhaustion of send buffer memory or long signal memory caused data nodes to crash. Now an appropriate error message is provided instead when this situation occurs. ([Bug#48852](#))
- Under certain conditions, accounting of the number of free scan records in the local query handler could be incorrect, so that during node recovery or a local checkpoint operations, the LQH could find itself lacking a scan record that is expected to find, causing the node to crash. ([Bug#48697](#))

See also [Bug#48564](#).

- The creation of an ordered index on a table undergoing DDL operations could cause a data node crash under certain timing-dependent conditions. ([Bug#48604](#))
- During an LCP master takeover, when the newly elected master did not receive a `COPY_GCI` LCP protocol message but other nodes participating in the local checkpoint had received one, the new master could use an uninitialized variable, which caused it to crash. ([Bug#48584](#))
- When running many parallel scans, a local checkpoint (which performs a scan internally) could find itself not getting a scan record, which led to a data node crash. Now an extra scan record is reserved for this purpose, and a problem with obtaining the scan record returns an appropriate error (error code 489, `TOO MANY ACTIVE SCANS`). ([Bug#48564](#))
- During a node restart, logging was enabled on a per-fragment basis as the copying of each fragment was completed but local checkpoints were not enabled until all fragments were copied, making it possible to run out of redo log file space (`NDB` error code 410) before the restart was complete. Now logging is enabled only after all fragments have been copied, just prior to enabling local checkpoints. ([Bug#48474](#))
- When employing `NDB` native backup to back up and restore an empty `NDB` table that used a non-sequential `AUTO_INCREMENT` value, the `AUTO_INCREMENT` value was not restored correctly. ([Bug#48005](#))
- `ndb_config --xml --configinfo` now indicates that parameters belonging in the `[SCI]`, `[SCI DEFAULT]`, `[SHM]`, and `[SHM DEFAULT]` sections of the `config.ini` file are deprecated or experimental, as appropriate. ([Bug#47365](#))
- `NDB` stores blob column data in a separate, hidden table that is not accessible from MySQL. If this table was missing for some reason (such as accidental deletion of the file corresponding to the hidden table) when making a MySQL Cluster native backup, `ndb_restore` crashed when attempting to restore the backup. Now in such cases, `ndb_restore` fails with the error message `TABLE TABLE_NAME HAS BLOB COLUMN (COLUMN_NAME) WITH MISSING PARTS TABLE IN BACKUP` instead. ([Bug#47289](#))
- `DROP DATABASE` failed when there were stale temporary `NDB` tables in the database. This situation could occur if `mysqld` crashed during execution of a `DROP TABLE` statement after the table definition had been removed from `NDBCLUSTER` but before the corresponding `.ndb` file had been removed from the crashed SQL node's data directory. Now, when `mysqld` executes `DROP DATABASE`, it checks for these files and removes them if there are no corresponding table definitions for them found in `NDBCLUSTER`. ([Bug#44529](#))
- Creating an `NDB` table with an excessive number of large `BIT` columns caused the cluster to fail. Now, an attempt to create such a table is rejected with error 791 (`TOO MANY TOTAL BITS IN BITFIELDS`). ([Bug#42046](#))

See also [Bug#42047](#).

- When a long-running transaction lasting long enough to cause Error 410 (`REDO LOG FILES OVERLOADED`) was later committed or rolled back, it could happen that `NDBCLUSTER` was not able to release the space used for the REDO log, so that the error condition persisted indefinitely.

The most likely cause of such transactions is a bug in the application using MySQL Cluster. This fix should handle most cases where this might occur. ([Bug#36500](#))

- Deprecation and usage information obtained from `ndb_config --configinfo` regarding the `PortNumber` and

`ServerPort` configuration parameters was improved. ([Bug#24584](#))

- **Disk Data:** When running a write-intensive workload with a very large disk page buffer cache, CPU usage approached 100% during a local checkpoint of a cluster containing Disk Data tables. ([Bug#49532](#))
- **Disk Data:** Repeatedly creating and then dropping Disk Data tables could eventually lead to data node failures. ([Bug#45794](#), [Bug#48910](#))
- **Disk Data:** When the `FileSystemPathUndoFiles` configuration parameter was set to an non-existent path, the data nodes shut down with the generic error code 2341 (`INTERNAL PROGRAM ERROR`). Now in such cases, the error reported is error 2815 (`FILE NOT FOUND`).
- **Cluster API:** When a DML operation failed due to a uniqueness violation on an `NDB` table having more than one unique index, it was difficult to determine which constraint caused the failure; it was necessary to obtain an `NdbError` object, then decode its `details` property, which in could lead to memory management issues in application code.

To help solve this problem, a new API method `Ndb::getNdbErrorDetail()` is added, providing a well-formatted string containing more precise information about the index that caused the unique constraint violation. The following additional changes are also made in the NDB API:

- Use of `NdbError.details` is now deprecated in favor of the new method.
- The `NdbDictionary::listObjects()` method has been modified to provide more information.

For more information, see `Ndb::getNdbErrorDetail()`, [The NdbError Structure](#), and `Dictionary::listObjects()`. ([Bug#48851](#))

- **Cluster API:** When using blobs, calling `getBlobHandle()` requires the full key to have been set using `equal()`, because `getBlobHandle()` must access the key for adding blob table operations. However, if `getBlobHandle()` was called without first setting all parts of the primary key, the application using it crashed. Now, an appropriate error code is returned instead. ([Bug#28116](#), [Bug#48973](#))

## Changes in MySQL Cluster NDB 6.3.28a (5.1.39-ndb-6.3.28a)

Bugs fixed:

- When the combined length of all names of tables using the `NDB` storage engine was greater than or equal to 1024 bytes, issuing the `START BACKUP` command in the `ndb_mgm` client caused the cluster to crash. ([Bug#48531](#))

## Changes in MySQL Cluster NDB 6.3.27 (5.1.37-ndb-6.3.27)

Functionality added or changed:

- **Disk Data:** Two new columns have been added to the output of `ndb_desc` to make it possible to determine how much of the disk space allocated to a given table or fragment remains free. (This information is not available from the `INFORMATION_SCHEMA.FILES` table, since the `FILES` table applies only to Disk Data files.) For more information, see [Section 17.4.9, “ndb\\_desc — Describe NDB Tables”](#). ([Bug#47131](#))

Bugs fixed:

- `mysqld` allocated an excessively large buffer for handling `BLOB` values due to overestimating their size. (For each row, enough space was allocated to accommodate *every* `BLOB` or `TEXT` column value in the result set.) This could adversely affect performance when using tables containing `BLOB` or `TEXT` columns; in a few extreme cases, this issue could also cause the host system to run out of memory unexpectedly. ([Bug#47574](#))

See also [Bug#47572](#), [Bug#47573](#).

- `NDBCCLUSTER` uses a dynamically-allocated buffer to store `BLOB` or `TEXT` column data that is read from rows in MySQL Cluster tables.

When an instance of the `NDBCCLUSTER` table handler was recycled (this can happen due to table definition cache pressure or to operations such as `FLUSH TABLES` or `ALTER TABLE`), if the last row read contained blobs of zero length, the buffer was not freed, even though the reference to it was lost. This resulted in a memory leak.

For example, consider the table defined and populated as shown here:

```
CREATE TABLE t (a INT PRIMARY KEY, b LONGTEXT) ENGINE=NDB;
INSERT INTO t VALUES (1, REPEAT('F', 20000));
INSERT INTO t VALUES (2, '');
```

Now execute repeatedly a `SELECT` on this table, such that the zero-length `LONGTEXT` row is last, followed by a `FLUSH TABLES` statement (which forces the handler object to be re-used), as shown here:

```
SELECT a, length(b) FROM b1 ORDER BY a;
FLUSH TABLES;
```

Prior to the fix, this resulted in a memory leak proportional to the size of the stored `LONGTEXT` value each time these two statements were executed. ([Bug#47573](#))

See also [Bug#47572](#), [Bug#47574](#).

- Large transactions involving joins between tables containing `BLOB` columns used excessive memory. ([Bug#47572](#))

See also [Bug#47573](#), [Bug#47574](#).

- A variable was left uninitialized while a data node copied data from its peers as part of its startup routine; if the starting node died during this phase, this could lead a crash of the cluster when the node was later restarted. ([Bug#47505](#))
- When a data node restarts, it first runs the redo log until reaching the latest restorable global checkpoint; after this it scans the remainder of the redo log file, searching for entries that should be invalidated so they are not used in any subsequent restarts. (It is possible, for example, if restoring GCI number 25, that there might be entries belonging to GCI 26 in the redo log.) However, under certain rare conditions, during the invalidation process, the redo log files themselves were not always closed while scanning ahead in the redo log. In rare cases, this could lead to `MaxNoOfOpenFiles` being exceeded, causing the data node to crash. ([Bug#47171](#))
- For very large values of `MaxNoOfTables` + `MaxNoOfAttributes`, the calculation for `StringMemory` could overflow when creating large numbers of tables, leading to NDB error 773 (OUT OF STRING MEMORY, PLEASE MODIFY STRINGMEMORY CONFIG PARAMETER), even when `StringMemory` was set to 100 (100 percent). ([Bug#47170](#))
- The default value for the `StringMemory` configuration parameter, unlike other MySQL Cluster configuration parameters, was not set in `ndb/src/mgmsrv/ConfigInfo.cpp`. ([Bug#47166](#))
- Signals from a failed API node could be received after an `API_FAILREQ` signal (see [Operations and Signals](#)) has been received from that node, which could result in invalid states for processing subsequent signals. Now, all pending signals from a failing API node are processed before any `API_FAILREQ` signal is received. ([Bug#47039](#))

See also [Bug#44607](#).

- Using triggers on `NDB` tables caused `ndb_autoincrement_prefetch_sz` to be treated as having the NDB kernel's internal default value (32) and the value for this variable as set on the cluster's SQL nodes to be ignored. ([Bug#46712](#))
- Running an `ALTER TABLE` statement while an NDB backup was in progress caused `mysqld` to crash. ([Bug#44695](#))
- When performing auto-discovery of tables on individual SQL nodes, `NDBCLUSTER` attempted to overwrite existing `MyISAM.frm` files and corrupted them.

**Workaround.** In the `mysql` client, create a new table (`t2`) with same definition as the corrupted table (`t1`). Use your system shell or file manager to rename the old `.MYD` file to the new file name (for example, `mv t1.MYD t2.MYD`). In the `mysql` client, repair the new table, drop the old one, and rename the new table using the old file name (for example, `RENAME TABLE t2 TO t1`).

([Bug#42614](#))

- Running `ndb_restore` with the `--print` or `--print_log` option could cause it to crash. ([Bug#40428](#), [Bug#33040](#))
- An insert on an `NDB` table was not always flushed properly before performing a scan. One way in which this issue could manifest was that `LAST_INSERT_ID()` sometimes failed to return correct values when using a trigger on an `NDB` table. ([Bug#38034](#))
- When a data node received a `TAKE_OVERTCCONF` signal from the master before that node had received a `NODE_FAILREP`, a race condition could in theory result. ([Bug#37688](#))

See also [Bug#25364](#), [Bug#28717](#).

- Some joins on large `NDB` tables having `TEXT` or `BLOB` columns could cause `mysqld` processes to leak memory. The joins did

not need to reference the `TEXT` or `BLOB` columns directly for this issue to occur. ([Bug#36701](#))

- On Mac OS X 10.5, commands entered in the management client failed and sometimes caused the client to hang, although management client commands invoked using the `--execute` (or `-e`) option from the system shell worked normally.

For example, the following command failed with an error and hung until killed manually, as shown here:

```
ndb_mgm> SHOW
WARNING, EVENT THREAD STARTUP FAILED, DEGRADED PRINTOUTS AS RESULT, ERNO=36
^C
```

However, the same management client command, invoked from the system shell as shown here, worked correctly:

```
shell> ndb_mgm -e "SHOW"
```

([Bug#35751](#))

See also [Bug#34438](#).

- **Disk Data:** Calculation of free space for Disk Data table fragments was sometimes done incorrectly. This could lead to unnecessary allocation of new extents even when sufficient space was available in existing ones for inserted data. In some cases, this might also lead to crashes when restarting data nodes.

### Note

This miscalculation was not reflected in the contents of the `INFORMATION_SCHEMA.FILES` table, as it applied to extents allocated to a fragment, and not to a file.

([Bug#47072](#))

- **Cluster API:** In some circumstances, if an API node encountered a data node failure between the creation of a transaction and the start of a scan using that transaction, then any subsequent calls to `startTransaction()` and `closeTransaction()` could cause the same transaction to be started and closed repeatedly. ([Bug#47329](#))
- **Cluster API:** Performing multiple operations using the same primary key within the same `NdbTransaction::execute()` call could lead to a data node crash.

### Note

This fix does not make change the fact that performing multiple operations using the same primary key within the same `execute()` is not supported; because there is no way to determine the order of such operations, the result of such combined operations remains undefined.

([Bug#44065](#))

See also [Bug#44015](#).

## Changes in MySQL Cluster NDB 6.3.26 (5.1.35-ndb-6.3.26)

Functionality added or changed:

- On Solaris platforms, the MySQL Cluster management server and NDB API applications now use `CLOCK_REALTIME` as the default clock. ([Bug#46183](#))
- A new option `--exclude-missing-columns` has been added for the `ndb_restore` program. In the event that any tables in the database or databases being restored to have fewer columns than the same-named tables in the backup, the extra columns in the backup's version of the tables are ignored. For more information, see [Section 17.4.17, “ndb\\_restore — Restore a MySQL Cluster Backup”](#). ([Bug#43139](#))
- 

### Note

This issue, originally resolved in MySQL 5.1.16, re-occurred due to a later (unrelated) change. The fix has been re-applied.

([Bug#25984](#))

Bugs fixed:

- Restarting the cluster following a local checkpoint and an online `ALTER TABLE` on a non-empty table caused data nodes to crash. ([Bug#46651](#))
- Full table scans failed to execute when the cluster contained more than 21 table fragments.

### Note

The number of table fragments in the cluster can be calculated as the number of data nodes, times 8 (that is, times the value of the internal constant `MAX_FRAG_PER_NODE`), divided by the number of replicas. Thus, when `NoOfReplicas = 1` at least 3 data nodes were required to trigger this issue, and when `NoOfReplicas = 2` at least 4 data nodes were required to do so.

([Bug#46490](#))

- Killing MySQL Cluster nodes immediately following a local checkpoint could lead to a crash of the cluster when later attempting to perform a system restart.

The exact sequence of events causing this issue was as follows:

1. Local checkpoint occurs.
2. Immediately following the LCP, kill the master data node.
3. Kill the remaining data nodes within a few seconds of killing the master.
4. Attempt to restart the cluster.

([Bug#46412](#))

- Ending a line in the `config.ini` file with an extra semicolon character (;) caused reading the file to fail with a parsing error. ([Bug#46242](#))
- When combining an index scan and a delete with a primary key delete, the index scan and delete failed to initialize a flag properly. This could in rare circumstances cause a data node to crash. ([Bug#46069](#))
- `OPTIMIZE TABLE` on an `NDB` table could in some cases cause SQL and data nodes to crash. This issue was observed with both `ndbd` and `ndbmtd`. ([Bug#45971](#))
- The `AutoReconnect` configuration parameter for API nodes (including SQL nodes) has been added. This is intended to prevent API nodes from re-using allocated node IDs during cluster restarts. For more information, see [Section 17.3.2.7, “Defining SQL and Other API Nodes in a MySQL Cluster”](#).

This fix also introduces two new methods of the `Ndb_cluster_connection` class in the NDB API. For more information, see `Ndb_cluster_connection::set_auto_reconnect()`, and `Ndb_cluster_connection::get_auto_reconnect()`. ([Bug#45921](#))

- The signals used by `ndb_restore` to send progress information about backups to the cluster log accessed the cluster transporter without using any locks. Because of this, it was theoretically possible that these signals could be interfered with by heartbeat signals if both were sent at the same time, causing the `ndb_restore` messages to be corrupted. ([Bug#45646](#))
- Problems could arise when using `VARCHAR` columns whose size was greater than 341 characters and which used the `utf8_unicode_ci` collation. In some cases, this combination of conditions could cause certain queries and `OPTIMIZE TABLE` statements to crash `mysqld`. ([Bug#45053](#))
- An internal NDB API buffer was not properly initialized. ([Bug#44977](#))
- When a data node had written its GCI marker to the first page of a megabyte, and that node was later killed during restart after having processed that page (marker) but before completing a LCP, the data node could fail with filesystem errors. ([Bug#44952](#))

See also [Bug#42564](#), [Bug#44291](#).

- The warning message `POSSIBLE BUG IN DBDIH::EXECBLOCK_COMMIT_ORD ...` could sometimes appear in the cluster log. This warning is obsolete, and has been removed. ([Bug#44563](#))
- In some cases, `OPTIMIZE TABLE` on an `NDB` table did not free any `DataMemory`. ([Bug#43683](#))
- If the cluster crashed during the execution of a `CREATE LOGFILE GROUP` statement, the cluster could not be restarted afterward. ([Bug#36702](#))

See also [Bug#34102](#).

- **Disk Data: Partitioning:** An `NDBCLUSTER` table created with a very large value for the `MAX_ROWS` option could—if this table was dropped and a new table with fewer partitions, but having the same table ID, was created—cause `ndbd` to crash when performing a system restart. This was because the server attempted to examine each partition whether or not it actually existed. ([Bug#45154](#))
- **Disk Data:** If the value set in the `config.ini` file for `FileSystemPathDD`, `FileSystemPathDataFiles`, or `FileSystemPathUndoFiles` was identical to the value set for `FileSystemPath`, that parameter was ignored when starting the data node with `--initial` option. As a result, the Disk Data files in the corresponding directory were not removed when performing an initial start of the affected data node or data nodes. ([Bug#46243](#))
- **Disk Data:** During a checkpoint, restore points are created for both the on-disk and in-memory parts of a Disk Data table. Under certain rare conditions, the in-memory restore point could include or exclude a row that should have been in the snapshot. This would later lead to a crash during or following recovery. ([Bug#41915](#))

See also [Bug#47832](#).

### Changes in MySQL Cluster NDB 6.3.25 (5.1.34-ndb-6.3.25)

Functionality added or changed:

- Two new server status variables `Ndb_scan_count` and `Ndb_pruned_scan_count` have been introduced. `Ndb_scan_count` gives the number of scans executed since the cluster was last started. `Ndb_pruned_scan_count` gives the number of scans for which `NDBCLUSTER` was able to use partition pruning. Together, these variables can be used to help determine in the MySQL server whether table scans are pruned by `NDBCLUSTER`. ([Bug#44153](#))
- The `ndb_config` utility program can now provide an offline dump of all MySQL Cluster configuration parameters including information such as default and permitted values, brief description, and applicable section of the `config.ini` file. A dump in text format is produced when running `ndb_config` with the new `--configinfo` option, and in XML format when the options `--configinfo --xml` are used together. For more information and examples, see [Section 17.4.6, “ndb\\_config—Extract MySQL Cluster Configuration Information”](#).

Bugs fixed:

- **Important Change: Partitioning:** User-defined partitioning of an `NDBCLUSTER` table without any primary key sometimes failed, and could cause `mysqld` to crash.

Now, if you wish to create an `NDBCLUSTER` table with user-defined partitioning, the table must have an explicit primary key, and all columns listed in the partitioning expression must be part of the primary key. The hidden primary key used by the `NDBCLUSTER` storage engine is not sufficient for this purpose. However, if the list of columns is empty (that is, the table is defined using `PARTITION BY [LINEAR] KEY()`), then no explicit primary key is required.

This change does not effect the partitioning of tables using any storage engine other than `NDBCLUSTER`. ([Bug#40709](#))

- **Important Change:** Previously, the configuration parameter `NoOfReplicas` had no default value. Now the default for `NoOfReplicas` is 2, which is the recommended value in most settings. ([Bug#44746](#))
- **Packaging:** The `pkg` installer for MySQL Cluster on Solaris did not perform a complete installation due to an invalid directory reference in the post-install script. ([Bug#41998](#))
- When `ndb_config` could not find the file referenced by the `--config-file` option, it tried to read `my.cnf` instead, then failed with a misleading error message. ([Bug#44846](#))
- When a data node was down so long that its most recent local checkpoint depended on a global checkpoint that was no longer restorable, it was possible for it to be unable to use optimized node recovery when being restarted later. ([Bug#44844](#))

See also [Bug#26913](#).

- `ndb_config --xml` did not output any entries for the `HostName` parameter. In addition, the default listed for `MaxNoOfFiles` was outside the permitted range of values. ([Bug#44749](#))

See also [Bug#44685](#), [Bug#44746](#).

- The output of `ndb_config --xml` did not provide information about all sections of the configuration file. ([Bug#44685](#))

See also [Bug#44746](#), [Bug#44749](#).

- Inspection of the code revealed that several assignment operators (`=`) were used in place of comparison operators (`==`) in `Db-`

`dihMain.cpp`. ([Bug#44567](#))

See also [Bug#44570](#).

- It was possible for NDB API applications to insert corrupt data into the database, which could subsequently lead to data node crashes. Now, stricter checking is enforced on input data for inserts and updates. ([Bug#44132](#))
- `ndb_restore` failed when trying to restore data on a big-endian machine from a backup file created on a little-endian machine. ([Bug#44069](#))
- The file `ndberror.c` contained a C++-style comment, which caused builds to fail with some C compilers. ([Bug#44036](#))
- When trying to use a data node with an older version of the management server, the data node crashed on startup. ([Bug#43699](#))
- In some cases, data node restarts during a system restart could fail due to insufficient redo log space. ([Bug#43156](#))
- `NDBCLUSTER` did not build correctly on Solaris 9 platforms. ([Bug#39080](#))

See also [Bug#39036](#), [Bug#39038](#).

- `ndb_restore --print_data` did not handle `DECIMAL` columns correctly. ([Bug#37171](#))
- The output of `ndbd --help` did not provide clear information about the program's `--initial` and `--initial-start` options. ([Bug#28905](#))
- It was theoretically possible for the value of a nonexistent column to be read as `NULL`, rather than causing an error. ([Bug#27843](#))
- **Disk Data:** This fix supercedes and improves on an earlier fix made for this bug in MySQL 5.1.18. ([Bug#24521](#))

## Changes in MySQL Cluster NDB 6.3.24 (5.1.32-ndb-6.3.24)

Bugs fixed:

- **Cluster Replication:** If data node failed during an event creation operation, there was a slight risk that a surviving data node could send an invalid table reference back to NDB, causing the operation to fail with a false Error 723 (`NO SUCH TABLE`). This could take place when a data node failed as a `mysqld` process was setting up MySQL Cluster Replication. ([Bug#43754](#))
- **Cluster API:** Partition pruning did not work correctly for queries involving multiple range scans.

As part of the fix for this issue, several improvements have been made in the NDB API, including the addition of a new `NdbScanOperation::getPruned()` method, a new variant of `NdbIndexScanOperation::setBound()`, and a new `Ndb::PartitionSpec` data structure. For more information about these changes, see `NdbScanOperation::getPruned()`, `NdbIndexScanOperation::setBound`, and [The PartitionSpec Structure](#). ([Bug#37934](#))

- **Cluster API:** Partition pruning did not work correctly for queries involving multiple range scans.

As part of the fix for this issue, several improvements have been made in the NDB API, including the addition of a new `NdbScanOperation::getPruned()` method, a new variant of `NdbIndexScanOperation::setBound()`, and a new `Ndb::PartitionSpec` data structure. For more information about these changes, see `NdbScanOperation::getPruned()`, `NdbIndexScanOperation::setBound`, and [The PartitionSpec Structure](#). ([Bug#37934](#))

- `TransactionDeadlockDetectionTimeout` values less than 100 were treated as 100. This could cause scans to time out unexpectedly. ([Bug#44099](#))
- A race condition could occur when a data node failed to restart just before being included in the next global checkpoint. This could cause other data nodes to fail. ([Bug#43888](#))
- `TimeBetweenLocalCheckpoints` was measured from the end of one local checkpoint to the beginning of the next, rather than from the beginning of one LCP to the beginning of the next. This meant that the time spent performing the LCP was not taken into account when determining the `TimeBetweenLocalCheckpoints` interval, so that LCPs were not started often enough, possibly causing data nodes to run out of redo log space prematurely. ([Bug#43567](#))
- Using indexes containing variable-sized columns could lead to internal errors when the indexes were being built. ([Bug#43226](#))
- When a data node process had been killed after allocating a node ID, but before making contact with any other data node processes, it was not possible to restart it due to a node ID allocation failure.

This issue could effect either `ndbd` or `ndbmt` processes. ([Bug#43224](#))

This regression was introduced by [Bug#42973](#).

- Some queries using combinations of logical and comparison operators on an indexed column in the `WHERE` clause could fail with the error `GOT_ERROR 4541 'INDEXBOUND HAS NO BOUND INFORMATION' FROM NDBCCLUSTER.` ([Bug#42857](#))
- `ndb_restore` crashed when trying to restore a backup made to a MySQL Cluster running on a platform having different endianness from that on which the original backup was taken. ([Bug#39540](#))
- When aborting an operation involving both an insert and a delete, the insert and delete were aborted separately. This was because the transaction coordinator did not know that the operations affected on same row, and, in the case of a committed-read (tuple or index) scan, the abort of the insert was performed first, then the row was examined after the insert was aborted but before the delete was aborted. In some cases, this would leave the row in a inconsistent state. This could occur when a local checkpoint was performed during a backup. This issue did not affect primary key operations or scans that used locks (these are serialized).

After this fix, for ordered indexes, all operations that follow the operation to be aborted are now also aborted.

- **Disk Data:** When a log file group had an undo log file whose size was too small, restarting data nodes failed with `READ UNDERFLOW` errors.

As a result of this fix, the minimum permitted `INITIAL_SIZE` for an undo log file is now `1M` (1 megabyte). ([Bug#29574](#))

- **Cluster API:** If the largest offset of a `RecordSpecification` used for an `NdbRecord` object was for the `NULL` bits (and thus not a column), this offset was not taken into account when calculating the size used for the `RecordSpecification`. This meant that the space for the `NULL` bits could be overwritten by key or other information. ([Bug#43891](#))
- **Cluster API:** `BIT` columns created using the native NDB API format that were not created as nullable could still sometimes be overwritten, or cause other columns to be overwritten.

This issue did not effect tables having `BIT` columns created using the mysqld format (always used by MySQL Cluster SQL nodes). ([Bug#43802](#))

- **Cluster API:** The default `NdbRecord` structures created by `NdbDictionary` could have overlapping null bits and data fields. ([Bug#43590](#))
- **Cluster API:** When performing insert or write operations, `NdbRecord` permits key columns to be specified in both the key record and in the attribute record. Only one key column value for each key column should be sent to the NDB kernel, but this was not guaranteed. This is now ensured as follows: For insert and write operations, key column values are taken from the key record; for scan takeover update operations, key column values are taken from the attribute record. ([Bug#42238](#))
- **Cluster API:** Ordered index scans using `NdbRecord` formerly expressed a `BoundEQ` range as separate lower and upper bounds, resulting in 2 copies of the column values being sent to the NDB kernel.

Now, when a range is specified by `NdbScanOperation::setBound()`, the passed pointers, key lengths, and inclusive bits are compared, and only one copy of the equal key columns is sent to the kernel. This makes such operations more efficient, as half the amount of `KeyInfo` is now sent for a `BoundEQ` range as before. ([Bug#38793](#))

## Changes in MySQL Cluster NDB 6.3.23 (5.1.32-ndb-6.3.23)

Functionality added or changed:

- A new data node configuration parameter `MaxLCPStartDelay` has been introduced to facilitate parallel node recovery by causing a local checkpoint to be delayed while recovering nodes are synchronizing data dictionaries and other meta-information. For more information about this parameter, see [Section 17.3.2.6, “Defining MySQL Cluster Data Nodes”](#). ([Bug#43053](#))

Bugs fixed:

- **Performance:** Updates of the `SYSTAB_0` system table to obtain a unique identifier did not use transaction hints for tables having no primary key. In such cases the NDB kernel used a cache size of 1. This meant that each insert into a table not having a primary key required an update of the corresponding `SYSTAB_0` entry, creating a potential performance bottleneck.

With this fix, inserts on `NDB` tables without primary keys can be under some conditions be performed up to 100% faster than previously. ([Bug#39268](#))

- **Packaging:** Packages for MySQL Cluster were missing the `libndbclient.so` and `libndbclient.a` files. ([Bug#42278](#))

- **Partitioning:** Executing `ALTER TABLE ... REORGANIZE PARTITION` on an `NDBCCLUSTER` table having only one partition caused `mysqld` to crash. ([Bug#41945](#))

See also [Bug#40389](#).

- Backup IDs greater than  $2^{31}$  were not handled correctly, causing negative values to be used in backup directory names and printouts. ([Bug#43042](#))
- When using `ndbmtd`, NDB kernel threads could hang while trying to start the data nodes with `LockPagesInMainMemory` set to 1. ([Bug#43021](#))
- When using multiple management servers and starting several API nodes (possibly including one or more SQL nodes) whose connectstrings listed the management servers in different order, it was possible for 2 API nodes to be assigned the same node ID. When this happened it was possible for an API node not to get fully connected, consequently producing a number of errors whose cause was not easily recognizable. ([Bug#42973](#))
- `ndb_error_reporter` worked correctly only with GNU `tar`. (With other versions of `tar`, it produced empty archives.) ([Bug#42753](#))
- Triggers on `NDBCCLUSTER` tables caused such tables to become locked. ([Bug#42751](#))

See also [Bug#16229](#), [Bug#18135](#).

- Given a MySQL Cluster containing no data (that is, whose data nodes had all been started using `--initial`, and into which no data had yet been imported) and having an empty backup directory, executing `START BACKUP` with a user-specified backup ID caused the data nodes to crash. ([Bug#41031](#))
- In some cases, `NDB` did not check correctly whether tables had changed before trying to use the query cache. This could result in a crash of the debug MySQL server. ([Bug#40464](#))
- **Disk Data:** It was not possible to add an in-memory column online to a table that used a table-level or column-level `STORAGE DISK` option. The same issue prevented `ALTER ONLINE TABLE ... REORGANIZE PARTITION` from working on Disk Data tables. ([Bug#42549](#))
- **Disk Data:** Creating a Disk Data tablespace with a very large extent size caused the data nodes to fail. The issue was observed when using extent sizes of 100 MB and larger. ([Bug#39096](#))
- **Disk Data:** Trying to execute a `CREATE LOGFILE GROUP` statement using a value greater than `150M` for `UNDO_BUFFER_SIZE` caused data nodes to crash.

As a result of this fix, the upper limit for `UNDO_BUFFER_SIZE` is now `600M`; attempting to set a higher value now fails gracefully with an error. ([Bug#34102](#))

See also [Bug#36702](#).

- **Disk Data:** When attempting to create a tablespace that already existed, the error message returned was `TABLE OR INDEX WITH GIVEN NAME ALREADY EXISTS`. ([Bug#32662](#))
- **Disk Data:** Using a path or filename longer than 128 characters for Disk Data undo log files and tablespace data files caused a number of issues, including failures of `CREATE LOGFILE GROUP`, `ALTER LOGFILE GROUP`, `CREATE TABLESPACE`, and `ALTER TABLESPACE` statements, as well as crashes of management nodes and data nodes.

With this fix, the maximum length for path and file names used for Disk Data undo log files and tablespace data files is now the same as the maximum for the operating system. ([Bug#31769](#), [Bug#31770](#), [Bug#31772](#))

- **Disk Data:** Attempting to perform a system restart of the cluster where there existed a logfile group without and undo log files caused the data nodes to crash.

### Note

While issuing a `CREATE LOGFILE GROUP` statement without an `ADD UNDOFILE` option fails with an error in the MySQL server, this situation could arise if an SQL node failed during the execution of a valid `CREATE LOGFILE GROUP` statement; it is also possible to create a logfile group without any undo log files using the NDB API.

([Bug#17614](#))

- **Cluster API:** Some error messages from `ndb_mgmd` contained newline (`\n`) characters. This could break the MGM API protocol, which uses the newline as a line separator. ([Bug#43104](#))
- **Cluster API:** When using an ordered index scan without putting all key columns in the read mask, this invalid use of the NDB API went undetected, which resulted in the use of uninitialized memory. ([Bug#42591](#))

## Changes in MySQL Cluster NDB 6.3.22 (5.1.31-ndb-6.3.22)

Functionality added or changed:

- New options are introduced for `ndb_restore` for determining which tables or databases should be restored:
  - `--include-tables` and `--include-databases` can be used to restore specific tables or databases.
  - `--exclude-tables` and `--exclude-databases` can be used to exclude the specified tables or databases from being restored.

For more information about these options, see [Section 17.4.17, “`ndb\_restore` — Restore a MySQL Cluster Backup”](#). ([Bug#40429](#))

Bugs fixed:

- When performing more than 32 index or tuple scans on a single fragment, the scans could be left hanging. This caused unnecessary timeouts, and in addition could possibly lead to a hang of an LCP. ([Bug#42559](#))
- A data node failure that occurred between calls to `NdbIndexScanOperation::readTuples(SF_OrderBy)` and `NdbTransaction::Execute()` was not correctly handled; a subsequent call to `nextResult()` caused a null pointer to be dereferenced, leading to a segfault in `mysqld`. ([Bug#42545](#))
- Issuing `SHOW GLOBAL STATUS LIKE 'NDB%'` before `mysqld` had connected to the cluster caused a segmentation fault. ([Bug#42458](#))
- Data node failures that occurred before all data nodes had connected to the cluster were not handled correctly, leading to additional data node failures. ([Bug#42422](#))
- When a cluster backup failed with Error 1304 (Node `node_id1`: Backup request from `node_id2` failed to start), no clear reason for the failure was provided.

As part of this fix, MySQL Cluster now retries backups in the event of sequence errors. ([Bug#42354](#))

See also [Bug#22698](#).

- Issuing `SHOW ENGINE NDBCLUSTER STATUS` on an SQL node before the management server had connected to the cluster caused `mysqld` to crash. ([Bug#42264](#))

## Changes in MySQL Cluster NDB 6.3.21 (5.1.31-ndb-6.3.21)

Functionality added or changed:

- **Important Change:** Formerly, when the management server failed to create a transporter for a data node connection, `net_write_timeout` seconds elapsed before the data node was actually permitted to disconnect. Now in such cases the disconnection occurs immediately. ([Bug#41965](#))

See also [Bug#41713](#).

- It is now possible while in Single User Mode to restart all data nodes using `ALL RESTART` in the management client. Restarting of individual nodes while in Single User Mode remains not permitted. ([Bug#31056](#))
- Formerly, when using MySQL Cluster Replication, records for “empty” epochs—that is, epochs in which no changes to `NDBCLUSTER` data or tables took place—were inserted into the `ndb_apply_status` and `ndb_binlog_index` tables on the slave even when `--log-slave-updates` was disabled. Beginning with MySQL Cluster NDB 6.2.16 and MySQL Cluster NDB 6.3.13 this was changed so that these “empty” epochs were no longer logged. However, it is now possible to re-enable the older behavior (and cause “empty” epochs to be logged) by using the `--ndb-log-empty-epochs` option. For more information, see [Section 16.1.3.3, “Replication Slave Options and Variables”](#).

See also [Bug#37472](#).

Bugs fixed:

- A maximum of 11 `TUP` scans were permitted in parallel. ([Bug#42084](#))

- Trying to execute an `ALTER ONLINE TABLE ... ADD COLUMN` statement while inserting rows into the table caused `mysqld` to crash. ([Bug#41905](#))
- If the master node failed during a global checkpoint, it was possible in some circumstances for the new master to use an incorrect value for the global checkpoint index. This could occur only when the cluster used more than one node group. ([Bug#41469](#))
- API nodes disconnected too aggressively from cluster when data nodes were being restarted. This could sometimes lead to the API node being unable to access the cluster at all during a rolling restart. ([Bug#41462](#))
- It was not possible to perform online upgrades from a MySQL Cluster NDB 6.2 release to MySQL Cluster NDB 6.3.8 or a later MySQL Cluster NDB 6.3 release. ([Bug#41435](#))
- Cluster log files were opened twice by internal log-handling code, resulting in a resource leak. ([Bug#41362](#))
- An abort path in the `DBLQH` kernel block failed to release a commit acknowledgment marker. This meant that, during node failure handling, the local query handler could be added multiple times to the marker record which could lead to additional node failures due to an array overflow. ([Bug#41296](#))
- During node failure handling (of a data node other than the master), there was a chance that the master was waiting for a `GCP_NODEFINISHED` signal from the failed node after having received it from all other data nodes. If this occurred while the failed node had a transaction that was still being committed in the current epoch, the master node could crash in the `DBTC` kernel block when discovering that a transaction actually belonged to an epoch which was already completed. ([Bug#41295](#))
- Issuing `EXIT` in the management client sometimes caused the client to hang. ([Bug#40922](#))
- In the event that a MySQL Cluster backup failed due to file permissions issues, conflicting reports were issued in the management client. ([Bug#34526](#))
- If all data nodes were shut down, MySQL clients were unable to access `NDBCLUSTER` tables and data even after the data nodes were restarted, unless the MySQL clients themselves were restarted. ([Bug#33626](#))
- **Disk Data:** Starting a cluster under load such that Disk Data tables used most of the undo buffer could cause data node failures. The fix for this bug also corrected an issue in the `LGMAN` kernel block where the amount of free space left in the undo buffer was miscalculated, causing buffer overruns. This could cause records in the buffer to be overwritten, leading to problems when restarting data nodes. ([Bug#28077](#))
- **Cluster API:** `mgmapi.h` contained constructs which only worked in C++, but not in C. ([Bug#27004](#))

### Changes in MySQL Cluster NDB 6.3.20 (5.1.30-ndb-6.3.20)

Functionality added or changed:

- **Cluster API:** Two new `Ndb_cluster_connection` methods have been added to help in diagnosing problems with NDB API client connections. The `get_latest_error()` method tells whether or not the latest connection attempt succeeded; if the attempt failed, `get_latest_error_msg()` provides an error message giving the reason. For more information, see `Ndb_cluster_connection::get_latest_error()`, and `Ndb_cluster_connection::get_latest_error_msg()`.

Bugs fixed:

- If a transaction was aborted during the handling of a data node failure, this could lead to the later handling of an API node failure not being completed. ([Bug#41214](#))
- Issuing `SHOW TABLES` repeatedly could cause `NDBCLUSTER` tables to be dropped. ([Bug#40854](#))
- Statements of the form `UPDATE ... ORDER BY ... LIMIT` run against `NDBCLUSTER` tables failed to update all matching rows, or failed with the error `CAN'T FIND RECORD IN 'TABLE_NAME'`. ([Bug#40081](#))
- Start phase reporting was inconsistent between the management client and the cluster log. ([Bug#39667](#))
- Status messages shown in the management client when restarting a management node were inappropriate and misleading. Now, when restarting a management node, the messages displayed are as follows, where `node_id` is the management node's node ID:

```
ndb_mgm> node_id RESTART
Shutting down MGM node node_id for restart
```

```
Node node_id is being restarted
ndb_mgm>
```

(Bug#29275)

- **Disk Data:** This improves on a previous fix for this issue that was made in MySQL Cluster 6.3.8. ([Bug#37116](#))  
See also [Bug#29186](#).
- **Cluster API:** When creating a scan using an `NdbScanFilter` object, it was possible to specify conditions against a `BIT` column, but the correct rows were not returned when the scan was executed.

As part of this fix, 4 new comparison operators have been implemented for use with scans on `BIT` columns:

- `COL_AND_MASK_EQ_MASK`
- `COL_AND_MASK_NE_MASK`
- `COL_AND_MASK_EQ_ZERO`
- `COL_AND_MASK_NE_ZERO`

For more information about these operators, see [The NdbScanFilter::BinaryCondition Type](#).

Equivalent methods are now also defined for `NdbInterpretedCode`; for more information, see [NdbInterpretedCode Bitwise Comparison Operations](#). ([Bug#40535](#))

### Changes in MySQL Cluster NDB 6.3.19 (5.1.29-ndb-6.3.19)

Functionality added or changed:

- **Cluster API: Important Change:** MGM API applications exited without raising any errors if the connection to the management server was lost. The fix for this issue includes two changes:
  1. The MGM API now provides its own `SIGPIPE` handler to catch the “broken pipe” error that occurs when writing to a closed or reset socket. This means that MGM API now behaves the same as NDB API in this regard.
  2. A new function `ndb_mgm_set_ignore_sigpipe()` has been added to the MGM API. This function makes it possible to bypass the `SIGPIPE` handler provided by the MGM API.  
([Bug#40498](#))
- When performing an initial start of a data node, fragment log files were always created sparsely—that is, not all bytes were written. Now it is possible to override this behavior using the new `InitFragmentLogFile` configuration parameter.  
([Bug#40847](#))

Bugs fixed:

- **Cluster API:** Failed operations on `BLOB` and `TEXT` columns were not always reported correctly to the originating SQL node. Such errors were sometimes reported as being due to timeouts, when the actual problem was a transporter overload due to insufficient buffer space. ([Bug#39867](#), [Bug#39879](#))
- **Cluster API:** Failed operations on `BLOB` and `TEXT` columns were not always reported correctly to the originating SQL node. Such errors were sometimes reported as being due to timeouts, when the actual problem was a transporter overload due to insufficient buffer space. ([Bug#39867](#), [Bug#39879](#))
- Undo logs and data files were created in 32K increments. Now these files are created in 512K increments, resulting in shorter creation times. ([Bug#40815](#))
- Redo log creation was very slow on some platforms, causing MySQL Cluster to start more slowly than necessary with some combinations of hardware and operating system. This was due to all write operations being synchronized to disk while creating a redo log file. Now this synchronization occurs only after the redo log has been created. ([Bug#40734](#))
- Transaction failures took longer to handle than was necessary.

When a data node acting as transaction coordinator (TC) failed, the surviving data nodes did not inform the API node initiating the transaction of this until the failure had been processed by all protocols. However, the API node needed only to know about

failure handling by the transaction protocol—that is, it needed to be informed only about the TC takeover process. Now, API nodes (including MySQL servers acting as cluster SQL nodes) are informed as soon as the TC takeover is complete, so that it can carry on operating more quickly. ([Bug#40697](#))

- It was theoretically possible for stale data to be read from `NDBCLUSTER` tables when the transaction isolation level was set to `ReadCommitted`. ([Bug#40543](#))
- The `LockExecuteThreadToCPU` and `LockMaintThreadsToCPU` parameters did not work on Solaris. ([Bug#40521](#))
- `SET SESSION ndb_optimized_node_selection = 1` failed with an invalid warning message. ([Bug#40457](#))
- A restarting data node could fail with an error in the `DBDIH` kernel block when a local or global checkpoint was started or triggered just as the node made a request for data from another data node. ([Bug#40370](#))
- Restoring a MySQL Cluster from a dump made using `mysqldump` failed due to a spurious error: `CAN'T EXECUTE THE GIVEN COMMAND BECAUSE YOU HAVE ACTIVE LOCKED TABLES OR AN ACTIVE TRANSACTION.` ([Bug#40346](#))
- `O_DIRECT` was incorrectly disabled when making MySQL Cluster backups. ([Bug#40205](#))
- Heavy DDL usage caused the `mysqld` processes to hang due to a timeout error (NDB error code 266). ([Bug#39885](#))
- Executing `EXPLAIN SELECT` on an `NDBCLUSTER` table could cause `mysqld` to crash. ([Bug#39872](#))
- Events logged after setting `ALL CLUSTERLOG STATISTICS=15` in the management client did not always include the node ID of the reporting node. ([Bug#39839](#))
- The MySQL Query Cache did not function correctly with `NDBCLUSTER` tables containing `TEXT` columns. ([Bug#39295](#))
- A segfault in `Logger::Log` caused `ndbd` to hang indefinitely. This fix improves on an earlier one for this issue, first made in MySQL Cluster NDB 6.2.16 and MySQL Cluster NDB 6.3.17. ([Bug#39180](#))

See also [Bug#38609](#).

- Memory leaks could occur in handling of strings used for storing cluster metadata and providing output to users. ([Bug#38662](#))
- A duplicate key or other error raised when inserting into an `NDBCLUSTER` table caused the current transaction to abort, after which any SQL statement other than a `ROLLBACK` failed. With this fix, the `NDBCLUSTER` storage engine now performs an implicit rollback when a transaction is aborted in this way; it is no longer necessary to issue an explicit `ROLLBACK` statement, and the next statement that is issued automatically begins a new transaction.

### Note

It remains necessary in such cases to retry the complete transaction, regardless of which statement caused it to be aborted.

([Bug#32656](#))

See also [Bug#47654](#).

- Error messages for `NDBCLUSTER` error codes 1224 and 1227 were missing. ([Bug#28496](#))
- **Disk Data:** Issuing concurrent `CREATE TABLESPACE`, `ALTER TABLESPACE`, `CREATE LOGFILE GROUP`, or `ALTER LOGFILE GROUP` statements on separate SQL nodes caused a resource leak that led to data node crashes when these statements were used again later. ([Bug#40921](#))
- **Disk Data:** Disk-based variable-length columns were not always handled like their memory-based equivalents, which could potentially lead to a crash of cluster data nodes. ([Bug#39645](#))
- **Disk Data:** `O_SYNC` was incorrectly disabled on platforms that do not support `O_DIRECT`. This issue was noted on Solaris but could have affected other platforms not having `O_DIRECT` capability. ([Bug#34638](#))
- **Cluster API:** The MGM API reset error codes on management server handles before checking them. This meant that calling an MGM API function with a null handle caused applications to crash. ([Bug#40455](#))
- **Cluster API:** It was not always possible to access parent objects directly from `NdbBlob`, `NdbOperation`, and `NdbScanOperation` objects. To alleviate this problem, a new `getNdbOperation()` method has been added to `NdbBlob` and new `getNdbTransaction()` methods have been added to `NdbOperation` and `NdbScanOperation`. In addition, a const variant of `NdbOperation::getErrorLine()` is now also available. ([Bug#40242](#))
- **Cluster API:** `NdbScanOperation::getBlobHandle()` failed when used with incorrect column names or numbers.

[Bug#40241](#))

- **Cluster API:** The MGM API function `ndb_mgm_listen_event()` ignored bind addresses.

As part of this fix, it is now possible to specify bind addresses in connectstrings. See [Section 17.3.2.3, “The MySQL Cluster Connectstring”](#), for more information. ([Bug#38473](#))

- **Cluster API:** The NDB API example programs included in MySQL Cluster source distributions failed to compile. ([Bug#37491](#))

See also [Bug#40238](#).

#### Changes in MySQL Cluster NDB 6.3.18 (5.1.28-ndb-6.3.18)

Functionality added or changed:

- It is no longer a requirement for database autodiscovery that an SQL node already be connected to the cluster at the time that a database is created on another SQL node. It is no longer necessary to issue `CREATE DATABASE` (or `CREATE SCHEMA`) statements on an SQL node joining the cluster after a database is created for the new SQL node to see the database and any `NDBCLUSTER` tables that it contains. ([Bug#39612](#))

Bugs fixed:

- When a transaction included a multi-row insert to an `NDBCLUSTER` table that caused a constraint violation, the transaction failed to roll back. ([Bug#395638](#))
- Starting the MySQL Server with the `--ndbcluster` option plus an invalid command-line option (for example, using `mysqld --ndbcluster --foobar`) caused it to hang while shutting down the binlog thread. ([Bug#39635](#))
- Dropping and then re-creating a database on one SQL node caused other SQL nodes to hang. ([Bug#39613](#))
- Setting a low value of `MaxNoOfLocalScans` (< 100) and performing a large number of (certain) scans could cause the Transaction Coordinator to run out of scan fragment records, and then crash. Now when this resource is exhausted, the cluster returns Error 291 (`OUT OF SCANFRAG RECORDS IN TC (INCREASE MAXNOOFLOCALSCANS)`) instead. ([Bug#39549](#))
- Creating a unique index on an `NDBCLUSTER` table caused a memory leak in the `NDB` subscription manager (`SUMA`) which could lead to mysqld hanging, due to the fact that the resource shortage was not reported back to the `NDB` kernel correctly. ([Bug#39518](#))

See also [Bug#39450](#).

- Embedded `libmysqld` with `NDB` did not drop table events. ([Bug#39450](#))
- Unique identifiers in tables having no primary key were not cached. This fix has been observed to increase the efficiency of `INSERT` operations on such tables by as much as 50%. ([Bug#39267](#))
- When restarting a data node, an excessively long shutdown message could cause the node process to crash. ([Bug#38580](#))
- After a forced shutdown and initial restart of the cluster, it was possible for SQL nodes to retain `.frm` files corresponding to `NDBCLUSTER` tables that had been dropped, and thus to be unaware that these tables no longer existed. In such cases, attempting to re-create the tables using `CREATE TABLE IF NOT EXISTS` could fail with a spurious `TABLE ... DOESN'T EXIST` error. ([Bug#37921](#))
- A statement of the form `DELETE FROM table WHERE primary_key=value` or `UPDATE table WHERE primary_key=value` where there was no row whose primary key column had the stated `value` appeared to succeed, with the server reporting that 1 row had been changed.

This issue was only known to affect MySQL Cluster NDB 6.3.11 and later NDB 6.3 versions. ([Bug#37153](#))

- **Cluster API:** Passing a value greater than 65535 to `NdbInterpretedCode::add_val()` and `NdbInterpretedCode::sub_val()` caused these methods to have no effect. ([Bug#39536](#))

#### Changes in MySQL Cluster NDB 6.3.17 (5.1.27-ndb-6.3.17)

Bugs fixed:

- **Packaging:** Support for the `InnoDB` storage engine was missing from the GPL source releases. An updated GPL source tarball `mysql-5.1.27-ndb-6.3.17-innodb.tar.gz` which includes code for building `InnoDB` can be found on [the MySQL FTP site](#).
- `MgmtSrvr::allocNodeId()` left a mutex locked following an `AMBIGUITY FOR NODE IF %D` error. ([Bug#39158](#))
- An invalid path specification caused `mysql-test-run.pl` to fail. ([Bug#39026](#))
- During transactional coordinator takeover (directly after node failure), the LQH finding an operation in the `LOG_COMMIT` state sent an `LQH_TRANS_CONF` signal twice, causing the TC to fail. ([Bug#38930](#))
- An invalid memory access caused the management server to crash on Solaris Sparc platforms. ([Bug#38628](#))
- A segfault in `Logger::Log` caused `ndbd` to hang indefinitely. ([Bug#38609](#))
- `ndb_mgmd` failed to start on older Linux distributions (2.4 kernels) that did not support e-polling. ([Bug#38592](#))
- `ndb_mgmd` sometimes performed unnecessary network I/O with the client. This in combination with other factors led to long-running threads that were attempting to write to clients that no longer existed. ([Bug#38563](#))
- `ndb_restore` failed with a floating point exception due to a division by zero error when trying to restore certain data files. ([Bug#38520](#))
- A failed connection to the management server could cause a resource leak in `ndb_mgmd`. ([Bug#38424](#))
- Failure to parse configuration parameters could cause a memory leak in the NDB log parser. ([Bug#38380](#))
- Renaming an `NDBCLUSTER` table on one SQL node, caused a trigger on this table to be deleted on another SQL node. ([Bug#36658](#))
- Attempting to add a `UNIQUE INDEX` twice to an `NDBCLUSTER` table, then deleting rows from the table could cause the MySQL Server to crash. ([Bug#35599](#))
- `ndb_restore` failed when a single table was specified. ([Bug#33801](#))
- `GCP_COMMIT` did not wait for transaction takeover during node failure. This could cause `GCP_SAVE_REQ` to be executed too early. This could also cause (very rarely) replication to skip rows. ([Bug#30780](#))
- **Cluster API:** Support for Multi-Range Read index scans using the old API (using, for example, `NdbIndexScanOperation::setBound()` or `NdbIndexScanOperation::end_of_bound()`) were dropped in MySQL Cluster NDB 6.2. This functionality is restored in MySQL Cluster NDB 6.3 beginning with 6.3.17, but remains unavailable in MySQL Cluster NDB 6.2. Both MySQL Cluster NDB 6.2 and 6.3 support Multi-Range Read scans through the `NdbRecord` API. ([Bug#38791](#))
- **Cluster API:** The `NdbScanOperation::readTuples()` method could be called multiple times without error. ([Bug#38717](#))
- **Cluster API:** Certain Multi-Range Read scans involving `IS NULL` and `IS NOT NULL` comparisons failed with an error in the `NDB` local query handler. ([Bug#38204](#))
- **Cluster API:** Problems with the public headers prevented `NDB` applications from being built with warnings turned on. ([Bug#38177](#))
- **Cluster API:** Creating an `NdbScanFilter` object using an `NdbScanOperation` object that had not yet had its `readTuples()` method called resulted in a crash when later attempting to use the `NdbScanFilter`. ([Bug#37986](#))
- **Cluster API:** Executing an `NdbRecord` interpreted delete created with an `ANYVALUE` option caused the transaction to abort. ([Bug#37672](#))

### Changes in MySQL Cluster NDB 6.3.16 (5.1.24-ndb-6.3.16)

Functionality added or changed:

- Event buffer lag reports are now written to the cluster log. ([Bug#37427](#))
- Added the `--no-binlog` option for `ndb_restore`. When used, this option prevents information being written to SQL node binary logs from the restoration of a cluster backup. ([Bug#30452](#))

Bugs fixed:

- **Cluster API:** Changing the system time on data nodes could cause MGM API applications to hang and the data nodes to crash. ([Bug#35607](#))
- **Cluster API:** Changing the system time on data nodes could cause MGM API applications to hang and the data nodes to crash. ([Bug#35607](#))
- Failure of a data node could sometimes cause mysqld to crash. ([Bug#37628](#))
- `DELETE ... WHERE unique_index_column=value` deleted the wrong row from the table. ([Bug#37516](#))
- If subscription was terminated while a node was down, the epoch was not properly acknowledged by that node. ([Bug#37442](#))
- `libmysqld` failed to wait for the cluster binlog thread to terminate before exiting. ([Bug#37429](#))
- In rare circumstances, a connection followed by a disconnection could give rise to a “stale” connection where the connection still existed but was not seen by the transporter. ([Bug#37338](#))
- Queries against `NDBCLUSTER` tables were cached only if `autocommit` was in use. ([Bug#36692](#))
- **Cluster API:** When some operations succeeded and some failed following a call to `NdbTransaction::execute(Commit, AO_IgnoreOnError)`, a race condition could cause spurious occurrences of NDB API Error 4011 (`INTERNAL_ERROR`). ([Bug#37158](#))
- **Cluster API:** Creating a table on an SQL node, then starting an NDB API application that listened for events from this table, then dropping the table from an SQL node, prevented data node restarts. ([Bug#32949](#), [Bug#37279](#))
- **Cluster API:** A buffer overrun in `NdbBlob::setValue()` caused erroneous results on Mac OS X. ([Bug#31284](#))

### Changes in MySQL Cluster NDB 6.3.15 (5.1.24-ndb-6.3.15)

Bugs fixed:

- In certain rare situations, `ndb_size.pl` could fail with the error `CAN'T USE STRING ("VALUE") AS A HASH REF WHILE "STRICT REFS" IN USE.` ([Bug#43022](#))
- Under some circumstances, a failed `CREATE TABLE` could mean that subsequent `CREATE TABLE` statements caused node failures. ([Bug#37092](#))
- A fail attempt to create an `NDB` table could in some cases lead to resource leaks or cluster failures. ([Bug#37072](#))
- Attempting to create a native backup of `NDB` tables having a large number of `NULL` columns and data could lead to node failures. ([Bug#37039](#))
- Checking of API node connections was not efficiently handled. ([Bug#36843](#))
- Attempting to delete a nonexistent row from a table containing a `TEXT` or `BLOB` column within a transaction caused the transaction to fail. ([Bug#36756](#))

See also [Bug#36851](#).

- If the combined total of tables and indexes in the cluster was greater than 4096, issuing `START BACKUP` caused data nodes to fail. ([Bug#36044](#))
- Where column values to be compared in a query were of the `VARCHAR` or `VARBINARY` types, `NDBCLUSTER` passed a value padded to the full size of the column, which caused unnecessary data to be sent to the data nodes. This also had the effect of wasting CPU and network bandwidth, and causing condition pushdown to be disabled where it could (and should) otherwise have been applied. ([Bug#35393](#))
- When dropping a table failed for any reason (such as when in single user mode) then the corresponding `.ndb` file was still removed.
- **Cluster API:** Ordered index scans were not pruned correctly where a partitioning key was specified with an EQ-bound. ([Bug#36950](#))
- **Cluster API:** When an insert operation involving `BLOB` data was attempted on a row which already existed, no duplicate key error was correctly reported and the transaction is incorrectly aborted. In some cases, the existing row could also become corrupted. ([Bug#36851](#))

See also [Bug#26756](#).

- **Cluster API:** `NdbApi.hpp` depended on `ndb_global.h`, which was not actually installed, causing the compilation of programs that used `NdbApi.hpp` to fail. ([Bug#35853](#))

### Changes in MySQL Cluster NDB 6.3.14 (5.1.24-ndb-6.3.14)

Bugs fixed:

- `SET GLOBAL ndb_extra_logging` caused `mysqld` to crash. ([Bug#36547](#))
- A race condition caused by a failure in epoll handling could cause data nodes to fail. ([Bug#36537](#))
- Under certain rare circumstances, the failure of the new master node while attempting a node takeover would cause takeover errors to repeat without being resolved. ([Bug#36199](#), [Bug#36246](#), [Bug#36247](#), [Bug#36276](#))
- When more than one SQL node connected to the cluster at the same time, creation of the `mysql.ndb_schema` table failed on one of them with an explicit `TABLE EXISTS` error, which was not necessary. ([Bug#35943](#))
- `mysqld` failed to start after running `mysql_upgrade`. ([Bug#35708](#))
- Notification of a cascading master node failures could sometimes not be transmitted correctly (that is, transmission of the `NF_COMPLETEREP` signal could fail), leading to transactions hanging and timing out (`NDB` error 4012), scans hanging, and failure of the management server process. ([Bug#32645](#))
- If an API node disconnected and then reconnected during Start Phase 8, then the connection could be “blocked”—that is, the `QMGR` kernel block failed to detect that the API node was in fact connected to the cluster, causing issues with the `NDB` Subscription Manager (`SUMA`).
- `NDB` error 1427 (`API NODE DIED, WHEN SUB_START_REQ REACHED NODE`) was incorrectly classified as a schema error rather than a temporary error.
- **Cluster API:** Accessing the debug version of `libndbclient` using `dlopen()` resulted in a segmentation fault. ([Bug#35927](#))
- **Cluster API:** Attempting to pass a nonexistent column name to the `equal()` and `setValue()` methods of `NdbOperation` caused `NDB` API applications to crash. Now the column name is checked, and an error is returned in the event that the column is not found. ([Bug#33747](#))

### Changes in MySQL Cluster NDB 6.3.13 (5.1.24-ndb-6.3.13)

Bugs fixed:

- **Important Change:** `mysqld_safe` now traps Signal 13 (`SIGPIPE`) so that this signal no longer kills the MySQL server process. ([Bug#33984](#))
- Node or system restarts could fail due an uninitialized variable in the `DTUP` kernel block. This issue was found in MySQL Cluster NDB 6.3.11. ([Bug#35797](#))
- If an error occurred while executing a statement involving a `BLOB` or `TEXT` column of an `NDB` table, a memory leak could result. ([Bug#35593](#))
- It was not possible to determine the value used for the `--ndb-cluster-connection-pool` option in the `mysql` client. Now this value is reported as a system status variable. ([Bug#35573](#))
- The `ndb_waiter` utility wrongly calculated timeouts. ([Bug#35435](#))
- A `SELECT` on a table with a nonindexed, large `VARCHAR` column which resulted in condition pushdown on this column could cause `mysqld` to crash. ([Bug#35413](#))
- `ndb_restore` incorrectly handled some data types when applying log files from backups. ([Bug#35343](#))
- In some circumstances, a stopped data node was handled incorrectly, leading to redo log space being exhausted following an initial restart of the node, or an initial or partial restart of the cluster (the wrong CGI might be used in such cases). This could happen, for example, when a node was stopped following the creation of a new table, but before a new LCP could be executed. ([Bug#35241](#))
- `SELECT ... LIKE ...` queries yielded incorrect results when used on `NDB` tables. As part of this fix, condition pushdown of such queries has been disabled; re-enabling it is expected to be done as part of a later, permanent fix for this issue.

**Bug#35185)**

- `ndb_mgmd` reported errors to `STDOUT` rather than to `STDERR`. ([Bug#35169](#))
- Nested Multi-Range Read scans failed when the second Multi-Range Read released the first read's unprocessed operations, sometimes leading to an SQL node crash. ([Bug#35137](#))
- In some situations, a problem with synchronizing checkpoints between nodes could cause a system restart or a node restart to fail with `ERROR 630 DURING RESTORE OF TX.` ([Bug#34756](#))
- A node failure during an initial node restart followed by another node start could cause the master data node to fail, because it incorrectly gave the node permission to start even if the invalidated node's LCP was still running. ([Bug#34702](#))
- When a secondary index on a `DECIMAL` column was used to retrieve data from an `NDB` table, no results were returned even if the target table had a matched value in the column that was defined with the secondary index. ([Bug#34515](#))
- An `UPDATE` on an `NDB` table that set a new value for a unique key column could cause subsequent queries to fail. ([Bug#34208](#))
- If a data node in one node group was placed in the “not started” state (using `node_id RESTART -n`), it was not possible to stop a data node in a different node group. ([Bug#34201](#))
- Numerous `NDBCLUSTER` test failures occurred in builds compiled using `icc` on IA64 platforms. ([Bug#31239](#))
- If a `START BACKUP` command was issued while `ndb_restore` was running, the backup being restored could be overwritten. ([Bug#26498](#))
- `REPLACE` statements did not work correctly with `NDBCLUSTER` tables when all columns were not explicitly listed. ([Bug#22045](#))
- `CREATE TABLE` and `ALTER TABLE` statements using `ENGINE=NDB` or `ENGINE=NDBCLUSTER` caused `mysqld` to fail on Solaris 10 for x86 platforms. ([Bug#19911](#))
- **Cluster API:** Closing a scan before it was executed caused the application to segfault. ([Bug#36375](#))
- **Cluster API:** Using NDB API applications from older MySQL Cluster versions with `libndbclient` from newer ones caused the cluster to fail. ([Bug#36124](#))
- **Cluster API:** Some ordered index scans could return tuples out of order. ([Bug#35908](#))
- **Cluster API:** Scans having no bounds set were handled incorrectly. ([Bug#35876](#))
- **Cluster API:** `NdbScanFilter::getNdbOperation()`, which was inadvertently removed in MySQL Cluster NDB 6.3.11, has been restored. ([Bug#35854](#))

**Changes in MySQL Cluster NDB 6.3.10 (5.1.23-ndb-6.3.10)**

Bugs fixed:

- Due to the reduction of the number of local checkpoints from 3 to 2 in MySQL Cluster NDB 6.3.8, a data node using ndbd from MySQL Cluster NDB 6.3.8 or later started using a file system from an earlier version could incorrectly invalidate local checkpoints too early during the startup process, causing the node to fail. ([Bug#34596](#))

**Changes in MySQL Cluster NDB 6.3.9 (5.1.23-ndb-6.3.9)**

Bugs fixed:

- Cluster failures could sometimes occur when performing more than three parallel takeovers during node restarts or system restarts. This affected MySQL Cluster NDB 6.3.x releases only. ([Bug#34445](#))
- Upgrades of a cluster using while a `DataMemory` setting in excess of 16 GB caused data nodes to fail. ([Bug#34378](#))
- Performing many SQL statements on `NDB` tables while in `autocommit` mode caused a memory leak in `mysqld`. ([Bug#34275](#))
- In certain rare circumstances, a race condition could occur between an aborted insert and a delete leading a data node crash. ([Bug#34260](#))
- Multi-table updates using ordered indexes during handling of node failures could cause other data nodes to fail. ([Bug#34216](#))

- When configured with `NDB` support, MySQL failed to compile using `gcc` 4.3 on 64bit FreeBSD systems. ([Bug#34169](#))
  - The failure of a DDL statement could sometimes lead to node failures when attempting to execute subsequent DDL statements. ([Bug#34160](#))
  - Extremely long `SELECT` statements (where the text of the statement was in excess of 50000 characters) against `NDB` tables returned empty results. ([Bug#34107](#))
  - When configured with `NDB` support, MySQL failed to compile on 64bit FreeBSD systems. ([Bug#34046](#))
  - Statements executing multiple inserts performed poorly on `NDB` tables having `AUTO_INCREMENT` columns. ([Bug#33534](#))
  - The `ndb_waiter` utility polled `ndb_mgmd` excessively when obtaining the status of cluster data nodes. ([Bug#32025](#))
- See also [Bug#32023](#).
- Transaction atomicity was sometimes not preserved between reads and inserts under high loads. ([Bug#31477](#))
  - Having tables with a great many columns could cause Cluster backups to fail. ([Bug#30172](#))
  - **Cluster Replication: Disk Data:** Statements violating unique keys on Disk Data tables (such as attempting to insert `NULL` into a `NOT NULL` column) could cause data nodes to fail. When the statement was executed from the binlog, this could also result in failure of the slave cluster. ([Bug#34118](#))
  - **Disk Data:** Updating in-memory columns of one or more rows of Disk Data table, followed by deletion of these rows and re-insertion of them, caused data node failures. ([Bug#33619](#))

### Changes in MySQL Cluster NDB 6.3.8 (5.1.23-ndb-6.3.8)

Functionality added or changed:

- **Cluster API: Important Change:** Because `NDB_LE_MemoryUsage.page_size_kb` shows memory page sizes in bytes rather than kilobytes, it has been renamed to `page_size_bytes`. The name `page_size_kb` is now deprecated and thus subject to removal in a future release, although it currently remains supported for reasons of backward compatibility. See [The Ndb\\_logevent\\_type Type](#), for more information about `NDB_LE_MemoryUsage`. ([Bug#30271](#))
- `ndb_restore` now supports basic *attribute promotion*; that is, data from a column of a given type can be restored to a column using a “larger” type. For example, Cluster backup data taken from a `SMALLINT` column can be restored to a `MEDIUMINT`, `INT`, or `BIGINT` column.

For more information, see [Section 17.4.17, “ndb\\_restore — Restore a MySQL Cluster Backup”](#).

- Now only 2 local checkpoints are stored, rather than 3 as in previous MySQL Cluster versions. This lowers disk space requirements and reduces the size and number of redo log files needed.
- The `mysqld` option `--ndb-batch-size` has been added. This enables control of the size of batches used for running transactions.
- Node recovery can now be done in parallel, rather than sequentially, which can result in much faster recovery times.
- Persistence of `NDB` tables can now be controlled using the session variables `ndb_table_temporary` and `ndb_table_no_logging`. `ndb_table_no_logging` causes `NDB` tables not to be checkpointed to disk. `ndb_table_temporary` has the same effect; in addition, when `ndb_table_temporary` is used, no `NDB` table schema files are created.
- `OPTIMIZE TABLE` can now be interrupted. This can be done, for example, by killing the SQL thread performing the `OPTIMIZE` operation.

Bugs fixed:

- **Disk Data: Important Change:** It is no longer possible on 32-bit systems to issue statements appearing to create Disk Data log files or data files greater than 4 GB in size. (Trying to create log files or data files larger than 4 GB on 32-bit systems led to unrecoverable data node failures; such statements now fail with `NDB` error 1515.) ([Bug#29186](#))
- **Replication:** The code implementing heartbeats did not check for possible errors in some circumstances; this kept the dump thread hanging while waiting for heartbeats loop even though the slave was no longer connected. ([Bug#33332](#))
- High numbers of insert operations, delete operations, or both could cause `NDB` error 899 (`ROWID ALREADY ALLOCATED`) to occur

unnecessarily. ([Bug#34033](#))

- A periodic failure to flush the send buffer by the `NDB` TCP transporter could cause a unnecessary delay of 10 ms between operations. ([Bug#34005](#))
- `DROP TABLE` did not free all data memory. This bug was observed in MySQL Cluster NDB 6.3.7 only. ([Bug#33802](#))
- A race condition could occur (very rarely) when the release of a GCI was followed by a data node failure. ([Bug#33793](#))
- Some tuple scans caused the wrong memory page to be accessed, leading to invalid results. This issue could affect both in-memory and Disk Data tables. ([Bug#33739](#))
- A failure to initialize an internal variable led to sporadic crashes during cluster testing. ([Bug#33715](#))
- The server failed to reject properly the creation of an `NDB` table having an unindexed `AUTO_INCREMENT` column. ([Bug#30417](#))
- Issuing an `INSERT ... ON DUPLICATE KEY UPDATE` concurrently with or following a `TRUNCATE TABLE` statement on an `NDB` table failed with `NDB` error 4350 `TRANSACTION ALREADY ABORTED`. ([Bug#29851](#))
- The Cluster backup process could not detect when there was no more disk space and instead continued to run until killed manually. Now the backup fails with an appropriate error when disk space is exhausted. ([Bug#28647](#))
- It was possible in `config.ini` to define cluster nodes having node IDs greater than the maximum permitted value. ([Bug#28298](#))
- Under some circumstances, a recovering data node did not use its own data, instead copying data from another node even when this was not required. This in effect bypassed the optimized node recovery protocol and caused recovery times to be unnecessarily long. ([Bug#26913](#))
- **Cluster API:** Transactions containing inserts or reads would hang during `NdbTransaction::execute()` calls made from NDB API applications built against a MySQL Cluster version that did not support micro-GCPs accessing a later version that supported micro-GCPs. This issue was observed while upgrading from MySQL Cluster NDB 6.1.23 to MySQL Cluster NDB 6.2.10 when the API application built against the earlier version attempted to access a data node already running the later version, even after disabling micro-GCPs by setting `TimeBetweenEpochs` equal to 0. ([Bug#33895](#))
- **Cluster API:** When reading a `BIT(64)` value using `NdbOperation::getValue()`, 12 bytes were written to the buffer rather than the expected 8 bytes. ([Bug#33750](#))

### Changes in MySQL Cluster NDB 6.3.7 (5.1.23-ndb-6.3.7)

Functionality added or changed:

- Compressed local checkpoints and backups are now supported, resulting in a space savings of 50% or more over uncompressed LCPs and backups. Compression of these can be enabled in the `config.ini` file using the two new data node configuration parameters `CompressedLCP` and `CompressedBackup`, respectively.
- `OPTIMIZE TABLE` is now supported for `NDBCCLUSTER` tables, subject to the following limitations:
  - Only in-memory tables are supported. `OPTIMIZE` still has no effect on Disk Data tables.
  - Only variable-length columns are supported. However, you can force columns defined using fixed-length data types to be dynamic using the `ROW_FORMAT` or `COLUMN_FORMAT` option with a `CREATE TABLE` or `ALTER TABLE` statement.

Memory reclaimed from an `NDB` table using `OPTIMIZE` is generally available to the cluster, and not confined to the table from which it was recovered, unlike the case with memory freed using `DELETE`.

The performance of `OPTIMIZE` on `NDB` tables can be regulated by adjusting the value of the `ndb_optimization_delay` system variable.

- It is now possible to cause statements occurring within the same transaction to be run as a batch by setting the session variable `transaction_allow_batching` to `1` or `ON`.

#### Note

To use this feature, `autocommit` must be disabled.

Bugs fixed:

- **Partitioning:** When partition pruning on an `NDB` table resulted in an ordered index scan spanning only one partition, any descending flag for the scan was wrongly discarded, causing `ORDER BY DESC` to be treated as `ORDER BY ASC, MAX()` to be handled incorrectly, and similar problems. ([Bug#33061](#))
- When all data and SQL nodes in the cluster were shut down abnormally (that is, other than by using `STOP` in the cluster management client), `ndb_mgm` used excessive amounts of CPU. ([Bug#33237](#))
- When using micro-GCPs, if a node failed while preparing for a global checkpoint, the master node would use the wrong GCI. ([Bug#32922](#))
- Under some conditions, performing an `ALTER TABLE` on an `NDBCLUSTER` table failed with a `TABLE IS FULL` error, even when only 25% of `DataMemory` was in use and the result should have been a table using less memory (for example, changing a `VARCHAR(100)` column to `VARCHAR(80)`). ([Bug#32670](#))

### Changes in MySQL Cluster NDB 6.3.6 (5.1.22-ndb-6.3.6)

Functionality added or changed:

- The output of the `ndb_mgm` client `SHOW` and `STATUS` commands now indicates when the cluster is in single user mode. ([Bug#27999](#))
- Unnecessary reads when performing a primary key or unique key update have been reduced, and in some cases, eliminated. (It is almost never necessary to read a record prior to an update, the lone exception to this being when a primary key is updated, since this requires a delete followed by an insert, which must be prepared by reading the record.) Depending on the number of primary key and unique key lookups that are performed per transaction, this can yield a considerable improvement in performance.
- Batched operations are now better supported for `DELETE` and `UPDATE`. (`UPDATE WHERE...` and multiple `DELETE`.)
- Introduced the `Ndb_execute_count` status variable, which measures the number of round trips made by queries to the `NDB` kernel.

Bugs fixed:

- An insert or update with combined range and equality constraints failed when run against an `NDB` table with the error `GOT UNKNOWN ERROR FROM NDB`. An example of such a statement would be `UPDATE t1 SET b = 5 WHERE a IN (7,8) OR a >= 10;`. ([Bug#31874](#))
- An error with an `if` statement in `sql/ha_ndbcluster.cc` could potentially lead to an infinite loop in case of failure when working with `AUTO_INCREMENT` columns in `NDB` tables. ([Bug#31810](#))
- The `NDB` storage engine code was not safe for strict-alias optimization in `gcc` 4.2.1. ([Bug#31761](#))
- `ndb_restore` displayed incorrect backup file version information. This meant (for example) that, when attempting to restore a backup made from a MySQL 5.1.22 cluster to a MySQL Cluster NDB 6.3.3 cluster, the restore process failed with the error `RESTORE PROGRAM OLDER THAN BACKUP VERSION. NOT SUPPORTED. USE NEW RESTORE PROGRAM.` ([Bug#31723](#))
- Following an upgrade, `ndb_mgmd` would fail with an `ArbitrationError`. ([Bug#31690](#))
- The `NDB` management client command `node_id REPORT MEMORY` provided no output when `node_id` was the node ID of a management or API node. Now, when this occurs, the management client responds with `Node node_id: is not a data node.` ([Bug#29485](#))
- Performing `DELETE` operations after a data node had been shut down could lead to inconsistent data following a restart of the node. ([Bug#26450](#))
- `UPDATE IGNORE` could sometimes fail on `NDB` tables due to the use of uninitialized data when checking for duplicate keys to be ignored. ([Bug#25817](#))

### Changes in MySQL Cluster NDB 6.3.5 (5.1.22-ndb-6.3.5)

Bugs fixed:

- A query against a table with `TEXT` or `BLOB` columns that would return more than a certain amount of data failed with `GOT ERROR 4350 'TRANSACTION ALREADY ABORTED' FROM NDBCLUSTER.` ([Bug#31482](#))

This regression was introduced by [Bug#29102](#).

### Changes in MySQL Cluster NDB 6.3.4 (5.1.22-ndb-6.3.4)

Functionality added or changed:

- **Incompatible Change:** The `--ndb_optimized_node_selection` startup option for `mysqld` now permits a wider range of values and corresponding behaviors for SQL nodes when selecting a transaction coordinator.

You should be aware that the default value and behavior as well as the value type used for this option have changed, and that you may need to update the setting used for this option in your `my.cnf` file prior to upgrading `mysqld`. See [Section 5.1.4, “Server System Variables”](#), for more information.

- **Incompatible Change:** The `--ndb_optimized_node_selection` startup option for `mysqld` now permits a wider range of values and corresponding behaviors for SQL nodes when selecting a transaction coordinator.

You should be aware that the default value and behavior as well as the value type used for this option have changed, and that you may need to update the setting used for this option in your `my.cnf` file prior to upgrading `mysqld`. See [Section 5.1.4, “Server System Variables”](#), for more information.

Bugs fixed:

- It was possible in some cases for a node group to be “lost” due to missed local checkpoints following a system restart. ([Bug#31525](#))
- `NDB` tables having names containing nonalphanumeric characters (such as “\$”) were not discovered correctly. ([Bug#31470](#))
- A node failure during a local checkpoint could lead to a subsequent failure of the cluster during a system restart. ([Bug#31257](#))
- A cluster restart could sometimes fail due to an issue with table IDs. ([Bug#30975](#))
- Transaction timeouts were not handled well in some circumstances, leading to excessive number of transactions being aborted unnecessarily. ([Bug#30379](#))
- In some cases, the cluster management server logged entries multiple times following a restart of `mgmd`. ([Bug#29565](#))
- `ndb_mgm --help` did not display any information about the `-a` option. ([Bug#29509](#))
- An interpreted program of sufficient size and complexity could cause all cluster data nodes to shut down due to buffer overruns. ([Bug#29390](#))
- The cluster log was formatted inconsistently and contained extraneous newline characters. ([Bug#25064](#))

### Changes in MySQL Cluster NDB 6.3.3 (5.1.22-ndb-6.3.3)

Functionality added or changed:

- Mapping of `NDB` error codes to MySQL storage engine error codes has been improved. ([Bug#28423](#))

Bugs fixed:

- **Partitioning:** `EXPLAIN PARTITIONS` reported partition usage by queries on `NDB` tables according to the standard MySQL hash function than the hash function used in the `NDB` storage engine. ([Bug#29550](#))
- Attempting to restore a backup made on a cluster host using one endian to a machine using the other endian could cause the cluster to fail. ([Bug#29674](#))
- The description of the `--print` option provided in the output from `ndb_restore --help` was incorrect. ([Bug#27683](#))
- Restoring a backup made on a cluster host using one endian to a machine using the other endian failed for `BLOB` and `DATE-TIME` columns. ([Bug#27543](#), [Bug#30024](#))

## Changes in MySQL Cluster NDB 6.3.2 (5.1.22-ndb-6.3.2)

Functionality added or changed:

- Online `ADD COLUMN`, `ADD INDEX`, and `DROP INDEX` operations can now be performed explicitly for `NDB` tables, as well as online renaming of tables and columns for `NDB` and `MyISAM` tables—that is, without copying or locking of the affected tables—using `ALTER ONLINE TABLE`.

Indexes can also be created and dropped online using `CREATE INDEX` and `DROP INDEX`, respectively, using the `ONLINE` keyword.

You can force operations that would otherwise be performed online to be done offline using the `OFFLINE` keyword.

See [Section 12.1.7, “ALTER TABLE Syntax”](#), [Section 12.1.13, “CREATE INDEX Syntax”](#), and [Section 12.1.24, “DROP INDEX Syntax”](#), for more information.

- It is now possible to control whether fixed-width or variable-width storage is used for a given column of an `NDB` table by means of the `COLUMN_FORMAT` specifier as part of the column's definition in a `CREATE TABLE` or `ALTER TABLE` statement.

It is also possible to control whether a given column of an `NDB` table is stored in memory or on disk, using the `STORAGE` specifier as part of the column's definition in a `CREATE TABLE` or `ALTER TABLE` statement.

For permitted values and other information about `COLUMN_FORMAT` and `STORAGE`, see [Section 12.1.17, “CREATE TABLE Syntax”](#).

- A new cluster management server startup option `--bind-address` makes it possible to restrict management client connections to `ndb_mgmd` to a single host and port. For more information, see [Section 17.4.4, “`ndb\_mgmd` — The MySQL Cluster Management Server Daemon”](#).

Bugs fixed:

- When an `NDB` event was left behind but the corresponding table was later recreated and received a new table ID, the event could not be dropped. ([Bug#30877](#))
- When creating an `NDB` table with a column that has `COLUMN_FORMAT = DYNAMIC`, but the table itself uses `ROW_FORMAT=FIXED`, the table is considered dynamic, but any columns for which the row format is unspecified default to `FIXED`. Now in such cases the server issues the warning `ROW FORMAT FIXED INCOMPATIBLE WITH DYNAMIC ATTRIBUTE COLUMN_NAME`. ([Bug#30276](#))
- An insufficiently descriptive and potentially misleading Error 4006 (`CONNECT FAILURE - OUT OF CONNECTION OBJECTS...`) was produced when either of the following two conditions occurred:
  1. There were no more transaction records in the transaction coordinator
  2. An `NDB` object in the `NDB` API was initialized with insufficient parallelismSeparate error messages are now generated for each of these two cases. ([Bug#11313](#))

## Changes in MySQL Cluster NDB 6.3.0 (5.1.19-ndb-6.3.0)

Functionality added or changed:

- Reporting functionality has been significantly enhanced in this release:
  - A new configuration parameter `BackupReportFrequency` now makes it possible to cause the management client to provide status reports at regular intervals as well as for such reports to be written to the cluster log (depending on cluster event logging levels). See [Section 17.3.2.6, “Defining MySQL Cluster Data Nodes”](#), for more information about this parameter.
  - A new `REPORT` command has been added in the cluster management client. `REPORT BackupStatus` enables you to obtain a backup status report at any time during a backup. `REPORT MemoryUsage` reports the current data memory and index memory used by each data node. For more about the `REPORT` command, see [Section 17.5.2, “Commands in the MySQL Cluster Management Client”](#).
  - `ndb_restore` now provides running reports of its progress when restoring a backup. In addition, a complete report status report on the backup is written to the cluster log.

- A new configuration parameter `ODirect` causes `NDB` to attempt using `O_DIRECT` writes for LCP, backups, and redo logs, often lowering CPU usage.

#### 17.7.6.4. Changes in the MySQL Cluster NDB 6.2 Series

This section contains unified change history highlights for all MySQL Cluster releases based on version 6.2 of the `NDBCLUSTER` storage engine through MySQL Cluster NDB 6.2.19. Included are all changelog entries in the categories *MySQL Cluster*, *Disk Data*, and *Cluster API*.

For an overview of features that were added in MySQL Cluster NDB 6.2, see [Section 17.1.4.4, “MySQL Cluster Development in MySQL Cluster NDB 6.2”](#).

- [Changes in MySQL Cluster NDB 6.2.19 \(5.1.47-ndb-6.2.19\)](#)
- [Changes in MySQL Cluster NDB 6.2.18 \(5.1.34-ndb-6.2.18\)](#)

##### **Changes in MySQL Cluster NDB 6.2.19 (5.1.47-ndb-6.2.19)**

Functionality added or changed:

- **Important Change:** More finely-grained control over restart-on-failure behavior is provided with two new data node configuration parameters `MaxStartFailRetries` and `StartFailRetryDelay`. `MaxStartFailRetries` limits the total number of retries made before giving up on starting the data node; `StartFailRetryDelay` sets the number of seconds between retry attempts.

These parameters are used only if `StopOnError` is set to 0.

For more information, see [Section 17.3.2.6, “Defining MySQL Cluster Data Nodes”](#). ([Bug#54341](#))

- **Cluster API:** It is now possible to determine, using the `ndb_desc` utility or the NDB API, which data nodes contain replicas of which partitions. For `ndb_desc`, a new `--extra-node-info` option is added to cause this information to be included in its output. A new method `NdbDictionary::Object::Table::getFragmentNodes()` is added to the NDB API for obtaining this information programmatically. ([Bug#51184](#))

- **Cluster API:** It is now possible to determine, using the `ndb_desc` utility or the NDB API, which data nodes contain replicas of which partitions. For `ndb_desc`, a new `--extra-node-info` option is added to cause this information to be included in its output. A new method `NdbDictionary::Object::Table::getFragmentNodes()` is added to the NDB API for obtaining this information programmatically. ([Bug#51184](#))
- On Solaris platforms, the MySQL Cluster management server and NDB API applications now use `CLOCK_REALTIME` as the default clock. ([Bug#46183](#))

Bugs fixed:

- **Important Change:** The `--with-ndb-port-base` option for `configure` did not function correctly, and has been deprecated. Attempting to use this option produces the warning `IGNORING DEPRECATED OPTION --WITH-NDP-PORT-BASE`.

Beginning with MySQL Cluster NDB 7.1.0, the deprecation warning itself is removed, and the `--with-ndb-port-base` option is simply handled as an unknown and invalid option if you try to use it. ([Bug#47941](#))

See also [Bug#38502](#).

- **Packaging:** The `pkg` installer for MySQL Cluster on Solaris did not perform a complete installation due to an invalid directory reference in the post-install script. ([Bug#41998](#))
- It was possible for a `DROP DATABASE` statement to remove NDB hidden blob tables without removing the parent tables, with the result that the tables, although hidden to MySQL clients, were still visible in the output of `ndb_show_tables` but could not be dropped using `ndb_drop_table`. ([Bug#54788](#))
- When performing an online alter table where 2 or more SQL nodes connected to the cluster were generating binary logs, an incorrect message could be sent from the data nodes, causing `mysqld` processes to crash. This problem was often difficult to detect, because restarting SQL node or data node processes could clear the error, and because the crash in `mysqld` did not occur until several minutes after the erroneous message was sent and received. ([Bug#54168](#))
- A table having the maximum number of attributes permitted could not be backed up using the `ndb_mgm` client.

### Note

The maximum number of attributes supported per table is not the same for all MySQL Cluster releases. See [Section 17.1.5.5, “Limits Associated with Database Objects in MySQL Cluster”](#), to determine the maximum that applies in the release which you are using.

([Bug#54155](#))

- Creating a Disk Data table, dropping it, then creating an in-memory table and performing a restart, could cause data node processes to fail with errors in the `DBTUP` kernel block if the new table's internal ID was the same as that of the old Disk Data table. This could occur because undo log handling during the restart did not check that the table having this ID was now in-memory only. ([Bug#53935](#))
- A table created while `ndb_table_no_logging` was enabled was not always stored to disk, which could lead to a data node crash with `ERROR OPENING DIH SCHEMA FILES FOR TABLE`. ([Bug#53934](#))
- An internal buffer allocator used by NDB has the form `alloc(wanted, minimum)` and attempts to allocate `wanted` pages, but is permitted to allocate a smaller number of pages, between `wanted` and `minimum`. However, this allocator could sometimes allocate fewer than `minimum` pages, causing problems with multi-threaded building of ordered indexes. ([Bug#53580](#))
- NDB truncated a column declared as `DECIMAL(65, 0)` to a length of 64. Now such a column is accepted and handled correctly. In cases where the maximum length (65) is exceeded, NDB now raises an error instead of truncating. ([Bug#53352](#))
- When a watchdog shutdown occurred due to an error, the process was not terminated quickly enough, sometimes resulting in a hang. (To correct this, the internal `_exit()` function is now called in such situations, rather than `exit()`.) ([Bug#53246](#))
- Setting `DataMemory` higher than 4G on 32-bit platforms caused `ndbd` to crash, instead of failing gracefully with an error. ([Bug#52536](#), [Bug#50928](#))
- When running a `SELECT` on an NDB table with `BLOB` or `TEXT` columns, memory was allocated for the columns but was not freed until the end of the `SELECT`. This could cause problems with excessive memory usage when dumping (using for example `mysqldump`) tables with such columns and having many rows, large column values, or both. ([Bug#52313](#))

See also [Bug#56488](#), [Bug#50310](#).

- When using `NoOfReplicas` equal to 1 or 2, if data nodes from one node group were restarted 256 times and applications

were running traffic such that it would encounter **NDB** error 1204 (**TEMPORARY FAILURE, DISTRIBUTION CHANGED**), the live node in the node group would crash, causing the cluster to crash as well. The crash occurred only when the error was encountered on the 256th restart; having the error on any previous or subsequent restart did not cause any problems. ([Bug#50930](#))

- If a query on an **NDB** table compared a constant string value to a column, and the length of the string was greater than that of the column, condition pushdown did not work correctly. (The string was truncated to fit the column length before being pushed down.) Now in such cases, the condition is no longer pushed down. ([Bug#49459](#))
- When performing tasks that generated large amounts of I/O (such as when using **ndb\_restore**), an internal memory buffer could overflow, causing data nodes to fail with signal 6.

Subsequent analysis showed that this buffer was not actually required, so this fix removes it. ([Bug#48861](#))

- Performing intensive inserts and deletes in parallel with a high scan load could a data node crashes due to a failure in the **DBACC** kernel block. This was because checking for when to perform bucket splits or merges considered the first 4 scans only. ([Bug#48700](#))
- The creation of an ordered index on a table undergoing DDL operations could cause a data node crash under certain timing-dependent conditions. ([Bug#48604](#))
- In certain cases, performing very large inserts on **NDB** tables when using **ndbmtd** caused the memory allocations for ordered or unique indexes (or both) to be exceeded. This could cause aborted transactions and possibly lead to data node failures. ([Bug#48037](#))

See also [Bug#48113](#).

- When employing **NDB** native backup to back up and restore an empty **NDB** table that used a non-sequential **AUTO\_INCREMENT** value, the **AUTO\_INCREMENT** value was not restored correctly. ([Bug#48005](#))
- **SHOW CREATE TABLE** did not display the **AUTO\_INCREMENT** value for **NDB** tables having **AUTO\_INCREMENT** columns. ([Bug#47865](#))
- Under some circumstances, when a scan encountered an error early in processing by the **DBTC** kernel block (see [The DBTC Block](#)), a node could crash as a result. Such errors could be caused by applications sending incorrect data, or, more rarely, by a **DROP TABLE** operation executed in parallel with a scan. ([Bug#47831](#))
- When starting a node and synchronizing tables, memory pages were allocated even for empty fragments. In certain situations, this could lead to insufficient memory. ([Bug#47782](#))
- **mysqld** allocated an excessively large buffer for handling **BLOB** values due to overestimating their size. (For each row, enough space was allocated to accommodate every **BLOB** or **TEXT** column value in the result set.) This could adversely affect performance when using tables containing **BLOB** or **TEXT** columns; in a few extreme cases, this issue could also cause the host system to run out of memory unexpectedly. ([Bug#47574](#))

See also [Bug#47572](#), [Bug#47573](#).

- **NDBCLUSTER** uses a dynamically-allocated buffer to store **BLOB** or **TEXT** column data that is read from rows in MySQL Cluster tables.

When an instance of the **NDBCLUSTER** table handler was recycled (this can happen due to table definition cache pressure or to operations such as **FLUSH TABLES** or **ALTER TABLE**), if the last row read contained blobs of zero length, the buffer was not freed, even though the reference to it was lost. This resulted in a memory leak.

For example, consider the table defined and populated as shown here:

```
CREATE TABLE t (a INT PRIMARY KEY, b LONGTEXT) ENGINE=NDB;
INSERT INTO t VALUES (1, REPEAT('F', 20000));
INSERT INTO t VALUES (2, '');
```

Now execute repeatedly a **SELECT** on this table, such that the zero-length **LONGTEXT** row is last, followed by a **FLUSH TABLES** statement (which forces the handler object to be re-used), as shown here:

```
SELECT a, length(b) FROM b1 ORDER BY a;
FLUSH TABLES;
```

Prior to the fix, this resulted in a memory leak proportional to the size of the stored **LONGTEXT** value each time these two statements were executed. ([Bug#47573](#))

See also [Bug#47572](#), [Bug#47574](#).

- Large transactions involving joins between tables containing `BLOB` columns used excessive memory. ([Bug#47572](#))  
See also [Bug#47573](#), [Bug#47574](#).
- A variable was left uninitialized while a data node copied data from its peers as part of its startup routine; if the starting node died during this phase, this could lead a crash of the cluster when the node was later restarted. ([Bug#47505](#))
- NDB stores blob column data in a separate, hidden table that is not accessible from MySQL. If this table was missing for some reason (such as accidental deletion of the file corresponding to the hidden table) when making a MySQL Cluster native backup, `ndb_restore` crashed when attempting to restore the backup. Now in such cases, `ndb_restore` fails with the error message `TABLE TABLE_NAME HAS BLOB COLUMN (COLUMN_NAME) WITH MISSING PARTS TABLE IN BACKUP` instead. ([Bug#47289](#))
- For very large values of `MaxNoOfTables + MaxNoOfAttributes`, the calculation for `StringMemory` could overflow when creating large numbers of tables, leading to NDB error 773 (`OUT OF STRING MEMORY, PLEASE MODIFY STRINGMEMORY CONFIG PARAMETER`), even when `StringMemory` was set to 100 (100 percent). ([Bug#47170](#))
- The default value for the `StringMemory` configuration parameter, unlike other MySQL Cluster configuration parameters, was not set in `ndb/src/mgmsrv/ConfigInfo.cpp`. ([Bug#47166](#))
- Signals from a failed API node could be received after an `API_FAILREQ` signal (see [Operations and Signals](#)) has been received from that node, which could result in invalid states for processing subsequent signals. Now, all pending signals from a failing API node are processed before any `API_FAILREQ` signal is received. ([Bug#47039](#))

See also [Bug#44607](#).

- Using triggers on NDB tables caused `ndb_autoincrement_prefetch_sz` to be treated as having the NDB kernel's internal default value (32) and the value for this variable as set on the cluster's SQL nodes to be ignored. ([Bug#46712](#))
- Full table scans failed to execute when the cluster contained more than 21 table fragments.

### Note

The number of table fragments in the cluster can be calculated as the number of data nodes, times 8 (that is, times the value of the internal constant `MAX_FRAG_PER_NODE`), divided by the number of replicas. Thus, when `NoOfReplicas = 1` at least 3 data nodes were required to trigger this issue, and when `NoOfReplicas = 2` at least 4 data nodes were required to do so.

([Bug#46490](#))

- Ending a line in the `config.ini` file with an extra semicolon character (`:`) caused reading the file to fail with a parsing error. ([Bug#46242](#))
- When combining an index scan and a delete with a primary key delete, the index scan and delete failed to initialize a flag properly. This could in rare circumstances cause a data node to crash. ([Bug#46069](#))
- Problems could arise when using `VARCHAR` columns whose size was greater than 341 characters and which used the `utf8_unicode_ci` collation. In some cases, this combination of conditions could cause certain queries and `OPTIMIZE TABLE` statements to crash `mysqld`. ([Bug#45053](#))
- Running an `ALTER TABLE` statement while an NDB backup was in progress caused `mysqld` to crash. ([Bug#44695](#))
- If a node failed while sending a fragmented long signal, the receiving node did not free long signal assembly resources that it had allocated for the fragments of the long signal that had already been received. ([Bug#44607](#))
- When performing auto-discovery of tables on individual SQL nodes, `NDBCLUSTER` attempted to overwrite existing `MyISAM.frm` files and corrupted them.

**Workaround.** In the `mysql` client, create a new table (`t2`) with same definition as the corrupted table (`t1`). Use your system shell or file manager to rename the old `.MYD` file to the new file name (for example, `mv t1.MYD t2.MYD`). In the `mysql` client, repair the new table, drop the old one, and rename the new table using the old file name (for example, `RENAME TABLE t2 TO t1`).

([Bug#42614](#))

- When starting a cluster with a great many tables, it was possible for MySQL client connections as well as the slave SQL thread to issue DML statements against MySQL Cluster tables before `mysqld` had finished connecting to the cluster and making all tables writeable. This resulted in `TABLE ... IS READ ONLY` errors for clients and the Slave SQL thread.

This issue is fixed by introducing the `--ndb-wait-setup` option for the MySQL server. This provides a configurable maximum amount of time that `mysqld` waits for all NDB tables to become writeable, before enabling MySQL clients or the slave SQL thread to connect. ([Bug#40679](#))

See also [Bug#46955](#).

- Running `ndb_restore` with the `--print` or `--print_log` option could cause it to crash. ([Bug#40428](#), [Bug#33040](#))
- When building MySQL Cluster, it was possible to configure the build using `--with-ndb-port` without supplying a port number. Now in such cases, `configure` fails with an error. ([Bug#38502](#))

See also [Bug#47941](#).

- An insert on an `NDB` table was not always flushed properly before performing a scan. One way in which this issue could manifest was that `LAST_INSERT_ID()` sometimes failed to return correct values when using a trigger on an `NDB` table. ([Bug#38034](#))
- If the cluster crashed during the execution of a `CREATE LOGFILE GROUP` statement, the cluster could not be restarted afterward. ([Bug#36702](#))

See also [Bug#34102](#).

- Some joins on large `NDB` tables having `TEXT` or `BLOB` columns could cause `mysqld` processes to leak memory. The joins did not need to reference the `TEXT` or `BLOB` columns directly for this issue to occur. ([Bug#36701](#))
- When the MySQL server SQL mode included `STRICT_TRANS_TABLES`, storage engine warnings and error codes specific to `NDB` were returned when errors occurred, instead of the MySQL server errors and error codes expected by some programming APIs (such as Connector/J) and applications. ([Bug#35990](#))
- On Mac OS X 10.5, commands entered in the management client failed and sometimes caused the client to hang, although management client commands invoked using the `--execute` (or `-e`) option from the system shell worked normally.

For example, the following command failed with an error and hung until killed manually, as shown here:

```
ndb_mgm> SHOW
WARNING, EVENT THREAD STARTUP FAILED, DEGRADED PRINTOUTS AS RESULT, ERRNO=36
^C
```

However, the same management client command, invoked from the system shell as shown here, worked correctly:

```
shell> ndb_mgm -e "SHOW"
```

([Bug#35751](#))

See also [Bug#34438](#).

- When a copying operation exhausted the available space on a data node while copying large `BLOB` columns, this could lead to failure of the data node and a `TABLE IS FULL` error on the SQL node which was executing the operation. Examples of such operations could include an `ALTER TABLE` that changed an `INT` column to a `BLOB` column, or a bulk insert of `BLOB` data that failed due to running out of space or to a duplicate key error. ([Bug#34583](#), [Bug#48040](#))

See also [Bug#41674](#), [Bug#45768](#).

- Trying to insert more rows than would fit into an `NDB` table caused data nodes to crash. Now in such situations, the insert fails gracefully with error 633 `TABLE FRAGMENT HASH INDEX HAS REACHED MAXIMUM POSSIBLE SIZE`. ([Bug#34348](#))
- The error message text for `NDB` error code 410 (`REDO LOG FILES OVERLOADED...`) was truncated. ([Bug#23662](#))
- **Disk Data:** As an optimization when inserting a row to an empty page, the page is not read, but rather simply initialized. However, this optimization was performed in all cases when an empty row was inserted, even though it should have been done only if it was the first time that the page had been used by a table or fragment. This is because, if the page had been in use, and then all records had been released from it, the page still needed to be read to learn its log sequence number (LSN).

This caused problems only if the page had been flushed using an incorrect LSN and the data node failed before any local checkpoint was completed—which would removed any need to apply the undo log, hence the incorrect LSN was ignored.

The user-visible result of the incorrect LSN was that it caused the data node to fail during a restart. It was perhaps also possible (although not conclusively proven) that this issue could lead to incorrect data. ([Bug#54986](#))

- **Disk Data:** Inserts of blob column values into a Disk Data table that exhausted the tablespace resulted in misleading error messages about rows not being found in the table rather than the expected error `OUT OF EXTENTS, TABLESPACE FULL`. ([Bug#48113](#))

See also [Bug#48037](#), [Bug#41674](#).

- **Disk Data:** A local checkpoint of an empty fragment could cause a crash during a system restart which was based on that LCP. ([Bug#47832](#))

See also [Bug#41915](#).

- **Disk Data:** Calculation of free space for Disk Data table fragments was sometimes done incorrectly. This could lead to unnecessary allocation of new extents even when sufficient space was available in existing ones for inserted data. In some cases, this might also lead to crashes when restarting data nodes.

### Note

This miscalculation was not reflected in the contents of the `INFORMATION_SCHEMA.FILES` table, as it applied to extents allocated to a fragment, and not to a file.

([Bug#47072](#))

- **Disk Data:** If the value set in the `config.ini` file for `FileSystemPathDD`, `FileSystemPathDataFiles`, or `FileSystemPathUndoFiles` was identical to the value set for `FileSystemPath`, that parameter was ignored when starting the data node with `--initial` option. As a result, the Disk Data files in the corresponding directory were not removed when performing an initial start of the affected data node or data nodes. ([Bug#46243](#))
- **Disk Data:** Repeatedly creating and then dropping Disk Data tables could eventually lead to data node failures. ([Bug#45794](#), [Bug#48910](#))
- **Disk Data:** When a crash occurs due to a problem in Disk Data code, the currently active page list is printed to `stdout` (that is, in one or more `ndb_nodeid_out.log` files). One of these lists could contain an endless loop; this caused a printout that was effectively never-ending. Now in such cases, a maximum of 512 entries is printed from each list. ([Bug#42431](#))
- **Cluster API:** When reading blob data with lock mode `LM_SimpleRead`, the lock was not upgraded as expected. ([Bug#51034](#))
- **Cluster API:** When a DML operation failed due to a uniqueness violation on an `NDB` table having more than one unique index, it was difficult to determine which constraint caused the failure; it was necessary to obtain an `NdbError` object, then decode its `details` property, which in could lead to memory management issues in application code.

To help solve this problem, a new API method `Ndb::getNdbErrorDetail()` is added, providing a well-formatted string containing more precise information about the index that caused the unique constraint violation. The following additional changes are also made in the NDB API:

- Use of `NdbError.details` is now deprecated in favor of the new method.
- The `NdbDictionary::listObjects()` method has been modified to provide more information.

For more information, see `Ndb::getNdbErrorDetail()`, [The NdbError Structure](#), and `Dictionary::listObjects()`. ([Bug#48851](#))

- **Cluster API:** The NDB API methods `Dictionary::listEvents()`, `Dictionary::listIndexes()`, `Dictionary::listObjects()`, and `NdbOperation::getErrorLine()` formerly had both `const` and non-`const` variants. The non-`const` versions of these methods have been removed. In addition, the `NdbOperation::getBlobHandle()` method has been re-implemented to provide consistent internal semantics. ([Bug#47798](#))
- **Cluster API:** In some circumstances, if an API node encountered a data node failure between the creation of a transaction and the start of a scan using that transaction, then any subsequent calls to `startTransaction()` and `closeTransaction()` could cause the same transaction to be started and closed repeatedly. ([Bug#47329](#))
- **Cluster API:** A duplicate read of a column caused NDB API applications to crash. ([Bug#45282](#))
- **Cluster API:** Performing multiple operations using the same primary key within the same `NdbTransaction::execute()` call could lead to a data node crash.

### Note

This fix does not make change the fact that performing multiple operations using the same primary key within the same `execute()` is not supported; because there is no way to determine the order of such operations, the result of such combined operations remains undefined.

([Bug#44065](#))

See also [Bug#44015](#).

- **Cluster API:** The error handling shown in the example file `ndbapi_scan.cpp` included with the MySQL Cluster distribu-

tion was incorrect. ([Bug#39573](#))

- **Cluster API:** When using blobs, calling `getBlobHandle()` requires the full key to have been set using `equal()`, because `getBlobHandle()` must access the key for adding blob table operations. However, if `getBlobHandle()` was called without first setting all parts of the primary key, the application using it crashed. Now, an appropriate error code is returned instead. ([Bug#28116](#), [Bug#48973](#))

## Changes in MySQL Cluster NDB 6.2.18 (5.1.34-ndb-6.2.18)

Bugs fixed:

- **Important Change: Partitioning:** User-defined partitioning of an `NDBCLUSTER` table without any primary key sometimes failed, and could cause `mysqld` to crash.

Now, if you wish to create an `NDBCLUSTER` table with user-defined partitioning, the table must have an explicit primary key, and all columns listed in the partitioning expression must be part of the primary key. The hidden primary key used by the `NDBCLUSTER` storage engine is not sufficient for this purpose. However, if the list of columns is empty (that is, the table is defined using `PARTITION BY [LINEAR] KEY()`), then no explicit primary key is required.

This change does not effect the partitioning of tables using any storage engine other than `NDBCLUSTER`. ([Bug#40709](#))

- An internal NDB API buffer was not properly initialized. ([Bug#44977](#))
- When a data node had written its GCI marker to the first page of a megabyte, and that node was later killed during restart after having processed that page (marker) but before completing a LCP, the data node could fail with filesystem errors. ([Bug#44952](#))

See also [Bug#42564](#), [Bug#44291](#).

- Inspection of the code revealed that several assignment operators (`=`) were used in place of comparison operators (`==`) in `Db-dihMain.cpp`. ([Bug#44567](#))

See also [Bug#44570](#).

- It was possible for NDB API applications to insert corrupt data into the database, which could subsequently lead to data node crashes. Now, stricter checking is enforced on input data for inserts and updates. ([Bug#44132](#))
- `TransactionDeadlockDetectionTimeout` values less than 100 were treated as 100. This could cause scans to time out unexpectedly. ([Bug#44099](#))
- The file `ndberror.c` contained a C++-style comment, which caused builds to fail with some C compilers. ([Bug#44036](#))
- A race condition could occur when a data node failed to restart just before being included in the next global checkpoint. This could cause other data nodes to fail. ([Bug#43888](#))
- When trying to use a data node with an older version of the management server, the data node crashed on startup. ([Bug#43699](#))
- Using indexes containing variable-sized columns could lead to internal errors when the indexes were being built. ([Bug#43226](#))
- In some cases, data node restarts during a system restart could fail due to insufficient redo log space. ([Bug#43156](#))
- Some queries using combinations of logical and comparison operators on an indexed column in the `WHERE` clause could fail with the error `GOT_ERROR 4541 'INDEXBOUND HAS NO BOUND INFORMATION' FROM NDBCLUSTER`. ([Bug#42857](#))
- `ndb_restore --print_data` did not handle `DECIMAL` columns correctly. ([Bug#37171](#))
- The output of `ndbd --help` did not provide clear information about the program's `--initial` and `--initial-start` options. ([Bug#28905](#))
- It was theoretically possible for the value of a nonexistent column to be read as `NULL`, rather than causing an error. ([Bug#27843](#))
- When aborting an operation involving both an insert and a delete, the insert and delete were aborted separately. This was because the transaction coordinator did not know that the operations affected on same row, and, in the case of a committed-read (tuple or index) scan, the abort of the insert was performed first, then the row was examined after the insert was aborted but before the delete was aborted. In some cases, this would leave the row in a inconsistent state. This could occur when a local checkpoint was performed during a backup. This issue did not affect primary key operations or scans that used locks (these are serialized).

After this fix, for ordered indexes, all operations that follow the operation to be aborted are now also aborted.

- **Disk Data: Partitioning:** An `NDBCLUSTER` table created with a very large value for the `MAX_ROWS` option could—if this table was dropped and a new table with fewer partitions, but having the same table ID, was created—cause `ndbd` to crash when performing a system restart. This was because the server attempted to examine each partition whether or not it actually existed. ([Bug#45154](#))
- **Disk Data:** During a checkpoint, restore points are created for both the on-disk and in-memory parts of a Disk Data table. Under certain rare conditions, the in-memory restore point could include or exclude a row that should have been in the snapshot. This would later lead to a crash during or following recovery. ([Bug#41915](#))

See also [Bug#47832](#).

- **Disk Data:** When a log file group had an undo log file whose size was too small, restarting data nodes failed with `READ UNDERFLOW` errors.

As a result of this fix, the minimum permitted `INITIAL_SIZE` for an undo log file is now `1M` (1 megabyte). ([Bug#29574](#))

- **Disk Data:** This fix supercedes and improves on an earlier fix made for this bug in MySQL 5.1.18. ([Bug#24521](#))
- **Cluster API:** If the largest offset of a `RecordSpecification` used for an `NdbRecord` object was for the `NULL` bits (and thus not a column), this offset was not taken into account when calculating the size used for the `RecordSpecification`. This meant that the space for the `NULL` bits could be overwritten by key or other information. ([Bug#43891](#))
- **Cluster API:** The default `NdbRecord` structures created by `NdbDictionary` could have overlapping null bits and data fields. ([Bug#43590](#))
- **Cluster API:** When performing insert or write operations, `NdbRecord` permits key columns to be specified in both the key record and in the attribute record. Only one key column value for each key column should be sent to the NDB kernel, but this was not guaranteed. This is now ensured as follows: For insert and write operations, key column values are taken from the key record; for scan takeover update operations, key column values are taken from the attribute record. ([Bug#42238](#))
- **Cluster API:** Ordered index scans using `NdbRecord` formerly expressed a `BoundEQ` range as separate lower and upper bounds, resulting in 2 copies of the column values being sent to the NDB kernel.

Now, when a range is specified by `NdbScanOperation::setBound()`, the passed pointers, key lengths, and inclusive bits are compared, and only one copy of the equal key columns is sent to the kernel. This makes such operations more efficient, as half the amount of `KeyInfo` is now sent for a `BoundEQ` range as before. ([Bug#38793](#))

## Changes in MySQL Cluster NDB 6.2.17 (5.1.32-ndb-6.2.17)

Functionality added or changed:

- **Important Change:** Formerly, when the management server failed to create a transporter for a data node connection, `net_write_timeout` seconds elapsed before the data node was actually permitted to disconnect. Now in such cases the disconnection occurs immediately. ([Bug#41965](#))

See also [Bug#41713](#).

- **Disk Data:** It is now possible to specify default locations for Disk Data data files and undo log files, either together or separately, using the data node configuration parameters `FileSystemPathDD`, `FileSystemPathDataFiles`, and `FileSystemPathUndoFiles`. For information about these configuration parameters, see [Disk Data filesystem parameters](#).

It is also now possible to specify a log file group, tablespace, or both, that is created when the cluster is started, using the `InitialLogFileGroup` and `InitialTablespace` data node configuration parameters. For information about these configuration parameters, see [Disk Data object creation parameters](#).

Bugs fixed:

- **Performance:** Updates of the `SYSTAB_0` system table to obtain a unique identifier did not use transaction hints for tables having no primary key. In such cases the NDB kernel used a cache size of 1. This meant that each insert into a table not having a primary key required an update of the corresponding `SYSTAB_0` entry, creating a potential performance bottleneck.

With this fix, inserts on `NDB` tables without primary keys can be under some conditions be performed up to 100% faster than previously. ([Bug#39268](#))

- **Packaging:** Packages for MySQL Cluster were missing the `libndbclient.so` and `libndbclient.a` files. ([Bug#42278](#))
- **Partitioning:** Executing `ALTER TABLE ... REORGANIZE PARTITION` on an `NDBCLUSTER` table having only one par-

tition caused `mysqld` to crash. ([Bug#41945](#))

See also [Bug#40389](#).

- **Cluster API:** Failed operations on `BLOB` and `TEXT` columns were not always reported correctly to the originating SQL node. Such errors were sometimes reported as being due to timeouts, when the actual problem was a transporter overload due to insufficient buffer space. ([Bug#39867](#), [Bug#39879](#))
- **Cluster API:** Failed operations on `BLOB` and `TEXT` columns were not always reported correctly to the originating SQL node. Such errors were sometimes reported as being due to timeouts, when the actual problem was a transporter overload due to insufficient buffer space. ([Bug#39867](#), [Bug#39879](#))
- Backup IDs greater than  $2^{31}$  were not handled correctly, causing negative values to be used in backup directory names and printouts. ([Bug#43042](#))
- When using `ndbmtd`, NDB kernel threads could hang while trying to start the data nodes with `LockPagesInMainMemory` set to 1. ([Bug#43021](#))
- When using multiple management servers and starting several API nodes (possibly including one or more SQL nodes) whose connectstrings listed the management servers in different order, it was possible for 2 API nodes to be assigned the same node ID. When this happened it was possible for an API node not to get fully connected, consequently producing a number of errors whose cause was not easily recognizable. ([Bug#42973](#))
- `ndb_error_reporter` worked correctly only with GNU `tar`. (With other versions of `tar`, it produced empty archives.) ([Bug#42753](#))
- Triggers on `NDBCLUSTER` tables caused such tables to become locked. ([Bug#42751](#))

See also [Bug#16229](#), [Bug#18135](#).

- When performing more than 32 index or tuple scans on a single fragment, the scans could be left hanging. This caused unnecessary timeouts, and in addition could possibly lead to a hang of an LCP. ([Bug#42559](#))
- A data node failure that occurred between calls to `NdbIndexScanOperation::readTuples(SF_OrderBy)` and `NdbTransaction::Execute()` was not correctly handled; a subsequent call to `nextResult()` caused a null pointer to be dereferenced, leading to a segfault in `mysqld`. ([Bug#42545](#))
- Issuing `SHOW GLOBAL STATUS LIKE 'NDB%'` before `mysqld` had connected to the cluster caused a segmentation fault. ([Bug#42458](#))
- Data node failures that occurred before all data nodes had connected to the cluster were not handled correctly, leading to additional data node failures. ([Bug#42422](#))
- When a cluster backup failed with Error 1304 (Node `node_id1`: Backup request from `node_id2` failed to start), no clear reason for the failure was provided.

As part of this fix, MySQL Cluster now retries backups in the event of sequence errors. ([Bug#42354](#))

See also [Bug#22698](#).

- Issuing `SHOW ENGINE NDBCLUSTER STATUS` on an SQL node before the management server had connected to the cluster caused `mysqld` to crash. ([Bug#42264](#))
- A maximum of 11 `TUP` scans were permitted in parallel. ([Bug#42084](#))
- Trying to execute an `ALTER ONLINE TABLE ... ADD COLUMN` statement while inserting rows into the table caused `mysqld` to crash. ([Bug#41905](#))
- If the master node failed during a global checkpoint, it was possible in some circumstances for the new master to use an incorrect value for the global checkpoint index. This could occur only when the cluster used more than one node group. ([Bug#41469](#))
- API nodes disconnected too aggressively from cluster when data nodes were being restarted. This could sometimes lead to the API node being unable to access the cluster at all during a rolling restart. ([Bug#41462](#))
- An abort path in the `DBLQH` kernel block failed to release a commit acknowledgment marker. This meant that, during node failure handling, the local query handler could be added multiple times to the marker record which could lead to additional node failures due to an array overflow. ([Bug#41296](#))
- During node failure handling (of a data node other than the master), there was a chance that the master was waiting for a `GCP_NODEFINISHED` signal from the failed node after having received it from all other data nodes. If this occurred while the

failed node had a transaction that was still being committed in the current epoch, the master node could crash in the `DBTC` kernel block when discovering that a transaction actually belonged to an epoch which was already completed. ([Bug#41295](#))

- If a transaction was aborted during the handling of a data node failure, this could lead to the later handling of an API node failure not being completed. ([Bug#41214](#))
- Given a MySQL Cluster containing no data (that is, whose data nodes had all been started using `--initial`, and into which no data had yet been imported) and having an empty backup directory, executing `START BACKUP` with a user-specified backup ID caused the data nodes to crash. ([Bug#41031](#))
- Issuing `EXIT` in the management client sometimes caused the client to hang. ([Bug#40922](#))
- Redo log creation was very slow on some platforms, causing MySQL Cluster to start more slowly than necessary with some combinations of hardware and operating system. This was due to all write operations being synchronized to disk while creating a redo log file. Now this synchronization occurs only after the redo log has been created. ([Bug#40734](#))
- Transaction failures took longer to handle than was necessary.

When a data node acting as transaction coordinator (TC) failed, the surviving data nodes did not inform the API node initiating the transaction of this until the failure had been processed by all protocols. However, the API node needed only to know about failure handling by the transaction protocol—that is, it needed to be informed only about the TC takeover process. Now, API nodes (including MySQL servers acting as cluster SQL nodes) are informed as soon as the TC takeover is complete, so that it can carry on operating more quickly. ([Bug#40697](#))

- It was theoretically possible for stale data to be read from `NDBCLUSTER` tables when the transaction isolation level was set to `ReadCommitted`. ([Bug#40543](#))
- In some cases, `NDB` did not check correctly whether tables had changed before trying to use the query cache. This could result in a crash of the debug MySQL server. ([Bug#40464](#))
- Restoring a MySQL Cluster from a dump made using `mysqldump` failed due to a spurious error: `CAN'T EXECUTE THE GIVEN COMMAND BECAUSE YOU HAVE ACTIVE LOCKED TABLES OR AN ACTIVE TRANSACTION.` ([Bug#40346](#))
- `O_DIRECT` was incorrectly disabled when making MySQL Cluster backups. ([Bug#40205](#))
- Events logged after setting `ALL CLUSTERLOG STATISTICS=15` in the management client did not always include the node ID of the reporting node. ([Bug#39839](#))
- Start phase reporting was inconsistent between the management client and the cluster log. ([Bug#39667](#))
- The MySQL Query Cache did not function correctly with `NDBCLUSTER` tables containing `TEXT` columns. ([Bug#39295](#))
- A segfault in `Logger::Log` caused `ndbd` to hang indefinitely. This fix improves on an earlier one for this issue, first made in MySQL Cluster NDB 6.2.16 and MySQL Cluster NDB 6.3.17. ([Bug#39180](#))

See also [Bug#38609](#).

- Memory leaks could occur in handling of strings used for storing cluster metadata and providing output to users. ([Bug#38662](#))
- In the event that a MySQL Cluster backup failed due to file permissions issues, conflicting reports were issued in the management client. ([Bug#34526](#))
- A duplicate key or other error raised when inserting into an `NDBCLUSTER` table caused the current transaction to abort, after which any SQL statement other than a `ROLLBACK` failed. With this fix, the `NDBCLUSTER` storage engine now performs an implicit rollback when a transaction is aborted in this way; it is no longer necessary to issue an explicit `ROLLBACK` statement, and the next statement that is issued automatically begins a new transaction.

### Note

It remains necessary in such cases to retry the complete transaction, regardless of which statement caused it to be aborted.

([Bug#32656](#))

See also [Bug#47654](#).

- Error messages for `NDBCLUSTER` error codes 1224 and 1227 were missing. ([Bug#28496](#))
- **Disk Data:** It was not possible to add an in-memory column online to a table that used a table-level or column-level `STORAGE DISK` option. The same issue prevented `ALTER ONLINE TABLE ... REORGANIZE PARTITION` from working on Disk Data tables. ([Bug#42549](#))

- **Disk Data:** Issuing concurrent `CREATE TABLESPACE`, `ALTER TABLESPACE`, `CREATE LOGFILE GROUP`, or `ALTER LOGFILE GROUP` statements on separate SQL nodes caused a resource leak that led to data node crashes when these statements were used again later. ([Bug#40921](#))
- **Disk Data:** Disk-based variable-length columns were not always handled like their memory-based equivalents, which could potentially lead to a crash of cluster data nodes. ([Bug#39645](#))
- **Disk Data:** Creating a Disk Data tablespace with a very large extent size caused the data nodes to fail. The issue was observed when using extent sizes of 100 MB and larger. ([Bug#39096](#))
- **Disk Data:** Creation of a tablespace data file whose size was greater than 4 GB failed silently on 32-bit platforms. ([Bug#37116](#))  
See also [Bug#29186](#).
- **Disk Data:** `O_SYNC` was incorrectly disabled on platforms that do not support `O_DIRECT`. This issue was noted on Solaris but could have affected other platforms not having `O_DIRECT` capability. ([Bug#34638](#))
- **Disk Data:** Trying to execute a `CREATE LOGFILE GROUP` statement using a value greater than `150M` for `UNDO_BUFFER_SIZE` caused data nodes to crash.

As a result of this fix, the upper limit for `UNDO_BUFFER_SIZE` is now `600M`; attempting to set a higher value now fails gracefully with an error. ([Bug#34102](#))

See also [Bug#36702](#).

- **Disk Data:** When attempting to create a tablespace that already existed, the error message returned was `TABLE OR INDEX WITH GIVEN NAME ALREADY EXISTS`. ([Bug#32662](#))
- **Disk Data:** Using a path or filename longer than 128 characters for Disk Data undo log files and tablespace data files caused a number of issues, including failures of `CREATE LOGFILE GROUP`, `ALTER LOGFILE GROUP`, `CREATE TABLESPACE`, and `ALTER TABLESPACE` statements, as well as crashes of management nodes and data nodes.

With this fix, the maximum length for path and file names used for Disk Data undo log files and tablespace data files is now the same as the maximum for the operating system. ([Bug#31769](#), [Bug#31770](#), [Bug#31772](#))

- **Disk Data:** Starting a cluster under load such that Disk Data tables used most of the undo buffer could cause data node failures. The fix for this bug also corrected an issue in the `LGMAN` kernel block where the amount of free space left in the undo buffer was miscalculated, causing buffer overruns. This could cause records in the buffer to be overwritten, leading to problems when restarting data nodes. ([Bug#28077](#))
- **Disk Data:** Attempting to perform a system restart of the cluster where there existed a logfile group without and undo log files caused the data nodes to crash.

### Note

While issuing a `CREATE LOGFILE GROUP` statement without an `ADD UNDOFILE` option fails with an error in the MySQL server, this situation could arise if an SQL node failed during the execution of a valid `CREATE LOGFILE GROUP` statement; it is also possible to create a logfile group without any undo log files using the NDB API.

([Bug#17614](#))

- **Cluster API:** Some error messages from `ndb_mgmd` contained newline (\n) characters. This could break the MGM API protocol, which uses the newline as a line separator. ([Bug#43104](#))
- **Cluster API:** When using an ordered index scan without putting all key columns in the read mask, this invalid use of the NDB API went undetected, which resulted in the use of uninitialized memory. ([Bug#42591](#))
- **Cluster API:** The MGM API reset error codes on management server handles before checking them. This meant that calling an MGM API function with a null handle caused applications to crash. ([Bug#40455](#))
- **Cluster API:** It was not always possible to access parent objects directly from `NdbBlob`, `NdbOperation`, and `NdbScanOperation` objects. To alleviate this problem, a new `getNdbOperation()` method has been added to `NdbBlob` and new `getNdbTransaction()` methods have been added to `NdbOperation` and `NdbScanOperation`. In addition, a const variant of `NdbOperation::getErrorLine()` is now also available. ([Bug#40242](#))
- **Cluster API:** `NdbScanOperation::getBlobHandle()` failed when used with incorrect column names or numbers. ([Bug#40241](#))
- **Cluster API:** The NDB API example programs included in MySQL Cluster source distributions failed to compile. ([Bug#37491](#))

See also [Bug#40238](#).

- **Cluster API:** `mgmapi.h` contained constructs which only worked in C++, but not in C. ([Bug#27004](#))

### Changes in MySQL Cluster NDB 6.2.16 (5.1.28-ndb-6.2.16)

Functionality added or changed:

- It is no longer a requirement for database autodiscovery that an SQL node already be connected to the cluster at the time that a database is created on another SQL node. It is no longer necessary to issue `CREATE DATABASE` (or `CREATE SCHEMA`) statements on an SQL node joining the cluster after a database is created for the new SQL node to see the database and any `NDBCLUSTER` tables that it contains. ([Bug#39612](#))

Bugs fixed:

- Heavy DDL usage caused the `mysqld` processes to hang due to a timeout error (`NDB` error code 266). ([Bug#39885](#))
- Executing `EXPLAIN SELECT` on an `NDBCLUSTER` table could cause `mysqld` to crash. ([Bug#39872](#))
- Starting the MySQL Server with the `--ndbcluster` option plus an invalid command-line option (for example, using `mysqld --ndbcluster --foobar`) caused it to hang while shutting down the binlog thread. ([Bug#39635](#))
- Dropping and then re-creating a database on one SQL node caused other SQL nodes to hang. ([Bug#39613](#))
- Setting a low value of `MaxNoOfLocalScans` (< 100) and performing a large number of (certain) scans could cause the Transaction Coordinator to run out of scan fragment records, and then crash. Now when this resource is exhausted, the cluster returns Error 291 (`OUT OF SCANFRAG RECORDS IN TC (INCREASE MAXNOFLOCALSCANS)`) instead. ([Bug#39549](#))
- Creating a unique index on an `NDBCLUSTER` table caused a memory leak in the `NDB` subscription manager (`SUMA`) which could lead to `mysqld` hanging, due to the fact that the resource shortage was not reported back to the `NDB` kernel correctly. ([Bug#39518](#))

See also [Bug#39450](#).

- Unique identifiers in tables having no primary key were not cached. This fix has been observed to increase the efficiency of `INSERT` operations on such tables by as much as 50%. ([Bug#39267](#))
- `MgmtSrvr::allocNodeId()` left a mutex locked following an `AMBIGUITY FOR NODE IF %D` error. ([Bug#39158](#))
- An invalid path specification caused `mysql-test-run.pl` to fail. ([Bug#39026](#))
- During transactional coordinator takeover (directly after node failure), the LQH finding an operation in the `LOG_COMMIT` state sent an `LQH_TRANS_CONF` signal twice, causing the TC to fail. ([Bug#38930](#))
- An invalid memory access caused the management server to crash on Solaris Sparc platforms. ([Bug#38628](#))
- A segfault in `Logger::Log` caused `ndbd` to hang indefinitely. ([Bug#38609](#))
- `ndb_mgmd` failed to start on older Linux distributions (2.4 kernels) that did not support e-polling. ([Bug#38592](#))
- When restarting a data node, an excessively long shutdown message could cause the node process to crash. ([Bug#38580](#))
- `ndb_mgmd` sometimes performed unnecessary network I/O with the client. This in combination with other factors led to long-running threads that were attempting to write to clients that no longer existed. ([Bug#38563](#))
- `ndb_restore` failed with a floating point exception due to a division by zero error when trying to restore certain data files. ([Bug#38520](#))
- A failed connection to the management server could cause a resource leak in `ndb_mgmd`. ([Bug#38424](#))
- Failure to parse configuration parameters could cause a memory leak in the `NDB` log parser. ([Bug#38380](#))
- After a forced shutdown and initial restart of the cluster, it was possible for SQL nodes to retain `.frm` files corresponding to `NDBCLUSTER` tables that had been dropped, and thus to be unaware that these tables no longer existed. In such cases, attempting to re-create the tables using `CREATE TABLE IF NOT EXISTS` could fail with a spurious `TABLE ... DOESN'T EXIST` error. ([Bug#37921](#))

- Renaming an `NDBCLUSTER` table on one SQL node, caused a trigger on this table to be deleted on another SQL node. ([Bug#36658](#))
- Attempting to add a `UNIQUE INDEX` twice to an `NDBCLUSTER` table, then deleting rows from the table could cause the MySQL Server to crash. ([Bug#35599](#))
- `ndb_restore` failed when a single table was specified. ([Bug#33801](#))
- `GCP_COMMIT` did not wait for transaction takeover during node failure. This could cause `GCP_SAVE_REQ` to be executed too early. This could also cause (very rarely) replication to skip rows. ([Bug#30780](#))
- **Cluster API:** Passing a value greater than 65535 to `NdbInterpretedCode::add_val()` and `NdbInterpretedCode::sub_val()` caused these methods to have no effect. ([Bug#39536](#))
- **Cluster API:** The `NdbScanOperation::readTuples()` method could be called multiple times without error. ([Bug#38717](#))
- **Cluster API:** Certain Multi-Range Read scans involving `IS NULL` and `IS NOT NULL` comparisons failed with an error in the `NDB` local query handler. ([Bug#38204](#))
- **Cluster API:** Problems with the public headers prevented `NDB` applications from being built with warnings turned on. ([Bug#38177](#))
- **Cluster API:** Creating an `NdbScanFilter` object using an `NdbScanOperation` object that had not yet had its `readTuples()` method called resulted in a crash when later attempting to use the `NdbScanFilter`. ([Bug#37986](#))
- **Cluster API:** Executing an `NdbRecord` interpreted delete created with an `ANYVALUE` option caused the transaction to abort. ([Bug#37672](#))
- **Cluster API:** Accesing the debug version of `libndbclient` using `dlopen()` resulted in a segmentation fault. ([Bug#35927](#))

### Changes in MySQL Cluster NDB 6.2.14 (5.1.23-ndb-6.2.14)

Functionality added or changed:

- Added the `MaxBufferedEpochs` data node configuration parameter, which controls the maximum number of unprocessed epochs by which a subscribing node can lag. Subscribers which exceed this number are disconnected and forced to reconnect.

See [Section 17.3.2.6, “Defining MySQL Cluster Data Nodes”](#), for more information.

Bugs fixed:

- **Incompatible Change:** The `UPDATE` statement permitted `NULL` to be assigned to `NOT NULL` columns (the implicit default value for the column data type was assigned). This was changed so that an error occurs.

This change was reverted, because the original report was determined not to be a bug: Assigning `NULL` to a `NOT NULL` column in an `UPDATE` statement should produce an error only in strict SQL mode and set the column to the implicit default with a warning otherwise, which was the original behavior. See [Section 10.1.4, “Data Type Default Values”](#), and [Bug#39265](#). ([Bug#33699](#))

- **Cluster API:** Closing a scan before it was executed caused the application to segfault. ([Bug#36375](#))
- **Cluster API:** Using NDB API applications from older MySQL Cluster versions with `libndbclient` from newer ones caused the cluster to fail. ([Bug#36124](#))
- **Cluster API:** Scans having no bounds set were handled incorrectly. ([Bug#35876](#))

### Changes in MySQL Cluster NDB 6.2.13 (5.1.23-ndb-6.2.13)

Bugs fixed:

- A node failure during an initial node restart followed by another node start could cause the master data node to fail, because it incorrectly gave the node permission to start even if the invalidated node's LCP was still running. ([Bug#34702](#))

## Changes in MySQL Cluster NDB 6.2.12 (5.1.23-ndb-6.2.12)

Bugs fixed:

- Upgrades of a cluster using while a `DataMemory` setting in excess of 16 GB caused data nodes to fail. ([Bug#34378](#))
- Performing many SQL statements on `NDB` tables while in `autocommit` mode caused a memory leak in `mysqld`. ([Bug#34275](#))
- In certain rare circumstances, a race condition could occur between an aborted insert and a delete leading a data node crash. ([Bug#34260](#))
- Multi-table updates using ordered indexes during handling of node failures could cause other data nodes to fail. ([Bug#34216](#))
- When configured with `NDB` support, MySQL failed to compile using `gcc` 4.3 on 64bit FreeBSD systems. ([Bug#34169](#))
- The failure of a DDL statement could sometimes lead to node failures when attempting to execute subsequent DDL statements. ([Bug#34160](#))
- Extremely long `SELECT` statements (where the text of the statement was in excess of 50000 characters) against `NDB` tables returned empty results. ([Bug#34107](#))
- Statements executing multiple inserts performed poorly on `NDB` tables having `AUTO_INCREMENT` columns. ([Bug#33534](#))
- The `ndb_warter` utility polled `ndb_mgmd` excessively when obtaining the status of cluster data nodes. ([Bug#32025](#))

See also [Bug#32023](#).

- Transaction atomicity was sometimes not preserved between reads and inserts under high loads. ([Bug#31477](#))
- Having tables with a great many columns could cause Cluster backups to fail. ([Bug#30172](#))
- **Cluster Replication: Disk Data:** Statements violating unique keys on Disk Data tables (such as attempting to insert `NULL` into a `NOT NULL` column) could cause data nodes to fail. When the statement was executed from the binlog, this could also result in failure of the slave cluster. ([Bug#34118](#))
- **Disk Data:** Updating in-memory columns of one or more rows of Disk Data table, followed by deletion of these rows and re-insertion of them, caused data node failures. ([Bug#33619](#))

## Changes in MySQL Cluster NDB 6.2.11 (5.1.23-ndb-6.2.11)

Functionality added or changed:

- **Cluster API: Important Change:** Because `NDB_LE_MemoryUsage.page_size_kb` shows memory page sizes in bytes rather than kilobytes, it has been renamed to `page_size_bytes`. The name `page_size_kb` is now deprecated and thus subject to removal in a future release, although it currently remains supported for reasons of backward compatibility. See [The Ndb\\_logevent\\_type Type](#), for more information about `NDB_LE_MemoryUsage`. ([Bug#30271](#))

Bugs fixed:

- High numbers of insert operations, delete operations, or both could cause `NDB` error 899 (`ROWID ALREADY ALLOCATED`) to occur unnecessarily. ([Bug#34033](#))
- A periodic failure to flush the send buffer by the `NDB` TCP transporter could cause a unnecessary delay of 10 ms between operations. ([Bug#34005](#))
- A race condition could occur (very rarely) when the release of a GCI was followed by a data node failure. ([Bug#33793](#))
- Some tuple scans caused the wrong memory page to be accessed, leading to invalid results. This issue could affect both in-memory and Disk Data tables. ([Bug#33739](#))
- The server failed to reject properly the creation of an `NDB` table having an unindexed `AUTO_INCREMENT` column. ([Bug#30417](#))
- Issuing an `INSERT ... ON DUPLICATE KEY UPDATE` concurrently with or following a `TRUNCATE TABLE` statement on an `NDB` table failed with `NDB` error 4350 `TRANSACTION ALREADY ABORTED`. ([Bug#29851](#))

- The Cluster backup process could not detect when there was no more disk space and instead continued to run until killed manually. Now the backup fails with an appropriate error when disk space is exhausted. ([Bug#28647](#))
- It was possible in `config.ini` to define cluster nodes having node IDs greater than the maximum permitted value. ([Bug#28298](#))
- **Cluster API:** Transactions containing inserts or reads would hang during `NdbTransaction::execute()` calls made from NDB API applications built against a MySQL Cluster version that did not support micro-GCPs accessing a later version that supported micro-GCPs. This issue was observed while upgrading from MySQL Cluster NDB 6.1.23 to MySQL Cluster NDB 6.2.10 when the API application built against the earlier version attempted to access a data node already running the later version, even after disabling micro-GCPs by setting `TimeBetweenEpochs` equal to 0. ([Bug#33895](#))
- **Cluster API:** When reading a `BIT(64)` value using `NdbOperation::getValue()`, 12 bytes were written to the buffer rather than the expected 8 bytes. ([Bug#33750](#))

### Changes in MySQL Cluster NDB 6.2.10 (5.1.23-ndb-6.2.10)

Bugs fixed:

- **Partitioning:** When partition pruning on an `NDB` table resulted in an ordered index scan spanning only one partition, any descending flag for the scan was wrongly discarded, causing `ORDER BY DESC` to be treated as `ORDER BY ASC, MAX()` to be handled incorrectly, and similar problems. ([Bug#33061](#))
- When all data and SQL nodes in the cluster were shut down abnormally (that is, other than by using `STOP` in the cluster management client), `ndb_mgm` used excessive amounts of CPU. ([Bug#33237](#))
- When using micro-GCPs, if a node failed while preparing for a global checkpoint, the master node would use the wrong GCI. ([Bug#32922](#))
- Under some conditions, performing an `ALTER TABLE` on an `NDBCCLUSTER` table failed with a `TABLE IS FULL` error, even when only 25% of `DataMemory` was in use and the result should have been a table using less memory (for example, changing a `VARCHAR(100)` column to `VARCHAR(80)`). ([Bug#32670](#))

### Changes in MySQL Cluster NDB 6.2.9 (5.1.22-ndb-6.2.9)

Functionality added or changed:

- Added the `ndb_mgm` client command `DUMP 8011`, which dumps all subscribers to the cluster log. See `DUMP 8011`, for more information.

Bugs fixed:

- A local checkpoint could sometimes be started before the previous LCP was restorable from a global checkpoint. ([Bug#32519](#))
- High numbers of API nodes on a slow or congested network could cause connection negotiation to time out prematurely, leading to the following issues:
  - Excessive retries
  - Excessive CPU usage
  - Partially connected API nodes ([Bug#32359](#))
- The failure of a master node could lead to subsequent failures in local checkpointing. ([Bug#32160](#))
- Adding a new `TINYTEXT` column to an `NDB` table which used `COLUMN_FORMAT = DYNAMIC`, and when binary logging was enabled, caused all cluster `mysqld` processes to crash. ([Bug#30213](#))
- After adding a new column of one of the `TEXT` or `BLOB` types to an `NDB` table which used `COLUMN_FORMAT = DYNAMIC`, it was no longer possible to access or drop the table using SQL. ([Bug#30205](#))
- A restart of the cluster failed when more than 1 REDO phase was in use. ([Bug#22696](#))

### Changes in MySQL Cluster NDB 6.2.8 (5.1.22-ndb-6.2.8)

---

Functionality added or changed:

- The output of the `ndb_mgm` client `SHOW` and `STATUS` commands now indicates when the cluster is in single user mode. ([Bug#27999](#))

Bugs fixed:

- In a cluster running in diskless mode and with arbitration disabled, the failure of a data node during an insert operation caused other data node to fail. ([Bug#31980](#))
- An insert or update with combined range and equality constraints failed when run against an `NDB` table with the error `GOT UNKNOWN ERROR FROM NDB`. An example of such a statement would be `UPDATE t1 SET b = 5 WHERE a IN (7,8) OR a >= 10;`. ([Bug#31874](#))
- An error with an `if` statement in `sql/ha_ndbcluster.cc` could potentially lead to an infinite loop in case of failure when working with `AUTO_INCREMENT` columns in `NDB` tables. ([Bug#31810](#))
- The `NDB` storage engine code was not safe for strict-alias optimization in `gcc 4.2.1`. ([Bug#31761](#))
- Following an upgrade, `ndb_mgmd` would fail with an `ArbitrationError`. ([Bug#31690](#))
- The `NDB` management client command `node_id REPORT MEMORY` provided no output when `node_id` was the node ID of a management or API node. Now, when this occurs, the management client responds with `Node node_id: is not a data node`. ([Bug#29485](#))
- Performing `DELETE` operations after a data node had been shut down could lead to inconsistent data following a restart of the node. ([Bug#26450](#))
- `UPDATE IGNORE` could sometimes fail on `NDB` tables due to the use of uninitialized data when checking for duplicate keys to be ignored. ([Bug#25817](#))

### Changes in MySQL Cluster NDB 6.2.7 (5.1.22-ndb-6.2.7)

Bugs fixed:

- It was possible in some cases for a node group to be “lost” due to missed local checkpoints following a system restart. ([Bug#31525](#))
- `NDB` tables having names containing nonalphanumeric characters (such as “\$”) were not discovered correctly. ([Bug#31470](#))
- A node failure during a local checkpoint could lead to a subsequent failure of the cluster during a system restart. ([Bug#31257](#))
- A cluster restart could sometimes fail due to an issue with table IDs. ([Bug#30975](#))
- Transaction timeouts were not handled well in some circumstances, leading to excessive number of transactions being aborted unnecessarily. ([Bug#30379](#))
- In some cases, the cluster management server logged entries multiple times following a restart of `mgmd`. ([Bug#29565](#))
- `ndb_mgm --help` did not display any information about the `-a` option. ([Bug#29509](#))
- The cluster log was formatted inconsistently and contained extraneous newline characters. ([Bug#25064](#))

### Changes in MySQL Cluster NDB 6.2.6 (5.1.22-ndb-6.2.6)

Functionality added or changed:

- Mapping of `NDB` error codes to MySQL storage engine error codes has been improved. ([Bug#28423](#))

Bugs fixed:

- **Partitioning:** `EXPLAIN PARTITIONS` reported partition usage by queries on `NDB` tables according to the standard MySQL hash function than the hash function used in the `NDB` storage engine. ([Bug#29550](#))

- When an **NDB** event was left behind but the corresponding table was later recreated and received a new table ID, the event could not be dropped. ([Bug#30877](#))
- Attempting to restore a backup made on a cluster host using one endian to a machine using the other endian could cause the cluster to fail. ([Bug#29674](#))
- The description of the `--print` option provided in the output from `ndb_restore --help` was incorrect. ([Bug#27683](#))
- Restoring a backup made on a cluster host using one endian to a machine using the other endian failed for **BLOB** and **DATE-TIME** columns. ([Bug#27543](#), [Bug#30024](#))
- An insufficiently descriptive and potentially misleading Error 4006 (`CONNECT FAILURE - OUT OF CONNECTION OBJECTS . . .`) was produced when either of the following two conditions occurred:
  1. There were no more transaction records in the transaction coordinator
  2. An **NDB** object in the NDB API was initialized with insufficient parallelismSeparate error messages are now generated for each of these two cases. ([Bug#11313](#))

### Changes in MySQL Cluster NDB 6.2.5 (5.1.22-ndb-6.2.5)

Functionality added or changed:

- The following improvements have been made in the `ndb_size.pl` utility:
    - The script can now be used with multiple databases; lists of databases and tables can also be excluded from analysis.
    - Schema name information has been added to index table calculations.
    - The database name is now an optional parameter, the exclusion of which causes all databases to be examined.
    - If selecting from `INFORMATION_SCHEMA` fails, the script now attempts to fall back to `SHOW TABLES`.
    - A `--real_table_name` option has been added; this designates a table to handle unique index size calculations.
    - The report title has been amended to cover cases where more than one database is being analyzed.
  - Support for a `--socket` option was also added.
- For more information, see [Section 17.4.21, “`ndb\_size.pl` — NDBCLUSTER Size Requirement Estimator”](#). ([Bug#28683](#), [Bug#28253](#))
- Online `ADD COLUMN`, `ADD INDEX`, and `DROP INDEX` operations can now be performed explicitly for **NDB** tables, as well as online renaming of tables and columns for **NDB** and **MyISAM** tables—that is, without copying or locking of the affected tables—using `ALTER ONLINE TABLE`.

Indexes can also be created and dropped online using `CREATE INDEX` and `DROP INDEX`, respectively, using the `ONLINE` keyword.

You can force operations that would otherwise be performed online to be done offline using the `OFFLINE` keyword.

See [Section 12.1.7, “`ALTER TABLE` Syntax”](#), [Section 12.1.13, “`CREATE INDEX` Syntax”](#), and [Section 12.1.24, “`DROP INDEX` Syntax”](#), for more information.

- It is now possible to control whether fixed-width or variable-width storage is used for a given column of an **NDB** table by means of the `COLUMN_FORMAT` specifier as part of the column's definition in a `CREATE TABLE` or `ALTER TABLE` statement.

It is also possible to control whether a given column of an **NDB** table is stored in memory or on disk, using the `STORAGE` specifier as part of the column's definition in a `CREATE TABLE` or `ALTER TABLE` statement.

For permitted values and other information about `COLUMN_FORMAT` and `STORAGE`, see [Section 12.1.17, “`CREATE TABLE` Syntax”](#).

- A new cluster management server startup option `--bind-address` makes it possible to restrict management client connections to `ndb_mgmd` to a single host and port. For more information, see [Section 17.4.4, “`ndb\_mgmd` — The MySQL Cluster Management Server Daemon”](#).

Bugs fixed:

- When handling `BLOB` columns, the addition of read locks to the lock queue was not handled correctly. ([Bug#30764](#))
- Discovery of `NDB` tables did not work correctly with `INFORMATION_SCHEMA`. ([Bug#30667](#))
- A file system close operation could fail during a node or system restart. ([Bug#30646](#))
- Using the `--ndb-cluster-connection-pool` option for `mysqld` caused DDL statements to be executed twice. ([Bug#30598](#))
- When creating an `NDB` table with a column that has `COLUMN_FORMAT = DYNAMIC`, but the table itself uses `ROW_FORMAT=FIXED`, the table is considered dynamic, but any columns for which the row format is unspecified default to `FIXED`. Now in such cases the server issues the warning `ROW FORMAT FIXED INCOMPATIBLE WITH DYNAMIC ATTRIBUTE COLUMN_NAME`. ([Bug#30276](#))
- `ndb_size.pl` failed on tables with `FLOAT` columns whose definitions included commas (for example, `FLOAT(6,2)`). ([Bug#29228](#))
- Reads on `BLOB` columns were not locked when they needed to be to guarantee consistency. ([Bug#29102](#))

See also [Bug#31482](#).

- A query using joins between several large tables and requiring unique index lookups failed to complete, eventually returning `UNKNOWN_ERROR` after a very long period of time. This occurred due to inadequate handling of instances where the Transaction Coordinator ran out of `TransactionBufferMemory`, when the cluster should have returned NDB error code 4012 (`REQUEST_NDBD_TIME-OUT`). ([Bug#28804](#))
- An attempt to perform a `SELECT ... FROM INFORMATION_SCHEMA.TABLES` whose result included information about NDB tables for which the user had no privileges crashed the MySQL Server on which the query was performed. ([Bug#26793](#))
- **Cluster API:** A call to `CHECK_TIMEDOUT_RET()` in `mgmapi.cpp` should have been a call to `DBG_CHECK_TIMEDOUT_RET()`. ([Bug#30681](#))

### Changes in MySQL Cluster NDB 6.2.4 (5.1.19-ndb-6.2.4)

Bugs fixed:

- When restarting a data node, queries could hang during that node's start phase 5, and continue only after the node had entered phase 6. ([Bug#29364](#))
- Replica redo logs were inconsistently handled during a system restart. ([Bug#29354](#))
- **Disk Data:** Performing Disk Data schema operations during a node restart could cause forced shutdowns of other data nodes. ([Bug#29501](#))
- **Disk Data:** Disk data meta-information that existed in `ndbd` might not be visible to `mysqld`. ([Bug#28720](#))
- **Disk Data:** The number of free extents was incorrectly reported for some tablespaces. ([Bug#28642](#))

### Changes in MySQL Cluster NDB 6.2.3 (5.1.19-ndb-6.2.3)

Functionality added or changed:

- **Important Change:** The `TimeBetweenWatchdogCheckInitial` configuration parameter was added to enable setting of a separate watchdog timeout for memory allocation during startup of the data nodes. See [Section 17.3.2.6, “Defining MySQL Cluster Data Nodes”](#), for more information. ([Bug#28899](#))
- **Cluster API: Important Change:** A new `NdbRecord` object has been added to the `NDB` API. This object provides mapping to a record stored in `NDB`. See [The NdbRecord Interface](#), for more information.
- `auto_increment_increment` and `auto_increment_offset` are now supported for `NDB` tables. ([Bug#26342](#))
- A `REPORT BackupStatus` command has been added in the cluster management client. This command enables you to obtain a backup status report at any time during a backup. For more about this command, see [Section 17.5.2, “Commands in the MySQL Cluster Management Client”](#).
- Reporting functionality has been significantly enhanced in this release:
  - A new configuration parameter `BackupReportFrequency` now makes it possible to cause the management client to

provide status reports at regular intervals as well as for such reports to be written to the cluster log (depending on cluster event logging levels). See [Section 17.3.2.6, “Defining MySQL Cluster Data Nodes”](#), for more information about this parameter.

- A new `REPORT` command has been added in the cluster management client. `REPORT BackupStatus` enables you to obtain a backup status report at any time during a backup. `REPORT MemoryUsage` reports the current data memory and index memory used by each data node. For more about the `REPORT` command, see [Section 17.5.2, “Commands in the MySQL Cluster Management Client”](#).
- `ndb_restore` now provides running reports of its progress when restoring a backup. In addition, a complete report status report on the backup is written to the cluster log.
- A new configuration parameter `ODirect` causes `NDB` to attempt using `O_DIRECT` writes for LCP, backups, and redo logs, often lowering CPU usage.
- `ndb_restore` now provides running reports of its progress when restoring a backup. In addition, a complete report status report on the backup is written to the cluster log.
- A new configuration parameter `BackupReportFrequency` now makes it possible to cause the management client to provide status reports at regular intervals as well as for such reports to be written to the cluster log (depending on cluster event logging levels). See [Section 17.3.2.6, “Defining MySQL Cluster Data Nodes”](#), for more information about this parameter.
- A new memory allocator has been implemented for the `NDB` kernel, which allocates memory to tables 32K page by 32K page rather than allocating it in variable-sized chunks as previously. This removes much of the memory overhead that was associated with the old memory allocator.

Bugs fixed:

- When a node failed to respond to a `COPY_GCI` signal as part of a global checkpoint, the master node was killed instead of the node that actually failed. ([Bug#29331](#))
- Memory corruption could occur due to a problem in the `DBTUP` kernel block. ([Bug#29229](#))
- A query having a large `IN(...)` or `NOT IN(...)` list in the `WHERE` condition on an `NDB` table could cause `mysqld` to crash. ([Bug#29185](#))
- In the event that two data nodes in the same node group and participating in a GCP crashed before they had written their respective `P0.sysfile` files, `QMGR` could refuse to start, issuing an invalid `INSUFFICIENT NODES FOR RESTART` error instead. ([Bug#29167](#))
- An invalid comparison made during `REDO` validation that could lead to an `ERROR WHILE READING REDO LOG` condition. ([Bug#29118](#))
- Attempting to restore a `NULL` row to a `VARBINARY` column caused `ndb_restore` to fail. ([Bug#29103](#))
- `ndb_error_reporter` now preserves timestamps on files. ([Bug#29074](#))
- The wrong data pages were sometimes invalidated following a global checkpoint. ([Bug#29067](#))
- If at least 2 files were involved in `REDO` invalidation, then file 0 of page 0 was not updated and so pointed to an invalid part of the redo log. ([Bug#29057](#))
- It is now possible to set the maximum size of the allocation unit for table memory using the `MaxAllocate` configuration parameter. ([Bug#29044](#))
- When shutting down `mysqld`, the `NDB` binlog process was not shut down before log cleanup began. ([Bug#28949](#))
- A corrupt schema file could cause a `FILE ALREADY OPEN` error. ([Bug#28770](#))
- Having large amounts of memory locked caused swapping to disk. ([Bug#28751](#))
- Setting `InitialNoOpenFiles` equal to `MaxNoOfOpenFiles` caused an error. This was due to the fact that the actual value of `MaxNoOfOpenFiles` as used by the cluster was offset by 1 from the value set in `config.ini`. ([Bug#28749](#))
- LCP files were not removed following an initial system restart. ([Bug#28726](#))
- `UPDATE IGNORE` statements involving the primary keys of multiple tables could result in data corruption. ([Bug#28719](#))

- A race condition could result when nonmaster nodes (in addition to the master node) tried to update active status due to a local checkpoint (that is, between `NODE_FAILREP` and `COPY_GCIREQ` events). Now only the master updates the active status. ([Bug#28717](#))
- A fast global checkpoint under high load with high usage of the redo buffer caused data nodes to fail. ([Bug#28653](#))
- The management client's response to `START BACKUP WAIT COMPLETED` did not include the backup ID. ([Bug#27640](#))
- **Disk Data:** When dropping a page, the stack's bottom entry could sometime be left “cold” rather than “hot”, violating the rules for stack pruning. ([Bug#29176](#))
- **Disk Data:** When loading data into a cluster following a version upgrade, the data nodes could forcibly shut down due to page and buffer management failures (that is, `ndbrequire` failures in `PGMAN`). ([Bug#28525](#))
- **Disk Data:** Repeated `INSERT` and `DELETE` operations on a Disk Data table having one or more large `VARCHAR` columns could cause data nodes to fail. ([Bug#20612](#))
- **Cluster API:** The timeout set using the MGM API `ndb_mgm_set_timeout()` function was incorrectly interpreted as seconds rather than as milliseconds. ([Bug#29063](#))
- **Cluster API:** An invalid error code could be set on transaction objects by `BLOB` handling code. ([Bug#28724](#))

### Changes in MySQL Cluster NDB 6.2.2 (5.1.18-ndb-6.2.2)

Functionality added or changed:

- New cluster management client `DUMP` commands were added to aid in tracking transactions, scan operations, and locks. See `DUMP 2350`, `DUMP 2352`, and `DUMP 2550`, for more information.
- Added the `mysqld` option `--ndb-cluster-connection-pool` that enables a single MySQL server to use multiple connections to the cluster. This enables scaling out using multiple MySQL clients per SQL node instead of or in addition to using multiple SQL nodes with the cluster.

For more information about this option, see [Section 17.3.4, “MySQL Server Options and Variables for MySQL Cluster”](#).

### Changes in MySQL Cluster NDB 6.2.1 (5.1.18-ndb-6.2.1)

Bugs fixed:

- Multiple operations involving deletes followed by reads were not handled correctly.

#### Note

This issue could also affect MySQL Cluster Replication.

([Bug#28276](#))

- **Cluster API:** Using `NdbBlob::writeData()` to write data in the middle of an existing blob value (that is, updating the value) could overwrite some data past the end of the data to be changed. ([Bug#27018](#))

### Changes in MySQL Cluster NDB 6.2.0 (5.1.16-ndb-6.2.0)

Functionality added or changed:

- An `ndb_wait_connected` system variable has been added for `mysqld`. It causes `mysqld` wait a specified amount of time to be connected to the cluster before accepting client connections. For more information, see [Section 17.3.4.3, “MySQL Cluster System Variables”](#).
- **Cluster API:** The `Ndb::startTransaction()` method now provides an alternative interface for starting a transaction. See `Ndb::startTransaction()`, for more information.
- **Cluster API:** Methods were added to the `Ndb_cluster_connection` class to facilitate iterating over existing `NDB` objects. See `ndb_cluster_connection::get_next_ndb_object()`, for more information.

## 17.7.6.5. Changes in the MySQL Cluster NDB 6.1 Series

This section contains unified change history highlights for all MySQL Cluster releases based on version 6.1 of the `NDBCLUSTER` storage engine through MySQL Cluster NDB 5.1.15-ndb-6.1.23. Included are all changelog entries in the categories *MySQL Cluster*, *Disk Data*, and *Cluster API*.

For an overview of features that were added in MySQL Cluster NDB 6.1, see [Section 17.1.4.5, “MySQL Cluster Development in MySQL Cluster NDB 6.1”](#).

### Note

MySQL Cluster NDB 6.1 is no longer being developed or maintained, and the information presented in this section should be considered to be of historical interest only. If you are using MySQL Cluster NDB 6.1, you should upgrade as soon as possible to the most recent version of MySQL Cluster NDB 6.2 or later MySQL Cluster release series.

### Changes in MySQL Cluster NDB 6.1.23 (5.1.15-ndb-6.1.23)

Bugs fixed:

- The `NDB` storage engine code was not safe for strict-alias optimization in `gcc` 4.2.1. ([Bug#31761](#))

### Changes in MySQL Cluster NDB 6.1.22 (5.1.15-ndb-6.1.22)

Bugs fixed:

- It was possible in some cases for a node group to be “lost” due to missed local checkpoints following a system restart. ([Bug#31525](#))

#### Changes in MySQL Cluster NDB 6.1.21 (5.1.15-ndb-6.1.21)

Bugs fixed:

- A node failure during a local checkpoint could lead to a subsequent failure of the cluster during a system restart. ([Bug#31257](#))
- A cluster restart could sometimes fail due to an issue with table IDs. ([Bug#30975](#))

#### Changes in MySQL Cluster NDB 6.1.19 (5.1.15-ndb-6.1.19)

Functionality added or changed:

- Whenever a TCP send buffer is over 80% full, temporary error 1218 (`SEND BUFFERS OVERLOADED IN NDB KERNEL`) is now returned. See [SendBufferMemory](#) for more information.

#### Changes in MySQL Cluster NDB 6.1.18 (5.1.15-ndb-6.1.18)

Bugs fixed:

- When restarting a data node, queries could hang during that node's start phase 5, and continue only after the node had entered phase 6. ([Bug#29364](#))
- **Disk Data:** Disk data meta-information that existed in `ndbd` might not be visible to `mysqld`. ([Bug#28720](#))
- **Disk Data:** The number of free extents was incorrectly reported for some tablespaces. ([Bug#28642](#))

#### Changes in MySQL Cluster NDB 6.1.17 (5.1.15-ndb-6.1.17)

Bugs fixed:

- Replica redo logs were inconsistently handled during a system restart. ([Bug#29354](#))

#### Changes in MySQL Cluster NDB 6.1.16 (5.1.15-ndb-6.1.16)

Bugs fixed:

- When a node failed to respond to a `COPY_GCI` signal as part of a global checkpoint, the master node was killed instead of the node that actually failed. ([Bug#29331](#))
- An invalid comparison made during `REDO` validation that could lead to an `ERROR WHILE READING REDO LOG` condition. ([Bug#29118](#))
- The wrong data pages were sometimes invalidated following a global checkpoint. ([Bug#29067](#))
- If at least 2 files were involved in `REDO` invalidation, then file 0 of page 0 was not updated and so pointed to an invalid part of the redo log. ([Bug#29057](#))
- **Disk Data:** When dropping a page, the stack's bottom entry could sometime be left “cold” rather than “hot”, violating the rules for stack pruning. ([Bug#29176](#))

#### Changes in MySQL Cluster NDB 6.1.15 (5.1.15-ndb-6.1.15)

Bugs fixed:

- Memory corruption could occur due to a problem in the `DBTUP` kernel block. ([Bug#29229](#))

### Changes in MySQL Cluster NDB 6.1.14 (5.1.15-ndb-6.1.14)

Bugs fixed:

- In the event that two data nodes in the same node group and participating in a GCP crashed before they had written their respective `P0.sysfile` files, `QMGR` could refuse to start, issuing an invalid `INSUFFICIENT NODES FOR RESTART` error instead. ([Bug#29167](#))

### Changes in MySQL Cluster NDB 6.1.13 (5.1.15-ndb-6.1.13)

Bugs fixed:

- **Cluster API:** `NdbApi.hpp` depended on `ndb_global.h`, which was not actually installed, causing the compilation of programs that used `NdbApi.hpp` to fail. ([Bug#35853](#))

### Changes in MySQL Cluster NDB 6.1.12 (5.1.15-ndb-6.1.12)

Functionality added or changed:

- New cluster management client `DUMP` commands were added to aid in tracking transactions, scan operations, and locks. See [DUMP 2350](#), [DUMP 2352](#), and [DUMP 2550](#).

Bugs fixed:

- It is now possible to set the maximum size of the allocation unit for table memory using the `MaxAllocate` configuration parameter. ([Bug#29044](#))

### Changes in MySQL Cluster NDB 6.1.11 (5.1.15-ndb-6.1.11)

Functionality added or changed:

- **Important Change:** The `TimeBetweenWatchdogCheckInitial` configuration parameter was added to enable setting of a separate watchdog timeout for memory allocation during startup of the data nodes. See [Section 17.3.2.6, “Defining MySQL Cluster Data Nodes”](#), for more information. ([Bug#28899](#))
- A new configuration parameter `ODirect` causes `NDB` to attempt using `O_DIRECT` writes for LCP, backups, and redo logs, often lowering CPU usage.

Bugs fixed:

- Having large amounts of memory locked caused swapping to disk. ([Bug#28751](#))
- LCP files were not removed following an initial system restart. ([Bug#28726](#))
- **Disk Data:** Repeated `INSERT` and `DELETE` operations on a Disk Data table having one or more large `VARCHAR` columns could cause data nodes to fail. ([Bug#20612](#))

### Changes in MySQL Cluster NDB 6.1.10 (5.1.15-ndb-6.1.10)

Functionality added or changed:

- A new `times` printout was added in the `ndbd` watchdog thread.
- Some unneeded printouts in the `ndbd` out file were removed.

Bugs fixed:

- A regression in the heartbeat monitoring code could lead to node failure under high load. This issue affected MySQL 5.1.19 and

MySQL Cluster NDB 6.1.10 only. ([Bug#28783](#))

- A corrupt schema file could cause a `FILE ALREADY OPEN` error. ([Bug#28770](#))
- Setting `InitialNoOpenFiles` equal to `MaxNoOfOpenFiles` caused an error. This was due to the fact that the actual value of `MaxNoOfOpenFiles` as used by the cluster was offset by 1 from the value set in `config.ini`. ([Bug#28749](#))
- A race condition could result when nonmaster nodes (in addition to the master node) tried to update active status due to a local checkpoint (that is, between `NODE_FAILREP` and `COPY_GCIREQ` events). Now only the master updates the active status. ([Bug#28717](#))
- A fast global checkpoint under high load with high usage of the redo buffer caused data nodes to fail. ([Bug#28653](#))
- **Disk Data:** When loading data into a cluster following a version upgrade, the data nodes could forcibly shut down due to page and buffer management failures (that is, `ndbrequire` failures in `PGMAN`). ([Bug#28525](#))

#### Changes in MySQL Cluster NDB 6.1.9 (5.1.15-ndb-6.1.9)

Bugs fixed:

- When an API node sent more than 1024 signals in a single batch, `NDB` would process only the first 1024 of these, and then hang. ([Bug#28443](#))
- **Disk Data:** The cluster backup process scanned in `ACC` index order, which had bad effects for disk data. ([Bug#28593](#))

#### Changes in MySQL Cluster NDB 6.1.8 (5.1.15-ndb-6.1.8)

Bugs fixed:

- Local checkpoint files relating to dropped `NDB` tables were not removed. ([Bug#28348](#))
- Repeated insertion of data generated by `mysqldump` into `NDB` tables could eventually lead to failure of the cluster. ([Bug#27437](#))
- **Disk Data:** Extremely large inserts into Disk Data tables could lead to data node failure in some circumstances. ([Bug#27942](#))
- **Cluster API:** In a multi-operation transaction, a delete operation followed by the insertion of an implicit `NULL` failed to overwrite an existing value. ([Bug#20535](#))

#### Changes in MySQL Cluster NDB 6.1.7 (5.1.15-ndb-6.1.7)

Functionality added or changed:

- **Cluster Replication: Incompatible Change:** The schema for the `ndb_apply_status` table in the `mysql` system database has changed. When upgrading to this release from a previous MySQL Cluster NDB 6.x or mainline MySQL 5.1 release, you must drop the `mysql.ndb_apply_status` table, then restart the server for the table to be re-created with the new schema.

See [Section 17.6.4, “MySQL Cluster Replication Schema and Tables”](#), for additional information.

Bugs fixed:

- The cluster waited 30 seconds instead of 30 milliseconds before reading table statistics. ([Bug#28093](#))
- Under certain rare circumstances, `ndbd` could get caught in an infinite loop when one transaction took a read lock and then a second transaction attempted to obtain a write lock on the same tuple in the lock queue. ([Bug#28073](#))
- Under some circumstances, a node restart could fail to update the Global Checkpoint Index (GCI). ([Bug#28023](#))
- An `INSERT` followed by a delete `DELETE` on the same `NDB` table caused a memory leak. ([Bug#27756](#))

This regression was introduced by [Bug#20612](#).

- Under certain rare circumstances performing a `DROP TABLE` or `TRUNCATE TABLE` on an `NDB` table could cause a node failure or forced cluster shutdown. ([Bug#27581](#))

- Memory usage of a `mysqld` process grew even while idle. ([Bug#27560](#))
- Performing a delete followed by an insert during a local checkpoint could cause a `ROWID ALREADY ALLOCATED` error. ([Bug#27205](#))
- **Cluster Replication: Disk Data:** An issue with replication of Disk Data tables could in some cases lead to node failure. ([Bug#28161](#))
- **Disk Data:** Changes to a Disk Data table made as part of a transaction could not be seen by the client performing the changes until the transaction had been committed. ([Bug#27757](#))
- **Disk Data:** When restarting a data node following the creation of a large number of Disk Data objects (approximately 200 such objects), the cluster could not assign a node ID to the restarting node. ([Bug#25741](#))
- **Disk Data:** Changing a column specification or issuing a `TRUNCATE TABLE` statement on a Disk Data table caused the table to become an in-memory table.

This fix supersedes an incomplete fix that was made for this issue in MySQL 5.1.15. ([Bug#24667](#), [Bug#25296](#))

- **Cluster API:** An issue with the way in which the `NdbDictionary::Dictionary::listEvents()` method freed resources could sometimes lead to memory corruption. ([Bug#27663](#))

### Changes in MySQL Cluster NDB 6.1.6 (5.1.15-ndb-6.1.6)

Functionality added or changed:

- **Cluster Replication: Incompatible Change:** The schema for the `ndb_apply_status` table in the `mysql` system database has changed. When upgrading to this release from a previous MySQL Cluster NDB 6.x or mainline MySQL 5.1 release, you must drop the `mysql.ndb_apply_status` table, then restart the server for the table to be re-created with the new schema.

See [Section 17.6.4, “MySQL Cluster Replication Schema and Tables”](#), for additional information.

Bugs fixed:

- A data node failing while another data node was restarting could leave the cluster in an inconsistent state. In certain rare cases, this could lead to a race condition and the eventual forced shutdown of the cluster. ([Bug#27466](#))
- It was not possible to set `LockPagesInMainMemory` equal to 0. ([Bug#27291](#))
- A race condition could sometimes occur if the node acting as master failed while node IDs were still being allocated during startup. ([Bug#27286](#))
- When a data node was taking over as the master node, a race condition could sometimes occur as the node was assuming responsibility for handling of global checkpoints. ([Bug#27283](#))
- `mysqld` could crash shortly after a data node failure following certain DML operations. ([Bug#27169](#))
- The same failed request from an API node could be handled by the cluster multiple times, resulting in reduced performance. ([Bug#27087](#))
- The failure of a data node while restarting could cause other data nodes to hang or crash. ([Bug#27003](#))
- `mysqld` processes would sometimes crash under high load.

#### Note

This fix improves on and replaces a fix for this bug that was made in MySQL Cluster NDB 6.1.5.

([Bug#26825](#))

- **Disk Data:** `DROP INDEX` on a Disk Data table did not always move data from memory into the tablespace. ([Bug#25877](#))
- **Cluster API:** An issue with the way in which the `NdbDictionary::Dictionary::listEvents()` method freed resources could sometimes lead to memory corruption. ([Bug#27663](#))
- **Cluster API:** A delete operation using a scan followed by an insert using a scan could cause a data node to fail. ([Bug#27203](#))

## Changes in MySQL Cluster NDB 6.1.5 (5.1.15-ndb-6.1.5)

Functionality added or changed:

- **Cluster Replication: Incompatible Change:** The schema for the `ndb_apply_status` table in the `mysql` system database has changed. When upgrading to this release from a previous MySQL Cluster NDB 6.x or mainline MySQL 5.1 release, you must drop the `mysql.ndb_apply_status` table, then restart the server for the table to be re-created with the new schema.

See [Section 17.6.4, “MySQL Cluster Replication Schema and Tables”](#), for additional information.

Bugs fixed:

- Creating a table on one SQL node while in single user mode caused other SQL nodes to crash. ([Bug#26997](#))
- `mysqld` processes would sometimes crash under high load.

### Note

This fix was reverted in MySQL Cluster NDB 6.1.6.

([Bug#26825](#))

- An infinite loop in an internal logging function could cause trace logs to fill up with `UNKNOWN SIGNAL TYPE` error messages and thus grow to unreasonable sizes. ([Bug#26720](#))
- **Disk Data:** When creating a log file group, setting `INITIAL_SIZE` to less than `UNDO_BUFFER_SIZE` caused data nodes to crash. ([Bug#25743](#))

## Changes in MySQL Cluster NDB 6.1.4 (5.1.15-ndb-6.1.4)

Functionality added or changed:

- An `ndb_wait_connected` system variable has been added for `mysqld`. It causes `mysqld` wait a specified amount of time to be connected to the cluster before accepting client connections. For more information, see [Section 17.3.4.3, “MySQL Cluster System Variables”](#).
- **Cluster API:** It is now possible to specify the transaction coordinator when starting a transaction. See `Ndb::startTransaction()`, for more information.
- **Cluster API:** It is now possible to iterate over all existing `NDB` objects using three new methods of the `Ndb_cluster_connection` class:

- `lock_ndb_objects()`
- `get_next_ndb_object()`
- `unlock_ndb_objects()`

For more information about these methods and their use, see `ndb_cluster_connection::get_next_ndb_object()`, in the MySQL Cluster API Guide.

Bugs fixed:

- Using only the `--print_data` option (and no other options) with `ndb_restore` caused `ndb_restore` to fail. ([Bug#26741](#))

This regression was introduced by [Bug#14612](#).

- An inadvertent use of unaligned data caused `ndb_restore` to fail on some 64-bit platforms, including Sparc and Itanium-2. ([Bug#26739](#))

## Changes in MySQL Cluster NDB 6.1.3 (5.1.15-ndb-6.1.3)

Functionality added or changed:

- The `ndbd_redo_log_reader` utility is now part of the default build. For more information, see [Section 17.4.16, “`ndbd\_redo\_log\_reader` — Check and Print Content of Cluster Redo Log”](#).
- The `ndb_show_tables` utility now displays information about table events. See [Section 17.4.20, “`ndb\_show\_tables` — Display List of NDB Tables”](#), for more information.
- **Cluster API:** A new `listEvents()` method has been added to the `Dictionary` class. See [Dictionary::listEvents\(\)](#), for more information.

Bugs fixed:

- An invalid pointer was returned following a `FSCLOSECONF` signal when accessing the REDO logs during a node restart or system restart. ([Bug#26515](#))
- The `InvalidUndoBufferSize` error used the same error code ([763](#)) as the `IncompatibleVersions` error. `InvalidUndoBufferSize` now uses its own error code ([779](#)). ([Bug#26490](#))
- The failure of a data node when restarting it with `--initial` could lead to failures of subsequent data node restarts. ([Bug#26481](#))
- Takeover for local checkpointing due to multiple failures of master nodes was sometimes incorrectly handled. ([Bug#26457](#))
- The `LockPagesInMainMemory` parameter was not read until after distributed communication had already started between cluster nodes. When the value of this parameter was `1`, this could sometimes result in data node failure due to missed heartbeats. ([Bug#26454](#))
- Under some circumstances, following the restart of a management node, all data nodes would connect to it normally, but some of them subsequently failed to log any events to the management node. ([Bug#26293](#))
- No appropriate error message was provided when there was insufficient REDO log file space for the cluster to start. ([Bug#25801](#))
- A memory allocation failure in `SUMA` (the cluster Subscription Manager) could cause the cluster to crash. ([Bug#25239](#))
- The message `ERROR 0 IN READAUTOINCREMENTVALUE( ) : NO_ERROR` was written to the error log whenever `SHOW TABLE STATUS` was performed on a Cluster table that did not have an `AUTO_INCREMENT` column.

### Note

This improves on and supersedes an earlier fix that was made for this issue in MySQL 5.1.12.

([Bug#21033](#))

- **Disk Data:** A memory overflow could occur with tables having a large amount of data stored on disk, or with queries using a very high degree of parallelism on Disk Data tables. ([Bug#26514](#))
- **Disk Data:** Use of a tablespace whose `INITIAL_SIZE` was greater than 1 GB could cause the cluster to crash. ([Bug#26487](#))

## Changes in MySQL Cluster NDB 6.1.2 (5.1.15-ndb-6.1.2)

Bugs fixed:

- Using node IDs greater than 48 could sometimes lead to incorrect memory access and a subsequent forced shutdown of the cluster. ([Bug#26267](#))

## Changes in MySQL Cluster NDB 6.1.1 (5.1.15-ndb-6.1.1)

Functionality added or changed:

- A single cluster can now support up to 255 API nodes, including MySQL servers acting as SQL nodes. See [Section 17.1.5.8, “Issues Exclusive to MySQL Cluster”](#), for more information.

Bugs fixed:

- A memory leak could cause problems during a node or cluster shutdown or failure. ([Bug#25997](#))
- **Cluster API: Disk Data:** A delete and a read performed in the same operation could cause one or more data nodes to crash. This could occur when the operation affected more than 5 columns concurrently, or when one or more of the columns was of the `VARCHAR` type and was stored on disk. ([Bug#25794](#))
- **Cluster API: Disk Data:** A delete and a read performed in the same operation could cause one or more data nodes to crash. This could occur when the operation affected more than 5 columns concurrently, or when one or more of the columns was of the `VARCHAR` type and was stored on disk. ([Bug#25794](#))

### Changes in MySQL Cluster NDB 6.1.0 (5.1.14-ndb-6.1.0)

Functionality added or changed:

- A new configuration parameter `MemReportFrequency` enables additional control of data node memory usage. Previously, only warnings at predetermined percentages of memory allocation were given; setting this parameter enables that behavior to be overridden. For more information, see [Section 17.3.2.6, “Defining MySQL Cluster Data Nodes”](#).

Bugs fixed:

- When a data node was shut down using the management client `STOP` command, a connection event (`NDB_LE_Connected`) was logged instead of a disconnection event (`NDB_LE_Disconnected`). ([Bug#22773](#))
- `SELECT` statements with a `BLOB` or `TEXT` column in the selected column list and a `WHERE` condition including a primary key lookup on a `VARCHAR` primary key produced empty result sets. ([Bug#19956](#))
- **Disk Data:** `MEDIUMTEXT` columns of Disk Data tables were stored in memory rather than on disk, even if the columns were not indexed. ([Bug#25001](#))
- **Disk Data:** Performing a node restart with a newly dropped Disk Data table could lead to failure of the node during the restart. ([Bug#24917](#))
- **Disk Data:** When restoring from backup a cluster containing any Disk Data tables with hidden primary keys, a node failure resulted which could lead to a crash of the cluster. ([Bug#24166](#))
- **Disk Data:** Repeated `CREATE`, `DROP`, or `TRUNCATE TABLE` in various combinations with system restarts between these operations could lead to the eventual failure of a system restart. ([Bug#21948](#))
- **Disk Data:** Extents that should have been available for re-use following a `DROP TABLE` operation were not actually made available again until after the cluster had performed a local checkpoint. ([Bug#17605](#))
- **Cluster API:** Invoking the `NdbTransaction::execute()` method using execution type `Commit` and abort option `AO_IgnoreError` could lead to a crash of the transaction coordinator (`DBTC`). ([Bug#25090](#))
- **Cluster API:** A unique index lookup on a nonexistent tuple could lead to a data node timeout (error 4012). ([Bug#25059](#))
- **Cluster API:** When using the `NdbTransaction::execute()` method, a very long timeout (greater than 5 minutes) could result if the last data node being polled was disconnected from the cluster. ([Bug#24949](#))
- **Cluster API:** Due to an error in the computation of table fragment arrays, some transactions were not executed from the correct starting point. ([Bug#24914](#))

---

# Chapter 18. Partitioning

This chapter discusses MySQL's implementation of *user-defined partitioning*. You can determine whether your MySQL Server supports partitioning by means of a `SHOW VARIABLES` statement such as this one:

```
mysql> SHOW VARIABLES LIKE '%partition%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| have_partitioning | YES |
+-----+-----+
1 row in set (0.00 sec)
```

## Note

Prior to MySQL 5.1.6, this variable was named `have_partition_engine`. ([Bug#16718](#))

You can also check the output of the `SHOW PLUGINS` statement, as shown here:

```
mysql> SHOW PLUGINS;
+-----+-----+-----+-----+-----+
| Name | Status | Type | Library | License |
+-----+-----+-----+-----+-----+
| binlog | ACTIVE | STORAGE ENGINE | NULL | GPL |
| partition | ACTIVE | STORAGE ENGINE | NULL | GPL |
| ARCHIVE | ACTIVE | STORAGE ENGINE | NULL | GPL |
| BLACKHOLE | ACTIVE | STORAGE ENGINE | NULL | GPL |
| CSV | ACTIVE | STORAGE ENGINE | NULL | GPL |
| FEDERATED | DISABLED | STORAGE ENGINE | NULL | GPL |
| MEMORY | ACTIVE | STORAGE ENGINE | NULL | GPL |
| InnoDB | ACTIVE | STORAGE ENGINE | NULL | GPL |
| MRG_MYISAM | ACTIVE | STORAGE ENGINE | NULL | GPL |
| MyISAM | ACTIVE | STORAGE ENGINE | NULL | GPL |
| ndbcluster | DISABLED | STORAGE ENGINE | NULL | GPL |
+-----+-----+-----+-----+-----+
11 rows in set (0.00 sec)
```

If you do not see the `have_partitioning` variable with the value `YES` listed in the output of an appropriate `SHOW VARIABLES` statement, or if you do not see the `partition` plugin listed with the value `ACTIVE` for the `Status` column in the output of `SHOW PLUGINS` (show in bold text in the example just given), then your version of MySQL was not built with partitioning support.

MySQL Community binaries provided by Oracle Corporation include partitioning support. For information about partitioning support offered in commercial MySQL Server binaries, see [MySQL Enterprise Server 5.1](#), on the MySQL Web site.

If you are compiling MySQL 5.1 from source, the build must be configured using `--with-partition` to enable partitioning.

If your MySQL binary is built with partitioning support, nothing further needs to be done to enable it (for example, no special entries are required in your `my.cnf` file).

If you want to disable partitioning support, you can start the MySQL Server with the `--skip-partition` option, in which case the value of `have_partitioning` is `DISABLED`. However, if you do this, you cannot access any partitioned tables until the server is once again restarted without the `--skip-partition` option.

An introduction to partitioning and partitioning concepts may be found in [Section 18.1, “Overview of Partitioning in MySQL”](#).

MySQL supports several types of partitioning, which are discussed in [Section 18.2, “Partition Types”](#), as well as subpartitioning, which is described in [Section 18.2.5, “Subpartitioning”](#).

Methods of adding, removing, and altering partitions in existing partitioned tables are covered in [Section 18.3, “Partition Management”](#).

Table maintenance commands for use with partitioned tables are discussed in [Section 18.3.3, “Maintenance of Partitions”](#).

Beginning with MySQL 5.1.6, the `PARTITIONS` table in the `INFORMATION_SCHEMA` database provides information about partitions and partitioned tables. See [Section 20.19, “The INFORMATION\\_SCHEMA PARTITIONS Table”](#), for more information; for some examples of queries against this table, see [Section 18.2.6, “How MySQL Partitioning Handles NULL”](#).

## Important

Partitioned tables created with MySQL versions prior to 5.1.6 cannot be read by a 5.1.6 or later MySQL Server. In addition, the `INFORMATION_SCHEMA.TABLES` table cannot be used if such tables are present on a 5.1.6 server. Beginning with MySQL 5.1.7, a suitable warning message is generated instead, to alert the user that incompatible partitioned tables have been found by the server.

If you are using partitioned tables which were created in MySQL 5.1.5 or earlier, be sure to see [Section C.1.51, “Changes in MySQL 5.1.6 \(01 February 2006\)”](#) for more information and suggested workarounds *before* upgrading to MySQL 5.1.6 or later.

The partitioning implementation in MySQL 5.1 is still undergoing development. For known issues with MySQL partitioning, see [Section 18.5, “Restrictions and Limitations on Partitioning”](#), where we have noted these.

You may also find the following resources to be useful when working with partitioned tables.

**Additional Resources.** Other sources of information about user-defined partitioning in MySQL include the following:

- [MySQL Partitioning Forum](#)

This is the official discussion forum for those interested in or experimenting with MySQL Partitioning technology. It features announcements and updates from MySQL developers and others. It is monitored by members of the Partitioning Development and Documentation Teams.

- [Mikael Ronström’s Blog](#)

MySQL Partitioning Architect and Lead Developer Mikael Ronström frequently posts articles here concerning his work with MySQL Partitioning and MySQL Cluster.

- [PlanetMySQL](#)

A MySQL news site featuring MySQL-related blogs, which should be of interest to anyone using MySQL. We encourage you to check here for links to blogs kept by those working with MySQL Partitioning, or to have your own blog added to those covered.

MySQL 5.1 binaries are available from <http://dev.mysql.com/downloads/mysql/5.1.html>. However, for the latest partitioning bug-fixes and feature additions, you can obtain the source from our Bazaar repository. To enable partitioning, you need to compile the server using the `--with-partition` option. For more information about building MySQL, see [Section 2.3, “Installing MySQL Using a Source Distribution”](#). If you have problems compiling a partitioning-enabled MySQL 5.1 build, check the [MySQL Partitioning Forum](#) and ask for assistance there if you do not find a solution to your problem already posted.

## 18.1. Overview of Partitioning in MySQL

This section provides a conceptual overview of partitioning in MySQL 5.1.

For information on partitioning restrictions and feature limitations, see [Section 18.5, “Restrictions and Limitations on Partitioning”](#).

The SQL standard does not provide much in the way of guidance regarding the physical aspects of data storage. The SQL language itself is intended to work independently of any data structures or media underlying the schemas, tables, rows, or columns with which it works. Nonetheless, most advanced database management systems have evolved some means of determining the physical location to be used for storing specific pieces of data in terms of the file system, hardware or even both. In MySQL, the [InnoDB](#) storage engine has long supported the notion of a tablespace, and the MySQL Server, even prior to the introduction of partitioning, could be configured to employ different physical directories for storing different databases (see [Section 7.9.7, “Using Symbolic Links”](#), for an explanation of how this is done).

*Partitioning* takes this notion a step further, by enabling you to distribute portions of individual tables across a file system according to rules which you can set largely as needed. In effect, different portions of a table are stored as separate tables in different locations. The user-selected rule by which the division of data is accomplished is known as a *partitioning function*, which in MySQL can be the modulus, simple matching against a set of ranges or value lists, an internal hashing function, or a linear hashing function. The function is selected according to the partitioning type specified by the user, and takes as its parameter the value of a user-supplied expression. This expression can be either an integer column value, or a function acting on one or more column values and returning an integer. The value of this expression is passed to the partitioning function, which returns an integer value representing the number of the partition in which that particular record should be stored. This function must be nonconstant and nonrandom. It may not contain any queries, but may use an SQL expression that is valid in MySQL, as long as that expression returns either `NULL` or an integer `intval` such that

```
-MAXVALUE <= intval <= MAXVALUE
```

(`MAXVALUE` is used to represent the least upper bound for the type of integer in question. `-MAXVALUE` represents the greatest lower bound.) There are some additional restrictions on partitioning functions; see [Section 18.5, “Restrictions and Limitations on Partitioning”](#), for more information about these.

Examples of partitioning functions can be found in the discussions of partitioning types later in this chapter (see [Section 18.2, “Partition Types”](#)), as well as in the partitioning syntax descriptions given in [Section 12.1.17, “CREATE TABLE Syntax”](#).

This is known as *horizontal partitioning*—that is, different rows of a table may be assigned to different physical partitions. MySQL

5.1 does not support *vertical partitioning*, in which different columns of a table are assigned to different physical partitions. There are not at this time any plans to introduce vertical partitioning into MySQL 5.1.

For information about determining whether your MySQL Server binary supports user-defined partitioning, see [Chapter 18, “Partitioning”](#).

For creating partitioned tables, you can use most storage engines that are supported by your MySQL server; the MySQL partitioning engine runs in a separate layer and can interact with any of these. In MySQL 5.1, all partitions of the same partitioned table must use the same storage engine; for example, you cannot use [MyISAM](#) for one partition and [InnoDB](#) for another. However, there is nothing preventing you from using different storage engines for different partitioned tables on the same MySQL server or even in the same database.

### Note

MySQL partitioning cannot be used with the [MERGE](#) or [CSV](#) storage engines. Beginning with MySQL 5.1.15, [FEDERATED](#) tables also cannot be partitioned ([Bug#22451](#)). Prior to MySQL 5.1.6, it was also not feasible to create a partitioned table using the [BLACKHOLE](#) storage engine ([Bug#14524](#)).

Partitioning by [KEY](#) or [LINEAR KEY](#) is possible with [NDBCLUSTER](#), but other types of user-defined partitioning are not supported for tables using this storage engine. In addition, an [NDBCLUSTER](#) table that employs user-defined partitioning must have an explicit primary key, and any columns referenced in the table's partitioning expression must be part of the primary key. However, if no columns are listed in the [PARTITION BY KEY](#) or [PARTITION BY LINEAR KEY](#) clause of the [CREATE TABLE](#) or [ALTER TABLE](#) statement used to create or modify a user-partitioned [NDBCLUSTER](#) table, then the table is not required to have an explicit primary key.

For more information, see [Section 18.5.2, “Partitioning Limitations Relating to Storage Engines”](#), and [Section 17.1.5.1, “Noncompliance with SQL Syntax in MySQL Cluster”](#).

To employ a particular storage engine for a partitioned table, it is necessary only to use the [\[ STORAGE \] ENGINE](#) option just as you would for a nonpartitioned table. However, you should keep in mind that [\[ STORAGE \] ENGINE](#) (and other table options) need to be listed *before* any partitioning options are used in a [CREATE TABLE](#) statement. This example shows how to create a table that is partitioned by hash into 6 partitions and which uses the [InnoDB](#) storage engine:

```
CREATE TABLE ti (id INT, amount DECIMAL(7,2), tr_date DATE)
 ENGINE=INNODB
 PARTITION BY HASH(MONTH(tr_date))
 PARTITIONS 6;
```

### Note

Each [PARTITION](#) clause can include a [\[ STORAGE \] ENGINE](#) option, but in MySQL 5.1 this has no effect.

### Important

Partitioning applies to all data and indexes of a table; you cannot partition only the data and not the indexes, or *vice versa*, nor can you partition only a portion of the table.

Data and indexes for each partition can be assigned to a specific directory using the [DATA DIRECTORY](#) and [INDEX DIRECTORY](#) options for the [PARTITION](#) clause of the [CREATE TABLE](#) statement used to create the partitioned table.

### Note

Prior to MySQL 5.1.18, these options were permitted even when the [NO\\_DIR\\_IN\\_CREATE](#) server SQL mode was in effect. ([Bug#24633](#))

The [DATA DIRECTORY](#) and [INDEX DIRECTORY](#) options have no effect when defining partitions for tables using the [InnoDB](#) storage engine.

[DATA DIRECTORY](#) and [INDEX DIRECTORY](#) are not supported for individual partitions or subpartitions on Windows. Beginning with MySQL 5.1.24, these options are ignored on Windows, except that a warning is generated. ([Bug#30459](#))

In addition, [MAX\\_ROWS](#) and [MIN\\_ROWS](#) can be used to determine the maximum and minimum numbers of rows, respectively, that can be stored in each partition. See [Section 18.3, “Partition Management”](#), for more information on these options.

Some of the advantages of partitioning include:

- Being able to store more data in one table than can be held on a single disk or file system partition.
- Data that loses its usefulness can often be easily removed from the table by dropping the partition containing only that data. Conversely, the process of adding new data can in some cases be greatly facilitated by adding a new partition specifically for

that data.

- Some queries can be greatly optimized in virtue of the fact that data satisfying a given `WHERE` clause can be stored only on one or more partitions, thereby excluding any remaining partitions from the search. Because partitions can be altered after a partitioned table has been created, you can reorganize your data to enhance frequent queries that may not have been so when the partitioning scheme was first set up. This capability, sometimes referred to as *partition pruning*, was implemented in MySQL 5.1.6. For more information, see [Section 18.4, “Partition Pruning”](#).

Other benefits usually associated with partitioning include those in the following list. These features are not currently implemented in MySQL Partitioning, but are high on our list of priorities.

- Queries involving aggregate functions such as `SUM()` and `COUNT()` can easily be parallelized. A simple example of such a query might be `SELECT salesperson_id, COUNT(orders) as order_total FROM sales GROUP BY salesperson_id;`. By “parallelized,” we mean that the query can be run simultaneously on each partition, and the final result obtained merely by summing the results obtained for all partitions.
- Achieving greater query throughput in virtue of spreading data seeks over multiple disks.

Be sure to check this section and chapter frequently for updates as Partitioning development continues.

## 18.2. Partition Types

This section discusses the types of partitioning which are available in MySQL 5.1. These include:

- **RANGE partitioning.** This type of partitioning assigns rows to partitions based on column values falling within a given range. See [Section 18.2.1, “RANGE Partitioning”](#).
- **LIST partitioning.** Similar to partitioning by `RANGE`, except that the partition is selected based on columns matching one of a set of discrete values. See [Section 18.2.2, “LIST Partitioning”](#).
- **HASH partitioning.** With this type of partitioning, a partition is selected based on the value returned by a user-defined expression that operates on column values in rows to be inserted into the table. The function may consist of any expression valid in MySQL that yields a nonnegative integer value. An extension to this type, `LINEAR HASH`, is also available. See [Section 18.2.3, “HASH Partitioning”](#).
- **KEY partitioning.** This type of partitioning is similar to partitioning by `HASH`, except that only one or more columns to be evaluated are supplied, and the MySQL server provides its own hashing function. These columns can contain other than integer values, since the hashing function supplied by MySQL guarantees an integer result regardless of the column data type. An extension to this type, `LINEAR KEY`, is also available. See [Section 18.2.4, “KEY Partitioning”](#).

A very common use of database partitioning is to segregate data by date. Some database systems support explicit date partitioning, which MySQL does not implement in 5.1. However, it is not difficult in MySQL to create partitioning schemes based on `DATE`, `TIME`, or `DATETIME` columns, or based on expressions making use of such columns.

When partitioning by `KEY` or `LINEAR KEY`, you can use a `DATE`, `TIME`, or `DATETIME` column as the partitioning column without performing any modification of the column value. For example, this table creation statement is perfectly valid in MySQL:

```
CREATE TABLE members (
 firstname VARCHAR(25) NOT NULL,
 lastname VARCHAR(25) NOT NULL,
 username VARCHAR(16) NOT NULL,
 email VARCHAR(35),
 joined DATE NOT NULL
)
PARTITION BY KEY(joined)
PARTITIONS 6;
```

MySQL's other partitioning types, however, require a partitioning expression that yields an integer value or `NULL`. If you wish to use date-based partitioning by `RANGE`, `LIST`, `HASH`, or `LINEAR HASH`, you can simply employ a function that operates on a `DATE`, `TIME`, or `DATETIME` column and returns such a value, as shown here:

```
CREATE TABLE members (
 firstname VARCHAR(25) NOT NULL,
 lastname VARCHAR(25) NOT NULL,
 username VARCHAR(16) NOT NULL,
 email VARCHAR(35),
 joined DATE NOT NULL
)
PARTITION BY RANGE(YEAR(joined)) (
 PARTITION p0 VALUES LESS THAN (1960),
```

```

 PARTITION p1 VALUES LESS THAN (1970),
 PARTITION p2 VALUES LESS THAN (1980),
 PARTITION p3 VALUES LESS THAN (1990),
 PARTITION p4 VALUES LESS THAN MAXVALUE
);

```

Additional examples of partitioning using dates may be found here:

- [Section 18.2.1, “RANGE Partitioning”](#)
- [Section 18.2.3, “HASH Partitioning”](#)
- [Section 18.2.3.1, “LINEAR HASH Partitioning”](#)

For more complex examples of date-based partitioning, see:

- [Section 18.4, “Partition Pruning”](#)
- [Section 18.2.5, “Subpartitioning”](#)

MySQL partitioning is optimized for use with the `TO_DAYS()` and `YEAR()` functions. However, you can use other date and time functions that return an integer or `NULL`, such as `WEEKDAY()`, `DAYOFYEAR()`, or `MONTH()`. See [Section 11.7, “Date and Time Functions”](#), for more information about such functions.

It is important to remember—regardless of the type of partitioning that you use—that partitions are always numbered automatically and in sequence when created, starting with `0`. When a new row is inserted into a partitioned table, it is these partition numbers that are used in identifying the correct partition. For example, if your table uses 4 partitions, these partitions are numbered `0`, `1`, `2`, and `3`. For the `RANGE` and `LIST` partitioning types, it is necessary to ensure that there is a partition defined for each partition number. For `HASH` partitioning, the user function employed must return an integer value greater than `0`. For `KEY` partitioning, this issue is taken care of automatically by the hashing function which the MySQL server employs internally.

Names of partitions generally follow the rules governing other MySQL identifiers, such as those for tables and databases. However, you should note that partition names are not case-sensitive. For example, the following `CREATE TABLE` statement fails as shown:

```

mysql> CREATE TABLE t2 (val INT
-> PARTITION BY LIST(val)(
-> PARTITION mypart VALUES IN (1,3,5),
-> PARTITION MyPart VALUES IN (2,4,6)
->);
ERROR 1488 (HY000): Duplicate partition name mypart

```

Failure occurs because MySQL sees no difference between the partition names `mypart` and `MyPart`.

When you specify the number of partitions for the table, this must be expressed as a positive, nonzero integer literal with no leading zeros, and may not be an expression such as `0.8E+01` or `6-2`, even if it evaluates to an integer value. (Beginning with MySQL 5.1.12, decimal fractions are no longer truncated, but instead are prohibited entirely.)

In the sections that follow, we do not necessarily provide all possible forms for the syntax that can be used for creating each partition type; this information may be found in [Section 12.1.17, “CREATE TABLE Syntax”](#).

## 18.2.1. RANGE Partitioning

A table that is partitioned by range is partitioned in such a way that each partition contains rows for which the partitioning expression value lies within a given range. Ranges should be contiguous but not overlapping, and are defined using the `VALUES LESS THAN` operator. For the next few examples, suppose that you are creating a table such as the following to hold personnel records for a chain of 20 video stores, numbered 1 through 20:

```

CREATE TABLE employees (
 id INT NOT NULL,
 fname VARCHAR(30),
 lname VARCHAR(30),
 hired DATE NOT NULL DEFAULT '1970-01-01',
 separated DATE NOT NULL DEFAULT '9999-12-31',
 job_code INT NOT NULL,
 store_id INT NOT NULL
);

```

This table can be partitioned by range in a number of ways, depending on your needs. One way would be to use the `store_id` column. For instance, you might decide to partition the table 4 ways by adding a `PARTITION BY RANGE` clause as shown here:

```

CREATE TABLE employees (
 id INT NOT NULL,
 fname VARCHAR(30),
 lname VARCHAR(30),
 hired DATE NOT NULL DEFAULT '1970-01-01',
 separated DATE NOT NULL DEFAULT '9999-12-31',
 job_code INT NOT NULL,
 store_id INT NOT NULL
)
PARTITION BY RANGE (store_id) (
 PARTITION p0 VALUES LESS THAN (6),
 PARTITION p1 VALUES LESS THAN (11),
 PARTITION p2 VALUES LESS THAN (16),
 PARTITION p3 VALUES LESS THAN (21)
);

```

In this partitioning scheme, all rows corresponding to employees working at stores 1 through 5 are stored in partition `p0`, to those employed at stores 6 through 10 are stored in partition `p1`, and so on. Note that each partition is defined in order, from lowest to highest. This is a requirement of the `PARTITION BY RANGE` syntax; you can think of it as being analogous to a series of `if ... elseif ...` statements in C or Java in this regard.

It is easy to determine that a new row containing the data `(72, 'Michael', 'Widenius', '1998-06-25', NULL, 13)` is inserted into partition `p2`, but what happens when your chain adds a 21<sup>st</sup> store? Under this scheme, there is no rule that covers a row whose `store_id` is greater than 20, so an error results because the server does not know where to place it. You can keep this from occurring by using a “catchall” `VALUES LESS THAN` clause in the `CREATE TABLE` statement that provides for all values greater than highest value explicitly named:

```

CREATE TABLE employees (
 id INT NOT NULL,
 fname VARCHAR(30),
 lname VARCHAR(30),
 hired DATE NOT NULL DEFAULT '1970-01-01',
 separated DATE NOT NULL DEFAULT '9999-12-31',
 job_code INT NOT NULL,
 store_id INT NOT NULL
)
PARTITION BY RANGE (store_id) (
 PARTITION p0 VALUES LESS THAN (6),
 PARTITION p1 VALUES LESS THAN (11),
 PARTITION p2 VALUES LESS THAN (16),
 PARTITION p3 VALUES LESS THAN MAXVALUE
);

```

### Note

Another way to avoid an error when no matching value is found is to use the `IGNORE` keyword as part of the `INSERT` statement. For an example, see [Section 18.2.2, “LIST Partitioning”](#). Also see [Section 12.2.5, “`INSERT` Syntax”](#), for general information about `IGNORE`.

`MAXVALUE` represents an integer value that is always greater than the largest possible integer value (in mathematical language, it serves as a *least upper bound*). Now, any rows whose `store_id` column value is greater than or equal to 16 (the highest value defined) are stored in partition `p3`. At some point in the future—when the number of stores has increased to 25, 30, or more—you can use an `ALTER TABLE` statement to add new partitions for stores 21-25, 26-30, and so on (see [Section 18.3, “Partition Management”](#), for details of how to do this).

In much the same fashion, you could partition the table based on employee job codes—that is, based on ranges of `job_code` column values. For example—assuming that two-digit job codes are used for regular (in-store) workers, three-digit codes are used for office and support personnel, and four-digit codes are used for management positions—you could create the partitioned table using the following:

```

CREATE TABLE employees (
 id INT NOT NULL,
 fname VARCHAR(30),
 lname VARCHAR(30),
 hired DATE NOT NULL DEFAULT '1970-01-01',
 separated DATE NOT NULL DEFAULT '9999-12-31',
 job_code INT NOT NULL,
 store_id INT NOT NULL
)
PARTITION BY RANGE (job_code) (
 PARTITION p0 VALUES LESS THAN (100),
 PARTITION p1 VALUES LESS THAN (1000),
 PARTITION p2 VALUES LESS THAN (10000)
);

```

In this instance, all rows relating to in-store workers would be stored in partition `p0`, those relating to office and support staff in `p1`, and those relating to managers in partition `p2`.

It is also possible to use an expression in `VALUES LESS THAN` clauses. However, MySQL must be able to evaluate the expression's return value as part of a `LESS THAN (<)` comparison.

Rather than splitting up the table data according to store number, you can use an expression based on one of the two `DATE` columns instead. For example, let us suppose that you wish to partition based on the year that each employee left the company; that is, the value of `YEAR(separated)`. An example of a `CREATE TABLE` statement that implements such a partitioning scheme is shown here:

```
CREATE TABLE employees (
 id INT NOT NULL,
 fname VARCHAR(30),
 lname VARCHAR(30),
 hired DATE NOT NULL DEFAULT '1970-01-01',
 separated DATE NOT NULL DEFAULT '9999-12-31',
 job_code INT,
 store_id INT
)
PARTITION BY RANGE (YEAR(separated)) (
 PARTITION p0 VALUES LESS THAN (1991),
 PARTITION p1 VALUES LESS THAN (1996),
 PARTITION p2 VALUES LESS THAN (2001),
 PARTITION p3 VALUES LESS THAN MAXVALUE
);
```

In this scheme, for all employees who left before 1991, the rows are stored in partition `p0`; for those who left in the years 1991 through 1995, in `p1`; for those who left in the years 1996 through 2000, in `p2`; and for any workers who left after the year 2000, in `p3`.

Range partitioning is particularly useful when:

- You want or need to delete “old” data. If you are using the partitioning scheme shown immediately above, you can simply use `ALTER TABLE employees DROP PARTITION p0;` to delete all rows relating to employees who stopped working for the firm prior to 1991. (See [Section 12.1.7, “ALTER TABLE Syntax”](#), and [Section 18.3, “Partition Management”](#), for more information.) For a table with a great many rows, this can be much more efficient than running a `DELETE` query such as `DELETE FROM employees WHERE YEAR(separated) <= 1990;`.
- You want to use a column containing date or time values, or containing values arising from some other series.
- You frequently run queries that depend directly on the column used for partitioning the table. For example, when executing a query such as `EXPLAIN PARTITIONS SELECT COUNT(*) FROM employees WHERE separated BETWEEN '2000-01-01' AND '2000-12-31' GROUP BY store_id;`, MySQL can quickly determine that only partition `p2` needs to be scanned because the remaining partitions cannot contain any records satisfying the `WHERE` clause. See [Section 18.4, “Partition Pruning”](#), for more information about how this is accomplished.

Beginning with MySQL 5.1.43, it is also possible to partition a table by `RANGE` based on the value of a `TIMESTAMP` column, using the `UNIX_TIMESTAMP()` function, as shown in this example:

```
CREATE TABLE quarterly_report_status (
 report_id INT NOT NULL,
 report_status VARCHAR(20) NOT NULL,
 report_updated TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP
)
PARTITION BY RANGE (UNIX_TIMESTAMP(report_updated)) (
 PARTITION p0 VALUES LESS THAN (UNIX_TIMESTAMP('2008-01-01 00:00:00')),
 PARTITION p1 VALUES LESS THAN (UNIX_TIMESTAMP('2008-04-01 00:00:00')),
 PARTITION p2 VALUES LESS THAN (UNIX_TIMESTAMP('2008-07-01 00:00:00')),
 PARTITION p3 VALUES LESS THAN (UNIX_TIMESTAMP('2008-10-01 00:00:00')),
 PARTITION p4 VALUES LESS THAN (UNIX_TIMESTAMP('2009-01-01 00:00:00')),
 PARTITION p5 VALUES LESS THAN (UNIX_TIMESTAMP('2009-04-01 00:00:00')),
 PARTITION p6 VALUES LESS THAN (UNIX_TIMESTAMP('2009-07-01 00:00:00')),
 PARTITION p7 VALUES LESS THAN (UNIX_TIMESTAMP('2009-10-01 00:00:00')),
 PARTITION p8 VALUES LESS THAN (UNIX_TIMESTAMP('2010-01-01 00:00:00')),
 PARTITION p9 VALUES LESS THAN (MAXVALUE)
);
```

Also beginning with MySQL 5.1.43, any other expressions involving `TIMESTAMP` values are not permitted. (See [Bug#42849](#).)

### Note

It is also possible in MySQL 5.1.43 and later to use `UNIX_TIMESTAMP(timestamp_column)` as a partitioning expression for tables that are partitioned by `LIST`. However, it is usually not practical to do so.

## 18.2.2. `LIST` Partitioning

List partitioning in MySQL is similar to range partitioning in many ways. As in partitioning by `RANGE`, each partition must be explicitly defined. The chief difference is that, in list partitioning, each partition is defined and selected based on the membership of a column value in one of a set of value lists, rather than in one of a set of contiguous ranges of values. This is done by using `PARTITION BY LIST(expr)` where `expr` is a column value or an expression based on a column value and returning an integer

value, and then defining each partition by means of a `VALUES IN (value_list)`, where `value_list` is a comma-separated list of integers.

### Note

In MySQL 5.1, it is possible to match against only a list of integers (and possibly `NULL`—see [Section 18.2.6, “How MySQL Partitioning Handles NULL”](#)) when partitioning by `LIST`.

Unlike the case with partitions defined by range, list partitions do not need to be declared in any particular order. For more detailed syntactical information, see [Section 12.1.17, “CREATE TABLE Syntax”](#).

For the examples that follow, we assume that the basic definition of the table to be partitioned is provided by the `CREATE TABLE` statement shown here:

```
CREATE TABLE employees (
 id INT NOT NULL,
 fname VARCHAR(30),
 lname VARCHAR(30),
 hired DATE NOT NULL DEFAULT '1970-01-01',
 separated DATE NOT NULL DEFAULT '9999-12-31',
 job_code INT,
 store_id INT
);
```

(This is the same table used as a basis for the examples in [Section 18.2.1, “RANGE Partitioning”](#).)

Suppose that there are 20 video stores distributed among 4 franchises as shown in the following table.

Region	Store ID Numbers
North	3, 5, 6, 9, 17
East	1, 2, 10, 11, 19, 20
West	4, 12, 13, 14, 18
Central	7, 8, 15, 16

To partition this table in such a way that rows for stores belonging to the same region are stored in the same partition, you could use the `CREATE TABLE` statement shown here:

```
CREATE TABLE employees (
 id INT NOT NULL,
 fname VARCHAR(30),
 lname VARCHAR(30),
 hired DATE NOT NULL DEFAULT '1970-01-01',
 separated DATE NOT NULL DEFAULT '9999-12-31',
 job_code INT,
 store_id INT
)
PARTITION BY LIST(store_id) (
 PARTITION pNorth VALUES IN (3,5,6,9,17),
 PARTITION pEast VALUES IN (1,2,10,11,19,20),
 PARTITION pWest VALUES IN (4,12,13,14,18),
 PARTITION pCentral VALUES IN (7,8,15,16)
);
```

This makes it easy to add or drop employee records relating to specific regions to or from the table. For instance, suppose that all stores in the West region are sold to another company. All rows relating to employees working at stores in that region can be deleted with the query `ALTER TABLE employees DROP PARTITION pWest`, which can be executed much more efficiently than the equivalent `DELETE` statement `DELETE FROM employees WHERE store_id IN (4,12,13,14,18)`. However, the `ALTER TABLE ... DROP PARTITION` statement also removes the partition itself from the definition for the table, and you must execute an `ALTER TABLE ... ADD PARTITION` statement to restore the table's original partitioning scheme. (This problem is resolved in MySQL 5.5, which adds the `ALTER TABLE ... TRUNCATE PARTITION` statement for removing all rows from a given partition without affecting the table definition.)

As with `RANGE` partitioning, it is possible to combine `LIST` partitioning with partitioning by hash or key to produce a composite partitioning (subpartitioning). See [Section 18.2.5, “Subpartitioning”](#).

Unlike the case with `RANGE` partitioning, there is no “catch-all” such as `MAXVALUE`; all expected values for the partitioning expression should be covered in `PARTITION ... VALUES IN (...)` clauses. An `INSERT` statement containing an unmatched partitioning column value fails with an error, as shown in this example:

```
mysql> CREATE TABLE h2 (
 -> c1 INT,
 -> c2 INT
 ->)
 -> PARTITION BY LIST(c1) (
 -> PARTITION p0 VALUES IN (1, 4, 7),
```

```

-> PARTITION p1 VALUES IN (2, 5, 8)
->);
Query OK, 0 rows affected (0.11 sec)

mysql> INSERT INTO h2 VALUES (3, 5);
ERROR 1525 (HY000): TABLE HAS NO PARTITION FOR VALUE 3

```

When inserting multiple rows using a single `INSERT` statement, any rows coming before the row containing the unmatched value are inserted, but any coming after it are not:

```

mysql> SELECT * FROM h2;
Empty set (0.00 sec)

mysql> INSERT INTO h2 VALUES (4, 7), (3, 5), (6, 0);
ERROR 1525 (HY000): TABLE HAS NO PARTITION FOR VALUE 3
mysql> SELECT * FROM h2;
+-----+-----+
| c1 | c2 |
+-----+-----+
| 4 | 7 |
+-----+-----+
1 row in set (0.00 sec)

```

You can cause this type of error to be ignored by using the `IGNORE` keyword. If you do so, rows containing unmatched partitioning column values are not inserted, but any rows with matching values *are* inserted, and no errors are reported:

```

mysql> TRUNCATE h2;
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM h2;
Empty set (0.00 sec)

mysql> INSERT IGNORE INTO h2 VALUES (2, 5), (6, 10), (7, 5), (3, 1), (1, 9);
Query OK, 3 rows affected (0.00 sec)
Records: 5 Duplicates: 2 Warnings: 0

mysql> SELECT * FROM h2;
+-----+-----+
| c1 | c2 |
+-----+-----+
| 7 | 5 |
| 1 | 9 |
| 2 | 5 |
+-----+-----+
3 rows in set (0.00 sec)

```

### 18.2.3. HASH Partitioning

Partitioning by `HASH` is used primarily to ensure an even distribution of data among a predetermined number of partitions. With range or list partitioning, you must specify explicitly into which partition a given column value or set of column values is to be stored; with hash partitioning, MySQL takes care of this for you, and you need only specify a column value or expression based on a column value to be hashed and the number of partitions into which the partitioned table is to be divided.

To partition a table using `HASH` partitioning, it is necessary to append to the `CREATE TABLE` statement a `PARTITION BY HASH (expr)` clause, where *expr* is an expression that returns an integer. This can simply be the name of a column whose type is one of MySQL's integer types. In addition, you will most likely want to follow this with a `PARTITIONS num` clause, where *num* is a positive integer representing the number of partitions into which the table is to be divided.

For example, the following statement creates a table that uses hashing on the `store_id` column and is divided into 4 partitions:

```

CREATE TABLE employees (
 id INT NOT NULL,
 fname VARCHAR(30),
 lname VARCHAR(30),
 hired DATE NOT NULL DEFAULT '1970-01-01',
 separated DATE NOT NULL DEFAULT '9999-12-31',
 job_code INT,
 store_id INT
)
PARTITION BY HASH(store_id)
PARTITIONS 4;

```

If you do not include a `PARTITIONS` clause, the number of partitions defaults to 1.

Using the `PARTITIONS` keyword without a number following it results in a syntax error.

You can also use an SQL expression that returns an integer for *expr*. For instance, you might want to partition based on the year in which an employee was hired. This can be done as shown here:

```

CREATE TABLE employees (
 id INT NOT NULL,
 fname VARCHAR(30),

```

```

 lname VARCHAR(30),
 hired DATE NOT NULL DEFAULT '1970-01-01',
 separated DATE NOT NULL DEFAULT '9999-12-31',
 job_code INT,
 store_id INT
)
PARTITION BY HASH(YEAR(hired))
PARTITIONS 4;

```

`expr` must return a nonconstant, nonrandom integer value (in other words, it should be varying but deterministic), and must not contain any prohibited constructs as described in [Section 18.5, “Restrictions and Limitations on Partitioning”](#). You should also keep in mind that this expression is evaluated each time a row is inserted or updated (or possibly deleted); this means that very complex expressions may give rise to performance issues, particularly when performing operations (such as batch inserts) that affect a great many rows at one time.

The most efficient hashing function is one which operates upon a single table column and whose value increases or decreases consistently with the column value, as this allows for “pruning” on ranges of partitions. That is, the more closely that the expression varies with the value of the column on which it is based, the more efficiently MySQL can use the expression for hash partitioning.

For example, where `date_col` is a column of type `DATE`, then the expression `TO_DAYS(date_col)` is said to vary directly with the value of `date_col`, because for every change in the value of `date_col`, the value of the expression changes in a consistent manner. The variance of the expression `YEAR(date_col)` with respect to `date_col` is not quite as direct as that of `TO_DAYS(date_col)`, because not every possible change in `date_col` produces an equivalent change in `YEAR(date_col)`. Even so, `YEAR(date_col)` is a good candidate for a hashing function, because it varies directly with a portion of `date_col` and there is no possible change in `date_col` that produces a disproportionate change in `YEAR(date_col)`.

By way of contrast, suppose that you have a column named `int_col` whose type is `INT`. Now consider the expression `POW(5-int_col,3) + 6`. This would be a poor choice for a hashing function because a change in the value of `int_col` is not guaranteed to produce a proportional change in the value of the expression. Changing the value of `int_col` by a given amount can produce by widely different changes in the value of the expression. For example, changing `int_col` from `5` to `6` produces a change of `-1` in the value of the expression, but changing the value of `int_col` from `6` to `7` produces a change of `-7` in the expression value.

In other words, the more closely the graph of the column value *versus* the value of the expression follows a straight line as traced by the equation `y=nx` where `n` is some nonzero constant, the better the expression is suited to hashing. This has to do with the fact that the more nonlinear an expression is, the more uneven the distribution of data among the partitions it tends to produce.

In theory, pruning is also possible for expressions involving more than one column value, but determining which of such expressions are suitable can be quite difficult and time-consuming. For this reason, the use of hashing expressions involving multiple columns is not particularly recommended.

When `PARTITION BY HASH` is used, MySQL determines which partition of `num` partitions to use based on the modulus of the result of the user function. In other words, for an expression `expr`, the partition in which the record is stored is partition number `N`, where `N = MOD(expr, num)`. Suppose that table `t1` is defined as follows, so that it has 4 partitions:

```

CREATE TABLE t1 (col1 INT, col2 CHAR(5), col3 DATE)
 PARTITION BY HASH(YEAR(col3))
 PARTITIONS 4;

```

If you insert a record into `t1` whose `col3` value is `'2005-09-15'`, then the partition in which it is stored is determined as follows:

```

MOD(YEAR('2005-09-01'),4)
= MOD(2005,4)
= 1

```

MySQL 5.1 also supports a variant of `HASH` partitioning known as *linear hashing* which employs a more complex algorithm for determining the placement of new rows inserted into the partitioned table. See [Section 18.2.3.1, “LINEAR HASH Partitioning”](#), for a description of this algorithm.

The user function is evaluated each time a record is inserted or updated. It may also—depending on the circumstances—be evaluated when records are deleted.

### Note

If a table to be partitioned has a `UNIQUE` key, then any columns supplied as arguments to the `HASH` user function or to the `KEY`'s `column_list` must be part of that key.

## 18.2.3.1. LINEAR HASH Partitioning

MySQL also supports linear hashing, which differs from regular hashing in that linear hashing utilizes a linear powers-of-two al-

gorithm whereas regular hashing employs the modulus of the hashing function's value.

Syntactically, the only difference between linear-hash partitioning and regular hashing is the addition of the `LINEAR` keyword in the `PARTITION BY` clause, as shown here:

```
CREATE TABLE employees (
 id INT NOT NULL,
 fname VARCHAR(30),
 lname VARCHAR(30),
 hired DATE NOT NULL DEFAULT '1970-01-01',
 separated DATE NOT NULL DEFAULT '9999-12-31',
 job_code INT,
 store_id INT
)
PARTITION BY LINEAR HASH(YEAR(hired))
PARTITIONS 4;
```

Given an expression `expr`, the partition in which the record is stored when linear hashing is used is partition number `N` from among `num` partitions, where `N` is derived according to the following algorithm:

1. Find the next power of 2 greater than `num`. We call this value `V`; it can be calculated as:

```
V = POWER(2, CEILING(LOG(2, num)))
```

(Suppose that `num` is 13. Then `LOG(2, 13)` is 3.7004397181411. `CEILING(3.7004397181411)` is 4, and `V = POWER(2, 4)`, which is 16.)

2. Set `N = F(column_list) & (V - 1)`.
3. While `N >= num`:
  - Set `V = CEIL(V / 2)`
  - Set `N = N & (V - 1)`

Suppose that the table `t1`, using linear hash partitioning and having 6 partitions, is created using this statement:

```
CREATE TABLE t1 (col1 INT, col2 CHAR(5), col3 DATE)
PARTITION BY LINEAR HASH(YEAR(col3))
PARTITIONS 6;
```

Now assume that you want to insert two records into `t1` having the `col3` column values '`2003-04-14`' and '`1998-10-19`'. The partition number for the first of these is determined as follows:

```
V = POWER(2, CEILING(LOG(2,6))) = 8
N = YEAR('2003-04-14') & (8 - 1)
= 2003 & 7
= 3

(3 >= 6 is FALSE: record stored in partition #3)
```

The number of the partition where the second record is stored is calculated as shown here:

```
V = 8
N = YEAR('1998-10-19') & (8-1)
= 1998 & 7
= 6

(6 >= 6 is TRUE: additional step required)

N = 6 & CEILING(8 / 2)
= 6 & 3
= 2

(2 >= 6 is FALSE: record stored in partition #2)
```

The advantage in partitioning by linear hash is that the adding, dropping, merging, and splitting of partitions is made much faster, which can be beneficial when dealing with tables containing extremely large amounts (terabytes) of data. The disadvantage is that data is less likely to be evenly distributed between partitions as compared with the distribution obtained using regular hash partitioning.

## 18.2.4. KEY Partitioning

Partitioning by key is similar to partitioning by hash, except that where hash partitioning employs a user-defined expression, the hashing function for key partitioning is supplied by the MySQL server. MySQL Cluster uses `MD5()` for this purpose; for tables using other storage engines, the server employs its own internal hashing function which is based on the same algorithm as `PASS-`

`WORD()`.

The syntax rules for `CREATE TABLE ... PARTITION BY KEY` are similar to those for creating a table that is partitioned by hash. The major differences are that:

- `KEY` is used rather than `HASH`.
- `KEY` takes only a list of one or more column names. Beginning with MySQL 5.1.5, the column or columns used as the partitioning key must comprise part or all of the table's primary key, if the table has one.

Beginning with MySQL 5.1.6, `KEY` takes a list of zero or more column names. Where no column name is specified as the partitioning key, the table's primary key is used, if there is one. For example, the following `CREATE TABLE` statement is valid in MySQL 5.1.6 or later:

```
CREATE TABLE k1 (
 id INT NOT NULL PRIMARY KEY,
 name VARCHAR(20)
)
PARTITION BY KEY()
PARTITIONS 2;
```

If there is no primary key but there is a unique key, then the unique key is used for the partitioning key:

```
CREATE TABLE k1 (
 id INT NOT NULL,
 name VARCHAR(20),
 UNIQUE KEY (id)
)
PARTITION BY KEY()
PARTITIONS 2;
```

However, if the unique key column were not defined as `NOT NULL`, then the previous statement would fail.

In both of these cases, the partitioning key is the `id` column, even though it is not shown in the output of `SHOW CREATE TABLE` or in the `PARTITION_EXPRESSION` column of the `INFORMATION_SCHEMA.PARTITIONS` table.

Unlike the case with other partitioning types, columns used for partitioning by `KEY` are not restricted to integer or `NULL` values. For example, the following `CREATE TABLE` statement is valid:

```
CREATE TABLE tm1 (
 s1 CHAR(32) PRIMARY KEY
)
PARTITION BY KEY(s1)
PARTITIONS 10;
```

The preceding statement would *not* be valid, were a different partitioning type to be specified.

### Note

In this case, simply using `PARTITION BY KEY()` would also be valid and have the same effect as `PARTITION BY KEY(s1)`, since `s1` is the table's primary key.

For additional information about this issue, see [Section 18.5, “Restrictions and Limitations on Partitioning”](#).

### Note

Also beginning with MySQL 5.1.6, tables using the `NDBCLUSTER` storage engine are implicitly partitioned by `KEY`, again using the table's primary key as the partitioning key. In the event that the MySQL Cluster table has no explicit primary key, the “hidden” primary key generated by the `NDBCLUSTER` storage engine for each MySQL Cluster table is used as the partitioning key.

Beginning with MySQL Cluster NDB 6.2.18, MySQL Cluster NDB 6.3.25, and MySQL Cluster NDB 7.0.6, if you define an explicit partitioning scheme for an `NDBCLUSTER` table, the table must have an explicit primary key, and any columns used in the partitioning expression must be part of this key. However, if the table uses an “empty” partitioning expression—that is, `PARTITION BY KEY()` with no column references—then no explicit primary key is required.

You can observe this partitioning using the `ndb_desc` utility (with the `-p` option).

### Important

For a key-partitioned table using any MySQL storage engine other than `NDBCLUSTER`, you cannot execute an `ALTER TABLE DROP PRIMARY KEY`, as doing so generates the error `ERROR 1466 (HY000): FIELD IN LIST`

**OF FIELDS FOR PARTITION FUNCTION NOT FOUND IN TABLE.** This is not an issue for MySQL Cluster tables which are partitioned by `KEY`; in such cases, the table is reorganized using the “hidden” primary key as the table’s new partitioning key. See [Chapter 17, MySQL Cluster NDB 6.X/7.X](#).

It is also possible to partition a table by linear key. Here is a simple example:

```
CREATE TABLE tk (
 col1 INT NOT NULL,
 col2 CHAR(5),
 col3 DATE
)
PARTITION BY LINEAR KEY (col1)
PARTITIONS 3;
```

Using `LINEAR` has the same effect on `KEY` partitioning as it does on `HASH` partitioning, with the partition number being derived using a powers-of-two algorithm rather than modulo arithmetic. See [Section 18.2.3.1, “LINEAR HASH Partitioning”](#), for a description of this algorithm and its implications.

## 18.2.5. Subpartitioning

Subpartitioning—also known as *composite partitioning*—is the further division of each partition in a partitioned table. For example, consider the following `CREATE TABLE` statement:

```
CREATE TABLE ts (id INT, purchased DATE)
PARTITION BY RANGE(YEAR(purchased))
SUBPARTITION BY HASH(TO_DAYS(purchased))
SUBPARTITIONS 2 (
 PARTITION p0 VALUES LESS THAN (1990),
 PARTITION p1 VALUES LESS THAN (2000),
 PARTITION p2 VALUES LESS THAN MAXVALUE
);
```

Table `ts` has 3 `RANGE` partitions. Each of these partitions—`p0`, `p1`, and `p2`—is further divided into 2 subpartitions. In effect, the entire table is divided into  $3 * 2 = 6$  partitions. However, due to the action of the `PARTITION BY RANGE` clause, the first 2 of these store only those records with a value less than 1990 in the `purchased` column.

In MySQL 5.1, it is possible to subpartition tables that are partitioned by `RANGE` or `LIST`. Subpartitions may use either `HASH` or `KEY` partitioning. This is also known as *composite partitioning*.

### Note

`SUBPARTITION BY HASH` and `SUBPARTITION BY KEY` generally follow the same syntax rules as `PARTITION BY HASH` and `PARTITION BY KEY`, respectively. An exception to this is that `SUBPARTITION BY KEY` (unlike `PARTITION BY KEY`) does not currently support a default column, so the column used for this purpose must be specified, even if the table has an explicit primary key. This is a known issue which we are working to address; see [Issues with subpartitions](#), for more information and an example.

It is also possible to define subpartitions explicitly using `SUBPARTITION` clauses to specify options for individual subpartitions. For example, a more verbose fashion of creating the same table `ts` as shown in the previous example would be:

```
CREATE TABLE ts (id INT, purchased DATE)
PARTITION BY RANGE(YEAR(purchased))
SUBPARTITION BY HASH(TO_DAYS(purchased)) (
 PARTITION p0 VALUES LESS THAN (1990) (
 SUBPARTITION s0,
 SUBPARTITION s1
),
 PARTITION p1 VALUES LESS THAN (2000) (
 SUBPARTITION s2,
 SUBPARTITION s3
),
 PARTITION p2 VALUES LESS THAN MAXVALUE (
 SUBPARTITION s4,
 SUBPARTITION s5
)
);
```

Some syntactical items of note:

- Each partition must have the same number of subpartitions.
- If you explicitly define any subpartitions using `SUBPARTITION` on any partition of a partitioned table, you must define them all. In other words, the following statement will fail:

```
CREATE TABLE ts (id INT, purchased DATE)
```

```

PARTITION BY RANGE(YEAR(purchased))
SUBPARTITION BY HASH(TO_DAYS(purchased)) (
 PARTITION p0 VALUES LESS THAN (1990) (
 SUBPARTITION s0,
 SUBPARTITION s1
),
 PARTITION p1 VALUES LESS THAN (2000),
 PARTITION p2 VALUES LESS THAN MAXVALUE (
 SUBPARTITION s2,
 SUBPARTITION s3
)
);

```

This statement would still fail even if it included a [SUBPARTITIONS 2](#) clause.

- Each [SUBPARTITION](#) clause must include (at a minimum) a name for the subpartition. Otherwise, you may set any desired option for the subpartition or allow it to assume its default setting for that option.
- In MySQL 5.1.7 and earlier, names of subpartitions were required to be unique within each partition, but did not have to be unique within the table as a whole. Beginning with MySQL 5.1.8, subpartition names must be unique across the entire table. For example, the following [CREATE TABLE](#) statement is valid in MySQL 5.1.8 and later:

```

CREATE TABLE ts (id INT, purchased DATE)
PARTITION BY RANGE(YEAR(purchased))
SUBPARTITION BY HASH(TO_DAYS(purchased)) (
 PARTITION p0 VALUES LESS THAN (1990) (
 SUBPARTITION s0,
 SUBPARTITION s1
),
 PARTITION p1 VALUES LESS THAN (2000) (
 SUBPARTITION s2,
 SUBPARTITION s3
),
 PARTITION p2 VALUES LESS THAN MAXVALUE (
 SUBPARTITION s4,
 SUBPARTITION s5
)
);

```

(The previous statement is also valid for versions of MySQL prior to 5.1.8.)

Subpartitions can be used with especially large tables to distribute data and indexes across many disks. Suppose that you have 6 disks mounted as `/disk0`, `/disk1`, `/disk2`, and so on. Now consider the following example:

```

CREATE TABLE ts (id INT, purchased DATE)
PARTITION BY RANGE(YEAR(purchased))
SUBPARTITION BY HASH(TO_DAYS(purchased)) (
 PARTITION p0 VALUES LESS THAN (1990) (
 SUBPARTITION s0
 DATA DIRECTORY = '/disk0/data'
 INDEX DIRECTORY = '/disk0/idx',
 SUBPARTITION s1
 DATA DIRECTORY = '/disk1/data'
 INDEX DIRECTORY = '/disk1/idx'
),
 PARTITION p1 VALUES LESS THAN (2000) (
 SUBPARTITION s2
 DATA DIRECTORY = '/disk2/data'
 INDEX DIRECTORY = '/disk2/idx',
 SUBPARTITION s3
 DATA DIRECTORY = '/disk3/data'
 INDEX DIRECTORY = '/disk3/idx'
),
 PARTITION p2 VALUES LESS THAN MAXVALUE (
 SUBPARTITION s4
 DATA DIRECTORY = '/disk4/data'
 INDEX DIRECTORY = '/disk4/idx',
 SUBPARTITION s5
 DATA DIRECTORY = '/disk5/data'
 INDEX DIRECTORY = '/disk5/idx'
)
);

```

In this case, a separate disk is used for the data and for the indexes of each [RANGE](#). Many other variations are possible; another example might be:

```

CREATE TABLE ts (id INT, purchased DATE)
PARTITION BY RANGE(YEAR(purchased))
SUBPARTITION BY HASH(TO_DAYS(purchased)) (
 PARTITION p0 VALUES LESS THAN (1990) (
 SUBPARTITION s0a
 DATA DIRECTORY = '/disk0'
 INDEX DIRECTORY = '/disk1',
 SUBPARTITION s0b
 DATA DIRECTORY = '/disk2'
)
);

```

```

 INDEX DIRECTORY = '/disk3'
),
PARTITION p1 VALUES LESS THAN (2000) (
 SUBPARTITION s1a
 DATA DIRECTORY = '/disk4/data'
 INDEX DIRECTORY = '/disk4/idx',
 SUBPARTITION s1b
 DATA DIRECTORY = '/disk5/data'
 INDEX DIRECTORY = '/disk5/idx'
),
PARTITION p2 VALUES LESS THAN MAXVALUE (
 SUBPARTITION s2a,
 SUBPARTITION s2b
)
);

```

Here, the storage is as follows:

- Rows with `purchased` dates from before 1990 take up a vast amount of space, so are split up 4 ways, with a separate disk dedicated to the data and to the indexes for each of the two subpartitions (`s0a` and `s0b`) making up partition `p0`. In other words:
  - The data for subpartition `s0a` is stored on `/disk0`.
  - The indexes for subpartition `s0a` are stored on `/disk1`.
  - The data for subpartition `s0b` is stored on `/disk2`.
  - The indexes for subpartition `s0b` are stored on `/disk3`.
- Rows containing dates ranging from 1990 to 1999 (partition `p1`) do not require as much room as those from before 1990. These are split between 2 disks (`/disk4` and `/disk5`) rather than 4 disks as with the legacy records stored in `p0`:
  - Data and indexes belonging to `p1`'s first subpartition (`s1a`) are stored on `/disk4`—the data in `/disk4/data`, and the indexes in `/disk4/idx`.
  - Data and indexes belonging to `p1`'s second subpartition (`s1b`) are stored on `/disk5`—the data in `/disk5/data`, and the indexes in `/disk5/idx`.
- Rows reflecting dates from the year 2000 to the present (partition `p2`) do not take up as much space as required by either of the two previous ranges. Currently, it is sufficient to store all of these in the default location.

In future, when the number of purchases for the decade beginning with the year 2000 grows to a point where the default location no longer provides sufficient space, the corresponding rows can be moved using an `ALTER TABLE ... REORGANIZE PARTITION` statement. See [Section 18.3, “Partition Management”](#), for an explanation of how this can be done.

Beginning with MySQL 5.1.18, the `DATA DIRECTORY` and `INDEX DIRECTORY` options are not permitted in partition definitions when the `NO_DIR_IN_CREATE` server SQL mode is in effect. However, this is not true when defining subpartitions; this is a known issue which is fixed in MySQL 5.5 ([Bug#42954](#)).

## 18.2.6. How MySQL Partitioning Handles `NULL`

Partitioning in MySQL does nothing to disallow `NULL` as the value of a partitioning expression, whether it is a column value or the value of a user-supplied expression. Even though it is permitted to use `NULL` as the value of an expression that must otherwise yield an integer, it is important to keep in mind that `NULL` is not a number. Beginning with MySQL 5.1.8, the partitioning implementation treats `NULL` as being less than any non-`NULL` value, just as `ORDER BY` does.

This means that treatment of `NULL` varies between partitioning of different types, and may produce behavior which you do not expect if you are not prepared for it. This being the case, we discuss in this section how each MySQL partitioning type handles `NULL` values when determining the partition in which a row should be stored, and provide examples for each.

**Handling of `NULL` with `RANGE` partitioning.** If you insert a row into a table partitioned by `RANGE` such that the column value used to determine the partition is `NULL`, the row is inserted into the lowest partition. For example, consider these two tables in a database named `p`, created as follows:

```

mysql> CREATE TABLE t1 (
-> c1 INT,
-> c2 VARCHAR(20)
->)
-> PARTITION BY RANGE(c1) (
-> PARTITION p0 VALUES LESS THAN (0),
-> PARTITION p1 VALUES LESS THAN (10),
-> PARTITION p2 VALUES LESS THAN MAXVALUE
->);
Query OK, 0 rows affected (0.09 sec)

```

```
mysql> CREATE TABLE t2 (
 -> c1 INT,
 -> c2 VARCHAR(20)
 ->)
 -> PARTITION BY RANGE(c1) (
 -> PARTITION p0 VALUES LESS THAN (-5),
 -> PARTITION p1 VALUES LESS THAN (0),
 -> PARTITION p2 VALUES LESS THAN (10),
 -> PARTITION p3 VALUES LESS THAN MAXVALUE
 ->);
Query OK, 0 rows affected (0.09 sec)
```

You can see the partitions created by these two `CREATE TABLE` statements using the following query against the `PARTITIONS` table in the `INFORMATION_SCHEMA` database:

```
mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
 > FROM INFORMATION_SCHEMA.PARTITIONS
 > WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME LIKE 't_';
+-----+-----+-----+-----+-----+
| TABLE_NAME | PARTITION_NAME | TABLE_ROWS | AVG_ROW_LENGTH | DATA_LENGTH |
+-----+-----+-----+-----+-----+
| t1 | p0 | 0 | 0 | 0 |
| t1 | p1 | 0 | 0 | 0 |
| t1 | p2 | 0 | 0 | 0 |
| t2 | p0 | 0 | 0 | 0 |
| t2 | p1 | 0 | 0 | 0 |
| t2 | p2 | 0 | 0 | 0 |
| t2 | p3 | 0 | 0 | 0 |
+-----+-----+-----+-----+-----+
7 rows in set (0.00 sec)
```

(For more information about this table, see [Section 20.19, “The INFORMATION\\_SCHEMA PARTITIONS Table”](#).) Now let us populate each of these tables with a single row containing a `NULL` in the column used as the partitioning key, and verify that the rows were inserted using a pair of `SELECT` statements:

```
mysql> INSERT INTO t1 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO t2 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM t1;
+-----+-----+
| id | name |
+-----+-----+
| NULL | mothra |
+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT * FROM t2;
+-----+-----+
| id | name |
+-----+-----+
| NULL | mothra |
+-----+-----+
1 row in set (0.00 sec)
```

You can see which partitions are used to store the inserted rows by rerunning the previous query against `INFORMATION_SCHEMA.PARTITIONS` and inspecting the output:

```
mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
 > FROM INFORMATION_SCHEMA.PARTITIONS
 > WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME LIKE 't_';
+-----+-----+-----+-----+-----+
| TABLE_NAME | PARTITION_NAME | TABLE_ROWS | AVG_ROW_LENGTH | DATA_LENGTH |
+-----+-----+-----+-----+-----+
| t1 | p0 | 1 | 20 | 20 |
| t1 | p1 | 0 | 0 | 0 |
| t1 | p2 | 0 | 0 | 0 |
| t2 | p0 | 1 | 20 | 20 |
| t2 | p1 | 0 | 0 | 0 |
| t2 | p2 | 0 | 0 | 0 |
| t2 | p3 | 0 | 0 | 0 |
+-----+-----+-----+-----+-----+
7 rows in set (0.01 sec)
```

You can also demonstrate that these rows were stored in the lowest partition of each table by dropping these partitions, and then re-running the `SELECT` statements:

```
mysql> ALTER TABLE t1 DROP PARTITION p0;
Query OK, 0 rows affected (0.16 sec)

mysql> ALTER TABLE t2 DROP PARTITION p0;
Query OK, 0 rows affected (0.16 sec)

mysql> SELECT * FROM t1;
Empty set (0.00 sec)

mysql> SELECT * FROM t2;
Empty set (0.00 sec)
```

(For more information on `ALTER TABLE ... DROP PARTITION`, see [Section 12.1.7, “ALTER TABLE Syntax”](#).)

### Important

Prior to MySQL 5.1.8, `RANGE` partitioning treated a partitioning expression value of `NULL` as 0 with respect to determining placement. (The only way to circumvent this behavior was to design tables so as not to permit nulls, usually by declaring columns `NOT NULL`.) If you have a `RANGE` partitioning scheme that depends on this earlier behavior, you must re-implement it when upgrading to MySQL 5.1.8 or later. ([Bug#15447](#))

`NULL` is also treated in this way for partitioning expressions that use SQL functions. Suppose that we define a table using a `CREATE TABLE` statement such as this one:

```
CREATE TABLE tndate (
 id INT,
 dt DATE
)
PARTITION BY RANGE(YEAR(dt)) (
 PARTITION p0 VALUES LESS THAN (1990),
 PARTITION p1 VALUES LESS THAN (2000),
 PARTITION p2 VALUES LESS THAN MAXVALUE
);
```

As with other MySQL functions, `YEAR(NULL)` returns `NULL`. A row with a `dt` column value of `NULL` is treated as though the partitioning expression evaluated to a value less than any other value, and so is inserted into partition `p0`.

**Handling of `NULL` with `LIST` partitioning.** A table that is partitioned by `LIST` admits `NULL` values if and only if one of its partitions is defined using that value-list that contains `NULL`. The converse of this is that a table partitioned by `LIST` which does not explicitly use `NULL` in a value list rejects rows resulting in a `NULL` value for the partitioning expression, as shown in this example:

```
mysql> CREATE TABLE ts1 (
-> c1 INT,
-> c2 VARCHAR(20)
->)
-> PARTITION BY LIST(c1) (
-> PARTITION p0 VALUES IN (0, 3, 6),
-> PARTITION p1 VALUES IN (1, 4, 7),
-> PARTITION p2 VALUES IN (2, 5, 8)
->);
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO ts1 VALUES (9, 'mothra');
ERROR 1504 (HY000): TABLE HAS NO PARTITION FOR VALUE 9

mysql> INSERT INTO ts1 VALUES (NULL, 'mothra');
ERROR 1504 (HY000): TABLE HAS NO PARTITION FOR VALUE NULL
```

Only rows having a `c1` value between 0 and 8 inclusive can be inserted into `ts1`. `NULL` falls outside this range, just like the number 9. We can create tables `ts2` and `ts3` having value lists containing `NULL`, as shown here:

```
mysql> CREATE TABLE ts2 (
-> c1 INT,
-> c2 VARCHAR(20)
->)
-> PARTITION BY LIST(c1) (
-> PARTITION p0 VALUES IN (0, 3, 6),
-> PARTITION p1 VALUES IN (1, 4, 7),
-> PARTITION p2 VALUES IN (2, 5, 8),
-> PARTITION p3 VALUES IN (NULL)
->);
Query OK, 0 rows affected (0.01 sec)

mysql> CREATE TABLE ts3 (
-> c1 INT,
-> c2 VARCHAR(20)
->)
-> PARTITION BY LIST(c1) (
-> PARTITION p0 VALUES IN (0, 3, 6),
-> PARTITION p1 VALUES IN (1, 4, 7, NULL),
-> PARTITION p2 VALUES IN (2, 5, 8)
->);
Query OK, 0 rows affected (0.01 sec)
```

When defining value lists for partitioning, you can (and should) treat `NULL` just as you would any other value. For example, both `VALUES IN (NULL)` and `VALUES IN (1, 4, 7, NULL)` are valid, as are `VALUES IN (1, NULL, 4, 7)`, `VALUES IN (NULL, 1, 4, 7)`, and so on. You can insert a row having `NULL` for column `c1` into each of the tables `ts2` and `ts3`:

```
mysql> INSERT INTO ts2 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO ts3 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)
```

By issuing the appropriate query against `INFORMATION_SCHEMA.PARTITIONS`, you can determine which partitions were used to store the rows just inserted (we assume, as in the previous examples, that the partitioned tables were created in the `tp` database):

```
mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
-> FROM INFORMATION_SCHEMA.PARTITIONS
```

> WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME LIKE 'ts_';				
TABLE_NAME	PARTITION_NAME	TABLE_ROWS	AVG_ROW_LENGTH	DATA_LENGTH
ts2	p0	0	0	0
ts2	p1	0	0	0
ts2	p2	0	0	0
{ ts2	p3	1	20	20
{ ts3	p0	0	0	0
{ ts3	p1	1	20	20
{ ts3	p2	0	0	0

7 rows in set (0.01 sec)

As shown earlier in this section, you can also verify which partitions were used for storing the rows by deleting these partitions and then performing a `SELECT`.

**Handling of `NULL` with `HASH` and `KEY` partitioning.** `NULL` is handled somewhat differently for tables partitioned by `HASH` or `KEY`. In these cases, any partition expression that yields a `NULL` value is treated as though its return value were zero. We can verify this behavior by examining the effects on the file system of creating a table partitioned by `HASH` and populating it with a record containing appropriate values. Suppose that you have a table `th` (also in the `p` database) created using the following statement:

```
mysql> CREATE TABLE th (
 -> c1 INT,
 -> c2 VARCHAR(20)
 ->)
 -> PARTITION BY HASH(c1)
 -> PARTITIONS 2;
Query OK, 0 rows affected (0.00 sec)
```

The partitions belonging to this table can be viewed like this:

```
mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
 > FROM INFORMATION_SCHEMA.PARTITIONS
 > WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME = 'th';
+-----+-----+-----+-----+-----+
| TABLE_NAME | PARTITION_NAME | TABLE_ROWS | AVG_ROW_LENGTH | DATA_LENGTH |
+-----+-----+-----+-----+-----+
| th | p0 | 0 | 0 | 0 |
| th | p1 | 0 | 0 | 0 |
+-----+-----+-----+-----+-----+
2 rows in set (0.00 sec)
```

Note that `TABLE_ROWS` for each partition is 0. Now insert two rows into `th` whose `c1` column values are `NULL` and 0, and verify that these rows were inserted:

```
mysql> INSERT INTO th VALUES (NULL, 'mothra'), (0, 'gigan');
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM th;
+---+---+
| c1 | c2 |
+---+---+
| NULL | mothra |
| 0 | gigan |
+---+---+
2 rows in set (0.01 sec)
```

Recall that for any integer `N`, the value of `NULL MOD N` is always `NULL`. For tables that are partitioned by `HASH` or `KEY`, this result is treated for determining the correct partition as 0. Checking the `INFORMATION_SCHEMA.PARTITIONS` table once again, we can see that both rows were inserted into partition `p0`:

```
mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
 > FROM INFORMATION_SCHEMA.PARTITIONS
 > WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME = 'th';
+-----+-----+-----+-----+-----+
| TABLE_NAME | PARTITION_NAME | TABLE_ROWS | AVG_ROW_LENGTH | DATA_LENGTH |
+-----+-----+-----+-----+-----+
| th | p0 | 2 | 20 | 20 |
| th | p1 | 0 | 0 | 0 |
+-----+-----+-----+-----+-----+
2 rows in set (0.00 sec)
```

If you repeat this example using `PARTITION BY KEY` in place of `PARTITION BY HASH` in the definition of the table, you can verify easily that `NULL` is also treated like 0 for this type of partitioning as well.

## 18.3. Partition Management

MySQL 5.1 provides a number of ways to modify partitioned tables. It is possible to add, drop, redefine, merge, or split existing partitions. All of these actions can be carried out using the partitioning extensions to the `ALTER TABLE` statement (see [Section 12.1.7, “`ALTER TABLE Syntax`”,](#) for syntax definitions). There are also ways to obtain information about partitioned tables and partitions. We discuss these topics in the sections that follow.

- For information about partition management in tables partitioned by `RANGE` or `LIST`, see [Section 18.3.1, “Management of](#)

[RANGE and LIST Partitions](#).

- For a discussion of managing `HASH` and `KEY` partitions, see [Section 18.3.2, “Management of HASH and KEY Partitions”](#).
- See [Section 18.3.4, “Obtaining Information About Partitions”](#), for a discussion of mechanisms provided in MySQL 5.1 for obtaining information about partitioned tables and partitions.
- For a discussion of performing maintenance operations on partitions, see [Section 18.3.3, “Maintenance of Partitions”](#).

### Note

In MySQL 5.1, all partitions of a partitioned table must have the same number of subpartitions, and it is not possible to change the subpartitioning once the table has been created.

The statement `ALTER TABLE ... PARTITION BY ...` is available and is functional beginning with MySQL 5.1.6; previously in MySQL 5.1, this was accepted as valid syntax, but the statement did nothing.

To change a table's partitioning scheme, it is necessary only to use the `ALTER TABLE` statement with a `partition_options` clause. This clause has the same syntax as that as used with `CREATE TABLE` for creating a partitioned table, and always begins with the keywords `PARTITION BY`. Suppose that you have a table partitioned by range using the following `CREATE TABLE` statement:

```
CREATE TABLE trb3 (id INT, name VARCHAR(50), purchased DATE)
PARTITION BY RANGE(YEAR(purchased)) (
 PARTITION p0 VALUES LESS THAN (1990),
 PARTITION p1 VALUES LESS THAN (1995),
 PARTITION p2 VALUES LESS THAN (2000),
 PARTITION p3 VALUES LESS THAN (2005)
);
```

To repartition this table so that it is partitioned by key into two partitions using the `id` column value as the basis for the key, you can use this statement:

```
ALTER TABLE trb3 PARTITION BY KEY(id) PARTITIONS 2;
```

This has the same effect on the structure of the table as dropping the table and re-creating it using `CREATE TABLE trb3 PARTITION BY KEY(id) PARTITIONS 2;`.

In MySQL 5.1.7 and earlier MySQL 5.1 releases, `ALTER TABLE ... ENGINE = ...` removed all partitioning from the affected table. Beginning with MySQL 5.1.8, this statement changes only the storage engine used by the table, and leaves the table's partitioning scheme intact. As of MySQL 5.1.8, use `ALTER TABLE ... REMOVE PARTITIONING` to remove a table's partitioning. See [Section 12.1.7, “ALTER TABLE Syntax”](#).

### Important

Only a single `PARTITION BY`, `ADD PARTITION`, `DROP PARTITION`, `REORGANIZE PARTITION`, or `COALESCE PARTITION` clause can be used in a given `ALTER TABLE` statement. If you (for example) wish to drop a partition and reorganize a table's remaining partitions, you must do so in two separate `ALTER TABLE` statements (one using `DROP PARTITION` and then a second one using `REORGANIZE PARTITIONS`).

## 18.3.1. Management of `RANGE` and `LIST` Partitions

Range and list partitions are very similar with regard to how the adding and dropping of partitions are handled. For this reason we discuss the management of both sorts of partitioning in this section. For information about working with tables that are partitioned by hash or key, see [Section 18.3.2, “Management of HASH and KEY Partitions”](#). Dropping a `RANGE` or `LIST` partition is more straightforward than adding one, so we discuss this first.

Dropping a partition from a table that is partitioned by either `RANGE` or by `LIST` can be accomplished using the `ALTER TABLE` statement with a `DROP PARTITION` clause. Here is a very basic example, which supposes that you have already created a table which is partitioned by range and then populated with 10 records using the following `CREATE TABLE` and `INSERT` statements:

```
mysql> CREATE TABLE tr (id INT, name VARCHAR(50), purchased DATE)
-> PARTITION BY RANGE(YEAR(purchased)) (
-> PARTITION p0 VALUES LESS THAN (1990),
-> PARTITION p1 VALUES LESS THAN (1995),
-> PARTITION p2 VALUES LESS THAN (2000),
-> PARTITION p3 VALUES LESS THAN (2005)
->);
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO tr VALUES
-> (1, 'desk organiser', '2003-10-15'),
-> (2, 'CD player', '1993-11-05'),
```

```

-> (3, 'TV set', '1996-03-10'),
-> (4, 'bookcase', '1982-01-10'),
-> (5, 'exercise bike', '2004-05-09'),
-> (6, 'sofa', '1987-06-05'),
-> (7, 'popcorn maker', '2001-11-22'),
-> (8, 'aquarium', '1992-08-04'),
-> (9, 'study desk', '1984-09-16'),
-> (10, 'lava lamp', '1998-12-25');
Query OK, 10 rows affected (0.01 sec)

```

You can see which items should have been inserted into partition `p2` as shown here:

```

mysql> SELECT * FROM tr
-> WHERE purchased BETWEEN '1995-01-01' AND '1999-12-31';
+----+-----+-----+
| id | name | purchased |
+----+-----+-----+
| 3 | TV set | 1996-03-10 |
| 10 | lava lamp | 1998-12-25 |
+----+-----+-----+
2 rows in set (0.00 sec)

```

To drop the partition named `p2`, execute the following command:

```

mysql> ALTER TABLE tr DROP PARTITION p2;
Query OK, 0 rows affected (0.03 sec)

```

### Note

The `NDBCLUSTER` storage engine does not support `ALTER TABLE ... DROP PARTITION`. It does, however, support the other partitioning-related extensions to `ALTER TABLE` that are described in this chapter.

It is very important to remember that, *when you drop a partition, you also delete all the data that was stored in that partition*. You can see that this is the case by re-running the previous `SELECT` query:

```

mysql> SELECT * FROM tr WHERE purchased
-> BETWEEN '1995-01-01' AND '1999-12-31';
Empty set (0.00 sec)

```

Because of this, the requirement was added in MySQL 5.1.10 that you have the `DROP` privilege for a table before you can execute `ALTER TABLE ... DROP PARTITION` on that table.

If you wish to drop all data from all partitions while preserving the table definition and its partitioning scheme, use the `TRUNCATE TABLE` statement. (See [Section 12.2.10, “TRUNCATE TABLE Syntax”](#).)

If you intend to change the partitioning of a table *without* losing data, use `ALTER TABLE ... REORGANIZE PARTITION` instead. See below or in [Section 12.1.7, “ALTER TABLE Syntax”](#), for information about `REORGANIZE PARTITION`.

If you now execute a `SHOW CREATE TABLE` statement, you can see how the partitioning makeup of the table has been changed:

```

mysql> SHOW CREATE TABLE tr\G
***** 1. row *****
 Table: tr
Create Table: CREATE TABLE `tr` (
 `id` int(11) default NULL,
 `name` varchar(50) default NULL,
 `purchased` date default NULL
) ENGINE=MyISAM DEFAULT CHARSET=latin1
PARTITION BY RANGE (YEAR(purchased)) (
 PARTITION p0 VALUES LESS THAN (1990) ENGINE = MyISAM,
 PARTITION p1 VALUES LESS THAN (1995) ENGINE = MyISAM,
 PARTITION p3 VALUES LESS THAN (2005) ENGINE = MyISAM
)
1 row in set (0.01 sec)

```

When you insert new rows into the changed table with `purchased` column values between `'1995-01-01'` and `'2004-12-31'` inclusive, those rows will be stored in partition `p3`. You can verify this as follows:

```

mysql> INSERT INTO tr VALUES (11, 'pencil holder', '1995-07-12');
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM tr WHERE purchased
-> BETWEEN '1995-01-01' AND '2004-12-31';
+----+-----+-----+
| id | name | purchased |
+----+-----+-----+
| 11 | pencil holder | 1995-07-12 |
| 1 | desk organiser | 2003-10-15 |
| 5 | exercise bike | 2004-05-09 |
| 7 | popcorn maker | 2001-11-22 |
+----+-----+-----+
4 rows in set (0.00 sec)

```

```
mysql> ALTER TABLE tr DROP PARTITION p3;
Query OK, 0 rows affected (0.03 sec)

mysql> SELECT * FROM tr WHERE purchased
-> BETWEEN '1995-01-01' AND '2004-12-31';
Empty set (0.00 sec)
```

Note that the number of rows dropped from the table as a result of `ALTER TABLE ... DROP PARTITION` is not reported by the server as it would be by the equivalent `DELETE` query.

Dropping `LIST` partitions uses exactly the same `ALTER TABLE ... DROP PARTITION` syntax as used for dropping `RANGE` partitions. However, there is one important difference in the effect this has on your use of the table afterward: You can no longer insert into the table any rows having any of the values that were included in the value list defining the deleted partition. (See [Section 18.2.2, “`LIST` Partitioning”](#), for an example.)

To add a new range or list partition to a previously partitioned table, use the `ALTER TABLE ... ADD PARTITION` statement. For tables which are partitioned by `RANGE`, this can be used to add a new range to the end of the list of existing partitions. Suppose that you have a partitioned table containing membership data for your organisation, which is defined as follows:

```
CREATE TABLE members (
 id INT,
 fname VARCHAR(25),
 lname VARCHAR(25),
 dob DATE
)
PARTITION BY RANGE(YEAR(dob)) (
 PARTITION p0 VALUES LESS THAN (1970),
 PARTITION p1 VALUES LESS THAN (1980),
 PARTITION p2 VALUES LESS THAN (1990)
);
```

Suppose further that the minimum age for members is 16. As the calendar approaches the end of 2005, you realize that you will soon be admitting members who were born in 1990 (and later in years to come). You can modify the `members` table to accommodate new members born in the years 1990 to 1999 as shown here:

```
ALTER TABLE ADD PARTITION (PARTITION p3 VALUES LESS THAN (2000));
```

### Important

With tables that are partitioned by range, you can use `ADD PARTITION` to add new partitions to the high end of the partitions list only. Trying to add a new partition in this manner between or before existing partitions will result in an error as shown here:

```
mysql> ALTER TABLE members
-> ADD PARTITION (
-> PARTITION p3 VALUES LESS THAN (1960));
ERROR 1463 (HY000): VALUES LESS THAN value must be strictly »
increasing for each partition
```

In a similar fashion, you can add new partitions to a table that is partitioned by `LIST`. For example, given a table defined like so:

```
CREATE TABLE tt (
 id INT,
 data INT
)
PARTITION BY LIST(data) (
 PARTITION p0 VALUES IN (5, 10, 15),
 PARTITION p1 VALUES IN (6, 12, 18)
);
```

You can add a new partition in which to store rows having the `data` column values `7`, `14`, and `21` as shown:

```
ALTER TABLE tt ADD PARTITION (PARTITION p2 VALUES IN (7, 14, 21));
```

Note that you *cannot* add a new `LIST` partition encompassing any values that are already included in the value list of an existing partition. If you attempt to do so, an error will result:

```
mysql> ALTER TABLE tt ADD PARTITION
-> (PARTITION np VALUES IN (4, 8, 12));
ERROR 1465 (HY000): Multiple definition of same constant »
in list partitioning
```

Because any rows with the `data` column value `12` have already been assigned to partition `p1`, you cannot create a new partition on table `tt` that includes `12` in its value list. To accomplish this, you could drop `p1`, and add `np` and then a new `p1` with a modified definition. However, as discussed earlier, this would result in the loss of all data stored in `p1`—and it is often the case that this

is not what you really want to do. Another solution might appear to be to make a copy of the table with the new partitioning and to copy the data into it using `CREATE TABLE ... SELECT ...`, then drop the old table and rename the new one, but this could be very time-consuming when dealing with a large amounts of data. This also might not be feasible in situations where high availability is a requirement.

Beginning with MySQL 5.1.6, you can add multiple partitions in a single `ALTER TABLE ... ADD PARTITION` statement as shown here:

```
CREATE TABLE employees (
 id INT NOT NULL,
 fname VARCHAR(50) NOT NULL,
 lname VARCHAR(50) NOT NULL,
 hired DATE NOT NULL
)
PARTITION BY RANGE(YEAR(hired)) (
 PARTITION p1 VALUES LESS THAN (1991),
 PARTITION p2 VALUES LESS THAN (1996),
 PARTITION p3 VALUES LESS THAN (2001),
 PARTITION p4 VALUES LESS THAN (2005)
);
ALTER TABLE employees ADD PARTITION (
 PARTITION p5 VALUES LESS THAN (2010),
 PARTITION p6 VALUES LESS THAN MAXVALUE
);
```

Fortunately, MySQL's partitioning implementation provides ways to redefine partitions without losing data. Let us look first at a couple of simple examples involving `RANGE` partitioning. Recall the `members` table which is now defined as shown here:

```
mysql> SHOW CREATE TABLE members\G
***** 1. row *****
Table: members
Create Table: CREATE TABLE `members` (
 `id` int(11) default NULL,
 `fname` varchar(25) default NULL,
 `lname` varchar(25) default NULL,
 `dob` date default NULL
) ENGINE=MyISAM DEFAULT CHARSET=latin1
PARTITION BY RANGE (YEAR(dob)) (
 PARTITION p0 VALUES LESS THAN (1970) ENGINE = MyISAM,
 PARTITION p1 VALUES LESS THAN (1980) ENGINE = MyISAM,
 PARTITION p2 VALUES LESS THAN (1990) ENGINE = MyISAM,
 PARTITION p3 VALUES LESS THAN (2000) ENGINE = MyISAM
)
```

Suppose that you would like to move all rows representing members born before 1960 into a separate partition. As we have already seen, this cannot be done using `ALTER TABLE ... ADD PARTITION`. However, you can use another partition-related extension to `ALTER TABLE` to accomplish this:

```
ALTER TABLE members REORGANIZE PARTITION p0 INTO (
 PARTITION s0 VALUES LESS THAN (1960),
 PARTITION s1 VALUES LESS THAN (1970)
);
```

In effect, this command splits partition `p0` into two new partitions `s0` and `s1`. It also moves the data that was stored in `p0` into the new partitions according to the rules embodied in the two `PARTITION ... VALUES ...` clauses, so that `s0` contains only those records for which `YEAR(dob)` is less than 1960 and `s1` contains those rows in which `YEAR(dob)` is greater than or equal to 1960 but less than 1970.

A `REORGANIZE PARTITION` clause may also be used for merging adjacent partitions. You can return the `members` table to its previous partitioning as shown here:

```
ALTER TABLE members REORGANIZE PARTITION s0,s1 INTO (
 PARTITION p0 VALUES LESS THAN (1970)
);
```

No data is lost in splitting or merging partitions using `REORGANIZE PARTITION`. In executing the above statement, MySQL moves all of the records that were stored in partitions `s0` and `s1` into partition `p0`.

The general syntax for `REORGANIZE PARTITION` is:

```
ALTER TABLE tbl_name
 REORGANIZE PARTITION partition_list
 INTO (partition_definitions);
```

Here, `tbl_name` is the name of the partitioned table, and `partition_list` is a comma-separated list of names of one or more existing partitions to be changed. `partition_definitions` is a comma-separated list of new partition definitions, which follow the same rules as for the `partition_definitions` list used in `CREATE TABLE` (see [Section 12.1.17, “CREATE TABLE Syntax”](#)). It should be noted that you are not limited to merging several partitions into one, or to splitting one partition into

many, when using `REORGANIZE PARTITION`. For example, you can reorganize all four partitions of the `members` table into two, as follows:

```
ALTER TABLE members REORGANIZE PARTITION p0,p1,p2,p3 INTO (
 PARTITION m0 VALUES LESS THAN (1980),
 PARTITION m1 VALUES LESS THAN (2000)
);
```

You can also use `REORGANIZE PARTITION` with tables that are partitioned by `LIST`. Let us return to the problem of adding a new partition to the list-partitioned `tt` table and failing because the new partition had a value that was already present in the value-list of one of the existing partitions. We can handle this by adding a partition that contains only nonconflicting values, and then reorganizing the new partition and the existing one so that the value which was stored in the existing one is now moved to the new one:

```
ALTER TABLE tt ADD PARTITION (PARTITION np VALUES IN (4, 8));
ALTER TABLE tt REORGANIZE PARTITION p1,np INTO (
 PARTITION p1 VALUES IN (6, 18),
 PARTITION np VALUES IN (4, 8, 12)
);
```

Here are some key points to keep in mind when using `ALTER TABLE ... REORGANIZE PARTITION` to repartition tables that are partitioned by `RANGE` or `LIST`:

- The `PARTITION` clauses used to determine the new partitioning scheme are subject to the same rules as those used with a `CREATE TABLE` statement.

Most importantly, you should remember that the new partitioning scheme cannot have any overlapping ranges (applies to tables partitioned by `RANGE`) or sets of values (when reorganizing tables partitioned by `LIST`).

### Note

Prior to MySQL 5.1.4, you could not reuse the names of existing partitions in the `INTO` clause, even when those partitions were being dropped or redefined. See [Section C.1.53, “Changes in MySQL 5.1.4 \(21 December 2005\)”, for more information.](#)

- The combination of partitions in the `partition_definitions` list should account for the same range or set of values overall as the combined partitions named in the `partition_list`.

For instance, in the `members` table used as an example in this section, partitions `p1` and `p2` together cover the years 1980 through 1999. Therefore, any reorganization of these two partitions should cover the same range of years overall.

- For tables partitioned by `RANGE`, you can reorganize only adjacent partitions; you cannot skip over range partitions.

For instance, you could not reorganize the `members` table used as an example in this section using a statement beginning with `ALTER TABLE members REORGANIZE PARTITION p0,p2 INTO ...` because `p0` covers the years prior to 1970 and `p2` the years from 1990 through 1999 inclusive, and thus the two are not adjacent partitions.

- You cannot use `REORGANIZE PARTITION` to change the table's partitioning type; that is, you cannot (for example) change `RANGE` partitions to `HASH` partitions or *vice versa*. You also cannot use this command to change the partitioning expression or column. To accomplish either of these tasks without dropping and re-creating the table, you can use `ALTER TABLE ... PARTITION BY ...`. For example:

```
ALTER TABLE members
 PARTITION BY HASH(YEAR(dob))
 PARTITIONS 8;
```

## 18.3.2. Management of `HASH` and `KEY` Partitions

Tables which are partitioned by hash or by key are very similar to one another with regard to making changes in a partitioning setup, and both differ in a number of ways from tables which have been partitioned by range or list. For that reason, this section addresses the modification of tables partitioned by hash or by key only. For a discussion of adding and dropping of partitions of tables that are partitioned by range or list, see [Section 18.3.1, “Management of RANGE and LIST Partitions”](#).

You cannot drop partitions from tables that are partitioned by `HASH` or `KEY` in the same way that you can from tables that are partitioned by `RANGE` or `LIST`. However, you can merge `HASH` or `KEY` partitions using the `ALTER TABLE ... COALESCE PARTITION` statement. Suppose that you have a table containing data about clients, which is divided into twelve partitions. The `clients` table is defined as shown here:

```
CREATE TABLE clients (
 id INT,
 fname VARCHAR(30),
```

```

 lname VARCHAR(30),
 signed DATE
)
PARTITION BY HASH(MONTH(signed))
PARTITIONS 12;

```

To reduce the number of partitions from twelve to eight, execute the following `ALTER TABLE` command:

```
mysql> ALTER TABLE clients COALESCE PARTITION 4;
Query OK, 0 rows affected (0.02 sec)
```

`COALESCE` works equally well with tables that are partitioned by `HASH`, `KEY`, `LINEAR HASH`, or `LINEAR KEY`. Here is an example similar to the previous one, differing only in that the table is partitioned by `LINEAR KEY`:

```

mysql> CREATE TABLE clients_lk (
 -> id INT,
 -> fname VARCHAR(30),
 -> lname VARCHAR(30),
 -> signed DATE
 ->)
 -> PARTITION BY LINEAR KEY(signed)
 -> PARTITIONS 12;
Query OK, 0 rows affected (0.03 sec)

mysql> ALTER TABLE clients_lk COALESCE PARTITION 4;
Query OK, 0 rows affected (0.06 sec)
Records: 0 Duplicates: 0 Warnings: 0

```

Note that the number following `COALESCE PARTITION` is the number of partitions to merge into the remainder—in other words, it is the number of partitions to remove from the table.

If you attempt to remove more partitions than the table has, the result is an error like the one shown:

```
mysql> ALTER TABLE clients COALESCE PARTITION 18;
ERROR 1478 (HY000): Cannot remove all partitions, use DROP TABLE instead
```

To increase the number of partitions for the `clients` table from 12 to 18, use `ALTER TABLE ... ADD PARTITION` as shown here:

```
ALTER TABLE clients ADD PARTITION PARTITIONS 6;
```

### 18.3.3. Maintenance of Partitions

A number of table and partition maintenance tasks can be carried out using SQL statements intended for such purposes on partitioned tables in MySQL 5.1.

Table maintenance of partitioned tables can be accomplished using the statements `CHECK TABLE`, `OPTIMIZE TABLE`, `ANALYZE TABLE`, and `REPAIR TABLE`, which are supported for partitioned tables as of MySQL 5.1.27.

Also beginning with MySQL 5.1.27, you can use a number of extensions to `ALTER TABLE` for performing operations of this type on one or more partitions directly, as described in the following list:

- **Rebuilding partitions.** Rebuilds the partition; this has the same effect as dropping all records stored in the partition, then reinserting them. This can be useful for purposes of defragmentation.

Example:

```
ALTER TABLE t1 REBUILD PARTITION p0, p1;
```

- **Optimizing partitions.** If you have deleted a large number of rows from a partition or if you have made many changes to a partitioned table with variable-length rows (that is, having `VARCHAR`, `BLOB`, or `TEXT` columns), you can use `ALTER TABLE ... OPTIMIZE PARTITION` to reclaim any unused space and to defragment the partition data file.

Example:

```
ALTER TABLE t1 OPTIMIZE PARTITION p0, p1;
```

Using `OPTIMIZE PARTITION` on a given partition is equivalent to running `CHECK PARTITION`, `ANALYZE PARTITION`, and `REPAIR PARTITION` on that partition.

- **Analyzing partitions.** This reads and stores the key distributions for partitions.

Example:

```
ALTER TABLE t1 ANALYZE PARTITION p3;
```

- **Repairing partitions.** This repairs corrupted partitions.

Example:

```
ALTER TABLE t1 REPAIR PARTITION p0,p1;
```

- **Checking partitions.** You can check partitions for errors in much the same way that you can use `CHECK TABLE` with non-partitioned tables.

Example:

```
ALTER TABLE trb3 CHECK PARTITION p1;
```

This command will tell you if the data or indexes in partition `p1` of table `t1` are corrupted. If this is the case, use `ALTER TABLE ... REPAIR PARTITION` to repair the partition.

Each of the statements in the list just shown also supports the keyword `ALL` in place of the list of partition names. Using `ALL` causes the statement to act on all partitions in the table.

#### Note

The statements `ALTER TABLE ... ANALYZE PARTITION`, `ALTER TABLE ... CHECK PARTITION`, `ALTER TABLE ... OPTIMIZE PARTITION`, and `ALTER TABLE ... REPAIR PARTITION` were originally introduced in MySQL 5.1.5, but did not work properly and were disabled in MySQL 5.1.24. They were re-introduced in MySQL 5.1.27. ([Bug#20129](#)) The use of these partitioning-specific `ALTER TABLE` statements with tables which are not partitioned is not supported; beginning with MySQL 5.1.31, it is expressly not permitted. ([Bug#39434](#))

`ALTER TABLE ... REBUILD PARTITION` was also introduced in MySQL 5.1.5.

### 18.3.4. Obtaining Information About Partitions

This section discusses obtaining information about existing partitions, which can be done in a number of ways. These include:

- Using the `SHOW CREATE TABLE` statement to view the partitioning clauses used in creating a partitioned table.
- Using the `SHOW TABLE STATUS` statement to determine whether a table is partitioned.
- Querying the `INFORMATION_SCHEMA.PARTITIONS` table.
- Using the statement `EXPLAIN PARTITIONS SELECT` to see which partitions are used by a given `SELECT`.

As discussed elsewhere in this chapter, `SHOW CREATE TABLE` includes in its output the `PARTITION BY` clause used to create a partitioned table. For example:

```
mysql> SHOW CREATE TABLE trb3\G
***** 1. row *****
 Table: trb3
Create Table: CREATE TABLE `trb3` (
 `id` int(11) default NULL,
 `name` varchar(50) default NULL,
 `purchased` date default NULL
) ENGINE=MyISAM DEFAULT CHARSET=latin1
PARTITION BY RANGE (YEAR(purchased)) (
 PARTITION p0 VALUES LESS THAN (1990) ENGINE = MyISAM,
 PARTITION p1 VALUES LESS THAN (1995) ENGINE = MyISAM,
 PARTITION p2 VALUES LESS THAN (2000) ENGINE = MyISAM,
 PARTITION p3 VALUES LESS THAN (2005) ENGINE = MyISAM
)
1 row in set (0.00 sec)
```

#### Note

In early MySQL 5.1 releases, the `PARTITIONS` clause was not shown for tables partitioned by `HASH` or `KEY`. This issue was fixed in MySQL 5.1.6.

`SHOW TABLE STATUS` works with partitioned tables. Beginning with MySQL 5.1.9, its output is the same as that for nonpartitioned tables, except that the `Create_options` column contains the string `partitioned`. In MySQL 5.1.8 and earlier, the `Engine` column always contained the value `PARTITION`; beginning with MySQL 5.1.9, this column contains the name of the storage engine used by all partitions of the table. (See [Section 12.4.5.38, “SHOW TABLE STATUS Syntax”](#), for more information about this statement.)

You can also obtain information about partitions from `INFORMATION_SCHEMA`, which contains a `PARTITIONS` table. See [Section 20.19, “The INFORMATION\\_SCHEMA PARTITIONS Table”](#).

Beginning with MySQL 5.1.5, it is possible to determine which partitions of a partitioned table are involved in a given `SELECT` query using `EXPLAIN PARTITIONS`. The `PARTITIONS` keyword adds a `partitions` column to the output of `EXPLAIN` listing the partitions from which records would be matched by the query.

Suppose that you have a table `tbl1` defined and populated as follows:

```
CREATE TABLE trb1 (id INT, name VARCHAR(50), purchased DATE)
PARTITION BY RANGE(id)
(
 PARTITION p0 VALUES LESS THAN (3),
 PARTITION p1 VALUES LESS THAN (7),
 PARTITION p2 VALUES LESS THAN (9),
 PARTITION p3 VALUES LESS THAN (11)
);

INSERT INTO trb1 VALUES
(1, 'desk organiser', '2003-10-15'),
(2, 'CD player', '1993-11-05'),
(3, 'TV set', '1996-03-10'),
(4, 'bookcase', '1982-01-10'),
(5, 'exercise bike', '2004-05-09'),
(6, 'sofa', '1987-06-05'),
(7, 'popcorn maker', '2001-11-22'),
(8, 'aquarium', '1992-08-04'),
(9, 'study desk', '1984-09-16'),
(10, 'lava lamp', '1998-12-25');
```

You can see which partitions are used in a query such as `SELECT * FROM trb1`, as shown here:

```
mysql> EXPLAIN PARTITIONS SELECT * FROM trb1\G
***** 1. row *****
 id: 1
 select_type: SIMPLE
 table: trb1
 partitions: p0,p1,p2,p3
 type: ALL
possible_keys: NULL
 key: NULL
 key_len: NULL
 ref: NULL
 rows: 10
 Extra: Using filesort
```

In this case, all four partitions are searched. However, when a limiting condition making use of the partitioning key is added to the query, you can see that only those partitions containing matching values are scanned, as shown here:

```
mysql> EXPLAIN PARTITIONS SELECT * FROM trb1 WHERE id < 5\G
***** 1. row *****
 id: 1
 select_type: SIMPLE
 table: trb1
 partitions: p0,p1
 type: ALL
possible_keys: NULL
 key: NULL
 key_len: NULL
 ref: NULL
 rows: 10
 Extra: Using where
```

`EXPLAIN PARTITIONS` provides information about keys used and possible keys, just as with the standard `EXPLAIN SELECT` statement:

```
mysql> ALTER TABLE trb1 ADD PRIMARY KEY (id);
Query OK, 10 rows affected (0.03 sec)
Records: 10 Duplicates: 0 Warnings: 0

mysql> EXPLAIN PARTITIONS SELECT * FROM trb1 WHERE id < 5\G
***** 1. row *****
 id: 1
 select_type: SIMPLE
 table: trb1
 partitions: p0,p1
 type: range
possible_keys: PRIMARY
```

```

key: PRIMARY
key_len: 4
ref: NULL
rows: 7
Extra: Using where

```

You should take note of the following restrictions and limitations on `EXPLAIN PARTITIONS`:

- You cannot use the `PARTITIONS` and `EXTENDED` keywords together in the same `EXPLAIN ... SELECT` statement. Attempting to do so produces a syntax error.
- If `EXPLAIN PARTITIONS` is used to examine a query against a nonpartitioned table, no error is produced, but the value of the `partitions` column is always `NULL`.

As of MySQL 5.1.28, the `rows` column of `EXPLAIN PARTITIONS` output always displays the total number of records in the table. Previously, this was the number of matching rows. ([Bug#35745](#))

See also [Section 12.8.2, “`EXPLAIN` Syntax”](#).

## 18.4. Partition Pruning

This section discusses an optimization known as *partition pruning*, which was implemented for partitioned tables in MySQL 5.1.6. The core concept behind partition pruning is relatively simple, and can be described as “Do not scan partitions where there can be no matching values”. Suppose that you have a partitioned table `t1` defined by this statement:

```

CREATE TABLE t1 (
 fname VARCHAR(50) NOT NULL,
 lname VARCHAR(50) NOT NULL,
 region_code TINYINT UNSIGNED NOT NULL,
 dob DATE NOT NULL
)
PARTITION BY RANGE(region_code) (
 PARTITION p0 VALUES LESS THAN (64),
 PARTITION p1 VALUES LESS THAN (128),
 PARTITION p2 VALUES LESS THAN (192),
 PARTITION p3 VALUES LESS THAN MAXVALUE
);

```

Consider the case where you wish to obtain results from a query such as this one:

```

SELECT fname, lname, region_code, dob
 FROM t1
 WHERE region_code > 125 AND region_code < 130;

```

It is easy to see that none of the rows which ought to be returned will be in either of the partitions `p0` or `p3`; that is, we need to search only in partitions `p1` and `p2` to find matching rows. By doing so, it is possible to expend much more time and effort in finding matching rows than it is to scan all partitions in the table. This “cutting away” of unneeded partitions is known as *pruning*. When the optimizer can make use of partition pruning in performing a query, execution of the query can be an order of magnitude faster than the same query against a nonpartitioned table containing the same column definitions and data.

The query optimizer can perform pruning whenever a `WHERE` condition can be reduced to either one of the following:

- `partition_column = constant`
- `partition_column IN (constant1, constant2, ..., constantN)`

In the first case, the optimizer simply evaluates the partitioning expression for the value given, determines which partition contains that value, and scans only this partition. In many cases, the equal sign can be replaced with another arithmetic comparison, including `<`, `>`, `<=`, `>=`, and `<>`. Some queries using `BETWEEN` in the `WHERE` clause can also take advantage of partition pruning. See the examples later in this section.

In the second case, the optimizer evaluates the partitioning expression for each value in the list, creates a list of matching partitions, and then scans only the partitions in this partition list.

Pruning can also be applied to short ranges, which the optimizer can convert into equivalent lists of values. For instance, in the previous example, the `WHERE` clause can be converted to `WHERE region_code IN (125, 126, 127, 128, 129, 130)`. Then the optimizer can determine that the first three values in the list are found in partition `p1`, the remaining three values in partition `p2`, and that the other partitions contain no relevant values and so do not need to be searched for matching rows.

This type of optimization can be applied whenever the partitioning expression consists of an equality or a range which can be re-

duced to a set of equalities, or when the partitioning expression represents an increasing or decreasing relationship. Pruning can also be applied for tables partitioned on a `DATE` or `DATETIME` column when the partitioning expression uses the `YEAR()` or `TO_DAYS()` function.

### Note

We plan to add pruning support in a future MySQL release for additional functions that act on a `DATE` or `DATETIME` value, return an integer, and are increasing or decreasing.

Suppose that table `t2`, defined as shown here, is partitioned on a `DATE` column:

```
CREATE TABLE t2 (
 fname VARCHAR(50) NOT NULL,
 lname VARCHAR(50) NOT NULL,
 region_code TINYINT UNSIGNED NOT NULL,
 dob DATE NOT NULL
)
PARTITION BY RANGE(YEAR(dob)) (
 PARTITION d0 VALUES LESS THAN (1970),
 PARTITION d1 VALUES LESS THAN (1975),
 PARTITION d2 VALUES LESS THAN (1980),
 PARTITION d3 VALUES LESS THAN (1985),
 PARTITION d4 VALUES LESS THAN (1990),
 PARTITION d5 VALUES LESS THAN (2000),
 PARTITION d6 VALUES LESS THAN (2005),
 PARTITION d7 VALUES LESS THAN MAXVALUE
);
```

The following queries on `t2` can make use of partition pruning:

```
SELECT * FROM t2 WHERE dob = '1982-06-23';
SELECT * FROM t2 WHERE dob BETWEEN '1991-02-15' AND '1997-04-25';
SELECT * FROM t2 WHERE dob >= '1984-06-21' AND dob <= '1999-06-21'
```

In the case of the last query, the optimizer can also act as follows:

1. *Find the partition containing the low end of the range.*

`YEAR('1984-06-21')` yields the value `1984`, which is found in partition `d3`.

2. *Find the partition containing the high end of the range.*

`YEAR('1999-06-21')` evaluates to `1999`, which is found in partition `d5`.

3. *Scan only these two partitions and any partitions that may lie between them.*

In this case, this means that only partitions `d3`, `d4`, and `d5` are scanned. The remaining partitions may be safely ignored (and are ignored).

### Important

Invalid `DATE` and `DATETIME` values referenced in the `WHERE` clause of a query on a partitioned table are treated as `NULL`. This means that a query such as `SELECT * FROM partitioned_table WHERE date_column < '2008-12-00'` does not return any values (see Bug#40972).

So far, we have looked only at examples using `RANGE` partitioning, but pruning can be applied with other partitioning types as well.

Consider a table that is partitioned by `LIST`, where the partitioning expression is increasing or decreasing, such as the table `t3` shown here. (In this example, we assume for the sake of brevity that the `region_code` column is limited to values between 1 and 10 inclusive.)

```
CREATE TABLE t3 (
 fname VARCHAR(50) NOT NULL,
 lname VARCHAR(50) NOT NULL,
 region_code TINYINT UNSIGNED NOT NULL,
 dob DATE NOT NULL
)
PARTITION BY LIST(region_code) (
 PARTITION r0 VALUES IN (1, 3),
 PARTITION r1 VALUES IN (2, 5, 8),
 PARTITION r2 VALUES IN (4, 9),
 PARTITION r3 VALUES IN (6, 7, 10)
);
```

For a query such as `SELECT * FROM t3 WHERE region_code BETWEEN 1 AND 3`, the optimizer determines in which partitions the values 1, 2, and 3 are found (`r0` and `r1`) and skips the remaining ones (`r2` and `r3`).

For tables that are partitioned by `HASH` or `KEY`, partition pruning is also possible in cases in which the `WHERE` clause uses a simple `=` relation against a column used in the partitioning expression. Consider a table created like this:

```
CREATE TABLE t4 (
 fname VARCHAR(50) NOT NULL,
 lname VARCHAR(50) NOT NULL,
 region_code TINYINT UNSIGNED NOT NULL,
 dob DATE NOT NULL
)
PARTITION BY KEY(region_code)
PARTITIONS 8;
```

Any query such as this one can be pruned:

```
SELECT * FROM t4 WHERE region_code = 7;
```

Pruning can also be employed for short ranges, because the optimizer can turn such conditions into `IN` relations. For example, using the same table `t4` as defined previously, queries such as these can be pruned:

```
SELECT * FROM t4 WHERE region_code > 2 AND region_code < 6;
SELECT * FROM t4 WHERE region_code BETWEEN 3 AND 5;
```

In both these cases, the `WHERE` clause is transformed by the optimizer into `WHERE region_code IN (3, 4, 5)`.

### Important

This optimization is used only if the range size is smaller than the number of partitions. Consider this query:

```
SELECT * FROM t4 WHERE region_code BETWEEN 4 AND 12;
```

The range in the `WHERE` clause covers 9 values (4, 5, 6, 7, 8, 9, 10, 11, 12), but `t4` has only 8 partitions. This means that the previous query cannot be pruned.

Pruning can be used only on integer columns of tables partitioned by `HASH` or `KEY`. For example, this query on table `t4` cannot use pruning because `dob` is a `DATE` column:

```
SELECT * FROM t4 WHERE dob >= '2001-04-14' AND dob <= '2005-10-15';
```

However, if the table stores year values in an `INT` column, then a query having `WHERE year_col >= 2001 AND year_col <= 2005` can be pruned.

## 18.5. Restrictions and Limitations on Partitioning

This section discusses current restrictions and limitations on MySQL partitioning support, as listed here:

- **Prohibited constructs.** Beginning with MySQL 5.1.12, the following constructs are not permitted in partitioning expressions:
  - Stored procedures, stored functions, UDFs, or plugins.
  - Declared variables or user variables.
 For a list of SQL functions which are permitted in partitioning expressions, see [Section 18.5.3, “Partitioning Limitations Relating to Functions”](#).
- **Arithmetic and logical operators.** Use of the arithmetic operators `+`, `-`, and `*` is permitted in partitioning expressions. However, the result must be an integer value or `NULL` (except in the case of `[LINEAR] KEY` partitioning, as discussed elsewhere in this chapter; see [Section 18.2, “Partition Types”](#), for more information).

Beginning with MySQL 5.1.23, the `DIV` operator is also supported, and the `/` operator is not permitted. ([Bug#30188](#), [Bug#33182](#))

Beginning with MySQL 5.1.12, the bit operators `|`, `&`, `^`, `<<`, `>>`, and `~` are not permitted in partitioning expressions.

- **Server SQL mode.** Tables employing user-defined partitioning do not preserve the SQL mode in effect at the time that they were created. As discussed in [Section 5.1.7, “Server SQL Modes”](#), the results of many MySQL functions and operators may change according to the server SQL mode. Therefore, a change in the SQL mode at any time after the creation of partitioned tables may lead to major changes in the behavior of such tables, and could easily lead to corruption or loss of data. For these

reasons, it is strongly recommended that you never change the server SQL mode after creating partitioned tables.

**Examples.** The following examples illustrate some changes in behavior of partitioned tables due to a change in the server SQL mode:

1. **Error handling.** Suppose that you create a partitioned table whose partitioning expression is one such as `column DIV 0` or `column MOD 0`, as shown here:

```
mysql> CREATE TABLE tn (c1 INT)
-> PARTITION BY LIST(1 DIV c1) (
-> PARTITION p0 VALUES IN (NULL),
-> PARTITION p1 VALUES IN (1)
->);
Query OK, 0 rows affected (0.05 sec)
```

The default behavior for MySQL is to return `NULL` for the result of a division by zero, without producing any errors:

```
mysql> SELECT @@SQL_MODE;
+-----+
| @@SQL_MODE |
+-----+
|
1 row in set (0.00 sec)

mysql> INSERT INTO tn VALUES (NULL), (0), (1);
Query OK, 3 rows affected (0.00 sec)
Records: 3 Duplicates: 0 Warnings: 0
```

However, changing the server SQL mode to treat division by zero as an error and to enforce strict error handling causes the same `INSERT` statement to fail, as shown here:

```
mysql> SET SQL_MODE='STRICT_ALL_TABLES,ERROR_FOR_DIVISION_BY_ZERO';
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO tn VALUES (NULL), (0), (1);
ERROR 1365 (22012): DIVISION BY 0
```

2. **Table accessibility.** Sometimes a change in the server SQL mode can make partitioned tables unusable. The following `CREATE TABLE` statement can be executed successfully only if the `NO_UNSIGNED_SUBTRACTION` mode is in effect:

```
mysql> SELECT @@SQL_MODE;
+-----+
| @@SQL_MODE |
+-----+
|
1 row in set (0.00 sec)

mysql> CREATE TABLE tu (c1 BIGINT UNSIGNED)
-> PARTITION BY RANGE(c1 - 10) (
-> PARTITION p0 VALUES LESS THAN (-5),
-> PARTITION p1 VALUES LESS THAN (0),
-> PARTITION p2 VALUES LESS THAN (5),
-> PARTITION p3 VALUES LESS THAN (10),
-> PARTITION p4 VALUES LESS THAN (MAXVALUE)
->);
ERROR 1563 (HY000): PARTITION CONSTANT IS OUT OF PARTITION FUNCTION DOMAIN

mysql> SET SQL_MODE='NO_UNSIGNED_SUBTRACTION';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @@SQL_MODE;
+-----+
| @@SQL_MODE |
+-----+
| NO_UNSIGNED_SUBTRACTION |
+-----+
1 row in set (0.00 sec)

mysql> CREATE TABLE tu (c1 BIGINT UNSIGNED)
-> PARTITION BY RANGE(c1 - 10) (
-> PARTITION p0 VALUES LESS THAN (-5),
-> PARTITION p1 VALUES LESS THAN (0),
-> PARTITION p2 VALUES LESS THAN (5),
-> PARTITION p3 VALUES LESS THAN (10),
-> PARTITION p4 VALUES LESS THAN (MAXVALUE)
->);
Query OK, 0 rows affected (0.05 sec)
```

If you remove the `NO_UNSIGNED_SUBTRACTION` server SQL mode after creating `tu`, you may no longer be able to access this table:

```
mysql> SET SQL_MODE='';
```

```
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT * FROM tu;
ERROR 1563 (HY000): PARTITION CONSTANT IS OUT OF PARTITION FUNCTION DOMAIN
mysql> INSERT INTO tu VALUES (20);
ERROR 1563 (HY000): PARTITION CONSTANT IS OUT OF PARTITION FUNCTION DOMAIN
```

Server SQL modes also impact replication of partitioned tables. Differing SQL modes on master and slave can lead to partitioning expressions being evaluated differently; this can cause the distribution of data among partitions to be different in the master's and slave's copies of a given table, and may even cause inserts into partitioned tables that succeed on the master to fail on the slave. For best results, you should always use the same server SQL mode on the master and on the slave.

- **Performance considerations.** Some affects of partitioning operations on performance are given in the following list:

- **File system operations.** Partitioning and repartitioning operations (such as `ALTER TABLE` with `PARTITION BY ...`, `REORGANIZE PARTITIONS`, or `REMOVE PARTITIONING`) depend on file system operations for their implementation. This means that the speed of these operations is affected by such factors as file system type and characteristics, disk speed, swap space, file handling efficiency of the operating system, and MySQL server options and variables that relate to file handling. In particular, you should make sure that `large_files_support` is enabled and that `open_files_limit` is set properly. For partitioned tables using the `MyISAM` storage engine, increasing `myisam_max_sort_file_size` may improve performance; partitioning and repartitioning operations involving `InnoDB` tables may be made more efficient by enabling `innodb_file_per_table`.

See also [Maximum number of partitions](#).

- **Table locks.** The process executing a partitioning operation on a table takes a write lock on the table. Reads from such tables are relatively unaffected; pending `INSERT` and `UPDATE` operations are performed as soon as the partitioning operation has completed.
- **Storage engine.** Partitioning operations, queries, and update operations generally tend to be faster with `MyISAM` tables than with `InnoDB` or `NDB` tables.
- **Use of indexes and partition pruning.** As with nonpartitioned tables, proper use of indexes can speed up queries on partitioned tables significantly. In addition, designing partitioned tables and queries on these tables to take advantage of *partition pruning* can improve performance dramatically. See [Section 18.4, “Partition Pruning”](#), for more information.
- **Performance with `LOAD DATA`.** Prior to MySQL 5.1.23, `LOAD DATA` performed very poorly when importing into partitioned tables. The statement now uses buffering to improve performance; however, the buffer uses 130 KB memory per partition to achieve this. ([Bug#26527](#))
- **Maximum number of partitions.** The maximum possible number of partitions for a given table is 1024. This includes subpartitions.

If, when creating tables with a large number of partitions (but less than the maximum), you encounter an error message such as `GOT_ERROR ... FROM STORAGE ENGINE: OUT_OF_RESOURCES WHEN OPENING FILE`, you may be able to address the issue by increasing the value of the `open_files_limit` system variable. However, this is dependent on the operating system, and may not be possible or advisable on all platforms; see [Section B.5.2.18, “FILE NOT FOUND and Similar Errors”](#), for more information. In some cases, using large numbers (hundreds) of partitions may also not be advisable due to other concerns, so using more partitions does not automatically lead to better results.

See also [File system operations](#).

- **Foreign keys not supported.** Partitioned tables do not support foreign keys. This means that:
  1. Definitions of tables employing user-defined partitioning may not contain foreign key references to other tables.
  2. No table definition may contain a foreign key reference to a partitioned table.The scope of these restrictions includes tables that use the `InnoDB` storage engine.
- **`ALTER TABLE ... ORDER BY`.** An `ALTER TABLE ... ORDER BY column` statement run against a partitioned table causes ordering of rows only within each partition.
- **FULLTEXT indexes.** Partitioned tables do not support `FULLTEXT` indexes. This includes partitioned tables employing the `MyISAM` storage engine.
- **Spatial columns.** Columns with spatial data types such as `POINT` or `GEOMETRY` cannot be used in partitioned tables.
- **Temporary tables.** As of MySQL 5.1.8, temporary tables cannot be partitioned. ([Bug#17497](#))
- **Log tables.** Beginning with MySQL 5.1.20, it is no longer possible to partition the log tables; beginning with that version, an `ALTER TABLE ... PARTITION BY ...` statement on such a table fails with an error. ([Bug#27816](#))

- **Data type of partitioning key.** A partitioning key must be either an integer column or an expression that resolves to an integer. The column or expression value may also be `NULL`. (See [Section 18.2.6, “How MySQL Partitioning Handles NULL”](#).)

The lone exception to this restriction occurs when partitioning by `[LINEAR] KEY`, where it is possible to use columns of other types as partitioning keys, because MySQL's internal key-hashing functions produce the correct data type from these types. For example, the following `CREATE TABLE` statement is valid:

```
CREATE TABLE tkc (c1 CHAR)
PARTITION BY KEY(c1)
PARTITIONS 4;
```

This exception does *not* apply to `BLOB` or `TEXT` column types.

- **Subqueries.** A partitioning key may not be a subquery, even if that subquery resolves to an integer value or `NULL`.
- **Issues with subpartitions.** Subpartitions must use `HASH` or `KEY` partitioning. Only `RANGE` and `LIST` partitions may be subpartitioned; `HASH` and `KEY` partitions cannot be subpartitioned.

Currently, `SUBPARTITION BY KEY` requires that the subpartitioning column or columns be specified explicitly, unlike the case with `PARTITION BY KEY`, where it can be omitted (in which case the table's primary key column is used by default). Consider table created by this statement:

```
CREATE TABLE ts (
 id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
 name VARCHAR(30)
);
```

You can create a table having the same columns, partitioned by `KEY`, using a statement such as this one:

```
CREATE TABLE ts (
 id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
 name VARCHAR(30)
)
PARTITION BY KEY()
PARTITIONS 4;
```

The previous statement is treated as though it had been written like this, with the table's primary key column used as the partitioning column:

```
CREATE TABLE ts (
 id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
 name VARCHAR(30)
)
PARTITION BY KEY(id)
PARTITIONS 4;
```

However, the following statement that attempts to create a subpartitioned table using the default column as the subpartitioning column fails, and the column must be specified for the statement to succeed, as shown here:

```
mysql> CREATE TABLE ts (
-> id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
-> name VARCHAR(30)
->)
-> PARTITION BY RANGE(id)
-> SUBPARTITION BY KEY()
-> SUBPARTITIONS 4
-> (
-> PARTITION p0 VALUES LESS THAN (100),
-> PARTITION p1 VALUES LESS THAN (MAXVALUE)
->);
ERROR 1064 (42000): YOU HAVE AN ERROR IN YOUR SQL SYNTAX; CHECK THE MANUAL THAT
CORRESPONDS TO YOUR MYSQL SERVER VERSION FOR THE RIGHT SYNTAX TO USE NEAR ' '

mysql> CREATE TABLE ts (
-> id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
-> name VARCHAR(30)
->)
-> PARTITION BY RANGE(id)
-> SUBPARTITION BY KEY(id)
-> SUBPARTITIONS 4
-> (
-> PARTITION p0 VALUES LESS THAN (100),
-> PARTITION p1 VALUES LESS THAN (MAXVALUE)
->);
Query OK, 0 rows affected (0.07 sec)
```

This is a known issue, which we are currently working to address ([Bug#51470](#)).

- **Key caches not supported.** Key caches are not supported for partitioned tables. The `CACHE INDEX` and `LOAD INDEX INTO CACHE` statements, when you attempt to use them on tables having user-defined partitioning, fail with the errors `THE STORAGE ENGINE FOR THE TABLE DOESN'T SUPPORT ASSIGN_TO_KEYCACHE` and `THE STORAGE ENGINE FOR THE TABLE DOESN'T SUPPORT PRELOAD_KEYS`, respectively.
- **DELAYED option not supported.** Use of `INSERT DELAYED` to insert rows into a partitioned table is not supported. Beginning with MySQL 5.1.23, attempting to do so fails with an error. ([Bug#31210](#))
- **DATA DIRECTORY and INDEX DIRECTORY options.** `DATA DIRECTORY` and `INDEX DIRECTORY` are subject to the following restrictions when used with partitioned tables:
  - Beginning with MySQL 5.1.23, table-level `DATA DIRECTORY` and `INDEX DIRECTORY` options are ignored. ([Bug#32091](#))
  - On Windows, the `DATA DIRECTORY` and `INDEX DIRECTORY` options are not supported for individual partitions or subpartitions ([Bug#30459](#)).
- **Repairing and rebuilding partitioned tables.** The statements `CHECK TABLE`, `OPTIMIZE TABLE`, `ANALYZE TABLE`, and `REPAIR TABLE` are supported for partitioned tables beginning with MySQL 5.1.27. (See [Bug#20129](#).) `mysqlcheck` and `myisamchk` are not supported with partitioned tables.

In addition, you can use `ALTER TABLE ... REBUILD PARTITION` to rebuild one or more partitions of a partitioned table; `ALTER TABLE ... REORGANIZE PARTITION` also causes partitions to be rebuilt. Both of these statements were added in MySQL 5.1.5. See [Section 12.1.7, “ALTER TABLE Syntax”](#), for more information about these two statements.

## 18.5.1. Partitioning Keys, Primary Keys, and Unique Keys

This section discusses the relationship of partitioning keys with primary keys and unique keys. The rule governing this relationship can be expressed as follows: All columns used in the partitioning expression for a partitioned table must be part of every unique key that the table may have.

In other words, *every unique key on the table must use every column in the table's partitioning expression*. (This also includes the table's primary key, since it is by definition a unique key. This particular case is discussed later in this section.) For example, each of the following table creation statements is invalid:

```
CREATE TABLE t1 (
 col1 INT NOT NULL,
 col2 DATE NOT NULL,
 col3 INT NOT NULL,
 col4 INT NOT NULL,
 UNIQUE KEY (col1, col2)
)
PARTITION BY HASH(col3)
PARTITIONS 4;

CREATE TABLE t2 (
 col1 INT NOT NULL,
 col2 DATE NOT NULL,
 col3 INT NOT NULL,
 col4 INT NOT NULL,
 UNIQUE KEY (col1),
 UNIQUE KEY (col3)
)
PARTITION BY HASH(col1 + col3)
PARTITIONS 4;
```

In each case, the proposed table would have at least one unique key that does not include all columns used in the partitioning expression.

Each of the following statements is valid, and represents one way in which the corresponding invalid table creation statement could be made to work:

```
CREATE TABLE t1 (
 col1 INT NOT NULL,
 col2 DATE NOT NULL,
 col3 INT NOT NULL,
 col4 INT NOT NULL,
 UNIQUE KEY (col1, col2, col3)
)
PARTITION BY HASH(col3)
PARTITIONS 4;

CREATE TABLE t2 (
 col1 INT NOT NULL,
 col2 DATE NOT NULL,
 col3 INT NOT NULL,
 col4 INT NOT NULL,
 UNIQUE KEY (col1, col3)
)
```

```
PARTITION BY HASH(col1 + col3)
PARTITIONS 4;
```

This example shows the error produced in such cases:

```
mysql> CREATE TABLE t3 (
-> col1 INT NOT NULL,
-> col2 DATE NOT NULL,
-> col3 INT NOT NULL,
-> col4 INT NOT NULL,
-> UNIQUE KEY (col1, col2),
-> UNIQUE KEY (col3)
->)
-> PARTITION BY HASH(col1 + col3)
-> PARTITIONS 4;
ERROR 1491 (HY000): A PRIMARY KEY MUST INCLUDE ALL COLUMNS IN THE TABLE'S PARTITIONING FUNCTION
```

The `CREATE TABLE` statement fails because both `col1` and `col3` are included in the proposed partitioning key, but neither of these columns is part of both of unique keys on the table. This shows one possible fix for the invalid table definition:

```
mysql> CREATE TABLE t3 (
-> col1 INT NOT NULL,
-> col2 DATE NOT NULL,
-> col3 INT NOT NULL,
-> col4 INT NOT NULL,
-> UNIQUE KEY (col1, col2, col3),
-> UNIQUE KEY (col3)
->)
-> PARTITION BY HASH(col3)
-> PARTITIONS 4;
Query OK, 0 rows affected (0.05 sec)
```

In this case, the proposed partitioning key `col3` is part of both unique keys, and the table creation statement succeeds.

The following table cannot be partitioned at all, because there is no way to include in a partitioning key any columns that belong to both unique keys:

```
CREATE TABLE t4 (
 col1 INT NOT NULL,
 col2 INT NOT NULL,
 col3 INT NOT NULL,
 col4 INT NOT NULL,
 UNQIUE KEY (col1, col3),
 UNQIUE KEY (col2, col4)
);
```

Since every primary key is by definition a unique key, this restriction also includes the table's primary key, if it has one. For example, the next two statements are invalid:

```
CREATE TABLE t5 (
 col1 INT NOT NULL,
 col2 DATE NOT NULL,
 col3 INT NOT NULL,
 col4 INT NOT NULL,
 PRIMARY KEY(col1, col2)
)
PARTITION BY HASH(col3)
PARTITIONS 4;

CREATE TABLE t6 (
 col1 INT NOT NULL,
 col2 DATE NOT NULL,
 col3 INT NOT NULL,
 col4 INT NOT NULL,
 PRIMARY KEY(col1, col3),
 UNIQUE KEY(col2)
)
PARTITION BY HASH(YEAR(col2))
PARTITIONS 4;
```

In both cases, the primary key does not include all columns referenced in the partitioning expression. However, both of the next two statements are valid:

```
CREATE TABLE t7 (
 col1 INT NOT NULL,
 col2 DATE NOT NULL,
 col3 INT NOT NULL,
 col4 INT NOT NULL,
 PRIMARY KEY(col1, col2)
)
PARTITION BY HASH(col1 + YEAR(col2))
PARTITIONS 4;

CREATE TABLE t8 (
```

```

 col1 INT NOT NULL,
 col2 DATE NOT NULL,
 col3 INT NOT NULL,
 col4 INT NOT NULL,
 PRIMARY KEY(col1, col2, col4),
 UNIQUE KEY(col2, col1)
)
PARTITION BY HASH(col1 + YEAR(col2))
PARTITIONS 4;

```

If a table has no unique keys—this includes having no primary key—then this restriction does not apply, and you may use any column or columns in the partitioning expression as long as the column type is compatible with the partitioning type.

For the same reason, you cannot later add a unique key to a partitioned table unless the key includes all columns used by the table's partitioning expression. Consider given the partitioned table defined as shown here:

```

mysql> CREATE TABLE t_no_pk (c1 INT, c2 INT)
-> PARTITION BY RANGE(c1) (
-> PARTITION p0 VALUES LESS THAN (10),
-> PARTITION p1 VALUES LESS THAN (20),
-> PARTITION p2 VALUES LESS THAN (30),
-> PARTITION p3 VALUES LESS THAN (40)
->);
Query OK, 0 rows affected (0.12 sec)

```

It is possible to add a primary key to `t_no_pk` using either of these `ALTER TABLE` statements:

```

possible PK
mysql> ALTER TABLE t_no_pk ADD PRIMARY KEY(c1);
Query OK, 0 rows affected (0.13 sec)
Records: 0 Duplicates: 0 Warnings: 0

drop this PK
mysql> ALTER TABLE t_no_pk DROP PRIMARY KEY;
Query OK, 0 rows affected (0.10 sec)
Records: 0 Duplicates: 0 Warnings: 0

use another possible PK
mysql> ALTER TABLE t_no_pk ADD PRIMARY KEY(c1, c2);
Query OK, 0 rows affected (0.12 sec)
Records: 0 Duplicates: 0 Warnings: 0

drop this PK
mysql> ALTER TABLE t_no_pk DROP PRIMARY KEY;
Query OK, 0 rows affected (0.09 sec)
Records: 0 Duplicates: 0 Warnings: 0

```

However, the next statement fails, because `c1` is part of the partitioning key, but is not part of the proposed primary key:

```

fails with error 1503
mysql> ALTER TABLE t_no_pk ADD PRIMARY KEY(c2);
ERROR 1503 (HY000): A PRIMARY KEY MUST INCLUDE ALL COLUMNS IN THE TABLE'S PARTITIONING FUNCTION

```

Since `t_no_pk` has only `c1` in its partitioning expression, attempting to adding a unique key on `c2` alone fails. However, you can add a unique key that uses both `c1` and `c2`.

These rules also apply to existing nonpartitioned tables that you wish to partition using `ALTER TABLE ... PARTITION BY`. Consider a table `np_pk` defined as shown here:

```

mysql> CREATE TABLE np_pk (
-> id INT NOT NULL AUTO_INCREMENT,
-> name VARCHAR(50),
-> added DATE,
-> PRIMARY KEY (id)
->);
Query OK, 0 rows affected (0.08 sec)

```

The following `ALTER TABLE` statements fails with an error, because the `added` column is not part of any unique key in the table:

```

mysql> ALTER TABLE np_pk
-> PARTITION BY HASH(TO_DAYS(added))
-> PARTITIONS 4;
ERROR 1503 (HY000): A PRIMARY KEY MUST INCLUDE ALL COLUMNS IN THE TABLE'S PARTITIONING FUNCTION

```

However, this statement using the `id` column for the partitioning column is valid, as shown here:

```

mysql> ALTER TABLE np_pk
-> PARTITION BY HASH(id)
-> PARTITIONS 4;
Query OK, 0 rows affected (0.11 sec)
Records: 0 Duplicates: 0 Warnings: 0

```

In the case of `np_pk`, the only column that may be used as part of a partitioning expression is `id`; if you wish to partition this table using any other column or columns in the partitioning expression, you must first modify the table, either by adding the desired column or columns to the primary key, or by dropping the primary key altogether.

We are working to remove this limitation in a future MySQL release series.

## 18.5.2. Partitioning Limitations Relating to Storage Engines

The following limitations apply to the use of storage engines with user-defined partitioning of tables.

**MERGE storage engine.** User-defined partitioning and the `MERGE` storage engine are not compatible. Tables using the `MERGE` storage engine cannot be partitioned. Partitioned tables cannot be merged.

**FEDERATED storage engine.** Partitioning of `FEDERATED` tables is not supported. Beginning with MySQL 5.1.15, it is not possible to create partitioned `FEDERATED` tables at all. We are working to remove this limitation in a future MySQL release.

**CSV storage engine.** Partitioned tables using the `CSV` storage engine are not supported. Starting with MySQL 5.1.12, it is not possible to create partitioned `CSV` tables at all.

**BLACKHOLE storage engine.** Prior to MySQL 5.1.6, tables using the `BLACKHOLE` storage engine also could not be partitioned.

**NDBCLUSTER storage engine (MySQL Cluster).** Partitioning by `KEY` (or `LINEAR KEY`) is the only type of partitioning supported for the `NDBCLUSTER` storage engine. Beginning with MySQL 5.1.12, it is not possible to create a MySQL Cluster table using any partitioning type other than `[LINEAR] KEY`, and attempting to do so fails with an error.

In addition, the maximum number of partitions that can be defined for an `NDBCLUSTER` table is 8 times the number of node groups in the cluster. (See [Section 17.1.2, “MySQL Cluster Nodes, Node Groups, Replicas, and Partitions”](#), for more information about node groups in MySQL Cluster.)

Beginning with MySQL Cluster NDB 6.2.18, MySQL Cluster NDB 6.3.25, and MySQL Cluster NDB 7.0.6, `CREATE TABLE` and `ALTER TABLE` statements that would cause a user-partitioned `NDBCLUSTER` table not to meet either or both of the following two requirements are not permitted, and fail with an error ([Bug#40709](#)):

1. The table must have an explicit primary key.
2. All columns listed in the table's partitioning expression must be part of the primary key.

**Exception.** If a user-partitioned `NDBCLUSTER` table is created using an empty column-list (that is, using `PARTITION BY KEY()` or `PARTITION BY LINEAR KEY()`), then no explicit primary key is required.

**Upgrading partitioned tables.** When performing an upgrade, tables which are partitioned by `KEY` and which use any storage engine other than `NDBCLUSTER` must be dumped and reloaded.

**Same storage engine for all partitions.** All partitions of a partitioned table must use the same storage engine and it must be the same storage engine used by the table as a whole. In addition, if one does not specify an engine on the table level, then one must do either of the following when creating or altering a partitioned table:

- Do *not* specify any engine for *any* partition or subpartition
- Specify the engine for *all* partitions or subpartitions

We are working to remove this limitation in a future MySQL release.

## 18.5.3. Partitioning Limitations Relating to Functions

This section discusses limitations in MySQL Partitioning relating specifically to functions used in partitioning expressions.

Beginning with MySQL 5.1.12, only the MySQL functions shown in the following table are supported in partitioning expressions:

<code>ABS()</code>	<code>CEILING()</code> (see <a href="#">CEILING()</a> and <a href="#">FLOOR()</a> )	<code>DAY()</code>
<code>DAYOFMONTH()</code>	<code>DAYOFWEEK()</code>	<code>DAYOFYEAR()</code>
<code>DATEDIFF()</code>	<code>EXTRACT()</code>	<code>FLOOR()</code> (see <a href="#">CEILING()</a> and <a href="#">FLOOR()</a> )
<code>HOUR()</code>	<code>MICROSECOND()</code>	<code>MINUTE()</code>

MOD( )	MONTH( )	QUARTER( )
SECOND( )	TIME_TO_SEC( )	TO_DAYS( )
UNIX_TIMESTAMP( ) (permitted in MySQL 5.1.43 and later, with TIMESTAMP columns)	WEEKDAY( )	YEAR( )
	YEARWEEK( )	

### Note

In MySQL 5.1, partition pruning is supported only for the `TO_DAYS( )` and `YEAR( )` functions. See [Section 18.4, “Partition Pruning”](#), for more information.

**CEILING( ) and FLOOR( ).** Each of these functions returns an integer only if it is passed an integer argument. This means, for example, that the following `CREATE TABLE` statement fails with an error, as shown here:

```
mysql> CREATE TABLE t (c FLOAT) PARTITION BY LIST(FLOOR(c))(
 -> PARTITION p0 VALUES IN (1,3,5),
 -> PARTITION p1 VALUES IN (2,4,6)
 ->);
ERROR 1490 (HY000): THE PARTITION FUNCTION RETURNS THE WRONG TYPE
```

See [Section 11.6.2, “Mathematical Functions”](#), for more information about the return types of these functions.

---

# Chapter 19. Stored Programs and Views

This chapter discusses stored programs and views, which are database objects defined in terms of SQL code that is stored on the server for later execution.

Stored programs include these objects:

- Stored routines, that is, stored procedures and functions. A stored procedure is invoked using the `CALL` statement. A procedure does not have a return value but can modify its parameters for later inspection by the caller. It can also generate result sets to be returned to the client program. A stored function is used much like a built-in function. You invoke it in an expression and it returns a value during expression evaluation.
- Triggers. A trigger is a named database object that is associated with a table and that is activated when a particular event occurs for the table, such as an insert or update.
- Events. An event is a task that the server runs according to schedule.

Views are stored queries that when referenced produce a result set. A view acts as a virtual table.

This chapter describes how to use stored programs and views. The following sections provide additional information about SQL syntax for statements related to these objects:

- For each object type, there are `CREATE`, `ALTER`, and `DROP` statements that control which objects exist and how they are defined. See [Section 12.1, “Data Definition Statements”](#).
- The `CALL` statement is used to invoke stored procedures. See [Section 12.2.1, “`CALL` Syntax”](#).
- Stored program definitions include a body that may use compound statements, loops, conditionals, and declared variables. See [Section 12.7, “MySQL Compound-Statement Syntax”](#).

## 19.1. Defining Stored Programs

Each stored program contains a body that consists of an SQL statement. This statement may be a compound statement made up of several statements separated by semicolon (`;`) characters. For example, the following stored procedure has a body made up of a `BEGIN ... END` block that contains a `SET` statement and a `REPEAT` loop that itself contains another `SET` statement:

```
CREATE PROCEDURE dorepeat(p1 INT)
BEGIN
 SET @x = 0;
 REPEAT SET @x = @x + 1; UNTIL @x > p1 END REPEAT;
END
```

If you use the `mysql` client program to define a stored program that contains the semicolon characters within its definition, a problem arises. By default, `mysql` itself recognizes semicolon as a statement delimiter, so you must redefine the delimiter temporarily to cause `mysql` to pass the entire stored program definition to the server.

To redefine the `mysql` delimiter, use the `delimiter` command. The following example shows how to do this for the `dorepeat()` procedure just shown. The delimiter is changed to `//` to enable the entire definition to be passed to the server as a single statement, and then restored to `;` before invoking the procedure. This enables the `;` delimiter used in the procedure body to be passed through to the server rather than being interpreted by `mysql` itself.

```
mysql> delimiter //
mysql> CREATE PROCEDURE dorepeat(p1 INT)
-> BEGIN
-> SET @x = 0;
-> REPEAT SET @x = @x + 1; UNTIL @x > p1 END REPEAT;
-> END
-> //
Query OK, 0 rows affected (0.00 sec)

mysql> delimiter ;
mysql> CALL dorepeat(1000);
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @x;
+-----+
| @x |
+-----+
| 1001 |
+-----+
```

```
1 row in set (0.00 sec)
```

You can redefine the delimiter to a string other than `//`, and the delimiter can consist of a single character or multiple characters. You should avoid the use of the backslash (“`\`”) character because that is the escape character for MySQL.

The following is an example of a function that takes a parameter, performs an operation using an SQL function, and returns the result. In this case, it is unnecessary to use `delimiter` because the function definition contains no internal `:` statement delimiters:

```
mysql> CREATE FUNCTION hello (s CHAR(20))
mysql> RETURNS CHAR(50) DETERMINISTIC
-> RETURN CONCAT('Hello, ',s,'!');
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT hello('world');
+-----+
| hello('world') |
+-----+
| Hello, world! |
+-----+
1 row in set (0.00 sec)
```

## 19.2. Using Stored Routines (Procedures and Functions)

Stored routines (procedures and functions) are supported in MySQL 5.1. A stored routine is a set of SQL statements that can be stored in the server. Once this has been done, clients don't need to keep reissuing the individual statements but can refer to the stored routine instead.

Stored routines require the `proc` table in the `mysql` database. This table is created during the MySQL 5.1 installation procedure. If you are upgrading to MySQL 5.1 from an earlier version, be sure to update your grant tables to make sure that the `proc` table exists. See [Section 4.4.8, “mysql\\_upgrade — Check Tables for MySQL Upgrade”](#).

Stored routines can be particularly useful in certain situations:

- When multiple client applications are written in different languages or work on different platforms, but need to perform the same database operations.
- When security is paramount. Banks, for example, use stored procedures and functions for all common operations. This provides a consistent and secure environment, and routines can ensure that each operation is properly logged. In such a setup, applications and users would have no access to the database tables directly, but can only execute specific stored routines.

Stored routines can provide improved performance because less information needs to be sent between the server and the client. The tradeoff is that this does increase the load on the database server because more of the work is done on the server side and less is done on the client (application) side. Consider this if many client machines (such as Web servers) are serviced by only one or a few database servers.

Stored routines also enable you to have libraries of functions in the database server. This is a feature shared by modern application languages that enable such design internally (for example, by using classes). Using these client application language features is beneficial for the programmer even outside the scope of database use.

MySQL follows the SQL:2003 syntax for stored routines, which is also used by IBM's DB2.

The MySQL implementation of stored routines is still in progress. All syntax described here is supported and any limitations and extensions are documented where appropriate.

### Additional Resources

- You may find the [Stored Procedures User Forum](#) of use when working with stored procedures and functions.
- For answers to some commonly asked questions regarding stored routines in MySQL, see [Section A.4, “MySQL 5.1 FAQ: Stored Procedures and Functions”](#).
- There are some restrictions on the use of stored routines. See [Section D.1, “Restrictions on Stored Routines, Triggers, and Events”](#).
- Binary logging for stored routines takes place as described in [Section 19.7, “Binary Logging of Stored Programs”](#).

### 19.2.1. Stored Routine Syntax

A stored routine is either a procedure or a function. Stored routines are created with the `CREATE PROCEDURE` and `CREATE`

FUNCTION statements (see [Section 12.1.15, “CREATE PROCEDURE and CREATE FUNCTION Syntax”](#)). A procedure is invoked using a CALL statement (see [Section 12.2.1, “CALL Syntax”](#)), and can only pass back values using output variables. A function can be called from inside a statement just like any other function (that is, by invoking the function’s name), and can return a scalar value. The body of a stored routine can use compound statements (see [Section 12.7, “MySQL Compound-Statement Syntax”](#)).

Stored routines can be dropped with the DROP PROCEDURE and DROP FUNCTION statements (see [Section 12.1.26, “DROP PROCEDURE and DROP FUNCTION Syntax”](#)), and altered with the ALTER PROCEDURE and ALTER FUNCTION statements (see [Section 12.1.5, “ALTER PROCEDURE Syntax”](#)).

A stored procedure or function is associated with a particular database. This has several implications:

- When the routine is invoked, an implicit USE db\_name is performed (and undone when the routine terminates). USE statements within stored routines are not permitted.
- You can qualify routine names with the database name. This can be used to refer to a routine that is not in the current database. For example, to invoke a stored procedure p or function f that is associated with the test database, you can say CALL test.p() or test.f().
- When a database is dropped, all stored routines associated with it are dropped as well.

Stored functions cannot be recursive.

Recursion in stored procedures is permitted but disabled by default. To enable recursion, set the max\_sp\_recursion\_depth server system variable to a value greater than zero. Stored procedure recursion increases the demand on thread stack space. If you increase the value of max\_sp\_recursion\_depth, it may be necessary to increase thread stack size by increasing the value of thread\_stack at server startup. See [Section 5.1.4, “Server System Variables”](#), for more information.

MySQL supports a very useful extension that enables the use of regular SELECT statements (that is, without using cursors or local variables) inside a stored procedure. The result set of such a query is simply sent directly to the client. Multiple SELECT statements generate multiple result sets, so the client must use a MySQL client library that supports multiple result sets. This means the client must use a client library from a version of MySQL at least as recent as 4.1. The client should also specify the CLI-ENT\_MULTI\_RESULTS option when it connects. For C programs, this can be done with the mysql\_real\_connect() C API function. See [Section 21.9.3.52, “mysql\\_real\\_connect\(\)”](#), and [Section 21.9.12, “C API Support for Multiple Statement Execution”](#).

## 19.2.2. Stored Routines and MySQL Privileges

The MySQL grant system takes stored routines into account as follows:

- The CREATE ROUTINE privilege is needed to create stored routines.
- The ALTER ROUTINE privilege is needed to alter or drop stored routines. This privilege is granted automatically to the creator of a routine if necessary, and dropped from the creator when the routine is dropped.
- The EXECUTE privilege is required to execute stored routines. However, this privilege is granted automatically to the creator of a routine if necessary (and dropped from the creator when the routine is dropped). Also, the default SQL SECURITY characteristic for a routine is DEFINER, which enables users who have access to the database with which the routine is associated to execute the routine.
- If the automatic\_sp\_privileges system variable is 0, the EXECUTE and ALTER ROUTINE privileges are not automatically granted to and dropped from the routine creator.
- The creator of a routine is the account used to execute the CREATE statement for it. This might not be the same as the account named as the DEFINER in the routine definition.

The server manipulates the mysql.proc table in response to statements that create, alter, or drop stored routines. It is not supported that the server will notice manual manipulation of this table.

## 19.2.3. Stored Routine Metadata

Metadata about stored routines can be obtained as follows:

- Query the ROUTINES table of the INFORMATION\_SCHEMA database. See [Section 20.14, “The INFORMATION\\_SCHEMA ROUTINES Table”](#).
- Use the SHOW CREATE PROCEDURE and SHOW CREATE FUNCTION statements to see routine definitions. See [Sec-](#)

tion 12.4.5.11, “SHOW CREATE PROCEDURE Syntax”.

- Use the `SHOW PROCEDURE STATUS` and `SHOW FUNCTION STATUS` statements to see routine characteristics. See Section 12.4.5.30, “SHOW PROCEDURE STATUS Syntax”.
- `INFORMATION_SCHEMA` does not have a `PARAMETERS` table until MySQL 5.5, so applications that need to acquire routine parameter information at runtime must use workarounds such as parsing the output of `SHOW CREATE` statements or the `param_list` column of the `mysql.proc` table. `param_list` contents can be processed from within a stored routine, unlike the output from `SHOW`.

## 19.2.4. Stored Procedures, Functions, Triggers, and `LAST_INSERT_ID()`

Within the body of a stored routine (procedure or function) or a trigger, the value of `LAST_INSERT_ID()` changes the same way as for statements executed outside the body of these kinds of objects (see Section 11.14, “Information Functions”). The effect of a stored routine or trigger upon the value of `LAST_INSERT_ID()` that is seen by following statements depends on the kind of routine:

- If a stored procedure executes statements that change the value of `LAST_INSERT_ID()`, the changed value is seen by statements that follow the procedure call.
- For stored functions and triggers that change the value, the value is restored when the function or trigger ends, so following statements do not see a changed value.

## 19.3. Using Triggers

A trigger is a named database object that is associated with a table, and that activates when a particular event occurs for the table. Some uses for triggers are to perform checks of values to be inserted into a table or to perform calculations on values involved in an update.

A trigger is defined to activate when an `INSERT`, `DELETE`, or `UPDATE` statement executes for the associated table. A trigger can be set to activate either before or after the triggering statement. For example, you can have a trigger activate before each row that is inserted into a table or after each row that is updated.

### Important

MySQL triggers are activated by SQL statements *only*. They are not activated by changes in views, nor by changes to tables made by APIs that do not transmit SQL statements to the MySQL Server. This means that:

- Triggers are not activated by changes in `INFORMATION_SCHEMA` tables, because these tables are actually views.
- Triggers are not activated by updates made using the `NDB API`.

To use triggers if you have upgraded to MySQL 5.1 from an older release that did not support triggers, you should upgrade your grant tables so that they contain the trigger-related privileges. See Section 4.4.8, “`mysql_upgrade` — Check Tables for MySQL Upgrade”.

The following discussion describes the syntax for creating and dropping triggers, and shows some examples of how to use them.

### Additional Resources

- You may find the [Triggers User Forum](#) of use when working with views.
- For answers to some commonly asked questions regarding triggers in MySQL, see Section A.5, “MySQL 5.1 FAQ: Triggers”.
- There are some restrictions on the use of triggers; see Section D.1, “Restrictions on Stored Routines, Triggers, and Events”.
- Binary logging for triggers takes place as described in Section 19.7, “Binary Logging of Stored Programs”.

### 19.3.1. Trigger Syntax

To create a trigger or drop a trigger, use the `CREATE TRIGGER` or `DROP TRIGGER` statement. The syntax for these statements is described in Section 12.1.19, “`CREATE TRIGGER` Syntax”, and Section 12.1.30, “`DROP TRIGGER` Syntax”.

Here is a simple example that associates a trigger with a table for `INSERT` statements. The trigger acts as an accumulator, summing the values inserted into one of the columns of the table.

```
mysql> CREATE TABLE account (acct_num INT, amount DECIMAL(10,2));
Query OK, 0 rows affected (0.03 sec)

mysql> CREATE TRIGGER ins_sum BEFORE INSERT ON account
 -> FOR EACH ROW SET @sum = @sum + NEW.amount;
Query OK, 0 rows affected (0.06 sec)
```

The `CREATE TRIGGER` statement creates a trigger named `ins_sum` that is associated with the `account` table. It also includes clauses that specify the trigger activation time, the triggering event, and what to do with the trigger activates:

- The keyword `BEFORE` indicates the trigger action time. In this case, the trigger should activate before each row inserted into the table. The other permissible keyword here is `AFTER`.
- The keyword `INSERT` indicates the event that activates the trigger. In the example, `INSERT` statements cause trigger activation. You can also create triggers for `DELETE` and `UPDATE` statements.
- The statement following `FOR EACH ROW` defines the statement to execute each time the trigger activates, which occurs once for each row affected by the triggering statement. In the example, the triggered statement is a simple `SET` that accumulates the values inserted into the `amount` column. The statement refers to the column as `NEW.amount` which means “the value of the `amount` column to be inserted into the new row.”

To use the trigger, set the accumulator variable to zero, execute an `INSERT` statement, and then see what value the variable has afterward:

```
mysql> SET @sum = 0;
mysql> INSERT INTO account VALUES(137,14.98),(141,1937.50),(97,-100.00);
mysql> SELECT @sum AS 'Total amount inserted';
+-----+
| Total amount inserted |
+-----+
| 1852.48 |
+-----+
```

In this case, the value of `@sum` after the `INSERT` statement has executed is `14.98 + 1937.50 - 100`, or `1852.48`.

To destroy the trigger, use a `DROP TRIGGER` statement. You must specify the schema name if the trigger is not in the default schema:

```
mysql> DROP TRIGGER test.ins_sum;
```

Triggers for a table are also dropped if you drop the table.

Trigger names exist in the schema namespace, meaning that all triggers must have unique names within a schema. Triggers in different schemas can have the same name.

In addition to the requirement that trigger names be unique for a schema, there are other limitations on the types of triggers you can create. In particular, you cannot have two triggers for a table that have the same activation time and activation event. For example, you cannot define two `BEFORE INSERT` triggers or two `AFTER UPDATE` triggers for a table. This should rarely be a significant limitation, because it is possible to define a trigger that executes multiple statements by using the `BEGIN ... END` compound statement construct after `FOR EACH ROW`. (An example appears later in this section.)

The `OLD` and `NEW` keywords enable you to access columns in the rows affected by a trigger. (`OLD` and `NEW` are not case sensitive.) In an `INSERT` trigger, only `NEW.col_name` can be used; there is no old row. In a `DELETE` trigger, only `OLD.col_name` can be used; there is no new row. In an `UPDATE` trigger, you can use `OLD.col_name` to refer to the columns of a row before it is updated and `NEW.col_name` to refer to the columns of the row after it is updated.

A column named with `OLD` is read only. You can refer to it (if you have the `SELECT` privilege), but not modify it. A column named with `NEW` can be referred to if you have the `SELECT` privilege for it. In a `BEFORE` trigger, you can also change its value with `SET NEW.col_name = value` if you have the `UPDATE` privilege for it. This means you can use a trigger to modify the values to be inserted into a new row or that are used to update a row.

In a `BEFORE` trigger, the `NEW` value for an `AUTO_INCREMENT` column is 0, not the automatically generated sequence number that will be generated when the new record actually is inserted.

`OLD` and `NEW` are MySQL extensions to triggers.

By using the `BEGIN ... END` construct, you can define a trigger that executes multiple statements. Within the `BEGIN` block, you also can use other syntax that is permitted within stored routines such as conditionals and loops. However, just as for stored

routines, if you use the `mysql` program to define a trigger that executes multiple statements, it is necessary to redefine the `mysql` statement delimiter so that you can use the `;` statement delimiter within the trigger definition. The following example illustrates these points. It defines an `UPDATE` trigger that checks the new value to be used for updating each row, and modifies the value to be within the range from 0 to 100. This must be a `BEFORE` trigger because the value needs to be checked before it is used to update the row:

```
mysql> delimiter //
mysql> CREATE TRIGGER upd_check BEFORE UPDATE ON account
 -> FOR EACH ROW
 -> BEGIN
 -> IF NEW.amount < 0 THEN
 -> SET NEW.amount = 0;
 -> ELSEIF NEW.amount > 100 THEN
 -> SET NEW.amount = 100;
 -> END IF;
 -> END//
mysql> delimiter ;
```

It can be easier to define a stored procedure separately and then invoke it from the trigger using a simple `CALL` statement. This is also advantageous if you want to invoke the same routine from within several triggers.

There are some limitations on what can appear in statements that a trigger executes when activated:

- The trigger cannot use the `CALL` statement to invoke stored procedures that return data to the client or that use dynamic SQL. (Stored procedures are permitted to return data to the trigger through `OUT` or `INOUT` parameters.)
- The trigger cannot use statements that explicitly or implicitly begin or end a transaction such as `START TRANSACTION`, `COMMIT`, or `ROLLBACK`.

MySQL handles errors during trigger execution as follows:

- If a `BEFORE` trigger fails, the operation on the corresponding row is not performed.
- A `BEFORE` trigger is activated by the *attempt* to insert or modify the row, regardless of whether the attempt subsequently succeeds.
- An `AFTER` trigger is executed only if the `BEFORE` trigger (if any) and the row operation both execute successfully.
- An error during either a `BEFORE` or `AFTER` trigger results in failure of the entire statement that caused trigger invocation.
- For transactional tables, failure of a statement should cause rollback of all changes performed by the statement. Failure of a trigger causes the statement to fail, so trigger failure also causes rollback. For nontransactional tables, such rollback cannot be done, so although the statement fails, any changes performed prior to the point of the error remain in effect.

### 19.3.2. Trigger Metadata

Metadata about triggers can be obtained as follows:

- Query the `TRIGGERS` table of the `INFORMATION_SCHEMA` database. See [Section 20.16, “The INFORMATION\\_SCHEMA TRIGGERS Table”](#).
- Use the `SHOW TRIGGERS` statement. See [Section 12.4.5.40, “SHOW TRIGGERS Syntax”](#).

## 19.4. Using the Event Scheduler

The *MySQL Event Scheduler* manages the scheduling and execution of events: Tasks that run according to schedule. Event support was added in MySQL 5.1.6. The following discussion covers the Event Scheduler and is divided into the following sections:

- [Section 19.4.1, “Event Scheduler Overview”](#), provides an introduction to and conceptual overview of MySQL Events.
- [Section 19.4.3, “Event Syntax”](#), discusses the SQL statements for creating, altering, and dropping MySQL Events.
- [Section 19.4.4, “Event Metadata”](#), shows how to obtain information about events and how this information is stored by the MySQL Server.
- [Section 19.4.6, “The Event Scheduler and MySQL Privileges”](#), discusses the privileges required to work with events and the

ramifications that events have with regard to privileges when executing.

Stored routines require the `event` table in the `mysql` database. This table is created during the MySQL 5.1 installation procedure. If you are upgrading to MySQL 5.1 from an earlier version, be sure to update your grant tables to make sure that the `event` table exists. See [Section 4.4.8, “mysql\\_upgrade — Check Tables for MySQL Upgrade”](#).

#### Additional Resources

- You may find the [MySQL Event Scheduler User Forum](#) of use when working with scheduled events.
- There are some restrictions on the use of events; see [Section D.1, “Restrictions on Stored Routines, Triggers, and Events”](#).
- Binary logging for events takes place as described in [Section 19.7, “Binary Logging of Stored Programs”](#).

### 19.4.1. Event Scheduler Overview

MySQL Events are tasks that run according to a schedule. Therefore, we sometimes refer to them as *scheduled* events. When you create an event, you are creating a named database object containing one or more SQL statements to be executed at one or more regular intervals, beginning and ending at a specific date and time. Conceptually, this is similar to the idea of the Unix `crontab` (also known as a “cron job”) or the Windows Task Scheduler.

Scheduled tasks of this type are also sometimes known as “temporal triggers”, implying that these are objects that are triggered by the passage of time. While this is essentially correct, we prefer to use the term *events* to avoid confusion with triggers of the type discussed in [Section 19.3, “Using Triggers”](#). Events should more specifically not be confused with “temporary triggers”. Whereas a trigger is a database object whose statements are executed in response to a specific type of event that occurs on a given table, a (scheduled) event is an object whose statements are executed in response to the passage of a specified time interval.

While there is no provision in the SQL Standard for event scheduling, there are precedents in other database systems, and you may notice some similarities between these implementations and that found in the MySQL Server.

MySQL Events have the following major features and properties:

- In MySQL 5.1.12 and later, an event is uniquely identified by its name and the schema to which it is assigned. (Previously, an event was also unique to its definer.)
- An event performs a specific action according to a schedule. This action consists of an SQL statement, which can be a compound statement in a `BEGIN . . . END` block if desired (see [Section 12.7, “MySQL Compound-Statement Syntax”](#)). An event's timing can be either *one-time* or *recurrent*. A one-time event executes one time only. A recurrent event repeats its action at a regular interval, and the schedule for a recurring event can be assigned a specific start day and time, end day and time, both, or neither. (By default, a recurring event's schedule begins as soon as it is created, and continues indefinitely, until it is disabled or dropped.)

If a repeating event does not terminate within its scheduling interval, the result may be multiple instances of the event executing simultaneously. If this is undesirable, you should institute a mechanism to prevent simultaneous instances. For example, you could use the `GET_LOCK()` function, or row or table locking.

- Users can create, modify, and drop scheduled events using SQL statements intended for these purposes. Syntactically invalid event creation and modification statements fail with an appropriate error message. *A user may include statements in an event's action which require privileges that the user does not actually have.* The event creation or modification statement succeeds but the event's action fails. See [Section 19.4.6, “The Event Scheduler and MySQL Privileges”](#) for details.
- Many of the properties of an event can be set or modified using SQL statements. These properties include the event's name, timing, persistence (that is, whether it is preserved following the expiration of its schedule), status (enabled or disabled), action to be performed, and the schema to which it is assigned. See [Section 12.1.2, “ALTER\\_EVENT Syntax”](#).

The default definer of an event is the user who created the event, unless the event has been altered, in which case the definer is the user who issued the last `ALTER_EVENT` statement affecting that event. An event can be modified by any user having the `EVENT` privilege on the database for which the event is defined. (Prior to MySQL 5.1.12, only an event's definer, or a user having privileges on the `mysql.event` table, could modify a given event.) See [Section 19.4.6, “The Event Scheduler and MySQL Privileges”](#).

- An event's action statement may include most SQL statements permitted within stored routines. For restrictions, see [Section D.1, “Restrictions on Stored Routines, Triggers, and Events”](#).

### 19.4.2. Event Scheduler Configuration

---

Events are executed by a special *event scheduler thread*; when we refer to the Event Scheduler, we actually refer to this thread. When running, the event scheduler thread and its current state can be seen by users having the `PROCESS` privilege in the output of `SHOW PROCESSLIST`, as shown in the discussion that follows.

The global `event_scheduler` system variable determines whether the Event Scheduler is enabled and running on the server. Beginning with MySQL 5.1.12, it has one of these 3 values, which affect event scheduling as described here:

- **OFF**: The Event Scheduler is stopped. The event scheduler thread does not run, is not shown in the output of `SHOW PROCESSLIST`, and no scheduled events are executed. `OFF` is the default value for `event_scheduler`.

When the Event Scheduler is stopped (`event_scheduler` is `OFF`), it can be started by setting the value of `event_scheduler` to `ON`. (See next item.)

- **ON**: The Event Scheduler is started; the event scheduler thread runs and executes all scheduled events.

When the Event Scheduler is `ON`, the event scheduler thread is listed in the output of `SHOW PROCESSLIST` as a daemon process, and its state is represented as shown here:

```
mysql> SHOW PROCESSLIST\G
***** 1. row *****
 Id: 1
 User: root
 Host: localhost
 db: NULL
Command: Query
 Time: 0
 State: NULL
 Info: show processlist
***** 2. row *****
 Id: 2
 User: event_scheduler
 Host: localhost
 db: NULL
Command: Daemon
 Time: 3
 State: Waiting for next activation
 Info: NULL
2 rows in set (0.00 sec)
```

Event scheduling can be stopped by setting the value of `event_scheduler` to `OFF`.

- **DISABLED**: This value renders the Event Scheduler nonoperational. When the Event Scheduler is `DISABLED`, the event scheduler thread does not run (and so does not appear in the output of `SHOW PROCESSLIST`). In addition, the Event Scheduler state cannot be changed at runtime.

If the Event Scheduler status has not been set to `DISABLED`, `event_scheduler` can be toggled between `ON` and `OFF` (using `SET`). It is also possible to use `0` for `OFF`, and `1` for `ON` when setting this variable. Thus, any of the following 4 statements can be used in the `mysql` client to turn on the Event Scheduler:

```
SET GLOBAL event_scheduler = ON;
SET @@global.event_scheduler = ON;
SET GLOBAL event_scheduler = 1;
SET @@global.event_scheduler = 1;
```

Similarly, any of these 4 statements can be used to turn off the Event Scheduler:

```
SET GLOBAL event_scheduler = OFF;
SET @@global.event_scheduler = OFF;
SET GLOBAL event_scheduler = 0;
SET @@global.event_scheduler = 0;
```

Although `ON` and `OFF` have numeric equivalents, the value displayed for `event_scheduler` by `SELECT` or `SHOW VARIABLES` is always one of `OFF`, `ON`, or `DISABLED`. `DISABLED` has no numeric equivalent. For this reason, `ON` and `OFF` are usually preferred over `1` and `0` when setting this variable.

Note that attempting to set `event_scheduler` without specifying it as a global variable causes an error:

```
mysql> SET @event_scheduler = OFF;
ERROR 1229 (HY000): VARIABLE 'EVENT_SCHEDULER' IS A GLOBAL
VARIABLE AND SHOULD BE SET WITH SET GLOBAL
```

## Important

It is possible to set the Event Scheduler to `DISABLED` only at server startup. If `event_scheduler` is `ON` or `OFF`,

**■** you cannot set it to `DISABLED` at runtime. Also, if the Event Scheduler is set to `DISABLED` at startup, you cannot change the value of `event_scheduler` at runtime.

To disable the event scheduler, use one of the following two methods:

- As a command-line option when starting the server:

```
--event_scheduler=DISABLED
```

- In the server configuration file (`my.cnf`, or `my.ini` on Windows systems), include the line where it will be read by the server (for example, in a `[mysqld]` section):

```
event_scheduler=DISABLED
```

To enable the Event Scheduler, restart the server without the `--event-scheduler=DISABLED` command-line option, or after removing or commenting out the line containing `event_scheduler=DISABLED` in the server configuration file, as appropriate. Alternatively, you can use `ON` (or `1`) or `OFF` (or `0`) in place of the `DISABLED` value when starting the server.

#### **Note**

**■** You can issue event-manipulation statements when `event_scheduler` is set to `DISABLED`. No warnings or errors are generated in such cases (provided that the statements are themselves valid). However, scheduled events cannot execute until this variable is set to `ON` (or `1`). Once this has been done, the event scheduler thread executes all events whose scheduling conditions are satisfied.

In MySQL 5.1.11, `event_scheduler` behaved as follows: this variable could take one of the values `0` (or `OFF`), `1` (or `ON`), or `2`. Setting it to `0` turned event scheduling off, so that the event scheduler thread did not run; the `event_scheduler` variable could not be set to this value while the server was running. Setting it to `1` so that the event scheduler thread ran and executed scheduled events. In this state, the event scheduler thread appeared to be sleeping when viewed with `SHOW PROCESSLIST`. When `event_scheduler` was set to `2` (which was the default value), the Event Scheduler was considered to be “suspended”; the event scheduler thread ran and could be seen in the output of `SHOW PROCESSLIST` (where `Suspended` was displayed in the `State` column), but did not execute any scheduled events. The value of `event_scheduler` could be changed only between `1` (or `ON`) and `2` while the server was running. Setting it to `0` (or `OFF`) required a server restart, as did changing its value from `0` (or `OFF`) to `1` (or `ON`) or `2`.

Prior to MySQL 5.1.11, `event_scheduler` could take one of only the 2 values `0|OFF` or `1|ON`, and the default value was `0|OFF`. It was also possible to start and stop the event scheduler thread while the MySQL server was running.

For more information concerning the reasons for these changes in behavior, see [Bug#17619](#).

Beginning with MySQL 5.1.17, starting the MySQL server with the `--skip-grant-tables` option causes `event_scheduler` to be set to `DISABLED`, overriding any other value set either on the command line or in the `my.cnf` or `my.ini` file ([Bug#26807](#)).

For SQL statements used to create, alter, and drop events, see [Section 19.4.3, “Event Syntax”](#).

MySQL 5.1.6 and later provides an `EVENTS` table in the `INFORMATION_SCHEMA` database. This table can be queried to obtain information about scheduled events which have been defined on the server. See [Section 19.4.4, “Event Metadata”](#), and [Section 20.20, “The INFORMATION\\_SCHEMA EVENTS Table”](#), for more information.

For information regarding event scheduling and the MySQL privilege system, see [Section 19.4.6, “The Event Scheduler and MySQL Privileges”](#).

### **19.4.3. Event Syntax**

MySQL 5.1.6 and later provides several SQL statements for working with scheduled events:

- New events are defined using the `CREATE EVENT` statement. See [Section 12.1.11, “CREATE EVENT Syntax”](#).
- The definition of an existing event can be changed by means of the `ALTER EVENT` statement. See [Section 12.1.2, “ALTER EVENT Syntax”](#).
- When a scheduled event is no longer wanted or needed, it can be deleted from the server by its definer using the `DROP EVENT` statement. See [Section 12.1.22, “DROP EVENT Syntax”](#). Whether an event persists past the end of its schedule also depends on its `ON COMPLETION` clause, if it has one. See [Section 12.1.11, “CREATE EVENT Syntax”](#).

An event can be dropped by any user having the `EVENT` privilege for the database on which the event is defined. Prior to

MySQL 5.1.12, a user other than the definer required privileges on the `mysql.event` table. See [Section 19.4.6, “The Event Scheduler and MySQL Privileges”](#).

## 19.4.4. Event Metadata

Metadata about events can be obtained as follows:

- Query the `event` table of the `mysql` database.
- Query the `EVENTS` table of the `INFORMATION_SCHEMA` database. See [Section 20.20, “The INFORMATION\\_SCHEMA EVENTS Table”](#).
- Use the `SHOW CREATE EVENT` statement. See [Section 12.4.5.9, “SHOW CREATE EVENT Syntax”](#).
- Use the `SHOW EVENTS` statement. See [Section 12.4.5.19, “SHOW EVENTS Syntax”](#).

### Event Scheduler Time Representation

Each session in MySQL has a session time zone (STZ). This is the session `time_zone` value that is initialized from the server's global `time_zone` value when the session begins but may be changed during the session.

The session time zone that is current when a `CREATE EVENT` or `ALTER EVENT` statement executes is used to interpret times specified in the event definition. This becomes the event time zone (ETZ); that is, the time zone that is used for event scheduling and is in effect within the event as it executes.

For representation of event information in the `mysql.event` table, the `execute_at`, `starts`, and `ends` times are converted to UTC and stored along with the event time zone. This enables event execution to proceed as defined regardless of any subsequent changes to the server time zone or daylight saving time effects. The `last_executed` time is also stored in UTC.

If you select information from `mysql.event`, the times just mentioned are retrieved as UTC values. These times can also be obtained by selecting from the `INFORMATION_SCHEMA.EVENTS` table or from `SHOW EVENTS`, but they are reported as ETZ values. Other times available from these sources indicate when an event was created or last altered; these are displayed as STZ values. The following table summarizes representation of event times.

Value	<code>mysql.event</code>	<code>INFORMATION_SCHEMA.EVENTS</code>	<code>SHOW EVENTS</code>
Execute at	UTC	ETZ	ETZ
Starts	UTC	ETZ	ETZ
Ends	UTC	ETZ	ETZ
Last executed	UTC	ETZ	n/a
Created	STZ	STZ	n/a
Last altered	STZ	STZ	n/a

The preceding table applies for MySQL 5.1.17 and up. Prior to MySQL 5.1.17, the event time zone is not stored in the `mysql.event` table or available from `INFORMATION_SCHEMA.EVENTS` or `SHOW EVENTS`. Times that are displayed using ETZ from 5.1.17 and up are displayed in UTC before 5.1.17, as shown in the following table.

Value	<code>mysql.event</code>	<code>INFORMATION_SCHEMA.EVENTS</code>	<code>SHOW EVENTS</code>
Execute at	UTC	UTC	UTC
Starts	UTC	UTC	UTC
Ends	UTC	UTC	UTC
Last executed	UTC	UTC	n/a
Created	STZ	STZ	n/a
Last altered	STZ	STZ	n/a

## 19.4.5. Event Scheduler Status

The Event Scheduler writes information about event execution that terminates with an error or warning to the MySQL Server's er-

ror log. See [Section 19.4.6, “The Event Scheduler and MySQL Privileges”](#) for an example. (Before MySQL 5.1.31, the Event Scheduler also logged messages when events started execution and terminated successfully.)

Information about the state of the Event Scheduler for debugging and troubleshooting purposes can be obtained as follows:

- In debugging builds of MySQL 5.1.11, you can use the `SHOW SCHEDULER STATUS` statement; see [Section 12.4.5.34, “SHOW SCHEDULER STATUS Syntax”](#). This statement was removed in MySQL 5.1.12. We intend to implement an SQL statement providing similar functionality in a future MySQL release.
- Beginning with MySQL 5.1.12, event scheduler status information can be obtained by running `mysqladmin debug` (see [Section 4.5.2, “mysqladmin — Client for Administering a MySQL Server”](#)); after running this command, the server's error log contains output relating to the Event Scheduler, similar to what is shown here:

```
Events status:
LLA = Last Locked At LUA = Last Unlocked At
WOC = Waiting On Condition DL = Data Locked

Event scheduler status:
State : INITIALIZED
Thread id : 0
LLA : init_scheduler:313
LUA : init_scheduler:318
WOC : NO
Workers : 0
Executed : 0
Data locked: NO

Event queue status:
Element count : 1
Data locked : NO
Attempting lock : NO
LLA : init_queue:148
LUA : init_queue:168
WOC : NO
Next activation : 0000-00-00 00:00:00
```

In statements that occur as part of events executed by the Event Scheduler, diagnostics messages (not only errors, but also warnings) are written to the error log, and, on Windows, to the application event log. For frequently executed events, it is possible for this to result in many logged messages. For example, for `SELECT ... INTO var_list` statements, if the query returns no rows, a warning with error code 1329 occurs (`No data`), and the variable values remain unchanged. If the query returns multiple rows, error 1172 occurs (`Result consisted of more than one row`). For either condition, you can avoid having the warnings be logged by declaring a condition handler; see [Section 12.7.4.2, “DECLARE for Handlers”](#). For statements that may retrieve multiple rows, another strategy is to use `LIMIT 1` to limit the result set to a single row.

## 19.4.6. The Event Scheduler and MySQL Privileges

To enable or disable the execution of scheduled events, it is necessary to set the value of the global `event_scheduler` system variable. This requires the `SUPER` privilege.

MySQL 5.1.6 introduces a privilege governing the creation, modification, and deletion of events, the `EVENT` privilege. This privilege can be bestowed using `GRANT`. For example, this `GRANT` statement confers the `EVENT` privilege for the schema named `myschema` on the user `jon@ghidora`:

```
GRANT EVENT ON myschema.* TO jon@ghidora;
```

(We assume that this user account already exists, and that we wish for it to remain unchanged otherwise.)

To grant this same user the `EVENT` privilege on all schemas, use the following statement:

```
GRANT EVENT ON *.* TO jon@ghidora;
```

The `EVENT` privilege has global or schema-level scope. Therefore, trying to grant it on a single table results in an error as shown:

```
mysql> GRANT EVENT ON myschema.mytable TO jon@ghidora;
ERROR 1144 (42000): ILLEGAL GRANT/REVOKE COMMAND; PLEASE
CONSULT THE MANUAL TO SEE WHICH PRIVILEGES CAN BE USED
```

It is important to understand that an event is executed with the privileges of its definer, and that it cannot perform any actions for which its definer does not have the requisite privileges. For example, suppose that `jon@ghidora` has the `EVENT` privilege for `myschema`. Suppose also that this user has the `SELECT` privilege for `myschema`, but no other privileges for this schema. It is possible for `jon@ghidora` to create a new event such as this one:

```
CREATE EVENT e_store_ts
```

```
ON SCHEDULE
EVERY 10 SECOND
DO
 INSERT INTO myschema.mytable VALUES (UNIX_TIMESTAMP());
```

The user waits for a minute or so, and then performs a `SELECT * FROM mytable;` query, expecting to see several new rows in the table. Instead, the table is empty. Since the user does not have the `INSERT` privilege for the table in question, the event has no effect.

If you inspect the MySQL error log (`hostname.err`), you can see that the event is executing, but the action it is attempting to perform fails, as indicated by `RetCode=0`:

```
060209 22:39:44 [Note] EVEX EXECUTING event newdb.e [EXPR:10]
060209 22:39:44 [Note] EVEX EXECUTING event newdb.e [EXPR:10]. RetCode=0
060209 22:39:54 [Note] EVEX EXECUTING event newdb.e [EXPR:10]
060209 22:39:54 [Note] EVEX EXECUTED event newdb.e [EXPR:10]. RetCode=0
060209 22:40:04 [Note] EVEX EXECUTING event newdb.e [EXPR:10]
060209 22:40:04 [Note] EVEX EXECUTED event newdb.e [EXPR:10]. RetCode=0
```

Since this user very likely does not have access to the error log, it is possible to verify whether the event's action statement is valid by executing it directly:

```
mysql> INSERT INTO myschema.mytable VALUES (UNIX_TIMESTAMP());
ERROR 1142 (42000): INSERT command denied to user
'JON'@'GHIDORA' FOR TABLE 'MYTABLE'
```

Inspection of the `INFORMATION_SCHEMA.EVENTS` table shows that `e_store_ts` exists and is enabled, but its `LAST_EXECUTED` column is `NULL`:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.EVENTS
> WHERE EVENT_NAME='e_store_ts'
> AND EVENT_SCHEMA='myschema'\G
***** 1. row *****
EVENT_CATALOG: NULL
EVENT_SCHEMA: myschema
EVENT_NAME: e_store_ts
DEFINER: jon@ghidora
EVENT_BODY: SQL
EVENT_DEFINITION: INSERT INTO myschema.mytable VALUES (UNIX_TIMESTAMP())
EVENT_TYPE: RECURRING
EXECUTE_AT: NULL
INTERVAL_VALUE: 5
INTERVAL_FIELD: SECOND
SQL_MODE: NULL
STARTS: 0000-00-00 00:00:00

LAST_ALTERED: 2006-02-09 22:36:06
LAST_EXECUTED: NULL
EVENT_COMMENT:
1 row in set (0.00 sec)
```

### Note

Prior to MySQL 5.1.12, there was no `EVENT_DEFINITION` column, and `EVENT_BODY` contained the SQL statement or statements to be executed. See [Section 20.20, “The INFORMATION\\_SCHEMA EVENTS Table”](#), for more information.

To rescind the `EVENT` privilege, use the `REVOKE` statement. In this example, the `EVENT` privilege on the schema `myschema` is removed from the `jon@ghidora` user account:

```
REVOKE EVENT ON myschema.* FROM jon@ghidora;
```

### Important

Revoking the `EVENT` privilege from a user does not delete or disable any events that may have been created by that user.

An event is not migrated or dropped as a result of renaming or dropping the user who created it.

Suppose that the user `jon@ghidora` has been granted the `EVENT` and `INSERT` privileges on the `myschema` schema. This user then creates the following event:

```
CREATE EVENT e_insert
 ON SCHEDULE
 EVERY 7 SECOND
```

```
DO
 INSERT INTO myschema.mytable;
```

After this event has been created, `root` revokes the `EVENT` privilege for `jon@ghidora`. However, `e_insert` continues to execute, inserting a new row into `mytable` each seven seconds. The same would be true if `root` had issued either of these statements:

- `DROP USER jon@ghidora;`
- `RENAME USER jon@ghidora TO someotherguy@ghidora;`

You can verify that this is true by examining the `mysql.event` table (discussed later in this section) or the `INFORMATION_SCHEMA.EVENTS` table (see [Section 20.20, “The INFORMATION\\_SCHEMA EVENTS Table”](#)) before and after issuing a `DROP USER` or `RENAME USER` statement.

Event definitions are stored in the `mysql.event` table, which was added in MySQL 5.1.6. To drop an event created by another user account, the MySQL `root` user (or another user with the necessary privileges) can delete rows from this table. For example, to remove the event `e_insert` shown previously, `root` can use the following statement:

```
DELETE FROM mysql.event
 WHERE db = 'myschema'
 AND definer = 'jon@ghidora'
 AND name = 'e_insert';
```

It is very important to match the event name, database schema name, and user account when deleting rows from the `mysql.event` table. This is because the same user can create different events of the same name in different schemas.

### Note

The namespace for scheduled events changed in MySQL 5.1.12. Prior to that MySQL version, different users could create different events having the same name in the same database; in MySQL 5.1.12 and later, that is no longer the case. When upgrading to MySQL 5.1.12 or later from MySQL 5.1.11 or earlier, it is extremely important to make sure that no events in the same database share the same name, *prior to performing the upgrade*.

Users' `EVENT` privileges are stored in the `Event_priv` columns of the `mysql.user` and `mysql.db` tables. In both cases, this column holds one of the values '`Y`' or '`N`'. '`N`' is the default. `mysql.user.Event_priv` is set to '`Y`' for a given user only if that user has the global `EVENT` privilege (that is, if the privilege was bestowed using `GRANT EVENT ON *.*`). For a schema-level `EVENT` privilege, `GRANT` creates a row in `mysql.db` and sets that row's `Db` column to the name of the schema, the `User` column to the name of the user, and the `Event_priv` column to '`Y`'. There should never be any need to manipulate these tables directly, since the `GRANT EVENT` and `REVOKE EVENT` statements perform the required operations on them.

MySQL 5.1.6 introduces five status variables providing counts of event-related operations (but *not* of statements executed by events; see [Section D.1, “Restrictions on Stored Routines, Triggers, and Events”](#)). These are:

- `Com_create_event`: The number of `CREATE EVENT` statements executed since the last server restart.
- `Com_alter_event`: The number of `ALTER EVENT` statements executed since the last server restart.
- `Com_drop_event`: The number of `DROP EVENT` statements executed since the last server restart.
- `Com_show_create_event`: The number of `SHOW CREATE EVENT` statements executed since the last server restart.
- `Com_show_events`: The number of `SHOW EVENTS` statements executed since the last server restart.

You can view current values for all of these at one time by running the statement `SHOW STATUS LIKE '%event%';`.

## 19.5. Using Views

Views (including updatable views) are available in MySQL Server 5.1. Views are stored queries that when invoked produce a result set. A view acts as a virtual table.

To use views if you have upgraded to MySQL 5.1 from an older release that did not support views, you should upgrade your grant tables so that they contain the view-related privileges. See [Section 4.4.8, “mysql\\_upgrade — Check Tables for MySQL Upgrade”](#).

The following discussion describes the syntax for creating and dropping views, and shows some examples of how to use them.

## Additional Resources

- You may find the [Views User Forum](#) of use when working with views.
- For answers to some commonly asked questions regarding views in MySQL, see [Section A.6, “MySQL 5.1 FAQ: Views”](#).
- There are some restrictions on the use of views; see [Section D.4, “Restrictions on Views”](#).

## 19.5.1. View Syntax

The `CREATE VIEW` statement creates a new view (see [Section 12.1.20, “CREATE VIEW Syntax”](#)). To alter the definition of a view or drop a view, use `ALTER VIEW` (see [Section 12.1.9, “ALTER VIEW Syntax”](#)), or `DROP VIEW` (see [Section 12.1.31, “DROP VIEW Syntax”](#)).

A view can be created from many kinds of `SELECT` statements. It can refer to base tables or other views. It can use joins, `UNION`, and subqueries. The `SELECT` need not even refer to any tables. The following example defines a view that selects two columns from another table, as well as an expression calculated from those columns:

```
mysql> CREATE TABLE t (qty INT, price INT);
mysql> INSERT INTO t VALUES(3, 50), (5, 60);
mysql> CREATE VIEW v AS SELECT qty, price, qty*price AS value FROM t;
mysql> SELECT * FROM v;
+---+---+---+
| qty | price | value |
+---+---+---+
| 3 | 50 | 150 |
| 5 | 60 | 300 |
+---+---+---+
mysql> SELECT * FROM v WHERE qty = 5;
+---+---+---+
| qty | price | value |
+---+---+---+
| 5 | 60 | 300 |
+---+---+---+
```

## 19.5.2. View Processing Algorithms

The optional `ALGORITHM` clause for `CREATE VIEW` or `ALTER VIEW` is a MySQL extension to standard SQL. It affects how MySQL processes the view. `ALGORITHM` takes three values: `MERGE`, `TEMPTABLE`, or `UNDEFINED`. The default algorithm is `UNDEFINED` if no `ALGORITHM` clause is present.

For `MERGE`, the text of a statement that refers to the view and the view definition are merged such that parts of the view definition replace corresponding parts of the statement.

For `TEMPTABLE`, the results from the view are retrieved into a temporary table, which then is used to execute the statement.

For `UNDEFINED`, MySQL chooses which algorithm to use. It prefers `MERGE` over `TEMPTABLE` if possible, because `MERGE` is usually more efficient and because a view cannot be updatable if a temporary table is used.

A reason to choose `TEMPTABLE` explicitly is that locks can be released on underlying tables after the temporary table has been created and before it is used to finish processing the statement. This might result in quicker lock release than the `MERGE` algorithm so that other clients that use the view are not blocked as long.

A view algorithm can be `UNDEFINED` for three reasons:

- No `ALGORITHM` clause is present in the `CREATE VIEW` statement.
- The `CREATE VIEW` statement has an explicit `ALGORITHM = UNDEFINED` clause.
- `ALGORITHM = MERGE` is specified for a view that can be processed only with a temporary table. In this case, MySQL generates a warning and sets the algorithm to `UNDEFINED`.

As mentioned earlier, `MERGE` is handled by merging corresponding parts of a view definition into the statement that refers to the view. The following examples briefly illustrate how the `MERGE` algorithm works. The examples assume that there is a view `v_merge` that has this definition:

```
CREATE ALGORITHM = MERGE VIEW v_merge (vc1, vc2) AS
SELECT c1, c2 FROM t WHERE c3 > 100;
```

Example 1: Suppose that we issue this statement:

```
SELECT * FROM v_merge;
```

MySQL handles the statement as follows:

- `v_merge` becomes `t`
- `*` becomes `vc1, vc2`, which corresponds to `c1, c2`
- The view `WHERE` clause is added

The resulting statement to be executed becomes:

```
SELECT c1, c2 FROM t WHERE c3 > 100;
```

Example 2: Suppose that we issue this statement:

```
SELECT * FROM v_merge WHERE vc1 < 100;
```

This statement is handled similarly to the previous one, except that `vc1 < 100` becomes `c1 < 100` and the view `WHERE` clause is added to the statement `WHERE` clause using an `AND` connective (and parentheses are added to make sure the parts of the clause are executed with correct precedence). The resulting statement to be executed becomes:

```
SELECT c1, c2 FROM t WHERE (c3 > 100) AND (c1 < 100);
```

Effectively, the statement to be executed has a `WHERE` clause of this form:

```
WHERE (select WHERE) AND (view WHERE)
```

If the `MERGE` algorithm cannot be used, a temporary table must be used instead. `MERGE` cannot be used if the view contains any of the following constructs:

- Aggregate functions (`SUM()`, `MIN()`, `MAX()`, `COUNT()`, and so forth)
- `DISTINCT`
- `GROUP BY`
- `HAVING`
- `LIMIT`
- `UNION` or `UNION ALL`
- Subquery in the select list
- Refers only to literal values (in this case, there is no underlying table)

### 19.5.3. Updatable and Insertable Views

Some views are updatable. That is, you can use them in statements such as `UPDATE`, `DELETE`, or `INSERT` to update the contents of the underlying table. For a view to be updatable, there must be a one-to-one relationship between the rows in the view and the rows in the underlying table. There are also certain other constructs that make a view nonupdatable. To be more specific, a view is not updatable if it contains any of the following:

- Aggregate functions (`SUM()`, `MIN()`, `MAX()`, `COUNT()`, and so forth)
- `DISTINCT`
- `GROUP BY`
- `HAVING`
- `UNION` or `UNION ALL`

- Subquery in the select list
- Certain joins (see additional join discussion later in this section)
- Nonupdatable view in the `FROM` clause
- A subquery in the `WHERE` clause that refers to a table in the `FROM` clause
- Refers only to literal values (in this case, there is no underlying table to update)
- Uses `ALGORITHM = TEMPTABLE` (use of a temporary table always makes a view nonupdatable)
- Multiple references to any column of a base table.

With respect to insertability (being updatable with `INSERT` statements), an updatable view is insertable if it also satisfies these additional requirements for the view columns:

- There must be no duplicate view column names.
- The view must contain all columns in the base table that do not have a default value.
- The view columns must be simple column references and not derived columns. A derived column is one that is not a simple column reference but is derived from an expression. These are examples of derived columns:

```
3.14159
col1 + 3
UPPER(col2)
col3 / col4
(subquery)
```

A view that has a mix of simple column references and derived columns is not insertable, but it can be updatable if you update only those columns that are not derived. Consider this view:

```
CREATE VIEW v AS SELECT col1, 1 AS col2 FROM t;
```

This view is not insertable because `col2` is derived from an expression. But it is updatable if the update does not try to update `col2`. This update is permissible:

```
UPDATE v SET col1 = 0;
```

This update is not permissible because it attempts to update a derived column:

```
UPDATE v SET col2 = 0;
```

It is sometimes possible for a multiple-table view to be updatable, assuming that it can be processed with the `MERGE` algorithm. For this to work, the view must use an inner join (not an outer join or a `UNION`). Also, only a single table in the view definition can be updated, so the `SET` clause must name only columns from one of the tables in the view. Views that use `UNION ALL` are not permitted even though they might be theoretically updatable, because the implementation uses temporary tables to process them.

For a multiple-table updatable view, `INSERT` can work if it inserts into a single table. `DELETE` is not supported.

`INSERT DELAYED` is not supported for views.

If a table contains an `AUTO_INCREMENT` column, inserting into an insertable view on the table that does not include the `AUTO_INCREMENT` column does not change the value of `LAST_INSERT_ID()`, because the side effects of inserting default values into columns not part of the view should not be visible.

The `WITH CHECK OPTION` clause can be given for an updatable view to prevent inserts or updates to rows except those for which the `WHERE` clause in the `select_statement` is true.

In a `WITH CHECK OPTION` clause for an updatable view, the `LOCAL` and `CASCDED` keywords determine the scope of check testing when the view is defined in terms of another view. The `LOCAL` keyword restricts the `CHECK OPTION` only to the view being defined. `CASCDED` causes the checks for underlying views to be evaluated as well. When neither keyword is given, the default is `CASCDED`. Consider the definitions for the following table and set of views:

```
mysql> CREATE TABLE t1 (a INT);
mysql> CREATE VIEW v1 AS SELECT * FROM t1 WHERE a < 2
 -> WITH CHECK OPTION;
mysql> CREATE VIEW v2 AS SELECT * FROM v1 WHERE a > 0
```

```
--> WITH LOCAL CHECK OPTION;
mysql> CREATE VIEW v3 AS SELECT * FROM v1 WHERE a > 0
--> WITH CASCADED CHECK OPTION;
```

Here the `v2` and `v3` views are defined in terms of another view, `v1`. `v2` has a `LOCAL` check option, so inserts are tested only against the `v2` check. `v3` has a `CASCADED` check option, so inserts are tested not only against its own check, but against those of underlying views. The following statements illustrate these differences:

```
mysql> INSERT INTO v2 VALUES (2);
Query OK, 1 row affected (0.00 sec)
mysql> INSERT INTO v3 VALUES (2);
ERROR 1369 (HY000): CHECK OPTION failed 'test.v3'
```

MySQL sets a flag, called the view updatability flag, at `CREATE VIEW` time. The flag is set to `YES` (true) if `UPDATE` and `DELETE` (and similar operations) are legal for the view. Otherwise, the flag is set to `NO` (false). The `IS_UPDATABLE` column in the `INFORMATION_SCHEMA.VIEWS` table displays the status of this flag. It means that the server always knows whether a view is updatable. If the view is not updatable, statements such `UPDATE`, `DELETE`, and `INSERT` are illegal and will be rejected. (Note that even if a view is updatable, it might not be possible to insert into it, as described elsewhere in this section.)

The updatability of views may be affected by the value of the `updatable_views_with_limit` system variable. See [Section 5.1.4, “Server System Variables”](#).

## 19.5.4. View Metadata

Metadata about views can be obtained as follows:

- Query the `VIEWS` table of the `INFORMATION_SCHEMA` database. See [Section 20.15, “The INFORMATION\\_SCHEMA VIEWS Table”](#).
- Use the `SHOW CREATE VIEW` statement. See [Section 12.4.5.14, “SHOW CREATE VIEW Syntax”](#).

## 19.6. Access Control for Stored Programs and Views

Stored programs and views are defined prior to use and, when referenced, execute within a security context that determines their privileges. These privileges are controlled by their `DEFINER` attribute, and, if there is one, their `SQL SECURITY` characteristic.

All stored programs (procedures, functions, triggers, and events) and views can have a `DEFINER` attribute that names a MySQL account. If the `DEFINER` attribute is omitted from a stored program or view definition, the default account is the user who creates the object.

In addition, stored routines (procedures and functions) and views can have a `SQL SECURITY` characteristic with a value of `DEFINER` or `INVOKER` to specify whether the object executes in definer or invoker context. If the `SQL SECURITY` characteristic is omitted, the default is definer context.

Triggers and events have no `SQL SECURITY` characteristic and always execute in definer context. The server invokes these objects automatically as necessary, so there is no invoking user.

Definer and invoker security contexts differ as follows:

- A stored program or view that executes in definer security context executes with the privileges of the account named by its `DEFINER` attribute. These privileges may be entirely different from those of the invoking user. The invoker must have appropriate privileges to reference the object (for example, `EXECUTE` to call a stored procedure or `SELECT` to select from a view), but when the object executes, the invoker's privileges are ignored and only the `DEFINER` account privileges matter. If this account has few privileges, the object is correspondingly limited in the operations it can perform. If the `DEFINER` account is highly privileged (such as a `root` account), the object can perform powerful operations *no matter who invokes it*.
- A stored routine or view that executes in invoker security context can perform only operations for which the invoker has privileges. The `DEFINER` attribute can be specified but has no effect for objects that execute in invoker context.

Consider the following stored procedure:

```
CREATE DEFINER = 'admin'@'localhost' PROCEDURE p1()
SQL SECURITY DEFINER
BEGIN
 UPDATE t1 SET counter = counter + 1;
END;
```

Any user who has the `EXECUTE` privilege for `p1` can invoke it with a `CALL` statement. However, when `p1` executes, it does so in

`DEFINER` security context and thus executes with the privileges of '`admin'@'localhost'`, the account named in the `DEFINER` attribute. This account must have the `EXECUTE` privilege for `p1` as well as the `UPDATE` privilege for the table `t1`. Otherwise, the procedure fails.

Now consider this stored procedure, which is identical to `p1` except that its `SQL SECURITY` characteristic is `INVOKER`:

```
CREATE DEFINER = 'admin'@'localhost' PROCEDURE p2()
SQL SECURITY INVOKER
BEGIN
 UPDATE t1 SET counter = counter + 1;
END;
```

`p2`, unlike `p1`, executes in `INVOKER` security context. The `DEFINER` attribute is irrelevant and `p2` executes with the privileges of the invoking user. `p2` fails if the invoker lacks the `EXECUTE` privilege for `p2` or the `UPDATE` privilege for the table `t1`.

MySQL uses the following rules to control which accounts a user can specify in an object `DEFINER` attribute:

- You can specify a `DEFINER` value other than your own account only if you have the `SUPER` privilege.
- If you do not have the `SUPER` privilege, the only legal user value is your own account, either specified literally or by using `CURRENT_USER`. You cannot set the definer to some other account.

To minimize the risk potential for stored program and view creation and use, follow these guidelines:

- For a stored routine or view, use `SQL SECURITY INVOKER` in the object definition when possible so that it can be used only by users with permissions appropriate for the operations performed by the object.
- If you create definer-context stored programs or views while using an account that has the `SUPER` privilege, specify an explicit `DEFINER` attribute that names an account possessing only the privileges required for the operations performed by the object. Specify a highly privileged `DEFINER` account only when absolutely necessary.
- Administrators can prevent users from specifying highly privileged `DEFINER` accounts by not granting them the `SUPER` privilege.
- Definer-context objects should be written keeping in mind that they may be able to access data for which the invoking user has no privileges. In some cases, you can prevent reference to these objects by not granting unauthorized users particular privileges:
  - A stored procedure or function cannot be referenced by a user who does not have the `EXECUTE` privilege for it.
  - A view cannot be referenced by a user who does not have the appropriate privilege for it (`SELECT` to select from it, `INSERT` to insert into it, and so forth).

However, no such control exists for triggers because users do not reference them directly. A trigger always executes in `DEFINER` context and is activated by access to the table with which it is associated, even ordinary table accesses by users with no special privileges. If the `DEFINER` account is highly privileged, the trigger can perform sensitive or dangerous operations. This remains true if the `SUPER` and `TRIGGER` privileges needed to create the trigger are revoked from the account of the user who created it. Administrators should be especially careful about granting users that combination of privileges.

## 19.7. Binary Logging of Stored Programs

The binary log contains information about SQL statements that modify database contents. This information is stored in the form of “events” that describe the modifications. The binary log has two important purposes:

- For replication, the binary log is used on master replication servers as a record of the statements to be sent to slave servers. The master server sends the events contained in its binary log to its slaves, which execute those events to make the same data changes that were made on the master. See [Section 16.2, “Replication Implementation”](#).
- Certain data recovery operations require use of the binary log. After a backup file has been restored, the events in the binary log that were recorded after the backup was made are re-executed. These events bring databases up to date from the point of the backup. See [Section 6.3.2, “Using Backups for Recovery”](#).

However, there are certain binary logging issues that apply with respect to stored programs (stored procedures and functions, triggers, and events), if logging occurs at the statement level:

- In some cases, it is possible that a statement will affect different sets of rows on a master and a slave.

- Replicated statements executed on a slave are processed by the slave SQL thread, which has full privileges. It is possible for a procedure to follow different execution paths on master and slave servers, so a user can write a routine containing a dangerous statement that will execute only on the slave where it is processed by a thread that has full privileges.
- If a stored program that modifies data is nondeterministic, it is not repeatable. This can result in different data on a master and slave, or cause restored data to differ from the original data.

This section describes how MySQL 5.1 handles binary logging for stored programs. It states the current conditions that the implementation places on the use of stored programs, and what you can do to avoid problems. It also provides additional information about the reasons for these conditions.

In general, the issues described here result when binary logging occurs at the SQL statement level. If you use row-based binary logging, the log contains changes made to individual rows as a result of executing SQL statements. When routines or triggers execute, row changes are logged, not the statements that make the changes. For stored procedures, this means that the `CALL` statement is not logged. For stored functions, row changes made within the function are logged, not the function invocation. For triggers, row changes made by the trigger are logged. On the slave side, only the row changes are seen, not the stored program invocation. For general information about row-based logging, see [Section 16.1.2, “Replication Formats”](#).

Unless noted otherwise, the remarks here assume that you have enabled binary logging by starting the server with the `--log-bin` option. (See [Section 5.2.4, “The Binary Log”](#).) If the binary log is not enabled, replication is not possible, nor is the binary log available for data recovery.

The current conditions on the use of stored functions in MySQL 5.1 can be summarized as follows. These conditions do not apply to stored procedures or Event Scheduler events and they do not apply unless binary logging is enabled.

- To create or alter a stored function, you must have the `SUPER` privilege, in addition to the `CREATE ROUTINE` or `ALTER ROUTINE` privilege that is normally required. (Depending on the `DEFINER` value in the function definition, `SUPER` might be required regardless of whether binary logging is enabled. See [Section 12.1.15, “CREATE PROCEDURE and CREATE FUNCTION Syntax”](#).)
- When you create a stored function, you must declare either that it is deterministic or that it does not modify data. Otherwise, it may be unsafe for data recovery or replication.

By default, for a `CREATE FUNCTION` statement to be accepted, at least one of `DETERMINISTIC`, `NO SQL`, or `READS SQL DATA` must be specified explicitly. Otherwise an error occurs:

```
ERROR 1418 (HY000): This function has none of DETERMINISTIC, NO SQL,
or READS SQL DATA in its declaration and binary logging is enabled
(you *might* want to use the less safe log_bin_trust_function_creators
variable)
```

This function is deterministic (and does not modify data), so it is safe:

```
CREATE FUNCTION f1(i INT)
RETURNS INT
DETERMINISTIC
READS SQL DATA
BEGIN
 RETURN i;
END;
```

This function uses `UUID()`, which is not deterministic, so the function also is not deterministic and is not safe:

```
CREATE FUNCTION f2()
RETURNS CHAR(36) CHARACTER SET utf8
BEGIN
 RETURN UUID();
END;
```

This function modifies data, so it may not be safe:

```
CREATE FUNCTION f3(p_id INT)
RETURNS INT
BEGIN
 UPDATE t SET modtime = NOW() WHERE id = p_id;
 RETURN ROW_COUNT();
END;
```

Assessment of the nature of a function is based on the “honesty” of the creator: MySQL does not check that a function declared `DETERMINISTIC` is free of statements that produce nondeterministic results.

- Although it is possible to create a deterministic stored function without specifying `DETERMINISTIC`, you cannot as of

MySQL 5.1.15 execute this function using statement-based binary logging. To execute such a function, you must use row-based or mixed binary logging. Alternatively, if you explicitly specify `DETERMINISTIC` in the function definition, you can use any kind of logging, including statement-based logging.

- To relax the preceding conditions on function creation (that you must have the `SUPER` privilege and that a function must be declared deterministic or to not modify data), set the global `log_bin_trust_function_creators` system variable to 1. By default, this variable has a value of 0, but you can change it like this:

```
mysql> SET GLOBAL log_bin_trust_function_creators = 1;
```

You can also set this variable by using the `--log-bin-trust-function-creators=1` option when starting the server.

If binary logging is not enabled, `log_bin_trust_function_creators` does not apply. `SUPER` is not required for function creation unless, as described previously, the `DEFINER` value in the function definition requires it.

- For information about built-in functions that may be unsafe for replication (and thus cause stored functions that use them to be unsafe as well), see [Section 16.4.1, “Replication Features and Issues”](#).

Triggers are similar to stored functions, so the preceding remarks regarding functions also apply to triggers with the following exception: `CREATE TRIGGER` does not have an optional `DETERMINISTIC` characteristic, so triggers are assumed to be always deterministic. However, this assumption might in some cases be invalid. For example, the `UUID()` function is nondeterministic (and does not replicate). You should be careful about using such functions in triggers.

Triggers can update tables, so error messages similar to those for stored functions occur with `CREATE TRIGGER` if you do not have the required privileges. On the slave side, the slave uses the trigger `DEFINER` attribute to determine which user is considered to be the creator of the trigger.

The rest of this section provides additional detail about the logging implementation and its implications. You need not read it unless you are interested in the background on the rationale for the current logging-related conditions on stored routine use. This discussion applies only for statement-based logging, and not for row-based logging, with the exception of the first item: `CREATE` and `DROP` statements are logged as statements regardless of the logging mode.

- The server writes `CREATE EVENT`, `CREATE PROCEDURE`, `CREATE FUNCTION`, `ALTER EVENT`, `ALTER PROCEDURE`, `ALTER FUNCTION`, `DROP EVENT`, `DROP PROCEDURE`, and `DROP FUNCTION` statements to the binary log.
- A stored function invocation is logged as a `SELECT` statement if the function changes data and occurs within a statement that would not otherwise be logged. This prevents nonreplication of data changes that result from use of stored functions in nonlogged statements. For example, `SELECT` statements are not written to the binary log, but a `SELECT` might invoke a stored function that makes changes. To handle this, a `SELECT func_name()` statement is written to the binary log when the given function makes a change. Suppose that the following statements are executed on the master:

```
CREATE FUNCTION f1(a INT) RETURNS INT
BEGIN
 IF (a < 3) THEN
 INSERT INTO t2 VALUES (a);
 END IF;
 RETURN 0;
END;

CREATE TABLE t1 (a INT);
INSERT INTO t1 VALUES (1),(2),(3);

SELECT f1(a) FROM t1;
```

When the `SELECT` statement executes, the function `f1()` is invoked three times. Two of those invocations insert a row, and MySQL logs a `SELECT` statement for each of them. That is, MySQL writes the following statements to the binary log:

```
SELECT f1(1);
SELECT f1(2);
```

The server also logs a `SELECT` statement for a stored function invocation when the function invokes a stored procedure that causes an error. In this case, the server writes the `SELECT` statement to the log along with the expected error code. On the slave, if the same error occurs, that is the expected result and replication continues. Otherwise, replication stops.

Note: Before MySQL 5.1.7, you will see these `SELECT func_name()` statements logged as `DO func_name()`. The change to `SELECT` was made because use of `DO` was found to yield insufficient control over error code checking.

- Logging stored function invocations rather than the statements executed by a function has a security implication for replication, which arises from two factors:
  - It is possible for a function to follow different execution paths on master and slave servers.

- Statements executed on a slave are processed by the slave SQL thread which has full privileges.

The implication is that although a user must have the `CREATE ROUTINE` privilege to create a function, the user can write a function containing a dangerous statement that will execute only on the slave where it is processed by a thread that has full privileges. For example, if the master and slave servers have server ID values of 1 and 2, respectively, a user on the master server could create and invoke an unsafe function `unsafe_func()` as follows:

```
mysql> delimiter //
mysql> CREATE FUNCTION unsafe_func () RETURNS INT
 -> BEGIN
 -> IF @@server_id=2 THEN dangerous_statement; END IF;
 -> RETURN 1;
 -> END;
 -> //
mysql> delimiter ;
mysql> INSERT INTO t VALUES(unsafe_func());
```

The `CREATE FUNCTION` and `INSERT` statements are written to the binary log, so the slave will execute them. Because the slave SQL thread has full privileges, it will execute the dangerous statement. Thus, the function invocation has different effects on the master and slave and is not replication-safe.

To guard against this danger for servers that have binary logging enabled, stored function creators must have the `SUPER` privilege, in addition to the usual `CREATE ROUTINE` privilege that is required. Similarly, to use `ALTER FUNCTION`, you must have the `SUPER` privilege in addition to the `ALTER ROUTINE` privilege. Without the `SUPER` privilege, an error will occur:

```
ERROR 1419 (HY000): You do not have the SUPER privilege and
binary logging is enabled (you *might* want to use the less safe
log_bin_trust_function_creators variable)
```

If you do not want to require function creators to have the `SUPER` privilege (for example, if all users with the `CREATE ROUTINE` privilege on your system are experienced application developers), set the global `log_bin_trust_function_creators` system variable to 1. You can also set this variable by using the `--log-bin-trust-function-creators=1` option when starting the server. If binary logging is not enabled, `log_bin_trust_function_creators` does not apply. `SUPER` is not required for function creation unless, as described previously, the `DEFINER` value in the function definition requires it.

- If a function that performs updates is nondeterministic, it is not repeatable. This can have two undesirable effects:
  - It will make a slave different from the master.
  - Restored data will be different from the original data.

To deal with these problems, MySQL enforces the following requirement: On a master server, creation and alteration of a function is refused unless you declare the function to be deterministic or to not modify data. Two sets of function characteristics apply here:

- The `DETERMINISTIC` and `NOT DETERMINISTIC` characteristics indicate whether a function always produces the same result for given inputs. The default is `NOT DETERMINISTIC` if neither characteristic is given. To declare that a function is deterministic, you must specify `DETERMINISTIC` explicitly.
- The `CONTAINS SQL`, `NO SQL`, `READS SQL DATA`, and `MODIFIES SQL DATA` characteristics provide information about whether the function reads or writes data. Either `NO SQL` or `READS SQL DATA` indicates that a function does not change data, but you must specify one of these explicitly because the default is `CONTAINS SQL` if no characteristic is given.

By default, for a `CREATE FUNCTION` statement to be accepted, at least one of `DETERMINISTIC`, `NO SQL`, or `READS SQL DATA` must be specified explicitly. Otherwise an error occurs:

```
ERROR 1418 (HY000): This function has none of DETERMINISTIC, NO SQL,
or READS SQL DATA in its declaration and binary logging is enabled
(you *might* want to use the less safe log_bin_trust_function_creators
variable)
```

If you set `log_bin_trust_function_creators` to 1, the requirement that functions be deterministic or not modify data is dropped.

- Stored procedure calls are logged at the statement level rather than at the `CALL` level. That is, the server does not log the `CALL` statement, it logs those statements within the procedure that actually execute. As a result, the same changes that occur on the master will be observed on slave servers. This prevents problems that could result from a procedure having different execution paths on different machines.

In general, statements executed within a stored procedure are written to the binary log using the same rules that would apply

were the statements to be executed in standalone fashion. Some special care is taken when logging procedure statements because statement execution within procedures is not quite the same as in nonprocedure context:

- A statement to be logged might contain references to local procedure variables. These variables do not exist outside of stored procedure context, so a statement that refers to such a variable cannot be logged literally. Instead, each reference to a local variable is replaced by this construct for logging purposes:

```
NAME_CONST(var_name, var_value)
```

`var_name` is the local variable name, and `var_value` is a constant indicating the value that the variable has at the time the statement is logged. `NAME_CONST()` has a value of `var_value`, and a “name” of `var_name`. Thus, if you invoke this function directly, you get a result like this:

```
mysql> SELECT NAME_CONST('myname', 14);
+-----+
| myname |
+-----+
| 14 |
+-----+
```

`NAME_CONST()` enables a logged standalone statement to be executed on a slave with the same effect as the original statement that was executed on the master within a stored procedure.

The use of `NAME_CONST()` can result in a problem for `CREATE TABLE ... SELECT` statements when the source column expressions refer to local variables. Converting these references to `NAME_CONST()` expressions can result in column names that are different on the master and slave servers, or names that are too long to be legal column identifiers. A workaround is to supply aliases for columns that refer to local variables. Consider this statement when `myvar` has a value of 1:

```
CREATE TABLE t1 SELECT myvar;
```

That will be rewritten as follows:

```
CREATE TABLE t1 SELECT NAME_CONST(myvar, 1);
```

To ensure that the master and slave tables have the same column names, write the statement like this:

```
CREATE TABLE t1 SELECT myvar AS myvar;
```

The rewritten statement becomes:

```
CREATE TABLE t1 SELECT NAME_CONST(myvar, 1) AS myvar;
```

- A statement to be logged might contain references to user-defined variables. To handle this, MySQL writes a `SET` statement to the binary log to make sure that the variable exists on the slave with the same value as on the master. For example, if a statement refers to a variable `@my_var`, that statement will be preceded in the binary log by the following statement, where `value` is the value of `@my_var` on the master:

```
SET @my_var = value;
```

- Procedure calls can occur within a committed or rolled-back transaction. Transactional context is accounted for so that the transactional aspects of procedure execution are replicated correctly. That is, the server logs those statements within the procedure that actually execute and modify data, and also logs `BEGIN`, `COMMIT`, and `ROLLBACK` statements as necessary. For example, if a procedure updates only transactional tables and is executed within a transaction that is rolled back, those updates are not logged. If the procedure occurs within a committed transaction, `BEGIN` and `COMMIT` statements are logged with the updates. For a procedure that executes within a rolled-back transaction, its statements are logged using the same rules that would apply if the statements were executed in standalone fashion:

- Updates to transactional tables are not logged.
- Updates to nontransactional tables are logged because rollback does not cancel them.
- Updates to a mix of transactional and nontransactional tables are logged surrounded by `BEGIN` and `ROLLBACK` so that slaves will make the same changes and rollbacks as on the master.
- A stored procedure call is *not* written to the binary log at the statement level if the procedure is invoked from within a stored function. In that case, the only thing logged is the statement that invokes the function (if it occurs within a statement that is logged) or a `DO` statement (if it occurs within a statement that is not logged). For this reason, care should be exercised in the use

of stored functions that invoke a procedure, even if the procedure is otherwise safe in itself.

---

# Chapter 20. INFORMATION\_SCHEMA Tables

[INFORMATION\\_SCHEMA](#) provides access to database metadata.

*Metadata* is data about the data, such as the name of a database or table, the data type of a column, or access privileges. Other terms that sometimes are used for this information are *data dictionary* and *system catalog*.

[INFORMATION\\_SCHEMA](#) is the information database, the place that stores information about all the other databases that the MySQL server maintains. Inside [INFORMATION\\_SCHEMA](#) there are several read-only tables. They are actually views, not base tables, so there are no files associated with them.

In effect, we have a database named [INFORMATION\\_SCHEMA](#), although the server does not create a database directory with that name. It is possible to select [INFORMATION\\_SCHEMA](#) as the default database with a `USE` statement, but it is possible only to read the contents of tables. You cannot insert into them, update them, or delete from them.

Here is an example of a statement that retrieves information from [INFORMATION\\_SCHEMA](#):

```
mysql> SELECT table_name, table_type, engine
 -> FROM information_schema.tables
 -> WHERE table_schema = 'db5'
 -> ORDER BY table_name DESC;
+-----+-----+-----+
| table_name | table_type | engine |
+-----+-----+-----+
| v56 | VIEW | NULL |
| v3 | VIEW | NULL |
| v2 | VIEW | NULL |
| v | VIEW | NULL |
| tables | BASE TABLE | MyISAM |
| t7 | BASE TABLE | MyISAM |
| t3 | BASE TABLE | MyISAM |
| t2 | BASE TABLE | MyISAM |
| t | BASE TABLE | MyISAM |
| pk | BASE TABLE | InnoDB |
| loop | BASE TABLE | MyISAM |
| kurs | BASE TABLE | MyISAM |
| k | BASE TABLE | MyISAM |
| into | BASE TABLE | MyISAM |
| goto | BASE TABLE | MyISAM |
| fk2 | BASE TABLE | InnoDB |
| fk | BASE TABLE | InnoDB |
+-----+-----+-----+
17 rows in set (0.01 sec)
```

Explanation: The statement requests a list of all the tables in database `db5`, in reverse alphabetic order, showing just three pieces of information: the name of the table, its type, and its storage engine.

The definition for character columns (for example, `TABLES.TABLE_NAME`) is generally `VARCHAR(N) CHARACTER SET utf8` where `N` is at least 64. MySQL uses the default collation for this character set (`utf8_general_ci`) for all searches, sorts, comparisons, and other string operations on such columns. However, searches in [INFORMATION\\_SCHEMA](#) string columns are also affected by file system case sensitivity. For more information, see [Section 9.1.7.9, “Collation and INFORMATION\\_SCHEMA Searches”](#).

Each MySQL user has the right to access these tables, but can see only the rows in the tables that correspond to objects for which the user has the proper access privileges. In some cases (for example, the `ROUTINE_DEFINITION` column in the [INFORMATION\\_SCHEMA.ROUTINES](#) table), users who have insufficient privileges will see `NULL`.

The `SELECT ... FROM INFORMATION_SCHEMA` statement is intended as a more consistent way to provide access to the information provided by the various `SHOW` statements that MySQL supports (`SHOW DATABASES`, `SHOW TABLES`, and so forth). Using `SELECT` has these advantages, compared to `SHOW`:

- It conforms to Codd's rules. That is, all access is done on tables.
- Nobody needs to learn a new statement syntax. Because they already know how `SELECT` works, they only need to learn the object names.
- The implementor need not worry about adding keywords.
- There are millions of possible output variations, instead of just one. This provides more flexibility for applications that have varying requirements about what metadata they need.
- Migration is easier because every other DBMS does it this way.

However, because `SHOW` is popular and because it might be confusing were it to disappear, the advantages of conventional syntax

are not a sufficient reason to eliminate `SHOW`. In fact, along with the implementation of `INFORMATION_SCHEMA`, there are enhancements to `SHOW` as well. These are described in [Section 20.28, “Extensions to SHOW Statements”](#).

There is no difference between the privileges required for `SHOW` statements and those required to select information from `INFORMATION_SCHEMA`. In either case, you have to have some privilege on an object in order to see information about it.

`INFORMATION_SCHEMA` queries that search for information from more than one database might take a long time and impact performance. To check the efficiency of a query, you can use `EXPLAIN`. For information about `EXPLAIN` output that is specific to interpreting the cost of `INFORMATION_SCHEMA` queries, see [Section 7.3.3, “`INFORMATION\_SCHEMA` Optimization”](#).

The implementation for the `INFORMATION_SCHEMA` table structures in MySQL follows the ANSI/ISO SQL:2003 standard Part 11 *Schemata*. Our intent is approximate compliance with SQL:2003 core feature F021 *Basic information schema*.

Users of SQL Server 2000 (which also follows the standard) may notice a strong similarity. However, MySQL has omitted many columns that are not relevant for our implementation, and added columns that are MySQL-specific. One such column is the `ENGINE` column in the `INFORMATION_SCHEMA.TABLES` table.

Although other DBMSs use a variety of names, like `syscat` or `system`, the standard name is `INFORMATION_SCHEMA`.

The following sections describe each of the tables and columns that are in `INFORMATION_SCHEMA`. For each column, there are three pieces of information:

- “`INFORMATION_SCHEMA` Name” indicates the name for the column in the `INFORMATION_SCHEMA` table. This corresponds to the standard SQL name unless the “Remarks” field says “MySQL extension.”
- “`SHOW` Name” indicates the equivalent field name in the closest `SHOW` statement, if there is one.
- “Remarks” provides additional information where applicable. If this field is `NULL`, it means that the value of the column is always `NULL`. If this field says “MySQL extension,” the column is a MySQL extension to standard SQL.

To avoid using any name that is reserved in the standard or in DB2, SQL Server, or Oracle, we changed the names of some columns marked “MySQL extension”. (For example, we changed `COLLATION` to `TABLE_COLLATION` in the `TABLES` table.) See the list of reserved words near the end of this article: [http://web.archive.org/web/20070409075643rn\\_1/www.dbazine.com/db2/db2-disarticles/gulutzan5](http://web.archive.org/web/20070409075643rn_1/www.dbazine.com/db2/db2-disarticles/gulutzan5).

Each section indicates what `SHOW` statement is equivalent to a `SELECT` that retrieves information from `INFORMATION_SCHEMA`, if there is such a statement. For `SHOW` statements that display information for the default database if you omit a `FROM db_name` clause, you can often select information for the default database by adding an `AND TABLE_SCHEMA = SCHEMA()` condition to the `WHERE` clause of a query that retrieves information from an `INFORMATION_SCHEMA` table.

### Note

At present, there are some missing columns and some columns out of order. We are working on this and updating the documentation as changes are made.

For answers to questions that are often asked concerning the `INFORMATION_SCHEMA` database, see [Section A.7, “MySQL 5.1 FAQ: `INFORMATION\_SCHEMA`”](#).

## 20.1. The `INFORMATION_SCHEMA SCHEMATA` Table

A schema is a database, so the `SCHEMATA` table provides information about databases.

<code>INFORMATION_SCHEMA</code> Name	<code>SHOW</code> Name	Remarks
<code>CATALOG_NAME</code>		<code>NULL</code>
<code>SCHEMA_NAME</code>		Database
<code>DEFAULT_CHARACTER_SET_NAME</code>		
<code>DEFAULT_COLLATION_NAME</code>		
<code>SQL_PATH</code>		<code>NULL</code>

The following statements are equivalent:

```
SELECT SCHEMA_NAME AS `Database`
 FROM INFORMATION_SCHEMA.SCHEMATA
 [WHERE SCHEMA_NAME LIKE 'wild']

SHOW DATABASES
 [LIKE 'wild']
```

## 20.2. The INFORMATION\_SCHEMA TABLES Table

The `TABLES` table provides information about tables in databases.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
TABLE_CATALOG		NULL
TABLE_SCHEMA	Table_...	
TABLE_NAME	Table_...	
TABLE_TYPE		
ENGINE	Engine	MySQL extension
VERSION	Version	The version number of the table's .frm file, MySQL extension
ROW_FORMAT	Row_format	MySQL extension
TABLE_ROWS	Rows	MySQL extension
AVG_ROW_LENGTH	Avg_row_length	MySQL extension
DATA_LENGTH	Data_length	MySQL extension
MAX_DATA_LENGTH	Max_data_length	MySQL extension
INDEX_LENGTH	Index_length	MySQL extension
DATA_FREE	Data_free	MySQL extension
AUTO_INCREMENT	Auto_increment	MySQL extension
CREATE_TIME	Create_time	MySQL extension
UPDATE_TIME	Update_time	MySQL extension
CHECK_TIME	Check_time	MySQL extension
TABLE_COLLATION	Collation	MySQL extension
CHECKSUM	Checksum	MySQL extension
CREATE_OPTIONS	Create_options	MySQL extension
TABLE_COMMENT	Comment	MySQL extension

### Notes:

- `TABLE_SCHEMA` and `TABLE_NAME` are a single field in a `SHOW` display, for example `Table_in_db1`.
  - `TABLE_TYPE` should be `BASE_TABLE` or `VIEW`. Currently, the `TABLES` table does not list `TEMPORARY` tables.
  - For partitioned tables, beginning with MySQL 5.1.9, the `ENGINE` column shows the name of the storage engine used by all partitions. (Previously, this column showed `PARTITION` for such tables.)
  - The `TABLE_ROWS` column is `NULL` if the table is in the `INFORMATION_SCHEMA` database.
- For `InnoDB` tables, the row count is only a rough estimate used in SQL optimization. (This is also true if the `InnoDB` table is partitioned.)
- Prior to MySQL 5.1.12, MySQL Cluster allocated storage for variable-width columns in 10-page extents of 32 kilobytes each; thus, the `DATA_LENGTH` for such columns was reported in increments of 320 KB. Beginning with MySQL 5.1.12, the `DATA_LENGTH` column reflects the true amount of storage for variable-width columns of `NDB` tables. ([Bug#18413](#))
  - Beginning with MySQL 5.1.28, the `DATA_FREE` column shows the free space in bytes for `InnoDB` tables.
  - We have nothing for the table's default character set. `TABLE_COLLATION` is close, because collation names begin with a character set name.
  - Beginning with MySQL 5.1.9, the `CREATE_OPTIONS` column shows `partitioned` if the table is partitioned.

The following statements are equivalent:

```
SELECT table_name FROM INFORMATION_SCHEMA.TABLES
WHERE table_schema = 'db_name'
```

```
[AND table_name LIKE 'wild']

SHOW TABLES
 FROM db_name
 [LIKE 'wild']
```

## 20.3. The INFORMATION\_SCHEMA COLUMNS Table

The `COLUMNS` table provides information about columns in tables.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
TABLE_CATALOG		NULL
TABLE_SCHEMA		
TABLE_NAME		
COLUMN_NAME	Field	
ORDINAL_POSITION		see notes
COLUMN_DEFAULT	Default	
IS_NULLABLE	Null	
DATA_TYPE	Type	
CHARACTER_MAXIMUM_LENGTH	Type	
CHARACTER_OCTET_LENGTH		
NUMERIC_PRECISION	Type	
NUMERIC_SCALE	Type	
CHARACTER_SET_NAME		
COLLATION_NAME	Collation	
COLUMN_TYPE	Type	MySQL extension
COLUMN_KEY	Key	MySQL extension
EXTRA	Extra	MySQL extension
PRIVILEGES	Privileges	MySQL extension
COLUMN_COMMENT	Comment	MySQL extension

### Notes:

- In `SHOW`, the `Type` display includes values from several different `COLUMNS` columns.
- `ORDINAL_POSITION` is necessary because you might want to say `ORDER BY ORDINAL_POSITION`. Unlike `SHOW, SELECT` does not have automatic ordering.
- `CHARACTER_OCTET_LENGTH` should be the same as `CHARACTER_MAXIMUM_LENGTH`, except for multi-byte character sets.
- `CHARACTER_SET_NAME` can be derived from `Collation`. For example, if you say `SHOW FULL COLUMNS FROM t`, and you see in the `Collation` column a value of `latin1_swedish_ci`, the character set is what is before the first underscore: `latin1`.

The following statements are nearly equivalent:

```
SELECT COLUMN_NAME, DATA_TYPE, IS_NULLABLE, COLUMN_DEFAULT
 FROM INFORMATION_SCHEMA.COLUMNS
 WHERE table_name = 'tbl_name'
 [AND table_schema = 'db_name']
 [AND column_name LIKE 'wild']

SHOW COLUMNS
 FROM tbl_name
 [FROM db_name]
 [LIKE 'wild']
```

## 20.4. The INFORMATION\_SCHEMA STATISTICS Table

The `STATISTICS` table provides information about table indexes.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
TABLE_CATALOG		NULL
TABLE_SCHEMA		= Database
TABLE_NAME	Table	
NON_UNIQUE	Non_unique	
INDEX_SCHEMA		= Database
INDEX_NAME	Key_name	
SEQ_IN_INDEX	Seq_in_index	
COLUMN_NAME	Column_name	
COLLATION	Collation	
CARDINALITY	Cardinality	
SUB_PART	Sub_part	MySQL extension
PACKED	Packed	MySQL extension
NULLABLE	Null	MySQL extension
INDEX_TYPE	Index_type	MySQL extension
COMMENT	Comment	MySQL extension

**Notes:**

- There is no standard table for indexes. The preceding list is similar to what SQL Server 2000 returns for `sp_statistics`, except that we replaced the name `QUALIFIER` with `CATALOG` and we replaced the name `OWNER` with `SCHEMA`.

Clearly, the preceding table and the output from `SHOW INDEX` are derived from the same parent. So the correlation is already close.

The following statements are equivalent:

```
SELECT * FROM INFORMATION_SCHEMA.STATISTICS
WHERE table_name = 'tbl_name'
AND table_schema = 'db_name'

SHOW INDEX
FROM tbl_name
FROM db_name
```

## 20.5. The INFORMATION\_SCHEMA USER\_PRIVILEGES Table

The `USER_PRIVILEGES` table provides information about global privileges. This information comes from the `mysql.user` grant table.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
GRANTEE		'user_name'@'host_name' value, MySQL extension
TABLE_CATALOG		NULL, MySQL extension
PRIVILEGE_TYPE		MySQL extension
IS_GRANTABLE		MySQL extension

**Notes:**

- This is a nonstandard table. It takes its values from the `mysql.user` table.

## 20.6. The INFORMATION\_SCHEMA SCHEMA\_PRIVILEGES Table

The `SCHEMA_PRIVILEGES` table provides information about schema (database) privileges. This information comes from the `mysql.db` grant table.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
GRANTEE		' <code>user_name</code> '@' <code>host_name</code> ' value, MySQL extension
TABLE_CATALOG		<code>NULL</code> , MySQL extension
TABLE_SCHEMA		MySQL extension
PRIVILEGE_TYPE		MySQL extension
IS_GRANTABLE		MySQL extension

**Notes:**

- This is a nonstandard table. It takes its values from the `mysql.db` table.

## 20.7. The INFORMATION\_SCHEMA TABLE\_PRIVILEGES Table

The `TABLE_PRIVILEGES` table provides information about table privileges. This information comes from the `mysql.tables_priv` grant table.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
GRANTEE		' <code>user_name</code> '@' <code>host_name</code> ' value
TABLE_CATALOG		<code>NULL</code>
TABLE_SCHEMA		
TABLE_NAME		
PRIVILEGE_TYPE		
IS_GRANTABLE		

**Notes:**

- `PRIVILEGE_TYPE` can contain one (and only one) of these values: `SELECT`, `INSERT`, `UPDATE`, `REFERENCES`, `ALTER`, `INDEX`, `DROP`, `CREATE VIEW`.

The following statements are *not* equivalent:

```
SELECT ... FROM INFORMATION_SCHEMA.TABLE_PRIVILEGES
SHOW GRANTS ...
```

## 20.8. The INFORMATION\_SCHEMA COLUMN\_PRIVILEGES Table

The `COLUMN_PRIVILEGES` table provides information about column privileges. This information comes from the `mysql.columns_priv` grant table.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
GRANTEE		' <code>user_name</code> '@' <code>host_name</code> ' value
TABLE_CATALOG		<code>NULL</code>
TABLE_SCHEMA		
TABLE_NAME		
COLUMN_NAME		
PRIVILEGE_TYPE		
IS_GRANTABLE		

**Notes:**

- In the output from `SHOW FULL COLUMNS`, the privileges are all in one field and in lowercase, for example, `select,insert,update,references`. In `COLUMN_PRIVILEGES`, there is one privilege per row, in uppercase.
- `PRIVILEGE_TYPE` can contain one (and only one) of these values: `SELECT, INSERT, UPDATE, REFERENCES`.
- If the user has `GRANT OPTION` privilege, `IS_GRANTABLE` should be `YES`. Otherwise, `IS_GRANTABLE` should be `NO`. The output does not list `GRANT OPTION` as a separate privilege.

The following statements are *not* equivalent:

```
SELECT ... FROM INFORMATION_SCHEMA.COLUMN_PRIVILEGES
SHOW GRANTS ...
```

## 20.9. The INFORMATION\_SCHEMA CHARACTER\_SETS Table

The `CHARACTER_SETS` table provides information about available character sets.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
<code>CHARACTER_SET_NAME</code>	<code>Charset</code>	
<code>DEFAULT_COLLATE_NAME</code>	<code>Default collation</code>	
<code>DESCRIPTION</code>	<code>Description</code>	MySQL extension
<code>MAXLEN</code>	<code>Maxlen</code>	MySQL extension

The following statements are equivalent:

```
SELECT * FROM INFORMATION_SCHEMA.CHARACTER_SETS
[WHERE CHARACTER_SET_NAME LIKE 'wild']

SHOW CHARACTER SET
[LIKE 'wild']
```

## 20.10. The INFORMATION\_SCHEMA COLLATIONS Table

The `COLLATIONS` table provides information about collations for each character set.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
<code>COLLATION_NAME</code>	<code>Collation</code>	
<code>CHARACTER_SET_NAME</code>	<code>Charset</code>	MySQL extension
<code>ID</code>	<code>Id</code>	MySQL extension
<code>IS_DEFAULT</code>	<code>Default</code>	MySQL extension
<code>IS_COMPILED</code>	<code>Compiled</code>	MySQL extension
<code>SORTLEN</code>	<code>Sortlen</code>	MySQL extension

- `COLLATION_NAME` is the collation name.
- `CHARACTER_SET_NAME` is the name of the character set with which the collation is associated.
- `ID` is the collation ID.
- `IS_DEFAULT` indicates whether the collation is the default for its character set.
- `IS_COMPILED` indicates whether the character set is compiled into the server.
- `SORTLEN` is related to the amount of memory required to sort strings expressed in the character set.

Collation information is also available from the `SHOW COLLATION` statement. The following statements are equivalent:

```
SELECT COLLATION_NAME FROM INFORMATION_SCHEMA.COLLATIONS
[WHERE COLLATION_NAME LIKE 'wild']
```

```
SHOW COLLATION
[LIKE 'wild']
```

## 20.11. The INFORMATION\_SCHEMA COLLATION\_CHARACTER\_SET\_APPLICABILITY Table

The `COLLATION_CHARACTER_SET_APPLICABILITY` table indicates what character set is applicable for what collation. The columns are equivalent to the first two display fields that we get from `SHOW COLLATION`.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
COLLATION_NAME	Collation	
CHARACTER_SET_NAME	Charset	

## 20.12. The INFORMATION\_SCHEMA TABLE\_CONSTRAINTS Table

The `TABLE_CONSTRAINTS` table describes which tables have constraints.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
CONSTRAINT_CATALOG		NULL
CONSTRAINT_SCHEMA		
CONSTRAINT_NAME		
TABLE_SCHEMA		
TABLE_NAME		
CONSTRAINT_TYPE		

**Notes:**

- The `CONSTRAINT_TYPE` value can be `UNIQUE`, `PRIMARY KEY`, or `FOREIGN KEY`.
- The `UNIQUE` and `PRIMARY KEY` information is about the same as what you get from the `Key_name` field in the output from `SHOW INDEX` when the `Non_unique` field is `0`.
- The `CONSTRAINT_TYPE` column can contain one of these values: `UNIQUE`, `PRIMARY KEY`, `FOREIGN KEY`, `CHECK`. This is a `CHAR` (not `ENUM`) column. The `CHECK` value is not available until we support `CHECK`.

## 20.13. The INFORMATION\_SCHEMA KEY\_COLUMN\_USAGE Table

The `KEY_COLUMN_USAGE` table describes which key columns have constraints.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
CONSTRAINT_CATALOG		NULL
CONSTRAINT_SCHEMA		
CONSTRAINT_NAME		
TABLE_CATALOG		
TABLE_SCHEMA		
TABLE_NAME		
COLUMN_NAME		
ORDINAL_POSITION		
POSITION_IN_UNIQUE_CONSTRAINT		
REFERENCED_TABLE_SCHEMA		
REFERENCED_TABLE_NAME		
REFERENCED_COLUMN_NAME		

**Notes:**

- If the constraint is a foreign key, then this is the column of the foreign key, not the column that the foreign key references.
- The value of `ORDINAL_POSITION` is the column's position within the constraint, not the column's position within the table. Column positions are numbered beginning with 1.
- The value of `POSITION_IN_UNIQUE_CONSTRAINT` is `NULL` for unique and primary-key constraints. For foreign-key constraints, it is the ordinal position in key of the table that is being referenced.

Suppose that there are two tables name `t1` and `t3` that have the following definitions:

```
CREATE TABLE t1
(
 s1 INT,
 s2 INT,
 s3 INT,
 PRIMARY KEY(s3)
) ENGINE=InnoDB;

CREATE TABLE t3
(
 s1 INT,
 s2 INT,
 s3 INT,
 KEY(s1),
 CONSTRAINT CO FOREIGN KEY (s2) REFERENCES t1(s3)
) ENGINE=InnoDB;
```

For those two tables, the `KEY_COLUMN_USAGE` table has two rows:

- One row with `CONSTRAINT_NAME = 'PRIMARY', TABLE_NAME = 't1', COLUMN_NAME = 's3', ORDINAL_POSITION = 1, POSITION_IN_UNIQUE_CONSTRAINT = NULL`.
- One row with `CONSTRAINT_NAME = 'CO', TABLE_NAME = 't3', COLUMN_NAME = 's2', ORDINAL_POSITION = 1, POSITION_IN_UNIQUE_CONSTRAINT = 1`.

## 20.14. The INFORMATION\_SCHEMA ROUTINES Table

The `ROUTINES` table provides information about stored routines (both procedures and functions). The `ROUTINES` table does not include user-defined functions (UDFs) at this time.

The column named “`mysql.proc name`” indicates the `mysql.proc` table column that corresponds to the `INFORMATION_SCHEMA.ROUTINES` table column, if any.

INFORMATION_SCHEMA Name	<code>mysql.proc</code> Name	Remarks
<code>SPECIFIC_NAME</code>	<code>specific_name</code>	
<code>ROUTINE_CATALOG</code>		<code>NULL</code>
<code>ROUTINE_SCHEMA</code>	<code>db</code>	
<code>ROUTINE_NAME</code>	<code>name</code>	
<code>ROUTINE_TYPE</code>	<code>type</code>	{ <code>PROCEDURE</code>   <code>FUNCTION</code> }
<code>DTD_IDENTIFIER</code>		data type descriptor
<code>ROUTINE_BODY</code>		<code>SQL</code>
<code>ROUTINE_DEFINITION</code>	<code>body</code>	
<code>EXTERNAL_NAME</code>		<code>NULL</code>
<code>EXTERNAL_LANGUAGE</code>	<code>language</code>	<code>NULL</code>
<code>PARAMETER_STYLE</code>		<code>SQL</code>
<code>IS_DETERMINISTIC</code>	<code>is_deterministic</code>	
<code>SQL_DATA_ACCESS</code>	<code>sql_data_access</code>	
<code>SQL_PATH</code>		<code>NULL</code>
<code>SECURITY_TYPE</code>	<code>security_type</code>	
<code>CREATED</code>	<code>created</code>	
<code>LAST_ALTERED</code>	<code>modified</code>	
<code>SQL_MODE</code>	<code>sql_mode</code>	MySQL extension

ROUTINE_COMMENT	comment	MySQL extension
DEFINER	definer	MySQL extension
CHARACTER_SET_CLIENT		MySQL extension
COLLATION_CONNECTION		MySQL extension
DATABASE_COLLATION		MySQL extension

**Notes:**

- MySQL calculates EXTERNAL\_LANGUAGE thus:
  - If `mysql.proc.language = 'SQL'`, EXTERNAL\_LANGUAGE is NULL
  - Otherwise, EXTERNAL\_LANGUAGE is what is in `mysql.proc.language`. However, we do not have external languages yet, so it is always NULL.
- `CHARACTER_SET_CLIENT` is the session value of the `character_set_client` system variable when the routine was created. `COLLATION_CONNECTION` is the session value of the `collation_connection` system variable when the routine was created. `DATABASE_COLLATION` is the collation of the database with which the routine is associated. These columns were added in MySQL 5.1.21.

## 20.15. The INFORMATION\_SCHEMA VIEWS Table

The `VIEWS` table provides information about views in databases. You must have the `SHOW VIEW` privilege to access this table.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
TABLE_CATALOG		NULL
TABLE_SCHEMA		
TABLE_NAME		
VIEW_DEFINITION		
CHECK_OPTION		
IS_UPDATABLE		
DEFINER		
SECURITY_TYPE		
CHARACTER_SET_CLIENT		MySQL extension
COLLATION_CONNECTION		MySQL extension

**Notes:**

- The `VIEW_DEFINITION` column has most of what you see in the `Create Table` field that `SHOW CREATE VIEW` produces. Skip the words before `SELECT` and skip the words `WITH CHECK OPTION`. Suppose that the original statement was:

```
CREATE VIEW v AS
 SELECT s2,s1 FROM t
 WHERE s1 > 5
 ORDER BY s1
 WITH CHECK OPTION;
```

Then the view definition looks like this:

```
SELECT s2,s1 FROM t WHERE s1 > 5 ORDER BY s1
```

- The `CHECK_OPTION` column has a value of `NONE`, `CASCADE`, or `LOCAL`.
- MySQL sets a flag, called the view updatability flag, at `CREATE VIEW` time. The flag is set to `YES` (true) if `UPDATE` and `DELETE` (and similar operations) are legal for the view. Otherwise, the flag is set to `NO` (false). The `IS_UPDATABLE` column in the `VIEWS` table displays the status of this flag. It means that the server always knows whether a view is updatable. If the view is not updatable, statements such `UPDATE`, `DELETE`, and `INSERT` are illegal and will be rejected. (Note that even if a view is updatable, it might not be possible to insert into it; for details, refer to Section 12.1.20, “`CREATE VIEW Syntax`”.)

- The `DEFINER` column indicates who defined the view. `SECURITY_TYPE` has a value of `DEFINER` or `INVOKER`.
- `CHARACTER_SET_CLIENT` is the session value of the `character_set_client` system variable when the view was created. `COLLATION_CONNECTION` is the session value of the `collation_connection` system variable when the view was created. These columns were added in MySQL 5.1.21.

MySQL lets you use different `sql_mode` settings to tell the server the type of SQL syntax to support. For example, you might use the `ANSI` SQL mode to ensure MySQL correctly interprets the standard SQL concatenation operator, the double bar (`||`), in your queries. If you then create a view that concatenates items, you might worry that changing the `sql_mode` setting to a value different from `ANSI` could cause the view to become invalid. But this is not the case. No matter how you write out a view definition, MySQL always stores it the same way, in a canonical form. Here is an example that shows how the server changes a double bar concatenation operator to a `CONCAT()` function:

```
mysql> SET sql_mode = 'ANSI';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE VIEW test.v AS SELECT 'a' || 'b' as col1;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT VIEW_DEFINITION FROM INFORMATION_SCHEMA.VIEWS
 -> WHERE TABLE_SCHEMA = 'test' AND TABLE_NAME = 'v';
+-----+
| VIEW_DEFINITION |
+-----+
| select concat('a','b') AS `col1` |
+-----+
1 row in set (0.00 sec)
```

The advantage of storing a view definition in canonical form is that changes made later to the value of `sql_mode` will not affect the results from the view. However an additional consequence is that comments prior to `SELECT` are stripped from the definition by the server.

## 20.16. The INFORMATION\_SCHEMA TRIGGERS Table

The `TRIGGERS` table provides information about triggers. You must have the `TRIGGER` privilege to access this table (prior to MySQL 5.1.22, you must have the `SUPER` privilege).

INFORMATION_SCHEMA Name	SHOW Name	Remarks
TRIGGER_CATALOG		NULL
TRIGGER_SCHEMA		
TRIGGER_NAME	Trigger	
EVENT_MANIPULATION	Event	
EVENT_OBJECT_CATALOG		NULL
EVENT_OBJECT_SCHEMA		
EVENT_OBJECT_TABLE	Table	
ACTION_ORDER	0	
ACTION_CONDITION		NULL
ACTION_STATEMENT	Statement	
ACTION_ORIENTATION		ROW
ACTION_TIMING	Timing	
ACTION_REFERENCE_OLD_TABLE		NULL
ACTION_REFERENCE_NEW_TABLE		NULL
ACTION_REFERENCE_OLD_ROW		OLD
ACTION_REFERENCE_NEW_ROW		NEW
CREATED		NULL (0)
SQL_MODE		MySQL extension
DEFINER		MySQL extension
CHARACTER_SET_CLIENT		MySQL extension
COLLATION_CONNECTION		MySQL extension
DATABASE_COLLATION		MySQL extension

**Notes:**

- The `TRIGGER_SCHEMA` and `TRIGGER_NAME` columns contain the name of the database in which the trigger occurs and the trigger name, respectively.
- The `EVENT_MANIPULATION` column contains one of the values '`INSERT`', '`DELETE`', or '`UPDATE`'.
- As noted in [Section 19.3, “Using Triggers”](#), every trigger is associated with exactly one table. The `EVENT_OBJECT_SCHEMA` and `EVENT_OBJECT_TABLE` columns contain the database in which this table occurs, and the table's name.
- The `ACTION_ORDER` statement contains the ordinal position of the trigger's action within the list of all similar triggers on the same table. Currently, this value is always `0`, because it is not possible to have more than one trigger with the same `EVENT_MANIPULATION` and `ACTION_TIMING` on the same table.
- The `ACTION_STATEMENT` column contains the statement to be executed when the trigger is invoked. This is the same as the text displayed in the `Statement` column of the output from `SHOW TRIGGERS`. Note that this text uses UTF-8 encoding.
- The `ACTION_ORIENTATION` column always contains the value '`ROW`'.
- The `ACTION_TIMING` column contains one of the two values '`BEFORE`' or '`AFTER`'.
- The columns `ACTION_REFERENCE_OLD_ROW` and `ACTION_REFERENCE_NEW_ROW` contain the old and new column identifiers, respectively. This means that `ACTION_REFERENCE_OLD_ROW` always contains the value '`OLD`' and `ACTION_REFERENCE_NEW_ROW` always contains the value '`NEW`'.
- The `SQL_MODE` column shows the server SQL mode that was in effect at the time when the trigger was created (and thus which remains in effect for this trigger whenever it is invoked, *regardless of the current server SQL mode*). The possible range of values for this column is the same as that of the `sql_mode` system variable. See [Section 5.1.7, “Server SQL Modes”](#).
- The `DEFINER` column was added in MySQL 5.1.2. `DEFINER` indicates who defined the trigger.
- `CHARACTER_SET_CLIENT` is the session value of the `character_set_client` system variable when the trigger was created. `COLLATION_CONNECTION` is the session value of the `collation_connection` system variable when the trigger was created. `DATABASE_COLLATION` is the collation of the database with which the trigger is associated. These columns were added in MySQL 5.1.21.
- The following columns currently always contain `NULL`: `TRIGGER_CATALOG`, `EVENT_OBJECT_CATALOG`, `ACTION_CONDITION`, `ACTION_REFERENCE_OLD_TABLE`, `ACTION_REFERENCE_NEW_TABLE`, and `CREATED`.

Example, using the `ins_sum` trigger defined in [Section 19.3, “Using Triggers”](#):

```
mysql> SELECT * FROM INFORMATION_SCHEMA.TRIGGERS\G
***** 1. row *****
 TRIGGER_CATALOG: NULL
 TRIGGER_SCHEMA: test
 TRIGGER_NAME: ins_sum
 EVENT_MANIPULATION: INSERT
 EVENT_OBJECT_CATALOG: NULL
 EVENT_OBJECT_SCHEMA: test
 EVENT_OBJECT_TABLE: account
 ACTION_ORDER: 0
 ACTION_CONDITION: NULL
 ACTION_STATEMENT: SET @sum = @sum + NEW.amount
 ACTION_ORIENTATION: ROW
 ACTION_TIMING: BEFORE
 ACTION_REFERENCE_OLD_TABLE: NULL
 ACTION_REFERENCE_NEW_TABLE: NULL
 ACTION_REFERENCE_OLD_ROW: OLD
 ACTION_REFERENCE_NEW_ROW: NEW
 CREATED: NULL
 SQL_MODE:
 DEFINER: me@localhost
```

See also [Section 12.4.5.40, “SHOW TRIGGERS Syntax”](#).

## 20.17. The INFORMATION\_SCHEMA PLUGINS Table

The `PLUGINS` table provides information about server plugins.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
<code>PLUGIN_NAME</code>	<code>Name</code>	MySQL extension
<code>PLUGIN_VERSION</code>		MySQL extension

PLUGIN_STATUS	Status	MySQL extension
PLUGIN_TYPE	Type	MySQL extension
PLUGIN_TYPE_VERSION		MySQL extension
PLUGIN_LIBRARY	Library	MySQL extension
PLUGIN_LIBRARY_VERSION		MySQL extension
PLUGIN_AUTHOR		MySQL extension
PLUGIN_DESCRIPTION		MySQL extension
PLUGIN_LICENSE		MySQL extension

**Notes:**

- The `PLUGINS` table is a nonstandard table. It was added in MySQL 5.1.5.
- `PLUGIN_NAME` is the name used to refer to the plugin in statements such as `INSTALL PLUGIN` and `UNINSTALL PLUGIN`.
- `PLUGIN_VERSION` is the version from the plugin's general type descriptor.
- `PLUGIN_STATUS` indicates the plugin status, one of `ACTIVE`, `INACTIVE`, `DISABLED`, or `DELETED`.
- `PLUGIN_TYPE` indicates the type of plugin, such as `STORAGE ENGINE` or `INFORMATION_SCHEMA`.
- `PLUGIN_TYPE_VERSION` is the version from the plugin's type-specific descriptor.
- `PLUGIN_LIBRARY` is the name of the plugin shared object file. This is the name used to refer to the plugin file in statements such as `INSTALL PLUGIN` and `UNINSTALL PLUGIN`. This file is located in the directory named by the `plugin_dir` system variable. If the library name is `NULL`, the plugin is compiled in and cannot be uninstalled with `UNINSTALL PLUGIN`.
- `PLUGIN_LIBRARY_VERSION` indicates the plugin API interface version.
- `PLUGIN_AUTHOR` names the plugin author.
- `PLUGIN_DESCRIPTION` provides a short description of the plugin.
- `PLUGIN_LICENSE` indicates how the plugin is licensed; for example, `GPL`. This column was added in MySQL 5.1.12.

For plugins installed with `INSTALL PLUGIN`, the `PLUGIN_NAME` and `PLUGIN_LIBARY` values are also registered in the `mysql.plugin` table.

These statements are equivalent:

```
SELECT
 PLUGIN_NAME, PLUGIN_STATUS, PLUGIN_TYPE,
 PLUGIN_LIBRARY, PLUGIN_LICENSE
FROM INFORMATION_SCHEMA.PLUGINS;

SHOW PLUGINS;
```

For information about plugin data structures that form the basis of the information in the `PLUGINS` table, see [Section 22.2, “The MySQL Plugin API”](#).

Plugin information is also available using the `SHOW PLUGINS` statement. See [Section 12.4.5.27, “SHOW PLUGINS Syntax”](#).

## 20.18. The INFORMATION\_SCHEMA ENGINES Table

The `PLUGINS` table provides information about storage engines.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
ENGINE	Engine	MySQL extension
SUPPORT	Support	MySQL extension
COMMENT	Comment	MySQL extension
TRANSACTIONS	Transactions	MySQL extension
XA	XA	MySQL extension

SAVEPOINTS	Savepoints	MySQL extension
------------	------------	-----------------

**Notes:**

- The `ENGINES` table is a nonstandard table. It was added in MySQL 5.1.5.

See also [Section 12.4.5.17, “SHOW ENGINES Syntax”](#).

## 20.19. The INFORMATION\_SCHEMA PARTITIONS Table

The `PARTITIONS` table provides information about table partitions. See [Chapter 18, “Partitioning”](#), for more information about partitioning tables.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
TABLE_CATALOG		MySQL extension
TABLE_SCHEMA		MySQL extension
TABLE_NAME		MySQL extension
PARTITION_NAME		MySQL extension
SUBPARTITION_NAME		MySQL extension
PARTITION_ORDINAL_POSITION		MySQL extension
SUBPARTITION_ORDINAL_POSITION		MySQL extension
PARTITION_METHOD		MySQL extension
SUBPARTITION_METHOD		MySQL extension
PARTITION_EXPRESSION		MySQL extension
SUBPARTITION_EXPRESSION		MySQL extension
PARTITION_DESCRIPTION		MySQL extension
TABLE_ROWS		MySQL extension
AVG_ROW_LENGTH		MySQL extension
DATA_LENGTH		MySQL extension
MAX_DATA_LENGTH		MySQL extension
INDEX_LENGTH		MySQL extension
DATA_FREE		MySQL extension
CREATE_TIME		MySQL extension
UPDATE_TIME		MySQL extension
CHECK_TIME		MySQL extension
CHECKSUM		MySQL extension
PARTITION_COMMENT		MySQL extension
NODEGROUP		MySQL extension
TABLESPACE_NAME		MySQL extension

**Notes:**

- The `PARTITIONS` table is a nonstandard table. It was added in MySQL 5.1.6.

Each record in this table corresponds to an individual partition or subpartition of a partitioned table.

- `TABLE_CATALOG`: This column is always `NULL`.
- `TABLE_SCHEMA`: This column contains the name of the database to which the table belongs.
- `TABLE_NAME`: This column contains the name of the table containing the partition.
- `PARTITION_NAME`: The name of the partition.

- **SUBPARTITION\_NAME**: If the `PARTITIONS` table record represents a subpartition, then this column contains the name of subpartition; otherwise it is `NULL`.
- **PARTITION\_ORDINAL\_POSITION**: All partitions are indexed in the same order as they are defined, with `1` being the number assigned to the first partition. The indexing can change as partitions are added, dropped, and reorganized; the number shown in this column reflects the current order, taking into account any indexing changes.
- **SUBPARTITION\_ORDINAL\_POSITION**: Subpartitions within a given partition are also indexed and reindexed in the same manner as partitions are indexed within a table.
- **PARTITION\_METHOD**: One of the values `RANGE`, `LIST`, `HASH`, `LINEAR HASH`, `KEY`, or `LINEAR KEY`; that is, one of the available partitioning types as discussed in [Section 18.2, “Partition Types”](#).
- **SUBPARTITION\_METHOD**: One of the values `HASH`, `LINEAR HASH`, `KEY`, or `LINEAR KEY`; that is, one of the available subpartitioning types as discussed in [Section 18.2.5, “Subpartitioning”](#).
- **PARTITION\_EXPRESSION**: This is the expression for the partitioning function used in the `CREATE TABLE` or `ALTER TABLE` statement that created the table's current partitioning scheme.

For example, consider a partitioned table created in the `test` database using this statement:

```
CREATE TABLE tp (
 c1 INT,
 c2 INT,
 c3 VARCHAR(25)
)
PARTITION BY HASH(c1 + c2)
PARTITIONS 4;
```

The `PARTITION_EXPRESSION` column in a `PARTITIONS` table record for a partition from this table displays `c1 + c2`, as shown here:

```
mysql> SELECT DISTINCT PARTITION_EXPRESSION
 > FROM INFORMATION_SCHEMA.PARTITIONS
 > WHERE TABLE_NAME='tp' AND TABLE_SCHEMA='test';
+-----+
| PARTITION_EXPRESSION |
+-----+
| c1 + c2 |
+-----+
1 row in set (0.09 sec)
```

- **SUBPARTITION\_EXPRESSION**: This works in the same fashion for the subpartitioning expression that defines the subpartitioning for a table as `PARTITION_EXPRESSION` does for the partitioning expression used to define a table's partitioning.

If the table has no subpartitions, then this column is `NULL`.

- **PARTITION\_DESCRIPTION**: This column is used for `RANGE` and `LIST` partitions. For a `RANGE` partition, it contains the value set in the partition's `VALUES LESS THAN` clause, which can be either an integer or `MAXVALUE`. For a `LIST` partition, this column contains the values defined in the partition's `VALUES IN` clause, which is a comma-separated list of integer values.

For partitions whose `PARTITION_METHOD` is other than `RANGE` or `LIST`, this column is always `NULL`.

- **TABLE\_ROWS**: The number of table rows in the partition.

For partitioned `InnoDB` tables, the row count given in the `TABLE_ROWS` column is only an estimated value used in SQL optimization, and may not always be exact.

For partitions of `NDB` tables, whether the tables use implicit or explicit partitioning, the `TABLE_ROWS` column value is always 0. However, you can obtain this information using the `ndb_desc` utility.

- **AVG\_ROW\_LENGTH**: The average length of the rows stored in this partition or subpartition, in bytes.

This is the same as `DATA_LENGTH` divided by `TABLE_ROWS`.

For partitions of `NDB` tables, whether the tables use implicit or explicit partitioning, the `AVG_ROW_LENGTH` column value is always 0. However, you can obtain equivalent information using the `ndb_desc` utility.

- **DATA\_LENGTH**: The total length of all rows stored in this partition or subpartition, in bytes—that is, the total number of bytes stored in the partition or subpartition.

For partitions of `NDB` tables, whether the tables use implicit or explicit partitioning, the `DATA_LENGTH` column value is always 0. However, you can obtain equivalent information using the `ndb_desc` utility.

- **MAX\_DATA\_LENGTH**: The maximum number of bytes that can be stored in this partition or subpartition.

For partitions of **NDB** tables, whether the tables use implicit or explicit partitioning, the **MAX\_DATA\_LENGTH** column value is always **NULL**. However, you can obtain equivalent information using the **ndb\_desc** utility.

- **INDEX\_LENGTH**: The length of the index file for this partition or subpartition, in bytes.

For partitions of **NDB** tables, whether the tables use implicit or explicit partitioning, the **INDEX\_LENGTH** column value is always 0. However, you can obtain equivalent information using the **ndb\_desc** utility.

- **DATA\_FREE**: The number of bytes allocated to the partition or subpartition but not used.

For partitions of **NDB** tables, whether the tables use implicit or explicit partitioning, the **DATA\_FREE** column value is always 0. However, you can obtain equivalent information using the **ndb\_desc** utility.

- **CREATE\_TIME**: The time of the partition's or subpartition's creation.
- **UPDATE\_TIME**: The time that the partition or subpartition was last modified.
- **CHECK\_TIME**: The last time that the table to which this partition or subpartition belongs was checked.

### Note

Some storage engines do not update this time; for tables using these storage engines, this value is always **NULL**.

- **CHECKSUM**: The checksum value, if any; otherwise, this column is **NULL**.
- **PARTITION\_COMMENT**: This column contains the text of any comment made for the partition.

The default value for this column is an empty string.
- **NODEGROUP**: This is the nodegroup to which the partition belongs. This is relevant only to MySQL Cluster tables; otherwise the value of this column is always **0**.
- **TABLESPACE\_NAME**: This column contains the name of the tablespace to which the partition belongs. Currently, the value of this column is always **DEFAULT**.

### Important

If any partitioned tables created in a MySQL version prior to MySQL 5.1.6 are present following an upgrade to MySQL 5.1.6 or later, it is not possible to **SELECT** from, **SHOW**, or **DESCRIBE** the **PARTITIONS** table. See [Section C.1.51, “Changes in MySQL 5.1.6 \(01 February 2006\)”](#) before upgrading from MySQL 5.1.5 or earlier to MySQL 5.1.6 or later.

- A nonpartitioned table has one record in **INFORMATION\_SCHEMA.PARTITIONS**; however, the values of the **PARTITION\_NAME**, **SUBPARTITION\_NAME**, **PARTITION\_ORDINAL\_POSITION**, **SUBPARTITION\_ORDINAL\_POSITION**, **PARTITION\_METHOD**, **SUBPARTITION\_METHOD**, **PARTITION\_EXPRESSION**, **SUBPARTITION\_EXPRESSION**, and **PARTITION\_DESCRIPTION** columns are all **NULL**. (The **PARTITION\_COMMENT** column in this case is blank.)

In MySQL 5.1, there is also only one record in the **PARTITIONS** table for a table using the **NDBCLUSTER** storage engine. The same columns are also **NULL** (or empty) as for a nonpartitioned table.

## 20.20. The INFORMATION\_SCHEMA EVENTS Table

The **EVENTS** table provides information about scheduled events, which are discussed in [Section 19.4, “Using the Event Scheduler”](#). The **SHOW Name** values correspond to column names of the **SHOW EVENTS** statement.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
EVENT_CATALOG		<b>NULL</b> , MySQL extension
EVENT_SCHEMA	Db	MySQL extension
EVENT_NAME	Name	MySQL extension
DEFINER	Definer	MySQL extension
TIME_ZONE	Time zone	MySQL extension
EVENT_BODY		MySQL extension
EVENT_DEFINITION		MySQL extension

EVENT_TYPE	Type	MySQL extension
EXECUTE_AT	Execute at	MySQL extension
INTERVAL_VALUE	Interval value	MySQL extension
INTERVAL_FIELD	Interval field	MySQL extension
SQL_MODE		MySQL extension
STARTS	Starts	MySQL extension
ENDS	Ends	MySQL extension
STATUS	Status	MySQL extension
ON_COMPLETION		MySQL extension
CREATED		MySQL extension
LAST_ALTERED		MySQL extension
LAST_EXECUTED		MySQL extension
EVENT_COMMENT		MySQL extension
ORIGINATOR	Originator	MySQL extension
CHARACTER_SET_CLIENT	character_set_client	MySQL extension
COLLATION_CONNECTION	collation_connection	MySQL extension
DATABASE_COLLATION	Database Collation	MySQL extension

**Notes:**

- The `EVENTS` table is a nonstandard table. It was added in MySQL 5.1.6.
- `EVENT_CATALOG`: The value of this column is always `NULL`.
- `EVENT_SCHEMA`: The name of the schema (database) to which this event belongs.
- `EVENT_NAME`: The name of the event.
- `DEFINER`: The account of the user who created the event, in '`user_name`'@'`host_name`' format.
- `TIME_ZONE`: The event time zone, which is the time zone used for scheduling the event and that is in effect within the event as it executes. The default value is `SYSTEM`.

This column was added in MySQL 5.1.17. See [Section C.1.40, “Changes in MySQL 5.1.17 \(04 April 2007\)](#), for important information if you are using the Event Scheduler and are upgrading to MySQL 5.1.17 or later from an earlier version.

- `EVENT_BODY`: The language used for the statements in the event's `DO` clause; in MySQL 5.1, this is always `SQL`.

This column was added in MySQL 5.1.12. It is not to be confused with the column of the same name (now named `EVENT_DEFINITION`) that existed in earlier MySQL versions.

- `EVENT_DEFINITION`: The text of the SQL statement making up the event's `DO` clause; in other words, the statement executed by this event.

**Note**

Prior to MySQL 5.1.12, this column was named `EVENT_BODY`.

- `EVENT_TYPE`: The event repetition type, either `ONE TIME` (transient) or `RECURRING` (repeating).
- `EXECUTE_AT`: For a one-time event, this is the `DATETIME` value specified in the `AT` clause of the `CREATE EVENT` statement used to create the event, or of the last `ALTER EVENT` statement that modified the event. The value shown in this column reflects the addition or subtraction of any `INTERVAL` value included in the event's `AT` clause. For example, if an event is created using `ON SCHEDULE AT CURRENT_TIMESTAMP + '1:6' DAY_HOUR`, and the event was created at 2006-02-09 14:05:30, the value shown in this column would be '2006-02-10 20:05:30'.

If the event's timing is determined by an `EVERY` clause instead of an `AT` clause (that is, if the event is recurring), the value of this column is `NULL`.

- `INTERVAL_VALUE`: For recurring events, this column contains the numeric portion of the event's `EVERY` clause.

For a one-time event (that is, an event whose timing is determined by an `AT` clause), this column is `NULL`.

- **INTERVAL\_FIELD:** For recurring events, this column contains the units portion of the `EVERY` clause governing the timing of the event. Thus, this column contains a value such as '`YEAR`', '`QUARTER`', '`DAY`', and so on.

### Note

In early MySQL 5.1 releases, this value was prefixed with '`INTERVAL_`', and was displayed as '`INTERVAL_YEAR`', '`INTERVAL_QUARTER`', '`INTERVAL_DAY`', and so on.

For a one-time event (that is, an event whose timing is determined by an `AT` clause), this column is `NULL`.

- **SQL\_MODE:** The SQL mode in effect at the time the event was created or altered.
- **STARTS:** For a recurring event whose definition includes a `STARTS` clause, this column contains the corresponding `DATETIME` value. As with the `EXECUTE_AT` column, this value resolves any expressions used.

If there is no `STARTS` clause affecting the timing of the event, this column is `NULL`. (Prior to MySQL 5.1.8, it contained `0000-00-00 00:00:00` in such cases.)

- **ENDS:** For a recurring event whose definition includes a `ENDS` clause, this column contains the corresponding `DATETIME` value. As with the `EXECUTE_AT` column, this value resolves any expressions used.

If there is no `ENDS` clause affecting the timing of the event, this column is `NULL`.

- **STATUS:** One of the three values `ENABLED`, `DISABLED`, or `SLAVESIDE_DISABLED`.

`SLAVESIDE_DISABLED` was added to the list of possible values for this column in MySQL 5.1.18. This value indicates that the creation of the event occurred on another MySQL server acting as a replication master and was replicated to the current MySQL server which is acting as a slave, but the event is not presently being executed on the slave. See [Section 16.4.1.9, “Replication of Invoked Features”](#), for more information.

- **ON\_COMPLETION:** One of the two values `PRESERVE` or `NOT PRESERVE`.
- **CREATED:** The date and time when the event was created. This is a `DATETIME` value.
- **LAST\_ALTERED:** The date and time when the event was last modified. This is a `DATETIME` value. If the event has not been modified since its creation, this column holds the same value as the `CREATED` column.
- **LAST\_EXECUTED:** The date and time when the event last executed. A `DATETIME` value. If the event has never executed, this column is `NULL`.

Before MySQL 5.1.23, `LAST_EXECUTED` indicates when event finished executing. As of 5.1.23, `LAST_EXECUTED` instead indicates when the event started. As a result, the `ENDS` column is never less than `LAST_EXECUTED`.

- **EVENT\_COMMENT:** The text of a comment, if the event has one. If not, the value of this column is an empty string.
- **ORIGINATOR:** The server ID of the MySQL server on which the event was created; used in replication. The default value is 0. This column was added in MySQL 5.1.18.
- **CHARACTER\_SET\_CLIENT** is the session value of the `character_set_client` system variable when the event was created. `COLLATION_CONNECTION` is the session value of the `collation_connection` system variable when the event was created. `DATABASE_COLLATION` is the collation of the database with which the event is associated. These columns were added in MySQL 5.1.21.

**Example:** Suppose the user `jon@ghidora` creates an event named `e_daily`, and then modifies it a few minutes later using an `ALTER EVENT` statement, as shown here:

```
DELIMITER |
CREATE EVENT e_daily
 ON SCHEDULE
 EVERY 1 DAY
 COMMENT 'Saves total number of sessions then clears the table each day'
 DO
 BEGIN
 INSERT INTO site_activity.totals (time, total)
 SELECT CURRENT_TIMESTAMP, COUNT(*)
 FROM site_activity.sessions;
 DELETE FROM site_activity.sessions;
 END |
DELIMITER ;
```

```
ALTER EVENT e_daily
ENABLED;
```

(Note that comments can span multiple lines.)

This user can then run the following `SELECT` statement, and obtain the output shown:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.EVENTS
 > WHERE EVENT_NAME = 'e_daily'
 > AND EVENT_SCHEMA = 'myschema'\G
***** 1. row *****
EVENT_CATALOG: NULL
EVENT_SCHEMA: test
EVENT_NAME: e_daily
DEFINER: paul@localhost
TIME_ZONE: SYSTEM
EVENT_BODY: SQL
EVENT_DEFINITION: BEGIN
 INSERT INTO site_activity.totals (time, total)
 SELECT CURRENT_TIMESTAMP, COUNT(*)
 FROM site_activity.sessions;
 DELETE FROM site_activity.sessions;
END
EVENT_TYPE: RECURRING
EXECUTE_AT: NULL
INTERVAL_VALUE: 1
INTERVAL_FIELD: DAY
SQL_MODE:
 STARTS: 2008-09-03 12:13:39
 ENDS: NULL
 STATUS: ENABLED
ON_COMPLETION: NOT PRESERVE
 CREATED: 2008-09-03 12:13:39
 LAST_ALTERED: 2008-09-03 12:13:39
 LAST_EXECUTED: NULL
EVENT_COMMENT: Saves total number of sessions then clears the
table each day
ORIGINATOR: 1
CHARACTER_SET_CLIENT: latin1
COLLATION_CONNECTION: latin1_swedish_ci
DATABASE_COLLATION: latin1_swedish_ci
```

Times in the `EVENTS` table are displayed using the event time zone or the current session time zone. Prior to MySQL 5.1.17, some of the times are displayed in UTC rather than the event time zone. For details, see [Section 19.4.4, “Event Metadata”](#).

See also [Section 12.4.5.19, “SHOW EVENTS Syntax”](#).

## 20.21. The INFORMATION\_SCHEMA FILES Table

The `FILES` table provides information about the files in which MySQL NDB Disk Data tables are stored.

### Note

This table provides information about Disk Data *files* only; you cannot use it for determining disk space allocation or availability for individual `NDB` tables. However, beginning with MySQL Cluster NDB 6.3.27 and MySQL Cluster NDB 7.0.8, it is possible to see how much space is allocated for each `NDB` table having data stored on disk, as well as how much remains available for storage of data on disk for that table, using `ndb_desc`. For more information, see [Section 17.4.9, “ndb\\_desc — Describe NDB Tables”](#).

INFORMATION_SCHEMA Name	SHOW Name	Remarks

EXTRA		MySQL extension

**Notes:**

- **FILE\_ID** column values are auto-generated.
- **FILE\_NAME** is the name of an **UNDO** log file created by **CREATE LOGFILE GROUP** or **ALTER LOGFILE GROUP**, or of a data file created by **CREATE TABLESPACE** or **ALTER TABLESPACE**.
- **FILE\_TYPE** is one of the values **UNDOFILE** or **DATAFILE**.

Beginning with MySQL Cluster NDB 6.2.19, MySQL Cluster NDB 6.3.32, MySQL Cluster NDB 7.0.13, and MySQL Cluster NDB 7.1.2, this column can also have the value **TABLESPACE**.

- **TABLESPACE\_NAME** is the name of the tablespace with which the file is associated.
- Currently, the value of the **TABLESPACE\_CATALOG** column is always **NULL**.
- **TABLE\_NAME** is the name of the Disk Data table with which the file is associated, if any.
- The **LOGFILE\_GROUP\_NAME** column gives the name of the log file group to which the log file or data file belongs.
- For an **UNDO** log file, the **LOGFILE\_GROUP\_NUMBER** contains the auto-generated ID number of the log file group to which the log file belongs.
- For a MySQL Cluster Disk Data log file or data file, the value of the **ENGINE** column is always **NDB** or **NDBCLUSTER**.
- For a MySQL Cluster Disk Data log file or data file, the value of the **FULLTEXT\_KEYS** column is always empty.
- The **FREE\_EXTENTS** column displays the number of extents which have not yet been used by the file. The **TOTAL\_EXTENTS** column show the total number of extents allocated to the file.

The difference between these two columns is the number of extents currently in use by the file:

```
SELECT TOTAL_EXTENTS - FREE_EXTENTS AS extents_used
 FROM INFORMATION_SCHEMA.FILES
 WHERE FILE_NAME = 'myfile.dat';
```

You can approximate the amount of disk space in use by the file by multiplying this difference by the value of the `EXTENT_SIZE` column, which gives the size of an extent for the file in bytes:

```
SELECT (TOTAL_EXTENTS - FREE_EXTENTS) * EXTENT_SIZE AS bytes_used
 FROM INFORMATION_SCHEMA.FILES
 WHERE FILE_NAME = 'myfile.dat';
```

Similarly, you can estimate the amount of space that remains available in a given file by multiplying `FREE_EXTENTS` by `EXTENT_SIZE`:

```
SELECT FREE_EXTENTS * EXTENT_SIZE AS bytes_free
 FROM INFORMATION_SCHEMA.FILES
 WHERE FILE_NAME = 'myfile.dat';
```

### Important

The byte values produced by the preceding queries are approximations only, and their precision is inversely proportional to the value of `EXTENT_SIZE`. That is, the larger `EXTENT_SIZE` becomes, the less accurate the approximations are.

It is also important to remember that once an extent is used, it cannot be freed again without dropping the data file of which it is a part. This means that deletes from a Disk Data table do *not* release disk space.

The extent size can be set in a `CREATE TABLESPACE` statement. See [Section 12.1.18, “CREATE TABLESPACE Syntax”](#), for more information.

- The `INITIAL_SIZE` column shows the size in bytes of the file. This is the same value that was used in the `INITIAL_SIZE` clause of the `CREATE LOGFILE GROUP`, `ALTER LOGFILE GROUP`, `CREATE TABLESPACE`, or `ALTER TABLESPACE` statement used to create the file.

For MySQL Cluster Disk Data files, the value of the `MAXIMUM_SIZE` column is always the same as `INITIAL_SIZE`, and the `AUTOEXTEND_SIZE` column is always empty.

- The `CREATION_TIME` column shows the date and time when the file was created. The `LAST_UPDATE_TIME` column displays the date and time when the file was last modified. The `LAST_ACCESSED` column provides the date and time when the file was last accessed by the server.

Currently, the values of these columns are as reported by the operating system, and are not supplied by the NDB storage engine. Where no value is provided by the operating system, these columns display `0000-00-00 00:00:00`.

- For MySQL Cluster Disk Data files, the value of the `RECOVER_TIME` and `TRANSACTION_COUNTER` columns is always `0`.
- For MySQL Cluster Disk Data files, the following columns are always `NULL`:

- `VERSION`
- `ROW_FORMAT`
- `TABLE_ROWS`
- `AVG_ROW_LENGTH`
- `DATA_LENGTH`
- `MAX_DATA_LENGTH`
- `INDEX_LENGTH`
- `DATA_FREE`
- `CREATE_TIME`
- `UPDATE_TIME`
- `CHECK_TIME`

- [CHECKSUM](#)
- For MySQL Cluster Disk Data files, the value of the [STATUS](#) column is always [NORMAL](#).
- For MySQL Cluster Disk Data files, the [EXTRA](#) column shows which data node the file belongs to, as each data node has its own copy of the file. Suppose that you use this statement on a MySQL Cluster with four data nodes:

```
CREATE LOGFILE GROUP mygroup
 ADD UNDOFILE 'new_undo.dat'
 INITIAL_SIZE 2G
 ENGINE NDB;
```

After running the `CREATE LOGFILE GROUP` statement successfully, you should see a result similar to the one shown here for this query against the `FILES` table:

```
mysql> SELECT LOGFILE_GROUP_NAME, FILE_TYPE, EXTRA
-> FROM INFORMATION_SCHEMA.FILES
-> WHERE FILE_NAME = 'new_undo.dat';
+-----+-----+-----+
| LOGFILE_GROUP_NAME | FILE_TYPE | EXTRA |
+-----+-----+-----+
| mygroup | UNDO FILE | CLUSTER_NODE=3 |
| mygroup | UNDO FILE | CLUSTER_NODE=4 |
| mygroup | UNDO FILE | CLUSTER_NODE=5 |
| mygroup | UNDO FILE | CLUSTER_NODE=6 |
+-----+-----+-----+
4 rows in set (0.01 sec)
```

- The `FILES` table is a nonstandard table. It was added in MySQL 5.1.6.
- Beginning with MySQL 5.1.14, an additional row is present in the `FILES` table following the creation of a log file group. This row has `NULL` for the value of the `FILE_NAME` column. For this row, the value of the `FILE_ID` column is always `0`, that of the `FILE_TYPE` column is always `UNDO FILE`, and that of the `STATUS` column is always `NORMAL`. Currently, the value of the `ENGINE` column is always `NDBCLUSTER`.

The `FREE_EXTENTS` column in this row shows the total number of free extents available to all undo files belonging to a given log file group whose name and number are shown in the `LOGFILE_GROUP_NAME` and `LOGFILE_GROUP_NUMBER` columns, respectively.

Suppose there are no existing log file groups on your MySQL Cluster, and you create one using the following statement:

```
mysql> CREATE LOGFILE GROUP lg1
-> ADD UNDOFILE 'undofile.dat'
-> INITIAL_SIZE = 16M
-> UNDO_BUFFER_SIZE = 1M
-> ENGINE = NDB;
Query OK, 0 rows affected (3.81 sec)
```

You can now see this `NULL` row when you query the `FILES` table:

```
mysql> SELECT DISTINCT
-> FILE_NAME AS File,
-> FREE_EXTENTS AS Free,
-> TOTAL_EXTENTS AS Total,
-> EXTENT_SIZE AS size,
-> INITIAL_SIZE AS Initial
-> FROM INFORMATION_SCHEMA.FILES;
+-----+-----+-----+-----+-----+
| File | Free | Total | Size | Initial |
+-----+-----+-----+-----+-----+
| undofile.dat | NULL | 4194304 | 4 | 16777216 |
| NULL | 4184068 | NULL | 4 | NULL |
+-----+-----+-----+-----+-----+
2 rows in set (0.01 sec)
```

The total number of free extents available for undo logging is always somewhat less than the sum of the `TOTAL_EXTENTS` column values for all undo files in the log file group due to overhead required for maintaining the undo files. This can be seen by adding a second undo file to the log file group, then repeating the previous query against the `FILES` table:

```
mysql> ALTER LOGFILE GROUP lg1
-> ADD UNDOFILE 'undofile02.dat'
-> INITIAL_SIZE = 4M
-> ENGINE = NDB;
Query OK, 0 rows affected (1.02 sec)

mysql> SELECT DISTINCT
-> FILE_NAME AS File,
-> FREE_EXTENTS AS Free,
-> TOTAL_EXTENTS AS Total,
-> EXTENT_SIZE AS size,
```

```

-> INITIAL_SIZE AS Initial
-> FROM INFORMATION_SCHEMA.FILES;
+-----+-----+-----+-----+-----+
| File | Free | Total | Size | Initial |
+-----+-----+-----+-----+-----+
| undofile.dat | NULL | 4194304 | 4 | 16777216 |
| undofile02.dat | NULL | 1048576 | 4 | 4194304 |
| NULL | 5223944 | NULL | 4 | NULL |
+-----+-----+-----+-----+-----+
3 rows in set (0.01 sec)

```

The amount of free space in bytes which is available for undo logging by Disk Data tables using this log file group can be approximated by multiplying the number of free extents by the initial size:

```

mysql> SELECT
-> FREE_EXTENTS AS 'Free Extents',
-> FREE_EXTENTS * EXTENT_SIZE AS 'Free Bytes'
-> FROM INFORMATION_SCHEMA.FILES
-> WHERE LOGFILE_GROUP_NAME = 'lg1'
-> AND FILE_NAME IS NULL;
+-----+-----+
| Free Extents | Free Bytes |
+-----+-----+
| 5223944 | 20895776 |
+-----+-----+
1 row in set (0.02 sec)

```

If you create a MySQL Cluster Disk Data table and then insert some rows into it, you can see approximately how much space remains for undo logging afterward, for example:

```

mysql> CREATE TABLESPACE ts1
-> ADD DATAFILE 'data1.dat'
-> USE LOGFILE GROUP lg1
-> INITIAL_SIZE 512M
-> ENGINE = NDB;
Query OK, 0 rows affected (8.71 sec)

mysql> CREATE TABLE dd (
-> c1 INT NOT NULL PRIMARY KEY,
-> c2 INT,
-> c3 DATE
->)
-> TABLESPACE ts1 STORAGE DISK
-> ENGINE = NDB;
Query OK, 0 rows affected (2.11 sec)

mysql> INSERT INTO dd VALUES
-> (NULL, 1234567890, '2007-02-02'),
-> (NULL, 1126789005, '2007-02-03'),
-> (NULL, 1357924680, '2007-02-04'),
-> (NULL, 1642097531, '2007-02-05');
Query OK, 4 rows affected (0.01 sec)

mysql> SELECT
-> FREE_EXTENTS AS 'Free Extents',
-> FREE_EXTENTS * EXTENT_SIZE AS 'Free Bytes'
-> FROM INFORMATION_SCHEMA.FILES
-> WHERE LOGFILE_GROUP_NAME = 'lg1'
-> AND FILE_NAME IS NULL;
+-----+-----+
| Free Extents | Free Bytes |
+-----+-----+
| 5207565 | 20830260 |
+-----+-----+
1 row in set (0.01 sec)

```

- Beginning with MySQL Cluster NDB 6.2.19, MySQL Cluster NDB 6.3.32, MySQL Cluster NDB 7.0.13, and MySQL Cluster NDB 7.1.2, an additional row is present in the `FILES` table for any tablespace, whether or not any data files are associated with the tablespace. This row has `NULL` for the value of the `FILE_NAME` column. For this row, the value of the `FILE_ID` column is always `0`, that of the `FILE_TYPE` column is always `TABLESPACE`, and that of the `STATUS` column is always `NORMAL`. Currently, the value of the `ENGINE` column is always `NDBCLUSTER`.
- There are no `SHOW` statements associated with the `FILES` table.
- For additional information, and examples of creating and dropping MySQL Cluster Disk Data objects, see [Section 17.5.10, “MySQL Cluster Disk Data Tables”](#).

## 20.22. The INFORMATION\_SCHEMA PROCESSLIST Table

The `PROCESSLIST` table provides information about which threads are running.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
-------------------------	-----------	---------

ID	<code>Id</code>	MySQL extension
USER	<code>User</code>	MySQL extension
HOST	<code>Host</code>	MySQL extension
DB	<code>db</code>	MySQL extension
COMMAND	<code>Command</code>	MySQL extension
TIME	<code>Time</code>	MySQL extension
STATE	<code>State</code>	MySQL extension
INFO	<code>Info</code>	MySQL extension

For an extensive description of the table columns, see [Section 12.4.5.31, “SHOW PROCESSLIST Syntax”](#).

**Notes:**

- The `PROCESSLIST` table is a nonstandard table. It was added in MySQL 5.1.7.
- Like the output from the corresponding `SHOW` statement, the `PROCESSLIST` table will only show information about your own threads, unless you have the `PROCESS` privilege, in which case you will see information about other threads, too. As an anonymous user, you cannot see any rows at all.
- If an SQL statement refers to `INFORMATION_SCHEMA.PROCESSLIST`, then MySQL will populate the entire table once, when statement execution begins, so there is read consistency during the statement. There is no read consistency for a multi-statement transaction, though.

The following statements are equivalent:

```
SELECT * FROM INFORMATION_SCHEMA.PROCESSLIST
SHOW FULL PROCESSLIST
```

## 20.23. The INFORMATION\_SCHEMA REFERENTIAL\_CONSTRAINTS Table

The `REFERENTIAL_CONSTRAINTS` table provides information about foreign keys.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
CONSTRAINT_CATALOG		NULL
CONSTRAINT_SCHEMA		
CONSTRAINT_NAME		
UNIQUE_CONSTRAINT_CATALOG		NULL
UNIQUE_CONSTRAINT_SCHEMA		
UNIQUE_CONSTRAINT_NAME		
MATCH_OPTION		
UPDATE_RULE		
DELETE_RULE		
TABLE_NAME		
REFERENCED_TABLE_NAME		

**Notes:**

- The `REFERENTIAL_CONSTRAINTS` table was added in MySQL 5.1.10. The `REFERENCED_TABLE_NAME` column was added in MySQL 5.1.16.
- `TABLE_NAME` has the same value as `TABLE_NAME` in `INFORMATION_SCHEMA.TABLE_CONSTRAINTS`.
- `CONSTRAINT_SCHEMA` and `CONSTRAINT_NAME` identify the foreign key.

- `UNIQUE_CONSTRAINT_SCHEMA`, `UNIQUE_CONSTRAINT_NAME`, and `REFERENCED_TABLE_NAME` identify the referenced key. (Note: Before MySQL 5.1.16, `UNIQUE_CONSTRAINT_NAME` incorrectly named the referenced table, not the constraint.)
- The only valid value at this time for `MATCH_OPTION` is `NONE`.
- The possible values for `UPDATE_RULE` or `DELETE_RULE` are `CASCADE`, `SET NULL`, `SET DEFAULT`, `RESTRICT`, `NO ACTION`.

## 20.24. The INFORMATION\_SCHEMA GLOBAL\_STATUS and SESSION\_STATUS Tables

The `GLOBAL_STATUS` and `SESSION_STATUS` tables provide information about server status variables. Their contents correspond to the information produced by the `SHOW GLOBAL STATUS` and `SHOW SESSION STATUS` statements (see [Section 12.4.5.37, “SHOW STATUS Syntax”](#)).

INFORMATION_SCHEMA Name	SHOW Name	Remarks
<code>VARIABLE_NAME</code>	<code>Variable_name</code>	
<code>VARIABLE_VALUE</code>	<code>Value</code>	

Notes:

- The `GLOBAL_STATUS` and `SESSION_STATUS` tables were added in MySQL 5.1.12.
- Beginning with MySQL 5.1.19, the `VARIABLE_VALUE` column for each of these tables is defined as `VARCHAR(20480)`. Previously, this column had the data type `DECIMAL(22,7)`, but was changed to avoid loss of data when working with status variables whose values were strings ([Bug#26994](#)).

## 20.25. The INFORMATION\_SCHEMA GLOBAL\_VARIABLES and SESSION\_VARIABLES Tables

The `GLOBAL_VARIABLES` and `SESSION_VARIABLES` tables provide information about server status variables. Their contents correspond to the information produced by the `SHOW GLOBAL VARIABLES` and `SHOW SESSION VARIABLES` statements (see [Section 12.4.5.41, “SHOW VARIABLES Syntax”](#)).

INFORMATION_SCHEMA Name	SHOW Name	Remarks
<code>VARIABLE_NAME</code>	<code>Variable_name</code>	
<code>VARIABLE_VALUE</code>	<code>Value</code>	

Notes:

- The `GLOBAL_VARIABLES` and `SESSION_VARIABLES` tables were added in MySQL 5.1.12.
- Beginning with MySQL 5.1.19, the `VARIABLE_VALUE` column for each of these tables is defined as `VARCHAR(20480)`. Previously, this column had the data type `LONGTEXT`; this was changed to make these tables consistent with the `GLOBAL_STATUS` and `SESSION_STATUS` tables, whose definitions had been changed in that version (see [Section 20.24, “The INFORMATION\\_SCHEMA GLOBAL\\_STATUS and SESSION\\_STATUS Tables”](#)).

## 20.26. The INFORMATION\_SCHEMA PROFILING Table

The `PROFILING` table provides statement profiling information. Its contents correspond to the information produced by the `SHOW PROFILES` and `SHOW PROFILE` statements (see [Section 12.4.5.33, “SHOW PROFILES Syntax”](#)). The table is empty unless the `profiling` session variable is set to 1.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
<code>QUERY_ID</code>	<code>Query_ID</code>	

SEQ	
STATE	Status
DURATION	Duration
CPU_USER	CPU_user
CPU_SYSTEM	CPU_system
CONTEXT_VOLUNTARY	Context_voluntary
CONTEXT_INVOLUNTARY	Context_involuntary
BLOCK_OPS_IN	Block_ops_in
BLOCK_OPS_OUT	Block_ops_out
MESSAGES_SENT	Messages_sent
MESSAGES RECEIVED	Messages_received
PAGE_FAULTS_MAJOR	Page_faults_major
PAGE_FAULTS_MINOR	Page_faults_minor
SWAPS	Swaps
SOURCE_FUNCTION	Source_function
SOURCE_FILE	Source_file
SOURCE_LINE	Source_line

**Notes:**

- The `PROFILING` table was added in MySQL 5.1.24 but contains no information unless the `SHOW PROFILE` feature is enabled. The `SHOW PROFILE` feature is not included in binary distributions by default until MySQL 5.1.28.
- `QUERY_ID` is a numeric statement identifier.
- `SEQ` is a sequence number indicating the display order for rows with the same `QUERY_ID` value.
- `STATE` is the profiling state to which the row measurements apply.
- `DURATION` indicates how long statement execution remained in the given state, in seconds.
- `CPU_USER` and `CPU_SYSTEM` indicate user and system CPU use, in seconds.
- `CONTEXT_VOLUNTARY` and `CONTEXT_INVOLUNTARY` indicate how many voluntary and involuntary context switches occurred.
- `BLOCK_OPS_IN` and `BLOCK_OPS_OUT` indicate the number of block input and output operations.
- `MESSAGES_SENT` and `MESSAGES_RECEIVED` indicate the number of communication messages sent and received.
- `PAGE_FAULTS_MAJOR` and `PAGE_FAULTS_MINOR` indicate the number of major and minor page faults.
- `SWAPS` indicates how many swaps occurred.
- `SOURCE_FUNCTION`, `SOURCE_FILE`, and `SOURCE_LINE` provide information indicating where in the source code the profiled state executes.

## 20.27. Other INFORMATION\_SCHEMA Tables

We intend to implement additional `INFORMATION_SCHEMA` tables. In particular, we acknowledge the need for the `PARAMETERS` table. (`PARAMETERS` is implemented in MySQL 5.5.)

## 20.28. Extensions to SHOW Statements

Some extensions to `SHOW` statements accompany the implementation of `INFORMATION_SCHEMA`:

- `SHOW` can be used to get information about the structure of `INFORMATION_SCHEMA` itself.

- Several `SHOW` statements accept a `WHERE` clause that provides more flexibility in specifying which rows to display.

`INFORMATION_SCHEMA` is an information database, so its name is included in the output from `SHOW DATABASES`. Similarly, `SHOW TABLES` can be used with `INFORMATION_SCHEMA` to obtain a list of its tables:

```
mysql> SHOW TABLES FROM INFORMATION_SCHEMA;
+-----+
| Tables_in_INFORMATION_SCHEMA |
+-----+
| CHARACTER_SETS
 COLLATIONS
 COLLATION_CHARACTER_SET_APPLICABILITY
 COLUMNS
 COLUMN_PRIVILEGES
 ENGINES
 EVENTS
 FILES
 GLOBAL_STATUS
 GLOBAL_VARIABLES
 KEY_COLUMN_USAGE
 PARTITIONS
 PLUGINS
 PROCESSLIST
 REFERENTIAL_CONSTRAINTS
 ROUTINES
 SCHEMATA
 SCHEMA_PRIVILEGES
 SESSION_STATUS
 SESSION_VARIABLES
 STATISTICS
 TABLES
 TABLE_CONSTRAINTS
 TABLE_PRIVILEGES
 TRIGGERS
 USER_PRIVILEGES
 VIEWS
+-----+
27 rows in set (0.00 sec)
```

`SHOW COLUMNS` and `DESCRIBE` can display information about the columns in individual `INFORMATION_SCHEMA` tables.

`SHOW` statements that accept a `LIKE` clause to limit the rows displayed also permit a `WHERE` clause that specifies more general conditions that selected rows must satisfy:

```
SHOW CHARACTER_SET
SHOW COLLATION
SHOW COLUMNS
SHOW DATABASES
SHOW FUNCTION STATUS
SHOW INDEX
SHOW OPEN_TABLES
SHOW PROCEDURE STATUS
SHOW STATUS
SHOW TABLE STATUS
SHOW TABLES
SHOW TRIGGERS
SHOW VARIABLES
```

The `WHERE` clause, if present, is evaluated against the column names displayed by the `SHOW` statement. For example, the `SHOW CHARACTER_SET` statement produces these output columns:

```
mysql> SHOW CHARACTER_SET;
+-----+-----+-----+-----+
| Charset | Description | Default collation | Maxlen |
+-----+-----+-----+-----+
| big5 | Big5 Traditional Chinese | big5_chinese_ci | 2 |
| dec8 | DEC West European | dec8_swedish_ci | 1 |
| cp850 | DOS West European | cp850_general_ci | 1 |
| hp8 | HP West European | hp8_english_ci | 1 |
| koi8r | KOI8-R Relcom Russian | koi8r_general_ci | 1 |
| latin1 | cp1252 West European | latin1_swedish_ci | 1 |
| latin2 | ISO 8859-2 Central European | latin2_general_ci | 1 |
...
```

To use a `WHERE` clause with `SHOW CHARACTER_SET`, you would refer to those column names. As an example, the following statement displays information about character sets for which the default collation contains the string '`japanese`':

```
mysql> SHOW CHARACTER_SET WHERE `Default collation` LIKE '%japanese%';
+-----+-----+-----+-----+
| Charset | Description | Default collation | Maxlen |
+-----+-----+-----+-----+
| ujis | EUC-JP Japanese | ujis_japanese_ci | 3 |
| sjis | Shift-JIS Japanese | sjis_japanese_ci | 2 |
| cp932 | SJIS for Windows Japanese | cp932_japanese_ci | 2 |
| eucjpms | UJIS for Windows Japanese | eucjpms_japanese_ci | 3 |

```

This statement displays the multi-byte character sets:

Charset	Description	Default collation	Maxlen
big5	Big5 Traditional Chinese	big5_chinese_ci	2
ujis	EUC-JP Japanese	ujis_japanese_ci	3
sjis	Shift-JIS Japanese	sjis_japanese_ci	2
euckr	EUC-KR Korean	euckr_korean_ci	2
gb2312	GB2312 Simplified Chinese	gb2312_chinese_ci	2
gbk	GBK Simplified Chinese	gbk_chinese_ci	2
utf8	UTF-8 Unicode	utf8_general_ci	3
ucs2	UCS-2 Unicode	ucs2_general_ci	2
cp932	SJIS for Windows Japanese	cp932_japanese_ci	2
eucjpms	UJIS for Windows Japanese	eucjpms_japanese_ci	3

---

# Chapter 21. Connectors and APIs

MySQL Connectors provide connectivity to the MySQL server for client programs. APIs provide low-level access to the MySQL protocol and MySQL resources. Both Connectors and the APIs enable you to connect and execute MySQL statements from another language or environment, including Java (JDBC), ODBC, Perl, Python, PHP, Ruby, and native C and embedded MySQL instances.

## Note

Connector version numbers do not correlate with MySQL Server version numbers. See also [Table 21.2, “MySQL Connector Versions and MySQL Server Versions”](#).

A number of connectors are developed by MySQL:

- Connector/ODBC provides driver support for connecting to a MySQL server using the Open Database Connectivity (ODBC) API. Support is available for ODBC connectivity from Windows, Unix and Mac OS X platforms.
- Connector/.NET enables developers to create .NET applications that use data stored in a MySQL database. Connector/.NET implements a fully functional ADO.NET interface and provides support for use with ADO.NET aware tools. Applications that want to use Connector/.NET can be written in any of the supported .NET languages.

The MySQL Visual Studio Plugin works with Connector/.NET and Visual Studio 2005. The plugin is a MySQL DDEX Provider, which means that you can use the schema and data manipulation tools within Visual Studio to create and edit objects within a MySQL database.

- Connector/J provides driver support for connecting to MySQL from a Java application using the standard Java Database Connectivity (JDBC) API.
- Connector/MXJ is a tool that enables easy deployment and management of MySQL server and database through your Java application.
- Connector/C++ is a tool that enables easy deployment and management of MySQL server and database through your C++ application.
- Connector/C is a stand-alone replacement for the MySQL Client Library ([libmysql](#)).
- Connector/OpenOffice.org is a tool that enables OpenOffice.org applications to connect to MySQL server.

There are two direct access methods for using MySQL natively within a C application:

- The C API provides low-level access to the MySQL protocol through the [libmysql](#) client library; this is the primary method used to connect to an instance of the MySQL server, and is used both by MySQL command line clients and many of the APIs also detailed in this section. MySQL Connector/C can now also be used for this purpose.
- [libmysqld](#) is an embedded MySQL server library that enables you to embed an instance of the MySQL server into your C applications.

If you need to access MySQL from a C application, or build an interface to MySQL for a language not supported by the Connectors or APIs in this chapter, the C API is where you would start. A number of programmers utilities are available to help with the process, and also covered in this section.

The remaining APIs provide an interface to MySQL from specific application languages. These solutions are not developed or supported by MySQL. Basic information on their usage and abilities is provided here for reference purposes only.

All the language APIs are developed using one of two methods, using [libmysql](#) or by building a *native driver*. The two solutions offer different benefits:

- Using [libmysql](#) offers complete compatibility with MySQL as it uses the same libraries as the MySQL client applications. However, the feature set is limited to the implementation and interfaces exposed through [libmysql](#) and the performance may be lower as data is copied between the native language, and the MySQL API components. MySQL Connector/C is a possible alternative to using [libmysql](#).
- *Native drivers* are an implementation of the MySQL network protocol entirely within the host language or environment. Native drivers are fast, as there is less copying of data between components, and they can offer advanced functionality not available through the standard MySQL API. Native drivers are also easier to build and deploy, as you do not need a copy of the MySQL client libraries to build the native driver components.

A list of many of the libraries and interfaces available for MySQL are shown in the table. See [Table 21.1, “MySQL APIs and Interfaces”](#).

**Table 21.1. MySQL APIs and Interfaces**

Environment	Type	Notes
Ada	<a href="#">MySQL Bindings for GNU Ada</a>	<a href="#">See MySQL Bindings for GNU Ada</a>
C	Connector/C	Replacement for <a href="#">libmysql</a> <a href="#">See Section 21.6, “MySQL Connector/C”.</a>

**Table 21.2. MySQL Connector Versions and MySQL Server Versions**

Connector	Connector version	MySQL Server version
Connector/C++	1.0.5 GA	5.1, 5.4, 5.5, 5.6

Connector	Connector version	MySQL Server version
Connector/OpenOffice.org	1.0 GA	5.0, 5.1, 5.4, 5.5, 5.6
Connector/J	5.1.8	4.1, 5.0, 5.1, 5.4, 5.5, 5.6
Connector/.NET	1.0 (No longer supported)	4.0, 5.0
Connector/.NET	5.2	5.0, 5.1, 5.4, 5.5, 5.6
Connector/.NET	6.0	5.0, 5.1, 5.4, 5.5, 5.6
Connector/.NET	6.1	5.0, 5.1, 5.4, 5.5, 5.6
Connector/ODBC	3.51 (Unicode not supported)	4.1, 5.0, 5.1, 5.4, 5.5, 5.6
Connector/ODBC	5.1	4.1.1+, 5.0, 5.1, 5.4, 5.5, 5.6

## 21.1. MySQL Connector/ODBC

The MySQL Connector/ODBC is the name for the family of MySQL ODBC drivers (previously called MyODBC drivers) that provide access to a MySQL database using the industry standard Open Database Connectivity (ODBC) API. This reference covers Connector/ODBC 3.51 and Connector/ODBC 5.1. Both releases provide an ODBC compliant interface to MySQL Server.

MySQL Connector/ODBC provides both driver-manager based and native interfaces to the MySQL database, which full support for MySQL functionality, including stored procedures, transactions and, with Connector/ODBC 5.1, full Unicode compliance.

For more information on the ODBC API standard and how to use it, refer to <http://support.microsoft.com/kb/110093>.

The application development part of this reference assumes a good working knowledge of C, general DBMS knowledge, and finally, but not least, familiarity with MySQL. For more information about MySQL functionality and its syntax, refer to [ht-tp://dev.mysql.com/doc/](http://dev.mysql.com/doc/).

Typically, you need to install Connector/ODBC only on Windows machines. For Unix and Mac OS X you can use the native MySQL network or named pipe to communicate with your MySQL database. You may need Connector/ODBC for Unix or Mac OS X if you have an application that requires an ODBC interface to communicate with the database. Applications that require ODBC to communicate with MySQL include ColdFusion, Microsoft Office, and Filemaker Pro.

### Key topics:

- For help installing Connector/ODBC see [Section 21.1.3, “Connector/ODBC Installation”](#).
- For information on the configuration options, see [Section 21.1.4.2, “Connector/ODBC Connection Parameters”](#).
- For more information on connecting to a MySQL database from a Windows host using Connector/ODBC see [Section 21.1.5.2, “Step-by-step Guide to Connecting to a MySQL Database through Connector/ODBC”](#).
- If you want to use Microsoft Access as an interface to a MySQL database using Connector/ODBC see [Section 21.1.5.4, “Using Connector/ODBC with Microsoft Access”](#).
- General tips on using Connector/ODBC, including obtaining the last auto-increment ID see [Section 21.1.7.1, “Connector/ODBC General Functionality”](#).
- For tips and common questions on using Connector/ODBC with specific application see [Section 21.1.7.2, “Connector/ODBC Application Specific Tips”](#).
- For a general list of Frequently Asked Questions see [Section 21.1.7.3, “Connector/ODBC Errors and Resolutions \(FAQ\)”](#).
- Additional support when using Connector/ODBC is available, see [Section 21.1.8, “Connector/ODBC Support”](#).

### 21.1.1. Connector/ODBC Versions

There are currently two version of Connector/ODBC available:

- Connector/ODBC 5.1, currently in GA status, is a partial rewrite of the of the 3.51 code base and is designed to work with all versions of MySQL from 4.1.1. It does not work with versions of MySQL Server prior to 4.1.1.

Connector/ODBC 5.1 also includes the following changes and improvements over the 3.51 release:

- Improved support on Windows 64-bit platforms.

- Full Unicode support at the driver level. This includes support for the `SQL_WCHAR` data type, and support for Unicode login, password and DSN configurations. For more information, see [Microsoft Knowledgebase Article #716246](#).
- Support for the `SQL_NUMERIC_STRUCT` data type, which provides easier access to the precise definition of numeric values. For more information, see [Microsoft Knowledgebase Article #714556](#)
- Native Windows setup library. This replaces the Qt library based interface for configuring DSN information within the ODBC Data Sources application.
- Support for the ODBC descriptor, which improves the handling and metadata of columns and parameter data. For more information, see [Microsoft Knowledgebase Article #716339](#).
- Connector/ODBC 3.51 is the current release of the 32-bit ODBC driver, also known as the MySQL ODBC 3.51 driver. Connector/ODBC 3.51 has support for ODBC 3.5x specification level 1 (complete core API + level 2 features) to continue to provide all functionality of ODBC for accessing MySQL.

The manual for versions of Connector/ODBC older than 3.51 can be located in the corresponding binary or source distribution. Please note that versions of Connector/ODBC earlier than the 3.51 revision were not fully compliant with the ODBC specification.

#### Note

From this section onward, the primary focus of this guide is the Connector/ODBC 3.51 and Connector/ODBC 5.1 drivers.

#### Note

Version numbers for MySQL products are formatted as X.X.X. However, Windows tools (Control Panel, properties display) may show the version numbers as XX.XX.XX. For example, the official MySQL formatted version number 5.0.9 may be displayed by Windows tools as 5.00.09. The two versions are the same; only the number display format is different.

## 21.1.2. Connector/ODBC Introduction

ODBC (Open Database Connectivity) provides a way for client programs to access a wide range of databases or data sources. ODBC is a standardized API that enables connections to SQL database servers. It was developed according to the specifications of the SQL Access Group and defines a set of function calls, error codes, and data types that can be used to develop database-independent applications. ODBC usually is used when database independence or simultaneous access to different data sources is required.

For more information about ODBC, refer to <http://support.microsoft.com/kb/110093>.

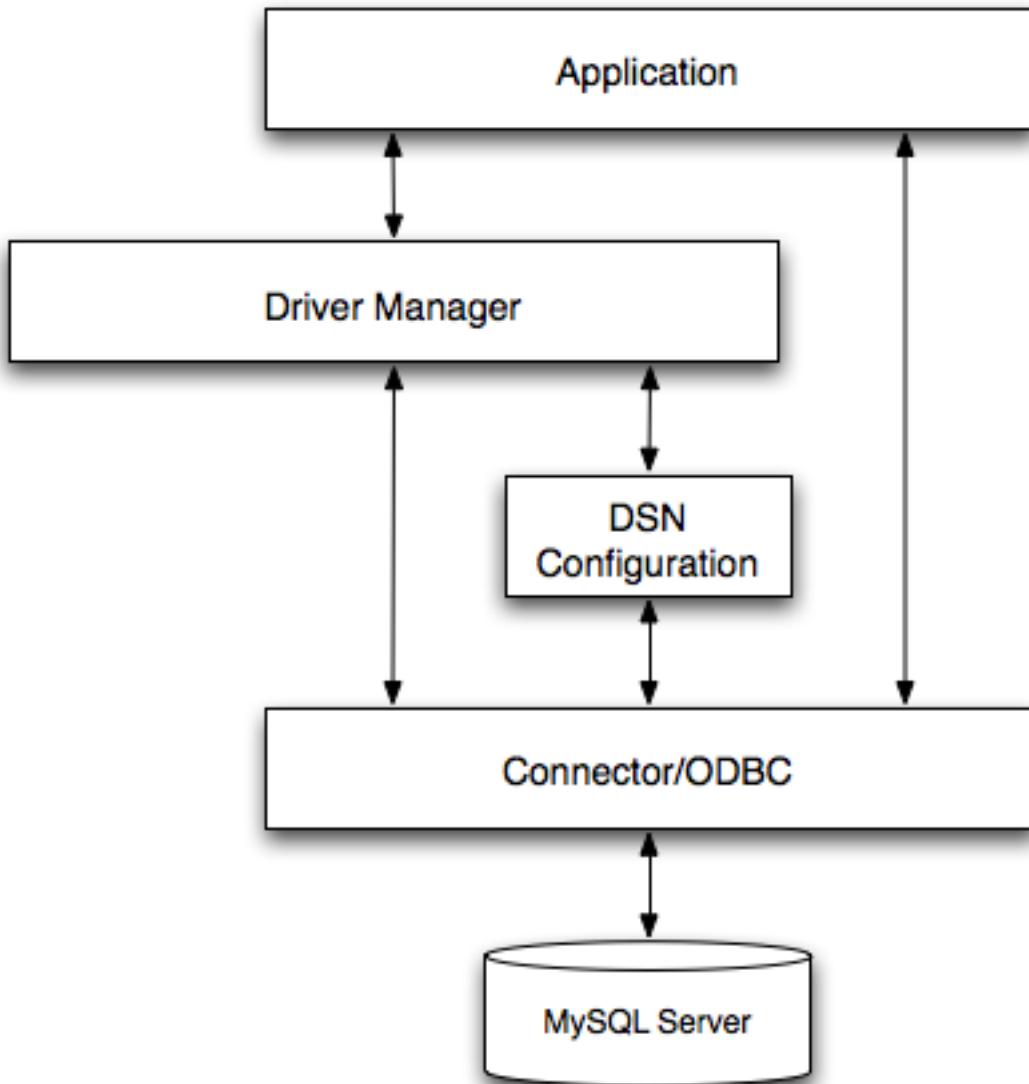

### 21.1.2.1. General Information About ODBC and Connector/ODBC

Open Database Connectivity (ODBC) is a widely accepted application-programming interface (API) for database access. It is based on the Call-Level Interface (CLI) specifications from X/Open and ISO/IEC for database APIs and uses Structured Query Language (SQL) as its database access language.

A survey of ODBC functions supported by Connector/ODBC is given at [Section 21.1.6.1, “Connector/ODBC API Reference”](#). For general information about ODBC, see <http://support.microsoft.com/kb/110093>.

#### 21.1.2.1.1. Connector/ODBC Architecture

The Connector/ODBC architecture is based on five components, as shown in the following diagram:

- **Application:**

The Application uses the ODBC API to access the data from the MySQL server. The ODBC API in turn communicates with the Driver Manager. The Application communicates with the Driver Manager using the standard ODBC calls. The Application does not care where the data is stored, how it is stored, or even how the system is configured to access the data. It needs to know only the Data Source Name (DSN).

A number of tasks are common to all applications, no matter how they use ODBC. These tasks are:

- Selecting the MySQL server and connecting to it
- Submitting SQL statements for execution
- Retrieving results (if any)
- Processing errors
- Committing or rolling back the transaction enclosing the SQL statement
- Disconnecting from the MySQL server

Because most data access work is done with SQL, the primary tasks for applications that use ODBC are submitting SQL statements and retrieving any results generated by those statements.

- **Driver manager:**

The Driver Manager is a library that manages communication between application and driver or drivers. It performs the following tasks:

- Resolves Data Source Names (DSN). The DSN is a configuration string that identifies a given database driver, database, database host and optionally authentication information that enables an ODBC application to connect to a database using a standardized reference.

Because the database connectivity information is identified by the DSN, any ODBC compliant application can connect to the data source using the same DSN reference. This eliminates the need to separately configure each application that needs access to a given database; instead you instruct the application to use a pre-configured DSN.

- Loading and unloading of the driver required to access a specific database as defined within the DSN. For example, if you have configured a DSN that connects to a MySQL database then the driver manager will load the Connector/ODBC driver to enable the ODBC API to communicate with the MySQL host.
- Processes ODBC function calls or passes them to the driver for processing.

- **Connector/ODBC Driver:**

The Connector/ODBC driver is a library that implements the functions supported by the ODBC API. It processes ODBC function calls, submits SQL requests to MySQL server, and returns results back to the application. If necessary, the driver modifies an application's request so that the request conforms to syntax supported by MySQL.

- **DSN Configuration:**

The ODBC configuration file stores the driver and database information required to connect to the server. It is used by the Driver Manager to determine which driver to be loaded according to the definition in the DSN. The driver uses this to read connection parameters based on the DSN specified. For more information, [Section 21.1.4, “Connector/ODBC Configuration”](#).

- **MySQL Server:**

The MySQL database where the information is stored. The database is used as the source of the data (during queries) and the destination for data (during inserts and updates).

### 21.1.2.1.2. ODBC Driver Managers

An ODBC Driver Manager is a library that manages communication between the ODBC-aware application and any drivers. Its main functionality includes:

- Resolving Data Source Names (DSN).
- Driver loading and unloading.
- Processing ODBC function calls or passing them to the driver.

Both Windows and Mac OS X include ODBC driver managers with the operating system. Most ODBC Driver Manager implementations also include an administration application that makes the configuration of DSN and drivers easier. Examples and information on these managers, including Unix ODBC driver managers are listed below:

- Microsoft Windows ODBC Driver Manager (`odbc32.dll`), <http://support.microsoft.com/kb/110093>.
- Mac OS X includes [ODBC Administrator](#), a GUI application that provides a simpler configuration mechanism for the Unix iODBC Driver Manager. You can configure DSN and driver information either through ODBC Administrator or through the iODBC configuration files. This also means that you can test ODBC Administrator configurations using the `iodbctest` command. <http://www.apple.com>.
- [unixODBC](#) Driver Manager for Unix (`libodbc.so`). See <http://www.unixodbc.org>, for more information. The [unixODBC](#) Driver Manager includes the Connector/ODBC driver 3.51 in the installation package, starting with version [unixODBC](#) 2.1.2.
- [iODBC](#) ODBC Driver Manager for Unix (`libiodbc.so`), see <http://www.iodbc.org>, for more information.

### 21.1.3. Connector/ODBC Installation

You can install the Connector/ODBC drivers using two different methods, a binary installation and a source installation. The binary

installation is the easiest and most straightforward method of installation. Using the source installation methods should only be necessary on platforms where a binary installation package is not available, or in situations where you want to customize or modify the installation process or Connector/ODBC drivers before installation.

### Where to Get Connector/ODBC

You can get a copy of the latest version of Connector/ODBC binaries and sources from our Web site at <http://dev.mysql.com/downloads/connector/odbc/>.

For more information about Connector/ODBC, visit <http://www.mysql.com/products/myodbc/>.

For more information about licensing, visit <http://www.mysql.com/company/legal/licensing/>.

### Supported Platforms

Connector/ODBC can be used on all major platforms supported by MySQL. You can install it on:

- Windows 95, 98, Me, NT, 2000, XP, and 2003
- All Unix-like Operating Systems, including: AIX, Amiga, BSDI, DEC, FreeBSD, HP-UX 10/11, Linux, NetBSD, OpenBSD, OS/2, SGI Irix, Solaris, SunOS, SCO OpenServer, SCO UnixWare, Tru64 Unix
- Mac OS X and Mac OS X Server

Using a binary distribution offers the most straightforward method for installing Connector/ODBC. If you want more control over the driver, the installation location and or to customize elements of the driver you will need to build and install from the source.

If a binary distribution is not available for a particular platform build the driver from the original source code. You can contribute the binaries you create to MySQL by sending a mail message to [<myodbc@lists.mysql.com>](mailto:<myodbc@lists.mysql.com>), so that it becomes available for other users.

#### Note

On all non-Windows platforms except Mac OS X, the driver is built against `unixODBC` and is expecting a 2-byte `SQLWCHAR`, not 4 bytes as `iODBC` is using. For this reason, the binaries are **only** compatible with `unixODBC` and you will need to recompile the driver against `iODBC` if you wish to use them together. For further information see [Section 21.1.2.1.2, “ODBC Driver Managers”](#).

For further instructions:

Platform	Binary	Source
Windows	<a href="#">Installation Instructions</a>	<a href="#">Build Instructions</a>
Unix/Linux	<a href="#">Installation Instructions</a>	<a href="#">Build Instructions</a>
Mac OS X	<a href="#">Installation Instructions</a>	

### 21.1.3.1. Installing Connector/ODBC from a Binary Distribution on Windows

Before installing the Connector/ODBC drivers on Windows you should ensure that your Microsoft Data Access Components (MDAC) are up to date. You can obtain the latest version from the [Microsoft Data Access and Storage](#) Web site.

There are three available distribution types to use when installing for Windows. The contents in each case are identical, it is only the installation method which is different.

- Zipped installer consists of a Zipped package containing a standalone installation application. To install from this package, you must unzip the installer, and then run the installation application. See [Section 21.1.3.1.1, “Installing the Windows Connector/ODBC Driver using an installer”](#) to complete the installation.
- MSI installer, an installation file that can be used with the installer included in Windows 2000, Windows XP and Windows Server 2003. See [Section 21.1.3.1.1, “Installing the Windows Connector/ODBC Driver using an installer”](#) to complete the installation.
- Zipped DLL package, containing the DLL files that need must be manually installed. See [Section 21.1.3.1.2, “Installing the Windows Connector/ODBC Driver using the Zipped DLL package”](#) to complete the installation.

**Note**

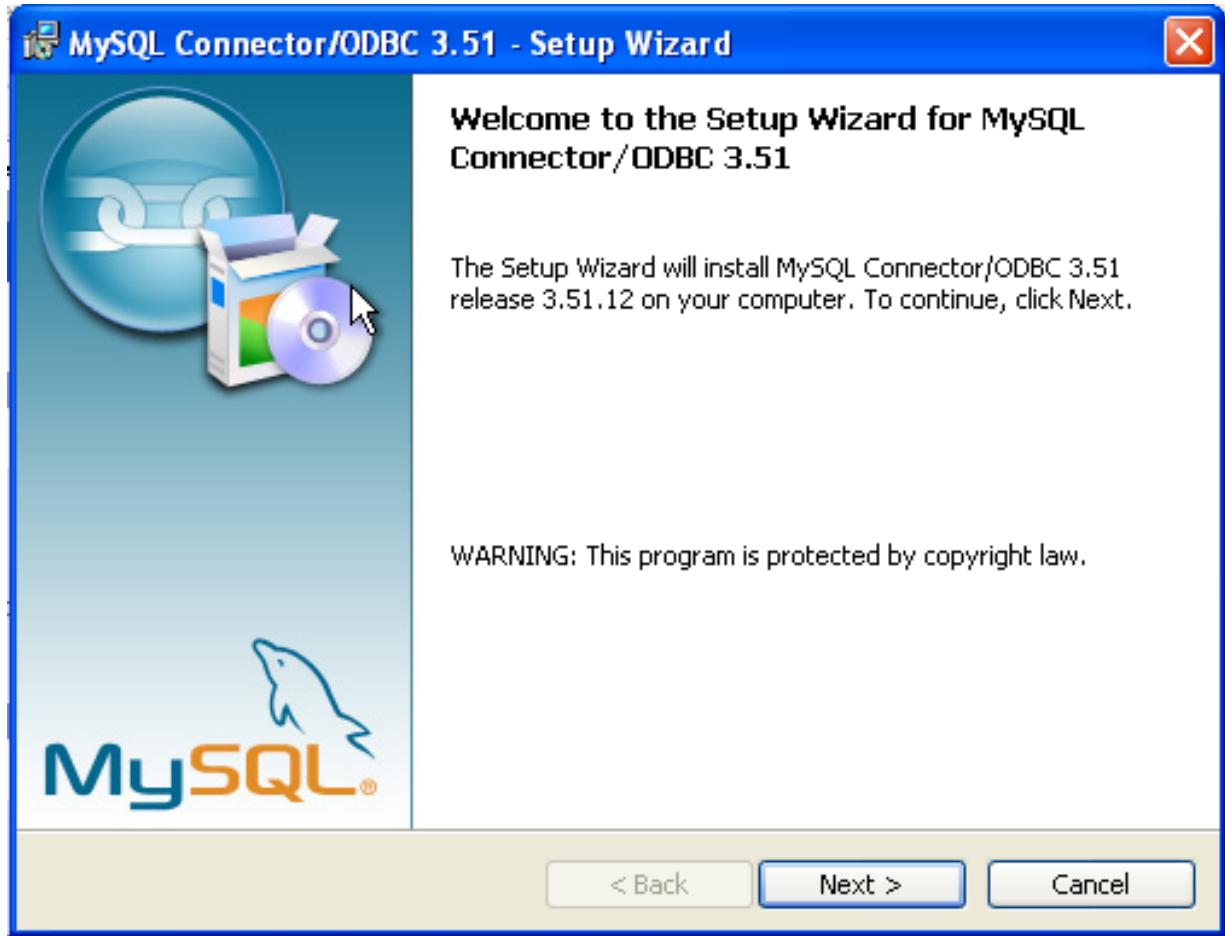

An OLEDB/ODBC driver for Windows 64-bit is available from [Microsoft Downloads](#).

### 21.1.3.1.1. Installing the Windows Connector/ODBC Driver using an installer

The installer packages offer a very simple method for installing the Connector/ODBC drivers. If you have downloaded the zipped installer then you must extract the installer application. The basic installation process is identical for both installers.

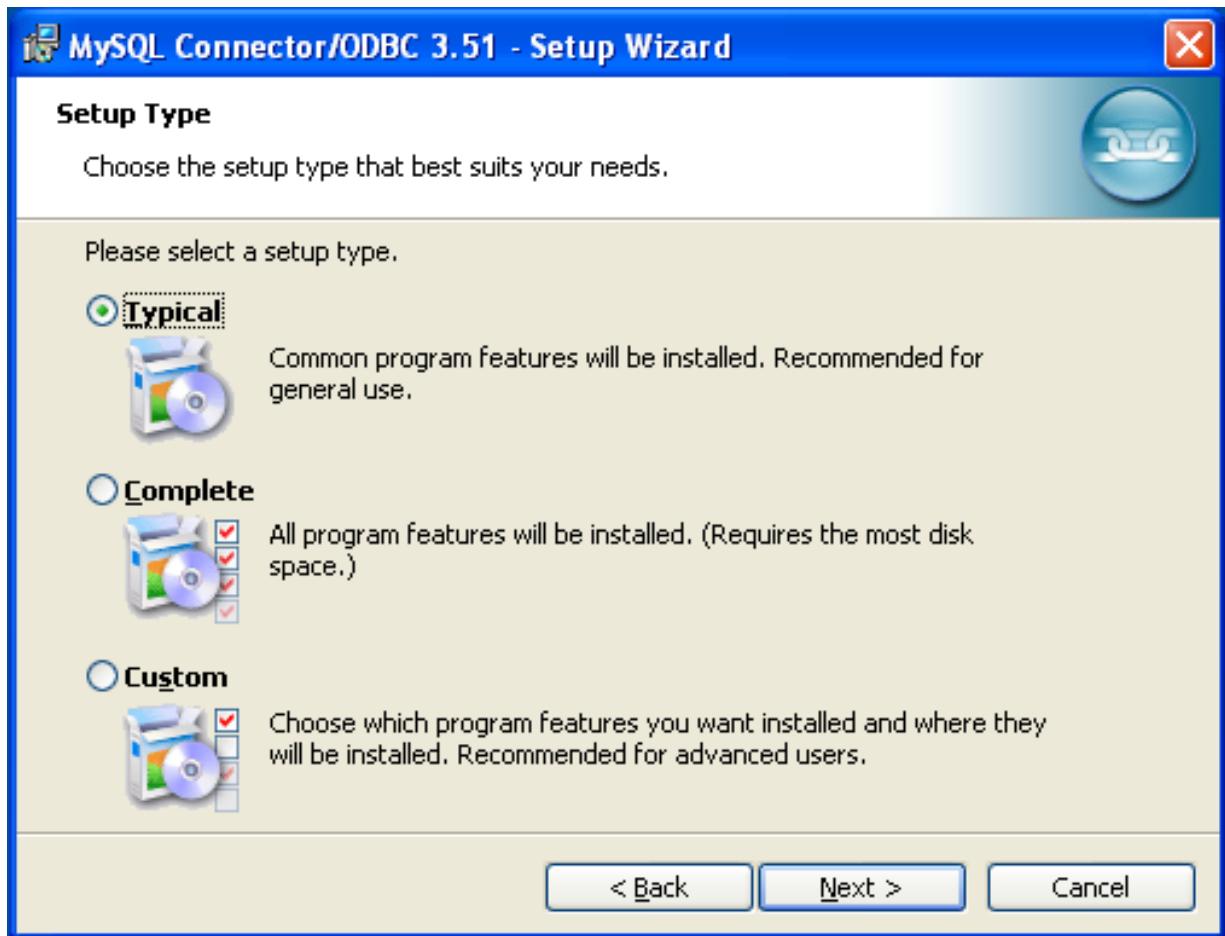

You should follow these steps to complete the installation:

1. Double-click the standalone installer that you extracted, or the MSI file you downloaded.
2. The MySQL Connector/ODBC 3.51 - Setup Wizard will start. Click the NEXT button to begin the installation process.

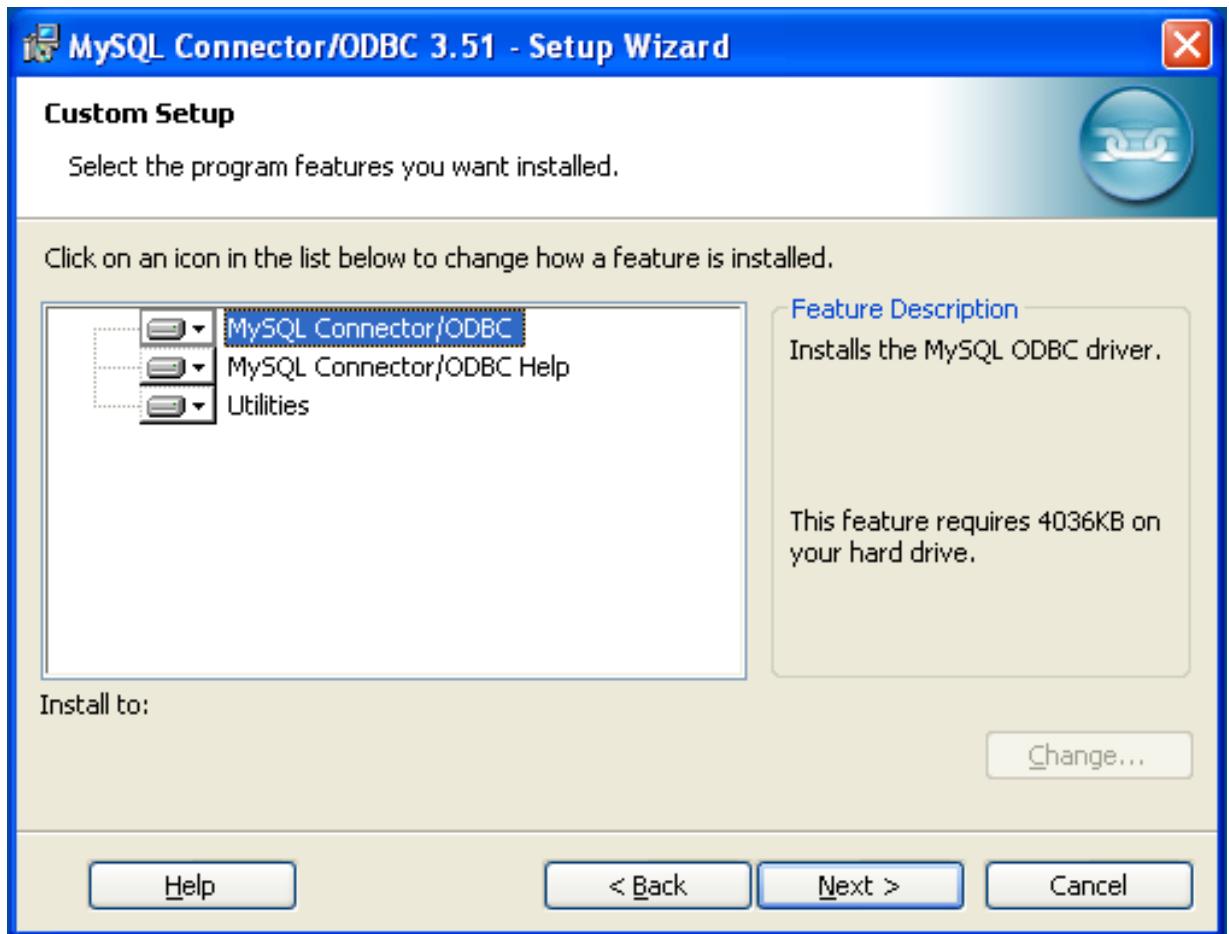

3. You will need to choose the installation type. The Typical installation provides the standard files you will need to connect to a MySQL database using ODBC. The Complete option installs all the available files, including debug and utility components. It is recommended you choose one of these two options to complete the installation. If choose one of these methods, click NEXT and then proceed to step 5.

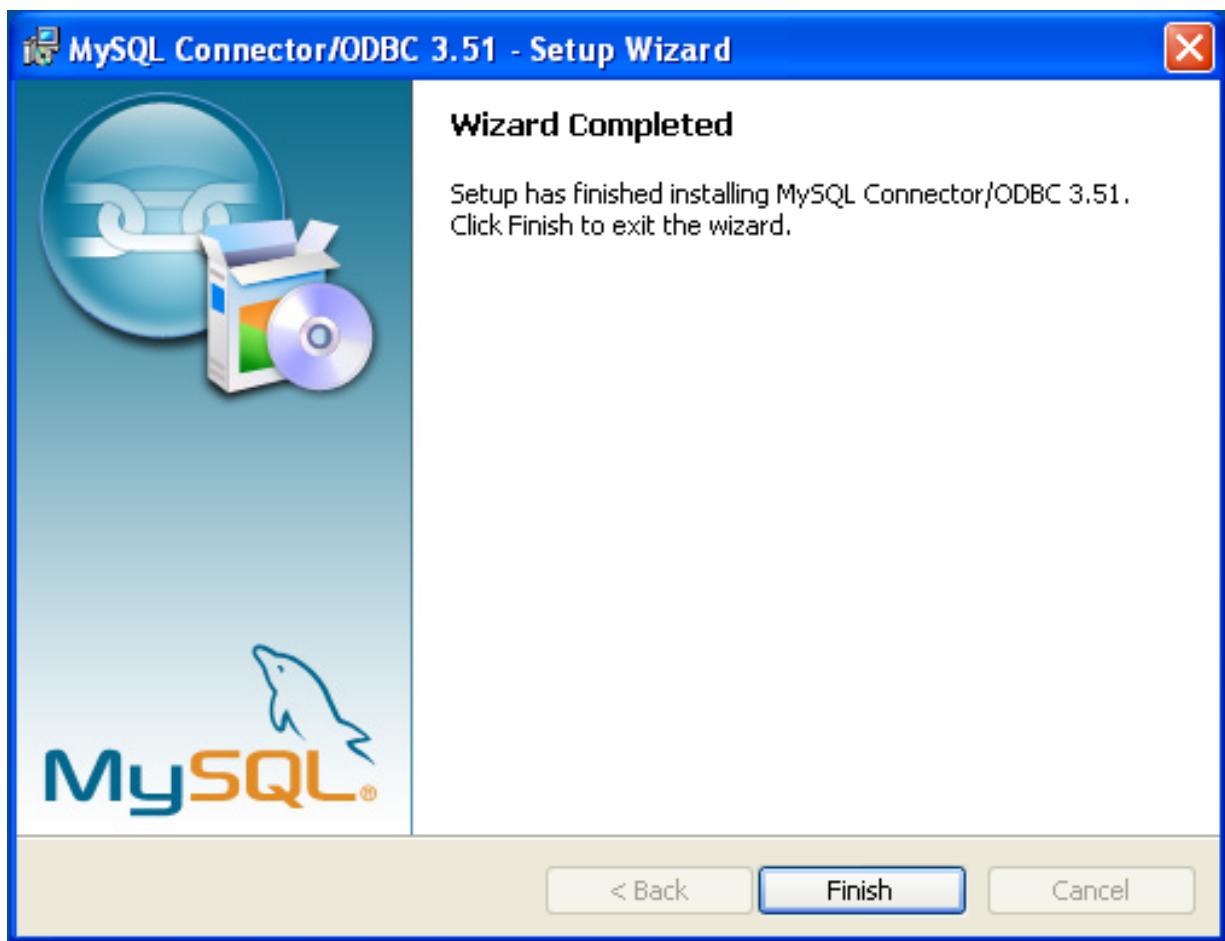

You may also choose a Custom installation, which enables you to select the individual components that you want to install. You have chosen this method, click NEXT and then proceed to step 4.

4. If you have chosen a custom installation, use the pop-ups to select which components to install and then click NEXT to install the necessary files.

5. Once the files have copied to your machine, the installation is complete. Click FINISH to exit the installer.

Now the installation is complete, you can continue to configure your ODBC connections using [Section 21.1.4, “Connector/ODBC Configuration”](#).

#### **21.1.3.1.2. Installing the Windows Connector/ODBC Driver using the Zipped DLL package**

If you have downloaded the Zipped DLL package then you must install the individual files required for Connector/ODBC operation manually. Once you have unzipped the installation files, you can either perform this operation by hand, executing each statement individually, or you can use the included Batch file to perform an installation to the default locations.

##### **Note**

The following instructions will only work for 32-bit Windows systems. If you have a 64-bit Windows system you are advised to use the MSI installer, which will install both the 32-bit and 64-bit drivers to the correct locations.

To install using the Batch file:

1. Unzip the Connector/ODBC Zipped DLL package.
2. Open a Command Prompt.
3. Change to the directory created when you unzipped the Connector/ODBC Zipped DLL package.
4. Run `Install.bat`:

```
C:\> Install.bat
```

This will copy the necessary files into the default location, and then register the Connector/ODBC driver with the Windows ODBC manager.

If you want to copy the files to an alternative location - for example, to run or test different versions of the Connector/ODBC driver

on the same machine, then you must copy the files by hand. It is however not recommended to install these files in a nonstandard location. To copy the files by hand to the default installation location use the following steps:

1. Unzip the Connector/ODBC Zipped DLL package.
2. Open a Command Prompt.
3. Change to the directory created when you unzipped the Connector/ODBC Zipped DLL package.
4. Copy the library files to a suitable directory. The default is to copy them into the default Windows system directory `\Windows\System32`:

```
C:\> copy lib\myodbc3S.dll \Windows\System32
C:\> copy lib\myodbc3S.lib \Windows\System32
C:\> copy lib\myodbc3.dll \Windows\System32
C:\> copy lib\myodbc3.lib \Windows\System32
```

5. Copy the Connector/ODBC tools. These must be placed into a directory that is in the system `PATH`. The default is to install these into the Windows system directory `\Windows\System32`:

```
C:\> copy bin\myodbc3i.exe \Windows\System32
C:\> copy bin\myodbc3m.exe \Windows\System32
C:\> copy bin\myodbc3c.exe \Windows\System32
```

6. Optionally copy the help files. For these files to be accessible through the help system, they must be installed in the Windows system directory:

```
C:\> copy doc*.hlp \Windows\System32
```

7. Finally, you must register the Connector/ODBC driver with the ODBC manager:

```
C:\> myodbc3i -a -d -t"MySQL ODBC 3.51 Driver; \
DRIVER=myodbc3.dll;SETUP=myodbc3S.dll"
```

You must change the references to the DLL files and command location in the above statement if you have not installed these files into the default location.

### 21.1.3.2. Installing Connector/ODBC from a Binary Distribution on Unix

There are two methods available for installing Connector/ODBC on Unix from a binary distribution. For most Unix environments you will need to use the tarball distribution. For Linux systems, there is also an RPM distribution available.

#### Note

To install Connector/ODBC 5.1 on Unix you require unixODBC 2.2.12 or later to be installed.

#### 21.1.3.2.1. Installing Connector/ODBC from a Binary Tarball Distribution

To install the driver from a tarball distribution (`.tar.gz` file), download the latest version of the driver for your operating system and follow these steps that demonstrate the process using the Linux version of the tarball:

```
shell> su root
shell> gunzip mysql-connector-odbc-3.51.11-i686-pc-linux.tar.gz
shell> tar xvf mysql-connector-odbc-3.51.11-i686-pc-linux.tar
shell> cd mysql-connector-odbc-3.51.11-i686-pc-linux
```

Read the installation instructions in the `INSTALL` file and execute these commands.

Then proceed on to [Section 21.1.4.5, “Configuring a Connector/ODBC DSN on Unix”](#), to configure the DSN for Connector/ODBC. For more information, refer to the `INSTALL` file that comes with your distribution.

#### 21.1.3.2.2. Installing Connector/ODBC from an RPM Distribution

To install or upgrade Connector/ODBC from an RPM distribution on Linux, simply download the RPM distribution of the latest version of Connector/ODBC and follow the instructions below. Use `su root` to become `root`, then install the RPM file.

If you are installing for the first time:

```
shell> su root
```

```
shell> rpm -ivh mysql-connector-odbc-3.51.12.i386.rpm
```

If the driver exists, upgrade it like this:

```
shell> su root
shell> rpm -Uvh mysql-connector-odbc-3.51.12.i386.rpm
```

If there is any dependency error for MySQL client library, `libmysqlclient`, simply ignore it by supplying the `--nodeps` option, and then make sure the MySQL client shared library is in the path or set through `LD_LIBRARY_PATH`.

This installs the driver libraries and related documents to `/usr/local/lib` and `/usr/share/doc/MyODBC`, respectively. Proceed onto [Section 21.1.4.5, “Configuring a Connector/ODBC DSN on Unix”](#).

To **uninstall** the driver, become `root` and execute an `rpm` command:

```
shell> su root
shell> rpm -e mysql-connector-odbc
```

### 21.1.3.3. Installing Connector/ODBC from a Binary Distribution on Mac OS X

Mac OS X is based on the FreeBSD operating system, and you can normally use the MySQL network port for connecting to MySQL servers on other hosts. Installing the Connector/ODBC driver enables you to connect to MySQL databases on any platform through the ODBC interface. You should only need to install the Connector/ODBC driver when your application requires an ODBC interface. Applications that require or can use ODBC (and therefore the Connector/ODBC driver) include ColdFusion, Filemaker Pro, 4th Dimension and many other applications.

Mac OS X includes its own ODBC manager, based on the `iODBC` manager. Mac OS X includes an administration tool that provides easier administration of ODBC drivers and configuration, updating the underlying `iODBC` configuration files.

The method for installing Connector/ODBC on Mac OS X depends on the version on Connector/ODBC you are using. For Connector/ODBC 3.51.14 and later, the package is provided as a compressed tar archive that you must manually install. For Connector/ODBC 3.51.13 and earlier the software was provided on a compressed disk image (`.dmg`) file and included an installer.

In either case, the driver is designed to work with the iODBC driver manager included with Mac OS X.

To install Connector/ODBC 3.51.14 and later:

1. Download the installation file. Note that versions are available for both PowerPC and Intel platforms.
2. Extract the archive:

```
shell> tar zxf mysql-connector-odbc-3.51.16-osx10.4-x86-32bit.tar.gz
```

3. The directory created will contain two subdirectories, `lib` and `bin`. You need to copy these to a suitable location such as `/usr/local`:

```
shell> cp bin/* /usr/local/bin
shell> cp lib/* /usr/local/lib
```

4. Finally, you must register the driver with iODBC using the `myodbc3i` tool you just installed:

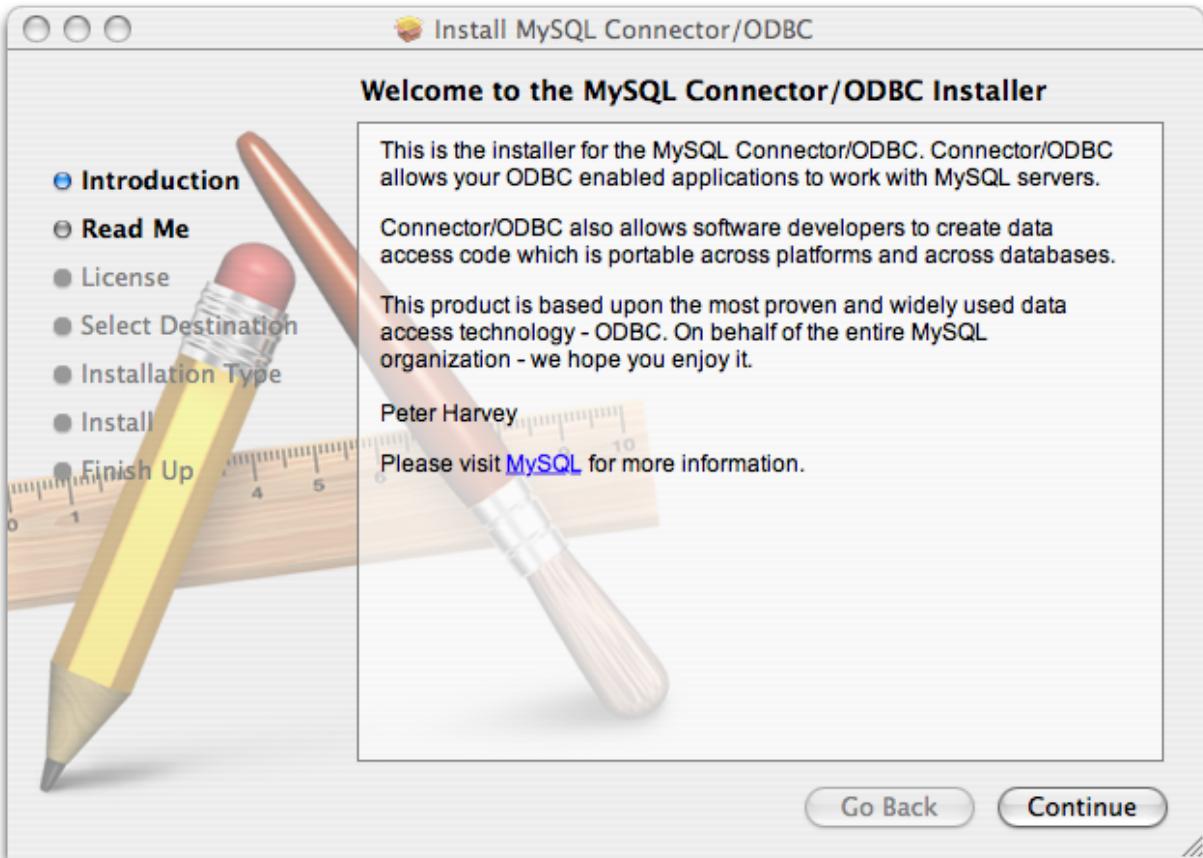

```
shell> myodbc3i -a -d -t"MySQL ODBC 3.51 Driver;Driver=/usr/local/lib/libmyodbc3.so;Setup=/usr/local/lib/libmyodbc3i.so"
```

You can verify the installed drivers either by using the ODBC Administrator application or the `myodbc3i` utility:

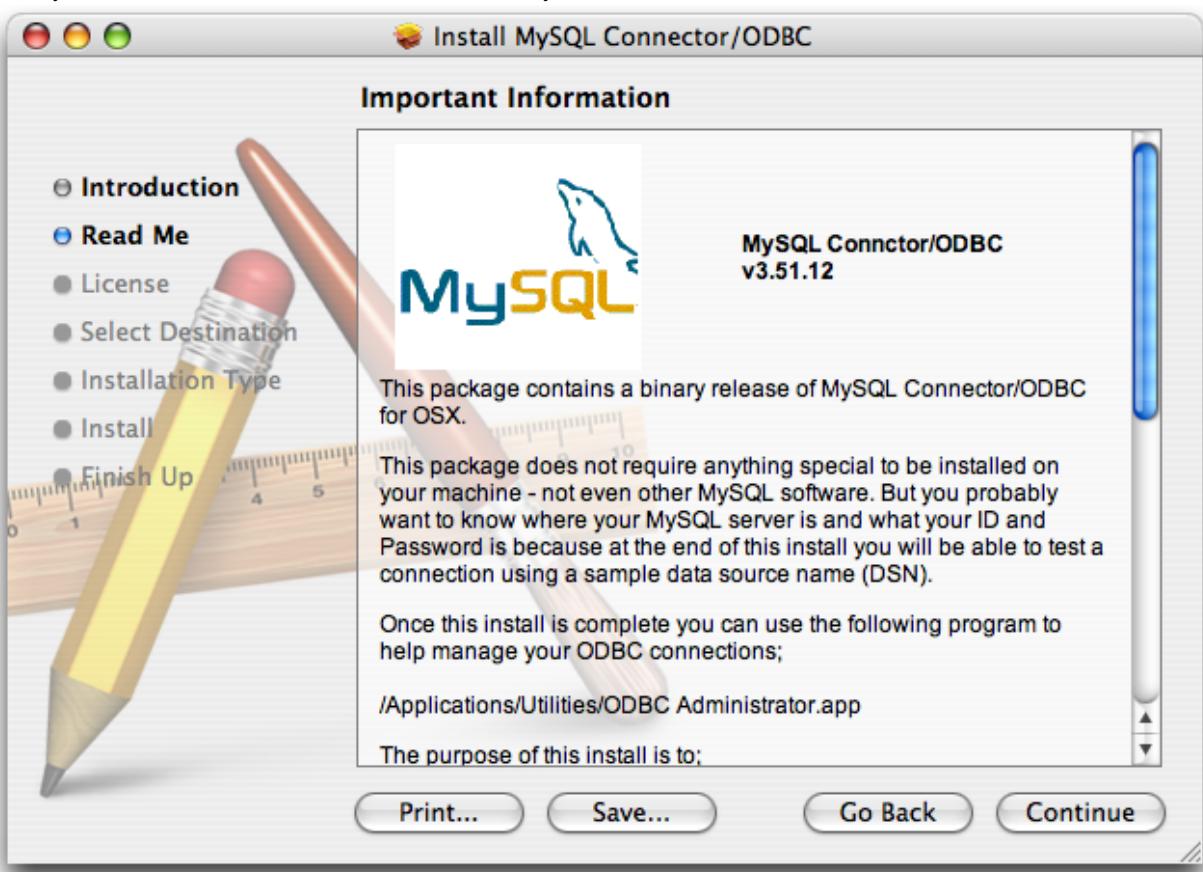

```
shell> myodbc3i -q -d
```

To install Connector/ODBC 3.51.13 and earlier, follow these steps:

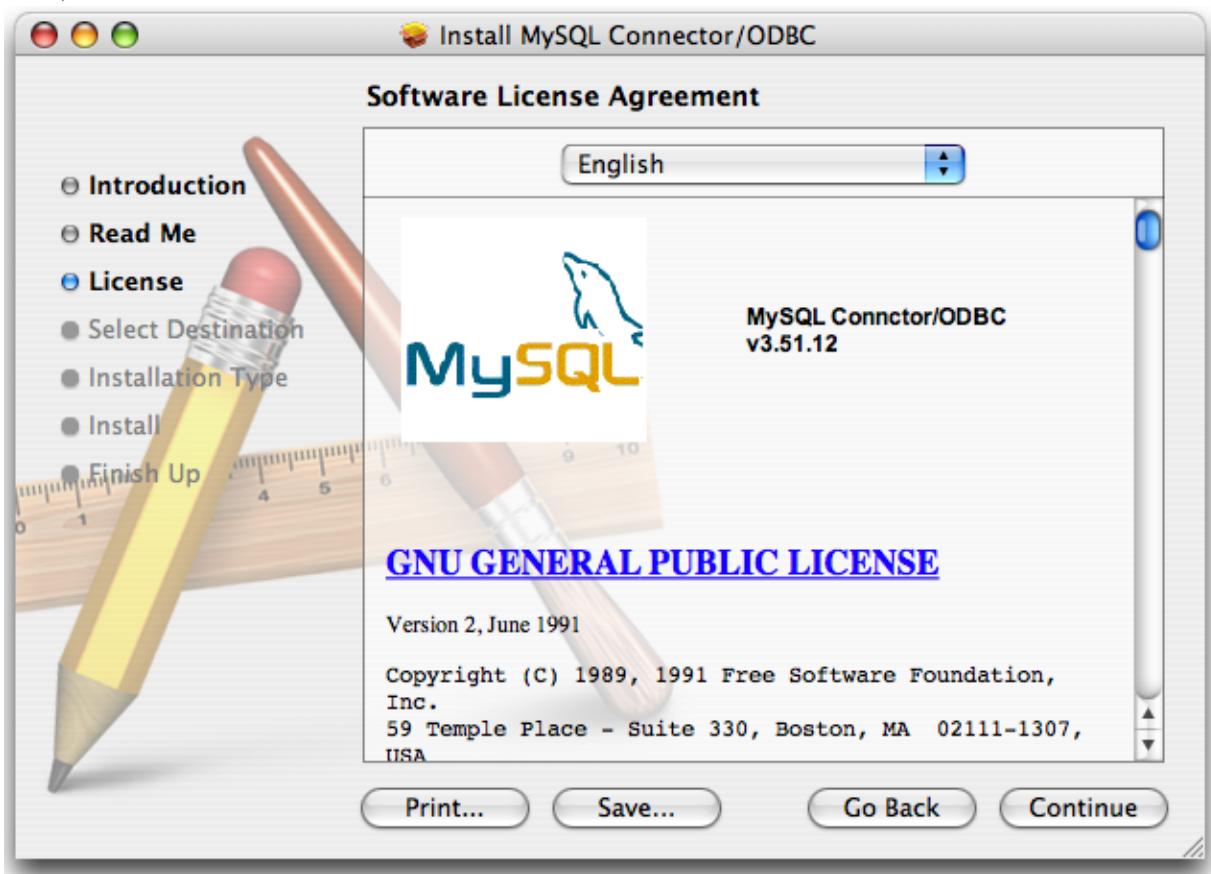

1. Download the file to your computer and double-click the downloaded image file.
2. Within the disk image you will find an installer package (with the `.pkg` extension). Double-click on this file to start the Mac OS X installer.
3. You will be presented with the installer welcome message. Click the CONTINUE button to begin the installation process.

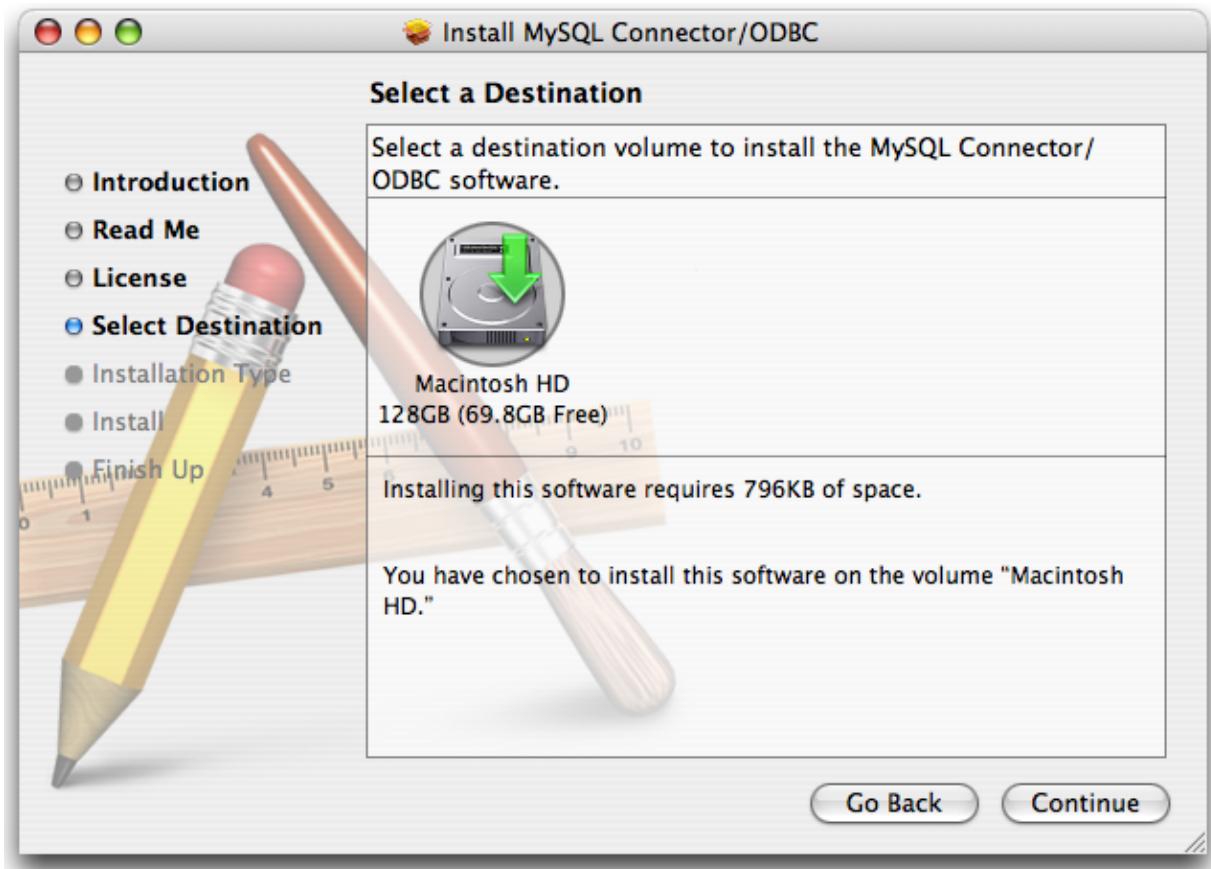

4. Please take the time to read the Important Information as it contains guidance on how to complete the installation process. Once you have read the notice and collected the necessary information, click CONTINUE.

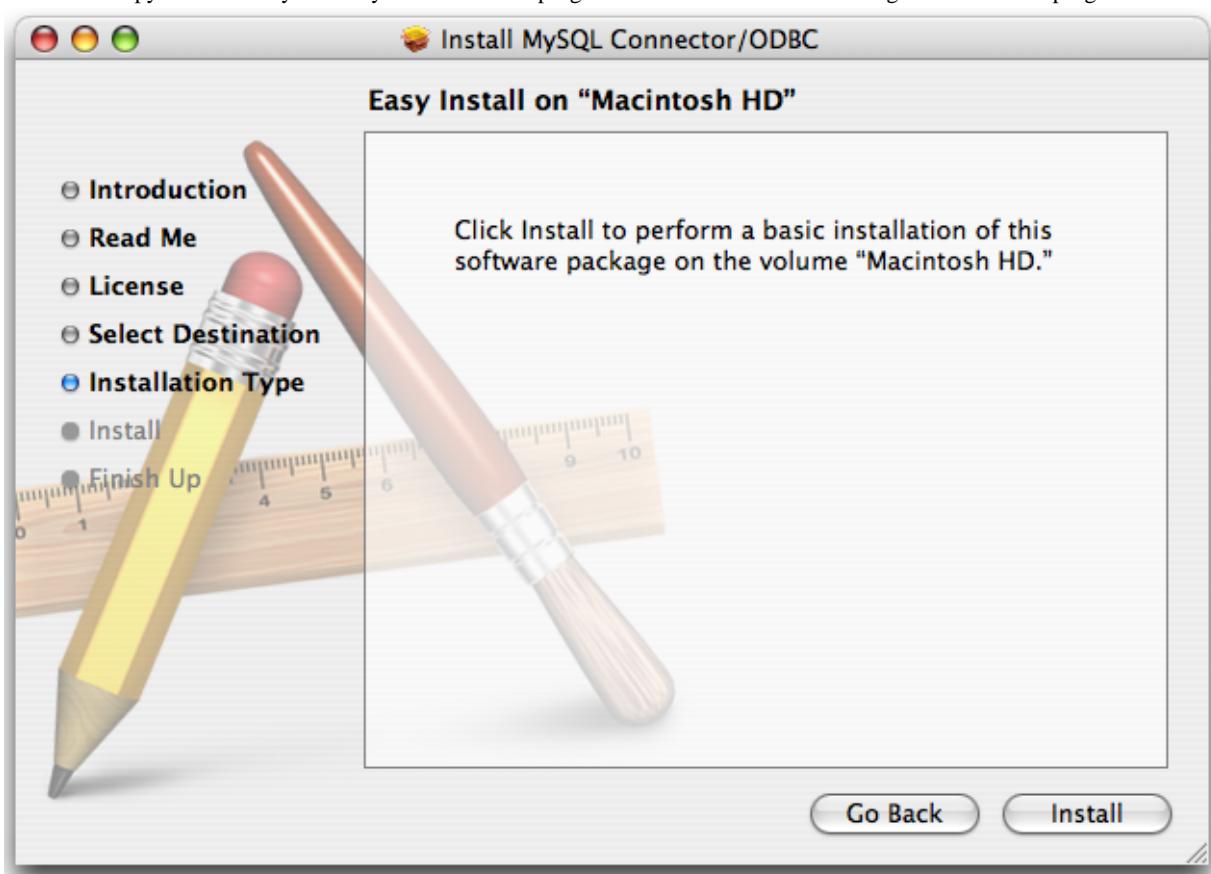

5. Connector/ODBC drivers are made available under the GNU General Public License. Please read the license if you are not familiar with it before continuing installation. Click CONTINUE to approve the license (you will be asked to confirm that decision) and continue the installation.

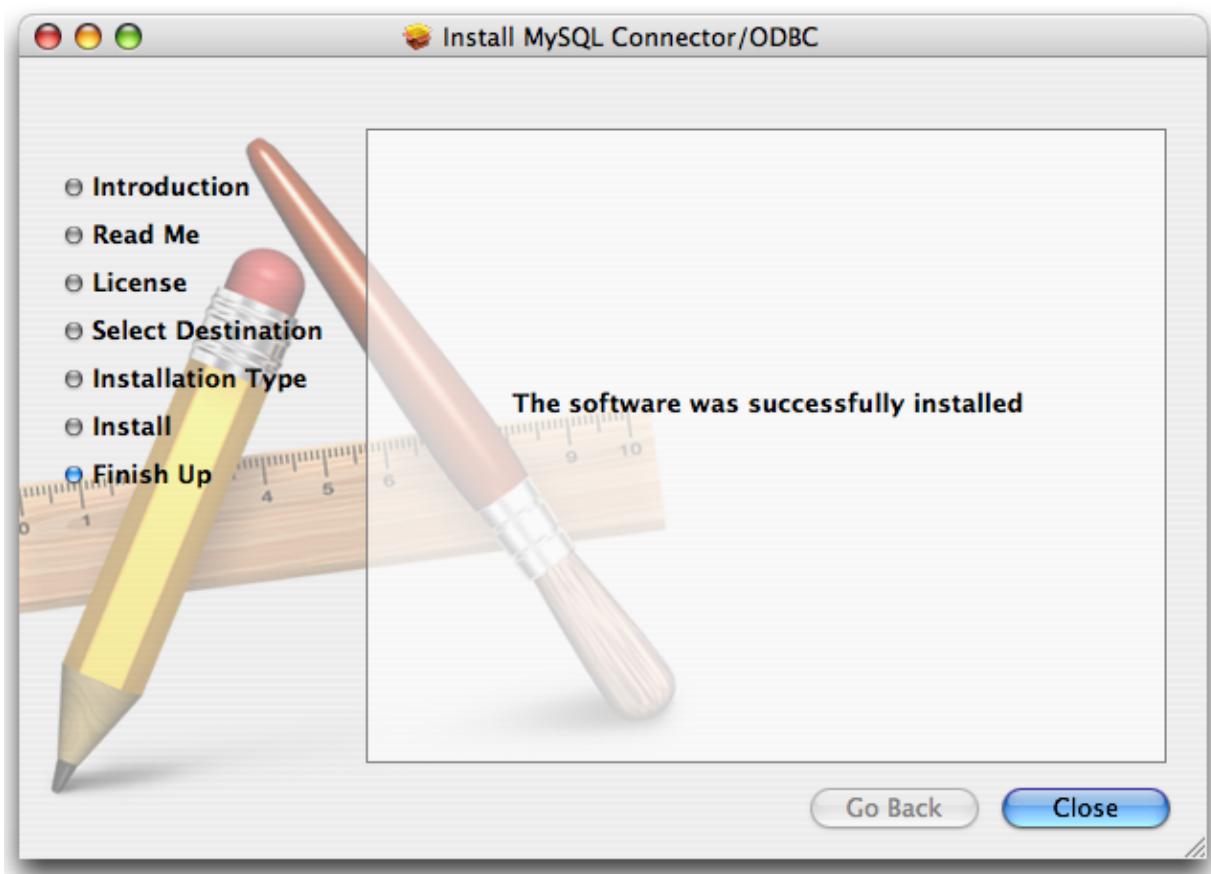

6. Choose a location to install the Connector/ODBC drivers and the ODBC Administrator application. You must install the files onto a drive with an operating system and you may be limited in the choices available. Select the drive you want to use, and then click CONTINUE.

7. The installer will automatically select the files that need to be installed on your machine. Click INSTALL to continue. The installer will copy the necessary files to your machine. A progress bar will be shown indicating the installation progress.

- When installation has been completed you will get a window like the one shown below. Click CLOSE to close and quit the installer.

#### 21.1.3.4. Installing Connector/ODBC from a Source Distribution on Windows

You should only need to install Connector/ODBC from source on Windows if you want to change or modify the source or installation. If you are unsure whether to install from source, please use the binary installation detailed in [Section 21.1.3.1, “Installing Connector/ODBC from a Binary Distribution on Windows”](#).

Installing Connector/ODBC from source on Windows requires a number of different tools and packages:

- MDAC, Microsoft Data Access SDK from <http://support.microsoft.com/kb/110093>.
- Suitable C compiler, such as Microsoft Visual C++ or the C compiler included with Microsoft Visual Studio.
- Compatible `make` tool. Microsoft's `nmake` is used in the examples in this section.
- MySQL client libraries and include files from MySQL 4.0.0 or higher. (Preferably MySQL 4.0.16 or higher). This is required because Connector/ODBC uses new calls and structures that exist only starting from this version of the library. To get the client libraries and include files, visit <http://dev.mysql.com/downloads/>.

##### 21.1.3.4.1. Building Connector/ODBC 3.51

Connector/ODBC source distributions include `Makefiles` that require the `nmake` or other `make` utility. In the distribution, you can find `Makefile` for building the release version and `Makefile_debug` for building debugging versions of the driver libraries and DLLs.

To build the driver, use this procedure:

- Download and extract the sources to a folder, then change directory into that folder. The following command assumes the folder is named `myodbc3-src`:

```
C:\> cd myodbc3-src
```

2. Edit `Makefile` to specify the correct path for the MySQL client libraries and header files. Then use the following commands to build and install the release version:

```
C:\> nmake -f Makefile
C:\> nmake -f Makefile install
```

`nmake -f Makefile` builds the release version of the driver and places the binaries in subdirectory called `Release`.

`nmake -f Makefile install` installs (copies) the driver DLLs and libraries (`myodbc3.dll`, `myodbc3.lib`) to your system directory.

3. To build the debug version, use `Makefile_Debug` rather than `Makefile`, as shown below:

```
C:\> nmake -f Makefile_debug
C:\> nmake -f Makefile_debug install
```

4. You can clean and rebuild the driver by using:

```
C:\> nmake -f Makefile clean
C:\> nmake -f Makefile install
```

### Note

- Make sure to specify the correct MySQL client libraries and header files path in the Makefiles (set the `MYSQL_LIB_PATH` and `MYSQL_INCLUDE_PATH` variables). The default header file path is assumed to be `C:\mysql\include`. The default library path is assumed to be `C:\mysql\lib\opt` for release DLLs and `C:\mysql\lib\debug` for debug versions.
- For the complete usage of `nmake`, visit [http://msdn.microsoft.com/library/default.asp?url=/library/en-us/dv\\_vcse4/html/evgrfRunningNMAKE.asp](http://msdn.microsoft.com/library/default.asp?url=/library/en-us/dv_vcse4/html/evgrfRunningNMAKE.asp).
- If you are using the Subversion tree for compiling, all Windows-specific `Makefiles` are named as `Win_Makefile*`.

#### 21.1.3.4.2. Testing

After the driver libraries are copied/installed to the system directory, you can test whether the libraries are properly built by using the samples provided in the `samples` subdirectory:

```
C:\> cd samples
C:\> nmake -f Makefile all
```

#### 21.1.3.5. Installing Connector/ODBC from a Source Distribution on Unix

You need the following tools to build MySQL from source on Unix:

- A working ANSI C++ compiler. `gcc` 2.95.2 or later, SGI C++, and SunPro C++ are some of the compilers that are known to work.
- A good `make` program. GNU `make` is always recommended and is sometimes required.
- MySQL client libraries and include files from MySQL 4.0.0 or higher. (Preferably MySQL 4.0.16 or higher). This is required because Connector/ODBC uses new calls and structures that exist only starting from this version of the library. To get the client libraries and include files, visit <http://dev.mysql.com/downloads/>.

If you have built your own MySQL server or client libraries from source, you must have used the `-enable-thread-safe-client` option to `configure` when the libraries were built.

You should also ensure that the `libmysqlclient` library were built and installed as a shared library.

- A compatible ODBC manager must be installed. Connector/ODBC is known to work with the `iODBC` and `unixODBC` managers. See [Section 21.1.2.1.2, “ODBC Driver Managers”](#), for more information.
- If you are using a character set that isn't compiled into the MySQL client library then you need to install the MySQL character

definitions from the `charsets` directory into `SHAREDIR` (by default, `/usr/local/mysql/share/mysql/charsets`). These should be in place if you have installed the MySQL server on the same machine. See [Section 9.1, “Character Set Support”](#), for more information on character set support.

Once you have all the required files, unpack the source files to a separate directory, you then have to run `configure` and build the library using `make`.

#### 21.1.3.5.1. Typical `configure` Options

The `configure` script gives you a great deal of control over how you configure your Connector/ODBC build. Typically you do this using options on the `configure` command line. You can also affect `configure` using certain environment variables. For a list of options and environment variables supported by `configure`, run this command:

```
shell> ./configure --help
```

Some of the more commonly used `configure` options are described here:

1. To compile Connector/ODBC, you need to supply the MySQL client include and library files path using the `--with-mysql-path=DIR` option, where `DIR` is the directory where MySQL is installed.

MySQL compile options can be determined by running `DIR/bin/mysql_config`.

2. Supply the standard header and library files path for your ODBC Driver Manager (`iODBC` or `unixODBC`).

- If you are using `iODBC` and `iODBC` is not installed in its default location (`/usr/local`), you might have to use the `--with-iodbc=DIR` option, where `DIR` is the directory where `iODBC` is installed.

If the `iODBC` headers do not reside in `DIR/include`, you can use the `--with-iodbc-includes=INCDIR` option to specify their location.

The applies to libraries. If they are not in `DIR/lib`, you can use the `--with-iodbc-libs=LIBDIR` option.

- If you are using `unixODBC`, use the `--with-unixODBC=DIR` option (case sensitive) to make `configure` look for `unixODBC` instead of `iODBC` by default, `DIR` is the directory where `unixODBC` is installed.

If the `unixODBC` headers and libraries aren't located in `DIR/include` and `DIR/lib`, use the `--with-unixODBC-includes=INCDIR` and `--with-unixODBC-libs=LIBDIR` options.

3. You might want to specify an installation prefix other than `/usr/local`. For example, to install the Connector/ODBC drivers in `/usr/local/odbc/lib`, use the `--prefix=/usr/local/odbc` option.

The final configuration command looks something like this:

```
shell> ./configure --prefix=/usr/local \
--with-iodbc=/usr/local \
--with-mysql-path=/usr/local/mysql
```

#### 21.1.3.5.2. Additional `configure` Options

There are a number of other options that you need, or want, to set when configuring the Connector/ODBC driver before it is built.

- To link the driver with MySQL thread safe client libraries `libmysqlclient_r.so` or `libmysqlclient_r.a`, you must specify the following `configure` option:

```
--enable-thread-safe
```

and can be disabled (default) using

```
--disable-thread-safe
```

This option enables the building of the driver thread-safe library `libmyodbc3_r.so` from by linking with MySQL thread-safe client library `libmysqlclient_r.so` (The extensions are OS dependent).

If the compilation with the thread-safe option fails, it may be because the correct thread-libraries on the system could not be located. You should set the value of `LIBS` to point to the correct thread library for your system.

```
LIBS="-lpthread" ./configure ..
```

- You can enable or disable the shared and static versions of Connector/ODBC using these options:

```
--enable-shared[=yes/no]
--disable-shared
--enable-static[=yes/no]
--disable-static
```

- By default, all the binary distributions are built as nondebugging versions (configured with `--without-debug`).

To enable debugging information, build the driver from source distribution and use the `--with-debug` option when you run `configure`.

- This option is available only for source trees that have been obtained from the Subversion repository. This option does not apply to the packaged source distributions.

By default, the driver is built with the `--without-docs` option. If you would like the documentation to be built, then execute `configure` with:

```
--with-docs
```

### 21.1.3.5.3. Building and Compilation

To build the driver libraries, you have to just execute `make`.

```
shell> make
```

If any errors occur, correct them and continue the build process. If you aren't able to build, then send a detailed email to [<myodbc@lists.mysql.com>](mailto:<myodbc@lists.mysql.com>) for further assistance.

### 21.1.3.5.4. Building Shared Libraries

On most platforms, MySQL does not build or support `.so` (shared) client libraries by default. This is based on our experience of problems when building shared libraries.

In cases like this, you have to download the MySQL distribution and configure it with these options:

```
--without-server --enable-shared
```

To build shared driver libraries, you must specify the `--enable-shared` option for `configure`. By default, `configure` does not enable this option.

If you have configured with the `--disable-shared` option, you can build the `.so` file from the static libraries using the following commands:

```
shell> cd mysql-connector-odbc-3.51.01
shell> make
shell> cd driver
shell> CC=/usr/bin/gcc \
$CC -bundle -flat_namespace -undefined error \
-o .libs/libmyodbc3-3.51.01.so \
catalog.o connect.o cursor.o dll.o error.o execute.o \
handle.o info.o misc.o myodbc3.o options.o prepare.o \
results.o transact.o utility.o \
-L/usr/local/mysql/lib/mysql/ \
-L/usr/local/iodbc/lib/ \
-lz -lc -lmysqlclient -liodbcinst
```

Make sure to change `-liodbcinst` to `-lodbcinst` if you are using `unixODBC` instead of `iODBC`, and configure the library paths accordingly.

This builds and places the `libmyodbc3-3.51.01.so` file in the `.libs` directory. Copy this file to the Connector/ODBC library installation directory (`/usr/local/lib` (or the `lib` directory under the installation directory that you supplied with the `--prefix`)).

```
shell> cd .libs
shell> cp libmyodbc3-3.51.01.so /usr/local/lib
shell> cd /usr/local/lib
shell> ln -s libmyodbc3-3.51.01.so libmyodbc3.so
```

To build the thread-safe driver library:

```
shell> CC=/usr/bin/gcc \
$CC -bundle -flat_namespace -undefined error
-o .libs/libmyodbc3_r-3.51.01.so
catalog.o connect.o cursor.o dll.o error.o execute.o
handle.o info.o misc.o myodbc3.o options.o prepare.o
results.o transact.o utility.o
-L/usr/local/mysql/lib/mysql/
-L/usr/local/iodbc/lib/
-lz -lc -lmysqlclient_r -liodbcinst
```

### 21.1.3.5.5. Installing Driver Libraries

To install the driver libraries, execute the following command:

```
shell> make install
```

That command installs one of the following sets of libraries:

For Connector/ODBC 3.51:

- `libmyodbc3.so`
- `libmyodbc3-3.51.01.so`, where 3.51.01 is the version of the driver
- `libmyodbc3.a`

For thread-safe Connector/ODBC 3.51:

- `libmyodbc3_r.so`
- `libmyodbc3-3_r.51.01.so`
- `libmyodbc3_r.a`

For more information on build process, refer to the `INSTALL` file that comes with the source distribution. Note that if you are trying to use the `make` from Sun, you may end up with errors. On the other hand, GNU `gmake` should work fine on all platforms.

### 21.1.3.5.6. Testing Connector/ODBC on Unix

To run the basic samples provided in the distribution with the libraries that you built, use the following command:

```
shell> make test
```

Before running the tests, create the DSN 'myodbc3' in `odbc.ini` and set the environment variable `ODBCINI` to the correct `odbc.ini` file; and MySQL server is running. You can find a sample `odbc.ini` with the driver distribution.

You can even modify the `samples/run-samples` script to pass the desired DSN, UID, and PASSWORD values as the command-line arguments to each sample.

### 21.1.3.5.7. Building Connector/ODBC from Source on Mac OS X

To build the driver on Mac OS X (Darwin), make use of the following `configure` example:

```
shell> ./configure --prefix=/usr/local
--with-unixODBC=/usr/local
--with-mysql-path=/usr/local/mysql
--disable-shared
--enable-gui=no
--host=powerpc-apple
```

The command assumes that the `unixODBC` and MySQL are installed in the default locations. If not, configure accordingly.

On Mac OS X, `--enable-shared` builds `.dylib` files by default. You can build `.so` files like this:

```
shell> make
shell> cd driver
shell> CC=/usr/bin/gcc \
$CC -bundle -flat_namespace -undefined error
```

```
-o .libs/libmyodbc3-3.51.01.so *.o
-L/usr/local/mysql/lib/
-L/usr/local/iodbc/lib
-liodbcinst -lmysqlclient -lz -lc
```

To build the thread-safe driver library:

```
shell> CC=/usr/bin/gcc \
$CC -bundle -flat_namespace -undefined error
-o .libs/libmyodbc3-3.51.01.so *.o
-L/usr/local/mysql/lib/
-L/usr/local/iodbc/lib
-liodbcinst -lmysqlclienti_r -lz -lc -lpthread
```

Make sure to change the `-liodbcinst` to `-lodbinst` in case of using `unixODBC` instead of `iODBC` and configure the libraries path accordingly.

In Apple's version of GCC, both `cc` and `gcc` are actually symbolic links to `gcc3`.

Copy this library to the `$prefix/lib` directory and symlink to `libmyodbc3.so`.

You can cross-check the output shared-library properties using this command:

```
shell> otool -LD .libs/libmyodbc3-3.51.01.so
```

### 21.1.3.5.8. Building Connector/ODBC from Source on HP-UX

To build the driver on HP-UX 10.x or 11.x, make use of the following `configure` example:

If using `cc`:

```
shell> CC="cc" \
CFLAGS="-z" \
LDFLAGS="-Wl,+b:-Wl,+s" \
./configure --prefix=/usr/local
--with-unixodbc=/usr/local
--with-mysql-path=/usr/local/mysql/lib/mysql
--enable-shared
--enable-thread-safe
```

If using `gcc`:

```
shell> CC="gcc" \
LDFLAGS="-Wl,+b:-Wl,+s" \
./configure --prefix=/usr/local
--with-unixodbc=/usr/local
--with-mysql-path=/usr/local/mysql
--enable-shared
--enable-thread-safe
```

Once the driver is built, cross-check its attributes using `chatr .libs/libmyodbc3.so` to determine whether you need to have set the MySQL client library path using the `SHLIB_PATH` environment variable. For static versions, ignore all shared-library options and run `configure` with the `--disable-shared` option.

### 21.1.3.5.9. Building Connector/ODBC from Source on AIX

To build the driver on AIX, make use of the following `configure` example:

```
shell> ./configure --prefix=/usr/local
--with-unixodbc=/usr/local
--with-mysql-path=/usr/local/mysql
--disable-shared
--enable-thread-safe
```

#### Note

For more information about how to build and set up the static and shared libraries across the different platforms refer to '[Using static and shared libraries across platforms](#)'.

### 21.1.3.6. Installing Connector/ODBC from the Development Source Tree

#### Caution

You should read this section only if you are interested in helping us test our new code. If you just want to get MySQL Connector/ODBC up and running on your system, you should use a standard release distribution.

To obtain the most recent development source tree, you first need to download and install Bazaar. You can obtain Bazaar from the [Bazaar VCS Web site](#). Bazaar is supported by any platform that supports Python, and is therefore compatible with any Linux, Unix, Windows or Mac OS X host. Instructions for downloading and installing Bazaar on the different platforms are available on the Bazaar Web site.

To build from the source trees, you need the following tools:

- autoconf 2.52 (or newer)
- automake 1.4 (or newer)
- libtool 1.4 (or newer)
- m4

The most recent development source tree is available from our public Subversion trees at <http://dev.mysql.com/tech-resources/sources.html>.

To checkout out the Connector/ODBC sources, change to the directory where you want the copy of the Connector/ODBC tree to be stored, then use the following command:

```
shell> bzr branch lp:myodbc
```

You should now have a copy of the entire Connector/ODBC source tree in the directory `connector-odbc3`. To build from this source tree on Unix or Linux follow these steps:

```
shell> cd myodbc
shell> aclocal
shell> autoheader
shell> libtoolize -c -f
shell> autoconf
shell> automake;
shell> ./configure # Add your favorite options here
shell> make
```

For more information on how to build, refer to the `INSTALL` file located in the same directory. For more information on options to `configure`, see [Section 21.1.3.5.1, “Typical configure Options”](#)

When the build is done, run `make install` to install the Connector/ODBC 3.51 driver on your system.

If you have gotten to the `make` stage and the distribution does not compile, please report it to [<myodbc@lists.mysql.com>](mailto:<myodbc@lists.mysql.com>).

On Windows, make use of Windows Makefiles `WIN-Makefile` and `WIN-Makefile_debug` in building the driver. For more information, see [Section 21.1.3.4, “Installing Connector/ODBC from a Source Distribution on Windows”](#).

After the initial checkout operation to get the source tree, you should run `bzr pull` periodically to update your source according to the latest version.

## 21.1.4. Connector/ODBC Configuration

Before you connect to a MySQL database using the Connector/ODBC driver you must configure an ODBC *Data Source Name*. The DSN associates the various configuration parameters required to communicate with a database to a specific name. You use the DSN in an application to communicate with the database, rather than specifying individual parameters within the application itself. DSN information can be user specific, system specific, or provided in a special file. ODBC data source names are configured in different ways, depending on your platform and ODBC driver.

### 21.1.4.1. Data Source Names

A Data Source Name associates the configuration parameters for communicating with a specific database. Generally a DSN consists of the following parameters:

- Name
- Host Name
- Database Name
- Login

- Password

In addition, different ODBC drivers, including Connector/ODBC, may accept additional driver-specific options and parameters.

There are three types of DSN:

- A *System DSN* is a global DSN definition that is available to any user and application on a particular system. A System DSN can normally only be configured by a systems administrator, or by a user who has specific permissions that let them create System DSNs.
- A *User DSN* is specific to an individual user, and can be used to store database connectivity information that the user regularly uses.
- A *File DSN* uses a simple file to define the DSN configuration. File DSNs can be shared between users and machines and are therefore more practical when installing or deploying DSN information as part of an application across many machines.

DSN information is stored in different locations depending on your platform and environment.

#### 21.1.4.2. Connector/ODBC Connection Parameters

You can specify the parameters in the following tables for Connector/ODBC when configuring a DSN. Users on Windows can use the Options and Advanced panels when configuring a DSN to set these parameters; see the table for information on which options relate to which fields and checkboxes. On Unix and Mac OS X, use the parameter name and value as the keyword/value pair in the DSN configuration. Alternatively, you can set these parameters within the `InConnectionString` argument in the `SQLDriverConnect()` call.

Parameter	Default Value	Comment
<code>user</code>	ODBC	The user name used to connect to MySQL.
<code>uid</code>	ODBC	Synonymous with <code>user</code> . Added in 3.51.16.
<code>server</code>	<code>localhost</code>	The host name of the MySQL server.
<code>database</code>		The default database.
<code>option</code>	0	Options that specify how Connector/ODBC should work. See below.
<code>port</code>	3306	The TCP/IP port to use if <code>server</code> is not <code>localhost</code> .
<code>initstmt</code>		Initial statement. A statement to execute when connecting to MySQL. In version 3.51 the parameter is called <code>stmt</code> . Note, the driver supports the initial statement being executed only at the time of the initial connection.
<code>password</code>		The password for the <code>user</code> account on <code>server</code> .
<code>pwd</code>		Synonymous with <code>password</code> . Added in 3.51.16.
<code>socket</code>		The Unix socket file or Windows named pipe to connect to if <code>server</code> is <code>localhost</code> .
<code>sslca</code>		The path to a file with a list of trust SSL CAs. Added in 3.51.16.
<code>sslcapath</code>		The path to a directory that contains trusted SSL CA certificates in PEM format. Added in 3.51.16.
<code>sslcert</code>		The name of the SSL certificate file to use for establishing a secure connection. Added in 3.51.16.
<code>sslcipher</code>		A list of permissible ciphers to use for SSL encryption. The cipher list has the same format as the <code>openssl ciphers</code> command Added in 3.51.16.
<code>sslkey</code>		The name of the SSL key file to use for establishing a secure connection. Added in 3.51.16.
<code>charset</code>		The character set to use for the connection. Added in 3.51.17.
<code>sslverify</code>		If set to 1, the SSL certificate will be verified when used with the MySQL connection. If not set, then the default behavior is to ignore SSL certificate verification.
<code>readtimeout</code>		The timeout in seconds for attempts to read from the server. Each attempt uses this timeout value and there are retries if necessary, so the total effective timeout value is three times the option value. You can set the value so that a lost connection can be detected earlier than the TCP/IP <code>Close_Wait_Timeout</code> value of 10 minutes. This option works only for TCP/IP connections, and only for Windows prior to MySQL 5.1.12. Corresponds to the <code>MYSQL_OPT_READ_TIMEOUT</code> option of the MySQL Client Library. This option was added in Connector/ODBC 3.51.27.

Parameter	Default Value	Comment
writetimeout		The timeout in seconds for attempts to write to the server. Each attempt uses this timeout value and there are <code>net_retry_count</code> retries if necessary, so the total effective timeout value is <code>net_retry_count</code> times the option value. This option works only for TCP/IP connections, and only for Windows prior to MySQL 5.1.12. Corresponds to the <code>MYSQL_OPT_WRITE_TIMEOUT</code> option of the MySQL Client Library. This option was added in Connector/ODBC 3.51.27.

### Note

The SSL configuration parameters can also be automatically loaded from a `my.ini` or `my.cnf` file.

The `option` argument is used to tell Connector/ODBC that the client isn't 100% ODBC compliant. On Windows, you normally select options by toggling the checkboxes in the connection screen, but you can also select them in the `option` argument. The following options are listed in the order in which they appear in the Connector/ODBC connect screen.

Value	Flagname	GUI Option	Description
1	<code>FLAG_FIELD_LENGTH</code>	Do not Optimize Column Width	The client cannot handle that Connector/ODBC returns the real width of a column. This option was removed in 3.51.18.
2	<code>FLAG_FOUND_ROWS</code>	Return Matching Rows	The client cannot handle that MySQL returns the true value of affected rows. If this flag is set, MySQL returns "found rows" instead. You must have MySQL 3.21.14 or newer to get this to work.
4	<code>FLAG_DEBUG</code>	Trace Driver Calls To myodbc.log	Make a debug log in <code>C:\myodbc.log</code> on Windows, or <code>/tmp/myodbc.log</code> on Unix variants. This option was removed in Connector/ODBC 3.51.18.
8	<code>FLAG_BIG_PACKETS</code>	Allow Big Results	Do not set any packet limit for results and bind parameters. Without this option, parameter binding will be truncated to 255 characters.
16	<code>FLAG_NO_PROMPT</code>	Do not Prompt Upon Connect	Do not prompt for questions even if driver would like to prompt.
32	<code>FLAG_DYNAMIC_CURSOR</code>	Enable Dynamic Cursor	Enable or disable the dynamic cursor support.
64	<code>FLAG_NO_SCHEMA</code>	Ignore # in Table Name	Ignore use of database name in <code>db_name.tbl_name.col_name</code> .
128	<code>FLAG_NO_DEFAULT_CURSOR</code>	User Manager Cursors	Force use of ODBC manager cursors (experimental).
256	<code>FLAG_NO_LOCALE</code>	Do not Use Set Locale	Disable the use of extended fetch (experimental).
512	<code>FLAG_PAD_SPACE</code>	Pad Char To Full Length	Pad <code>CHAR</code> columns to full column length.
1024	<code>FLAG_FULL_COLUMN_NAMES</code>	Return Table Names for SQLDescribeCol	<code>SQLDescribeCol()</code> returns fully qualified column names.
2048	<code>FLAG_COMPRESSED_PROTO</code>	Use Compressed Protocol	Use the compressed client/server protocol.
4096	<code>FLAG_IGNORE_SPACE</code>	Ignore Space After Function Names	Tell server to ignore space after function name and before "(" (needed by PowerBuilder). This makes all function names keywords.
8192	<code>FLAG_NAMED_PIPE</code>	Force Use of Named Pipes	Connect with named pipes to a <code>mysqld</code> server running on NT.
16384	<code>FLAG_NO_BIGINT</code>	Change BIGINT Columns to Int	Change <code>BIGINT</code> columns to <code>INT</code> columns (some applications cannot handle <code>BIGINT</code> ).
32768	<code>FLAG_NO_CATALOG</code>	No Catalog	Forces results from the catalog functions, such as <code>SQLTables</code> , to always return <code>NULL</code> and the driver to report that catalogs are not supported.
65536	<code>FLAG_USE_MYCNF</code>	Read Options From <code>my.cnf</code>	Read parameters from the <code>[client]</code> and <code>[odbc]</code> groups from <code>my.cnf</code> .
131072	<code>FLAG_SAFE</code>	Safe	Add some extra safety checks.
262144	<code>FLAG_NO_TRANSACTIONS</code>	Disable transactions	Disable transactions.
524288	<code>FLAG_LOG_QUERY</code>	Save queries to <code>myodbc.log</code>	Enable query logging to <code>c:\myodbc.sql(/</code>

		<code>bc.sql</code>	<code>tmp/myodbc.sql</code> ) file. (Enabled only in debug mode.)
1048576	<code>FLAG_NO_CACHE</code>	Do not Cache Result (forward only cursors)	Do not cache the results locally in the driver, instead read from server ( <code>mysql_use_result()</code> ). This works only for forward-only cursors. This option is very important in dealing with large tables when you do not want the driver to cache the entire result set.
2097152	<code>FLAG_FORWARD_CURSOR</code>	Force Use Of Forward Only Cursors	Force the use of <code>Forward-only</code> cursor type. In case of applications setting the default static/dynamic cursor type, and one wants the driver to use noncache result sets, then this option ensures the forward-only cursor behavior.
4194304	<code>FLAG_AUTO_RECONNECT</code>	Enable auto-reconnect.	Enables auto-reconnection functionality. You should not use this option with transactions, since a auto reconnection during a incomplete transaction may cause corruption. Note that an auto-reconnected connection will not inherit the same settings and environment as the original. This option was added in Connector/ODBC 3.51.13.
8388608	<code>FLAG_AUTO_IS_NULL</code>	Flag Auto Is Null	<p>When <code>FLAG_AUTO_IS_NULL</code> is set, the driver does not change the default value of <code>sql_auto_is_null</code>, leaving it at 1, so you get the MySQL default, not the SQL standard behavior.</p> <p>When <code>FLAG_AUTO_IS_NULL</code> is not set, the driver changes the default value of <code>SQL_AUTO_IS_NULL</code> to 0 after connecting, so you get the SQL standard, not the MySQL default behavior.</p> <p>Thus, omitting the flag disables the compatibility option and forces SQL standard behavior.</p> <p>See <code>IS NULL</code>. This option was added in Connector/ODBC 3.51.13.</p>
16777216	<code>FLAG_ZERO_DATE_TO_MIN</code>	Flag Zero Date to Min	Translates zero dates ( <code>XXXX-00-00</code> ) into the minimum date values supported by ODBC, <code>XXXX-01-01</code> . This resolves an issue where some statements will not work because the date returned and the minimum ODBC date value are incompatible. This option was added in Connector/ODBC 3.51.17.
33554432	<code>FLAG_MIN_DATE_TO_ZERO</code>	Flag Min Date to Zero	Translates the minimum ODBC date value ( <code>XXXX-01-01</code> ) to the zero date format supported by MySQL ( <code>XXXX-00-00</code> ). This resolves an issue where some statements will not work because the date returned and the minimum ODBC date value are incompatible. This option was added in Connector/ODBC 3.51.17.
67108864	<code>FLAG_MULTI_STATEMENTS</code>	Allow multiple statements	Enables support for batched statements. This option was added in Connector/ODBC 3.51.18.
134217728	<code>FLAG_COLUMN_SIZE_S32</code>	Limit column size to 32-bit value	Limits the column size to a signed 32-bit value to prevent problems with larger column sizes in applications that do not support them. This option is automatically enabled when working with ADO applications. This option was added in Connector/ODBC 3.51.22.
268435456	<code>FLAG_NO_BINARY_RESULT</code>	Always handle binary function results as character data	When set this option disables charset 63 for columns with an empty <code>org_table</code> . This option was added in Connector/ODBC 3.51.26.

To select multiple options, add together their values. For example, setting `option` to 12 (4+8) gives you debugging without packet limits.

### Note

From version of MySQL Connector/ODBC 5.1.6 onwards, it is possible to use the flag name directly as a parameter in the connection string, by using the flag name without the `FLAG_` prefix. So, in addition to using the `options` parameter with various flags set, it is now possible to use the flags directly as parameters. For example, `FIELD_LENGTH`, `FOUND_ROWS` and `DEBUG` could all be used as parameters.

The following table shows some recommended `option` values for various configurations.

Configuration	Option Value
Microsoft Access, Visual Basic	3
Driver trace generation (Debug mode)	4
Microsoft Access (with improved DELETE queries)	35
Large tables with too many rows	2049
Sybase PowerBuilder	135168
Query log generation (Debug mode)	524288
Generate driver trace as well as query log (Debug mode)	524292
Large tables with no-cache results	3145731

### 21.1.4.3. Configuring a Connector/ODBC DSN on Windows

The [ODBC Data Source Administrator](#) within Windows enables you to create DSNs, check driver installation and configure ODBC systems such as tracing (used for debugging) and connection pooling.

Different editions and versions of Windows store the [ODBC Data Source Administrator](#) in different locations depending on the version of Windows that you are using.

To open the [ODBC Data Source Administrator](#) in Windows Server 2003:

#### Tip

Because it is possible to create DSN using either the 32-bit or 64-bit driver, but using the same DNS identifier, it is advisable to include the driver being used within the DSN identifier. This will help you to identify the DSN when using it from applications such as Excel that are only compatible with the 32-bit driver. For example, you might add [Using32bitODBC](#) to the DSN identifier for the 32-bit interface and [Using64bitODBC](#) for those using the 64-bit Connector/ODBC driver.

1. On the [Start](#) menu, choose [Administrative Tools](#), and then click [Data Sources \(ODBC\)](#).

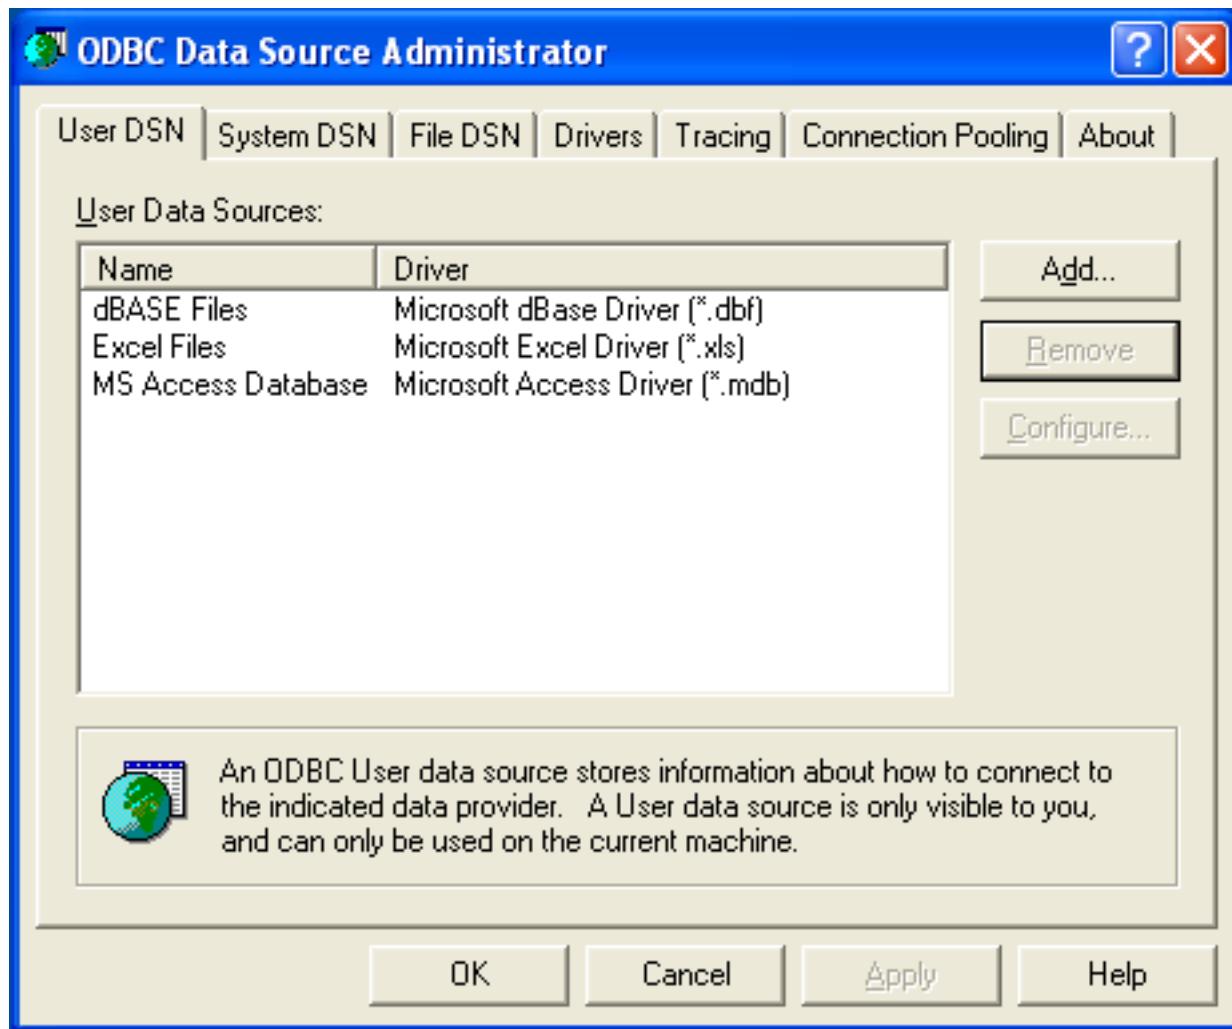

To open the [ODBC Data Source Administrator](#) in Windows 2000 Server or Windows 2000 Professional:

1. On the [Start](#) menu, choose [Settings](#), and then click [Control Panel](#).
2. In [Control Panel](#), click [Administrative Tools](#).
3. In [Administrative Tools](#), click [Data Sources \(ODBC\)](#).

To open the [ODBC Data Source Administrator](#) on Windows XP:

1. On the [Start](#) menu, click [Control Panel](#).
2. In the [Control Panel](#) when in [Category View](#) click [Performance and Maintenance](#) and then click [Administrative Tools..](#). If you are viewing the [Control Panel](#) in [Classic View](#), click [Administrative Tools](#).
3. In [Administrative Tools](#), click [Data Sources \(ODBC\)](#).

Irrespective of your Windows version, you should be presented the [ODBC Data Source Administrator](#) window:

Within Windows XP, you can add the [Administrative Tools](#) folder to your START menu to make it easier to locate the ODBC Data Source Administrator. To do this:

1. Right-click the START menu.
2. Select [Properties](#).
3. Click CUSTOMIZE....
4. Select the ADVANCED tab.
5. Within [Start menu items](#), within the [System Administrative Tools](#) section, select [Display on the All Programs menu](#).

Within both Windows Server 2003 and Windows XP you may want to permanently add the [ODBC Data Source Administrator](#) to your START menu. To do this, locate the [Data Sources \(ODBC\)](#) icon using the methods shown, then right-click on the icon and then choose PIN TO START MENU.

The interfaces for the 3.51 and 5.1 versions of the Connector/ODBC driver are different, although the fields and information that you need to enter remain the same.

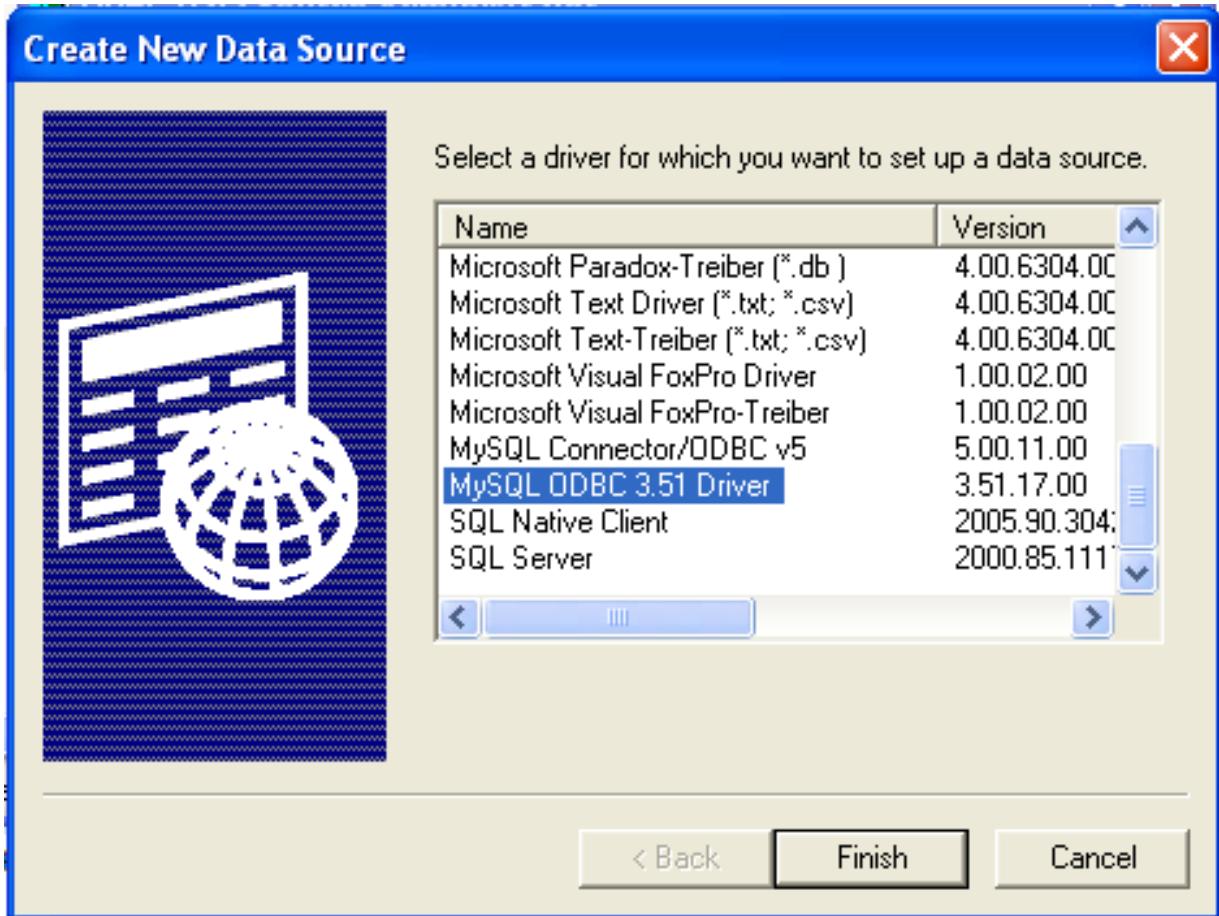

To configure a DSN using Connector/ODBC 3.51.x or Connector/ODBC 5.1.0, see [Section 21.1.4.3.1, “Configuring a Connector/ODBC 3.51 DSN on Windows”](#).

To configure a DSN using Connector/ODBC 5.1.1 or later, see [Section 21.1.4.3.2, “Configuring a Connector/ODBC 5.1 DSN on Windows”](#).

#### **21.1.4.3.1. Configuring a Connector/ODBC 3.51 DSN on Windows**

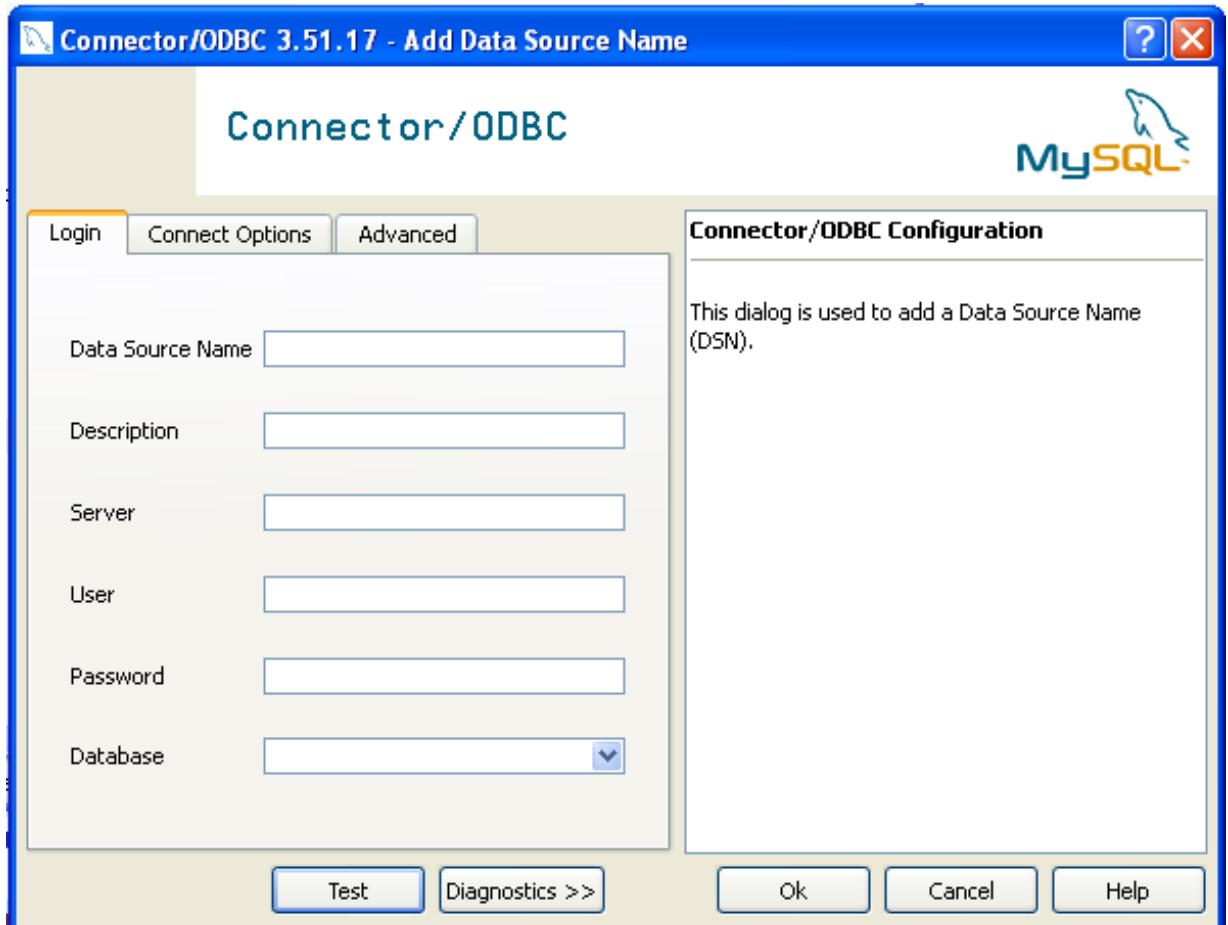

To add and configure a new Connector/ODBC data source on Windows, use the [ODBC Data Source Administrator](#):

1. Open the [ODBC Data Source Administrator](#).
2. To create a System DSN (which will be available to all users), select the [System DSN](#) tab. To create a User DSN, which will be unique only to the current user, click the ADD... button.
3. You will need to select the ODBC driver for this DSN.

Select [MySQL ODBC 3.51 Driver](#), then click FINISH.

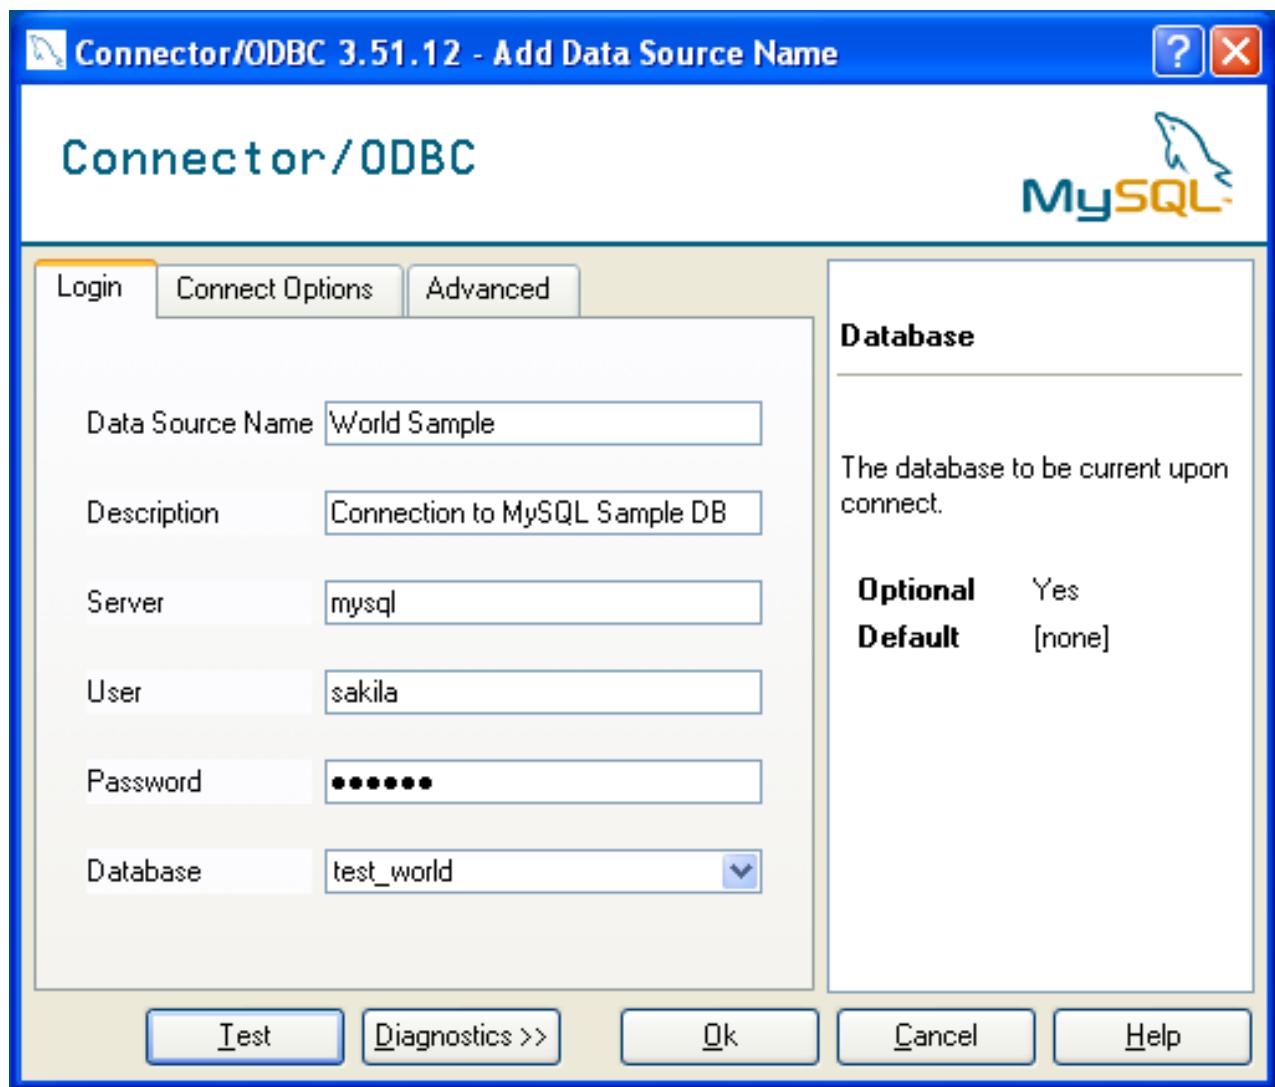

4. You now need to configure the specific fields for the DSN you are creating through the [Add Data Source Name](#) dialog.

In the **DATA SOURCE NAME** box, enter the name of the data source you want to access. It can be any valid name that you choose.

5. In the **DESCRIPTION** box, enter some text to help identify the connection.
6. In the **SERVER** field, enter the name of the MySQL server host that you want to access. By default, it is [localhost](#).
7. In the **USER** field, enter the user name to use for this connection.
8. In the **PASSWORD** field, enter the corresponding password for this connection.
9. The **DATABASE** pop-up should automatically populate with the list of databases that the user has permissions to access.
10. Click OK to save the DSN.

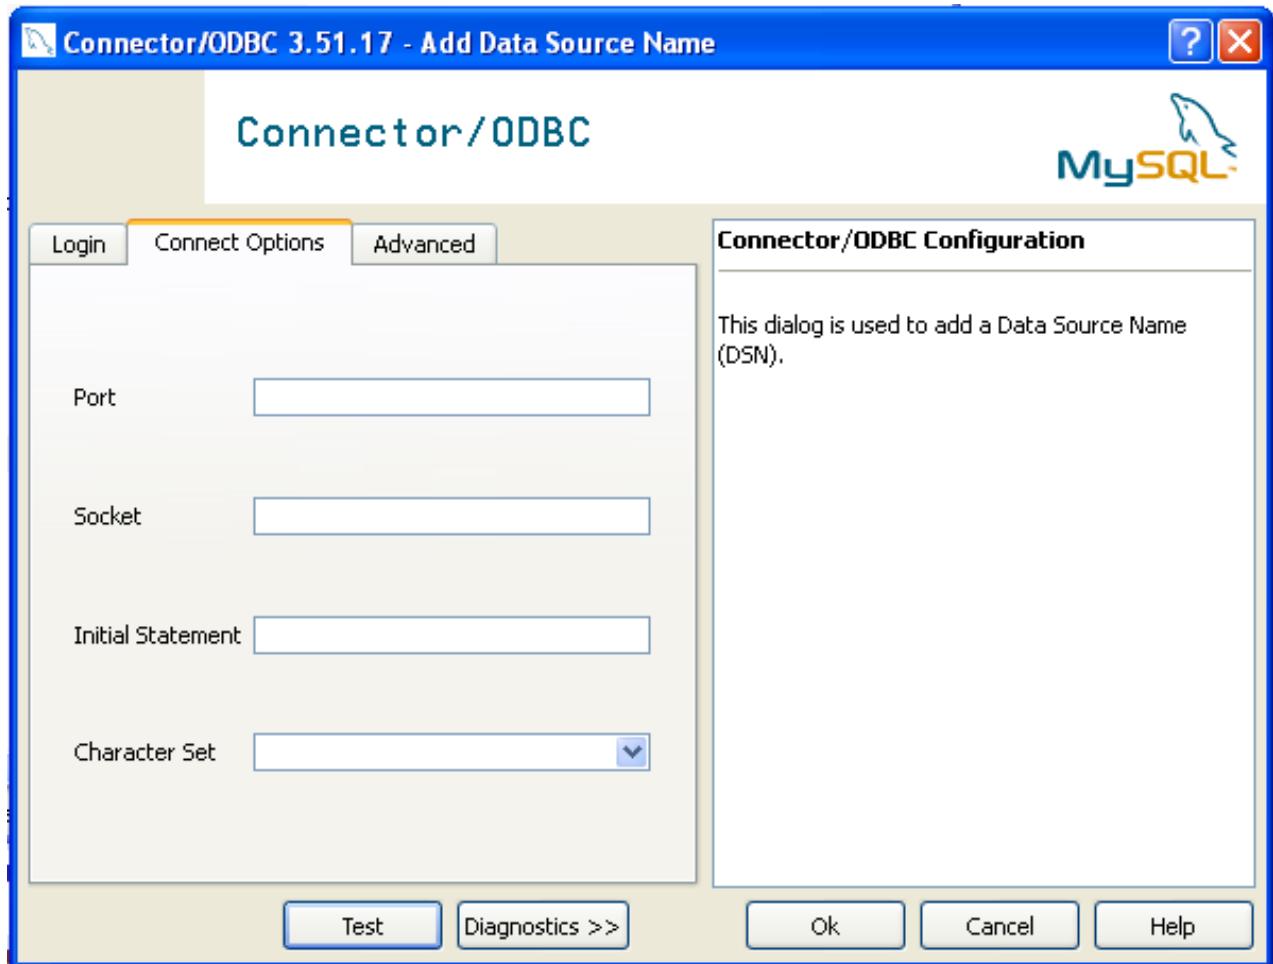

A completed DSN configuration may look like this:

You can verify the connection using the parameters you have entered by clicking the TEST button. If the connection could be made successfully, you will be notified with a `Success; connection was made!` dialog.

If the connection failed, you can obtain more information on the test and why it may have failed by clicking the DIAGNOSTICS... button to show additional error messages.

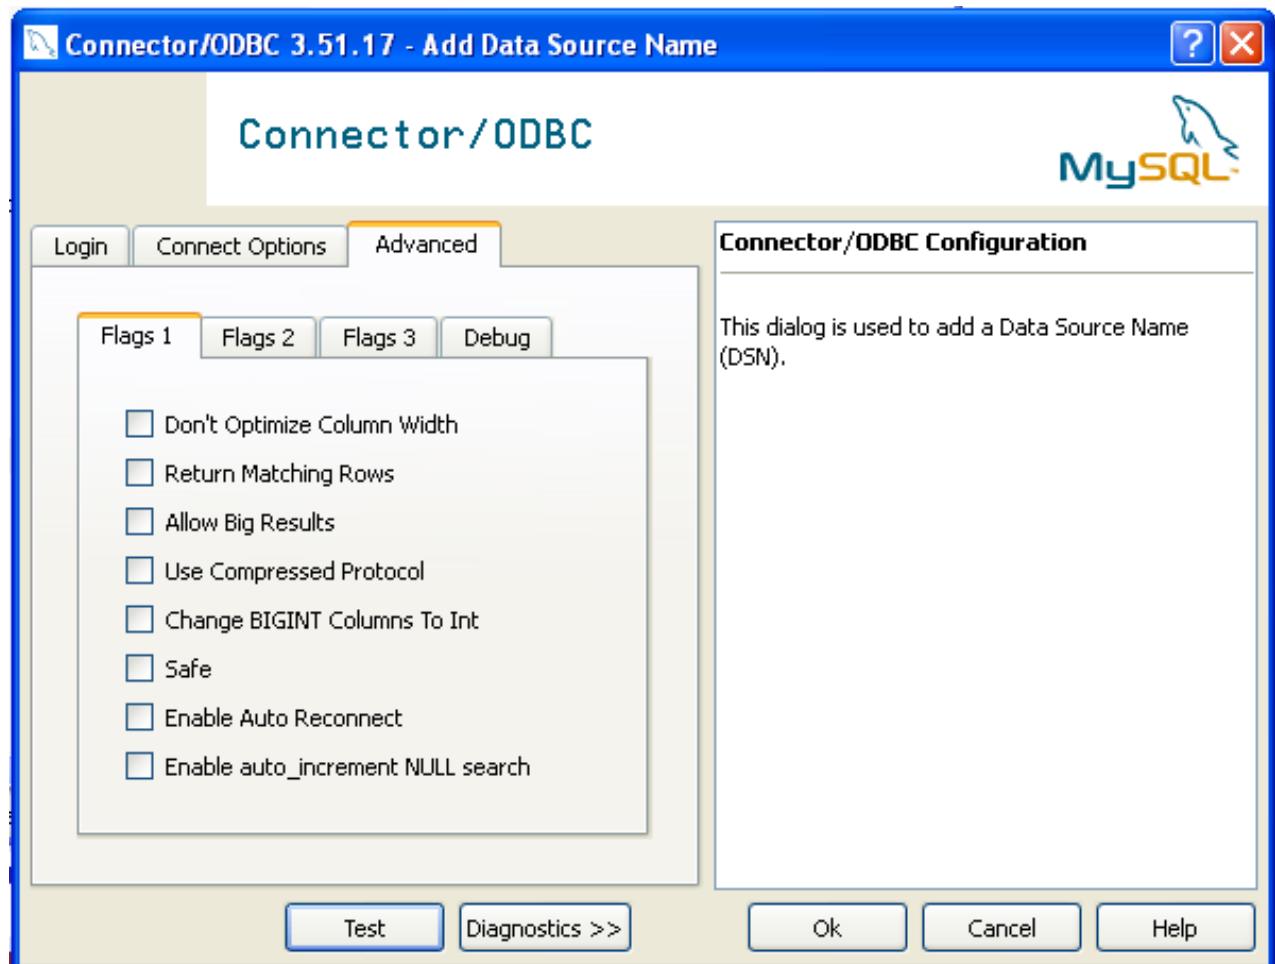

You can configure a number of options for a specific DSN by using either the CONNECT OPTIONS or ADVANCED tabs in the DSN configuration dialog.

The three options you can configure are:

- **PORT** sets the TCP/IP port number to use when communicating with MySQL. Communication with MySQL uses port 3306 by default. If your server is configured to use a different TCP/IP port, you must specify that port number here.
- **SOCKET** sets the name or location of a specific socket or Windows pipe to use when communicating with MySQL.
- **INITIAL STATEMENT** defines an SQL statement that will be executed when the connection to MySQL is opened. You can use this to set MySQL options for your connection, such as disabling autocommit.
- **CHARACTER SET** is a pop-up list from which you can select the default character set to be used with this connection. The Character Set option was added in 3.5.17.

The ADVANCED tab enables you to configure Connector/ODBC connection parameters. Refer to [Section 21.1.4.2, “Connector/ODBC Connection Parameters”](#), for information about the meaning of these options.

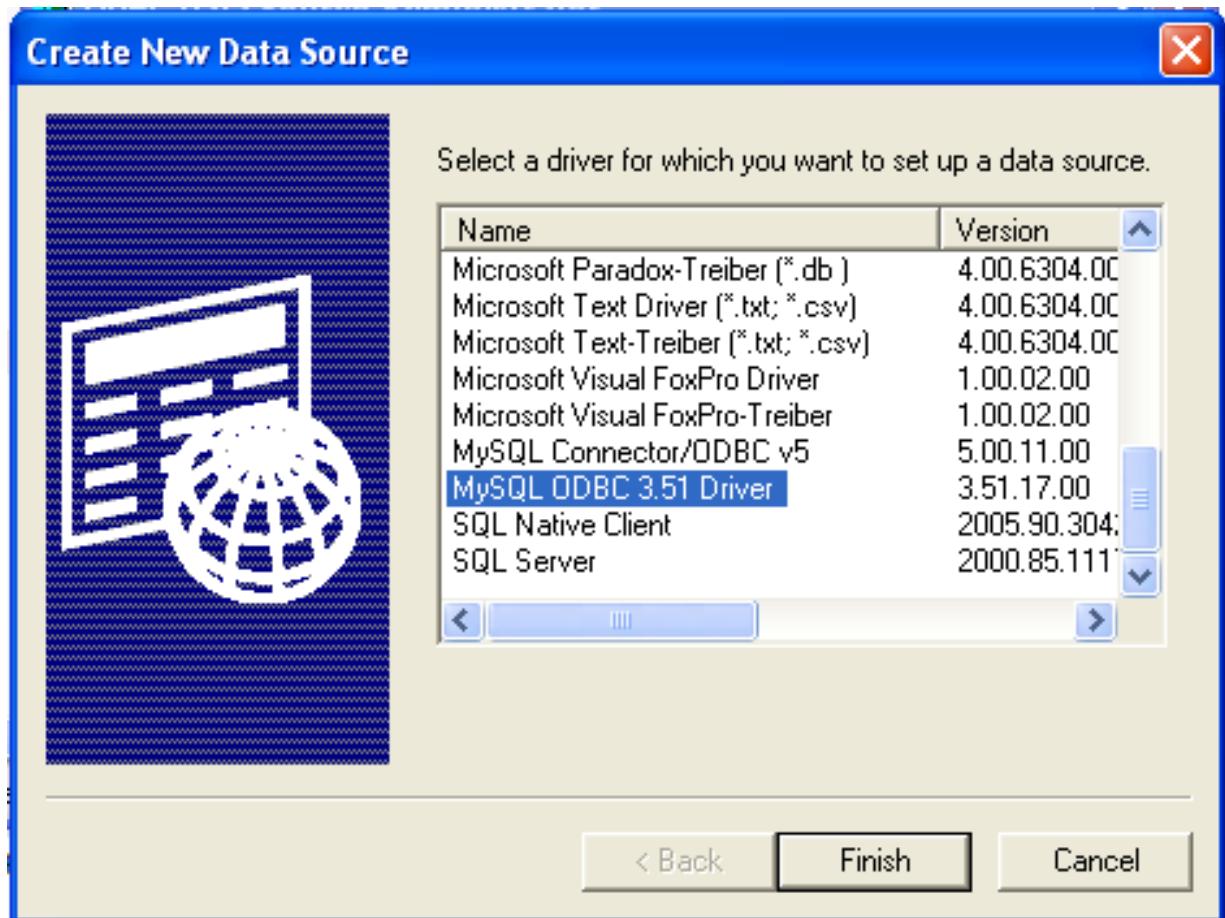

#### 21.1.4.3.2. Configuring a Connector/ODBC 5.1 DSN on Windows

The DSN configuration when using Connector/ODBC 5.1.1 and later has a slightly different layout. Also, due to the native Unicode support within Connector/ODBC 5.1, you no longer need to specify the initial character set to be used with your connection.

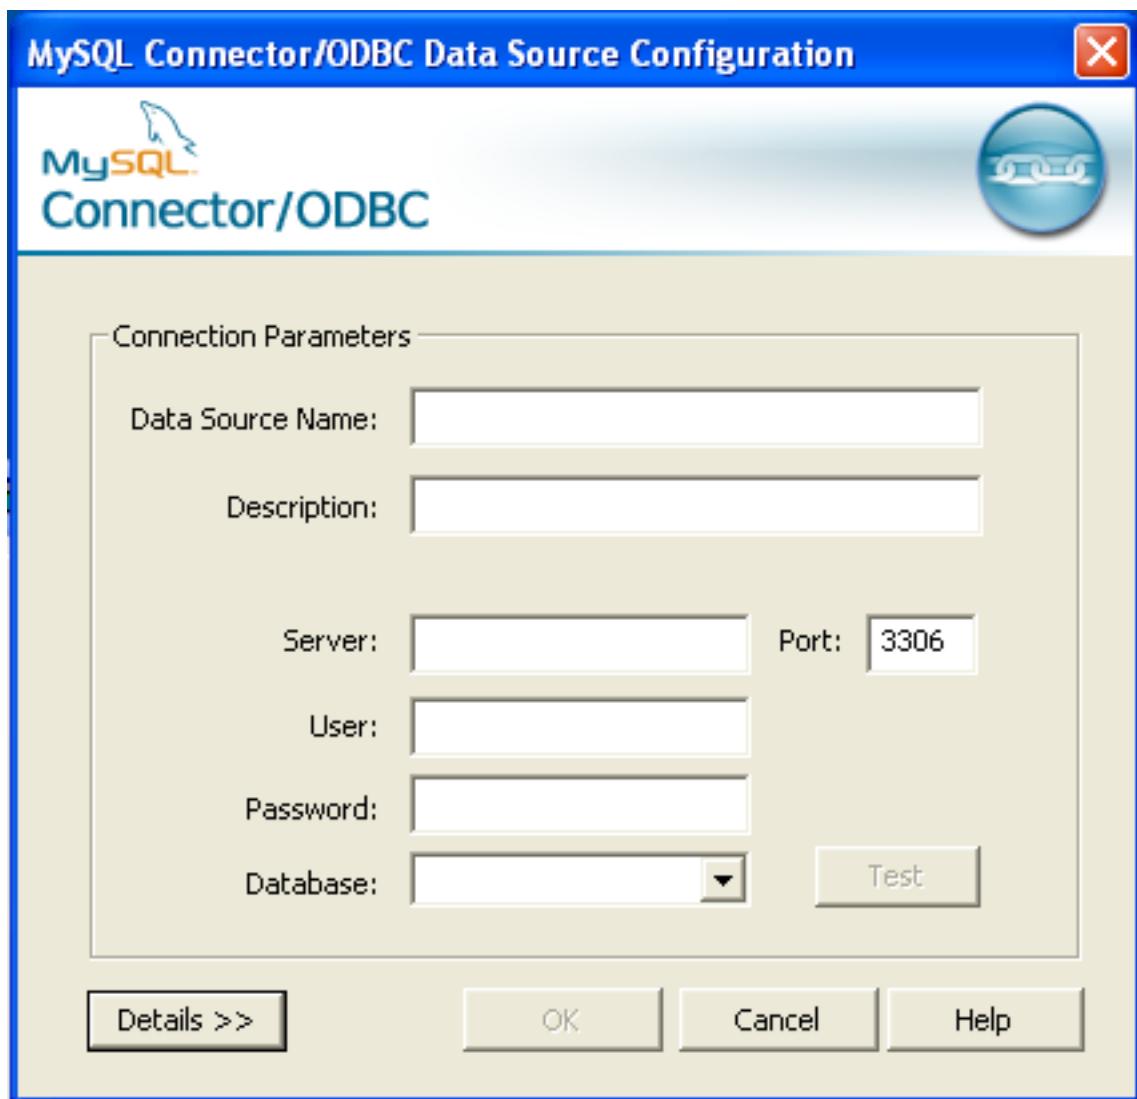

To configure a DSN using the Connector/ODBC 5.1.1 or later driver:

1. Open the [ODBC Data Source Administrator](#).
2. To create a System DSN (which will be available to all users), select the **SYSTEM DSN** tab. To create a User DSN, which will be unique only to the current user, click the ADD... button.
3. You will need to select the ODBC driver for this DSN.

Select [MySQL ODBC 5.1 Driver](#), then click FINISH.

4. You now need to configure the specific fields for the DSN you are creating through the [Connection Parameters](#) dialog.

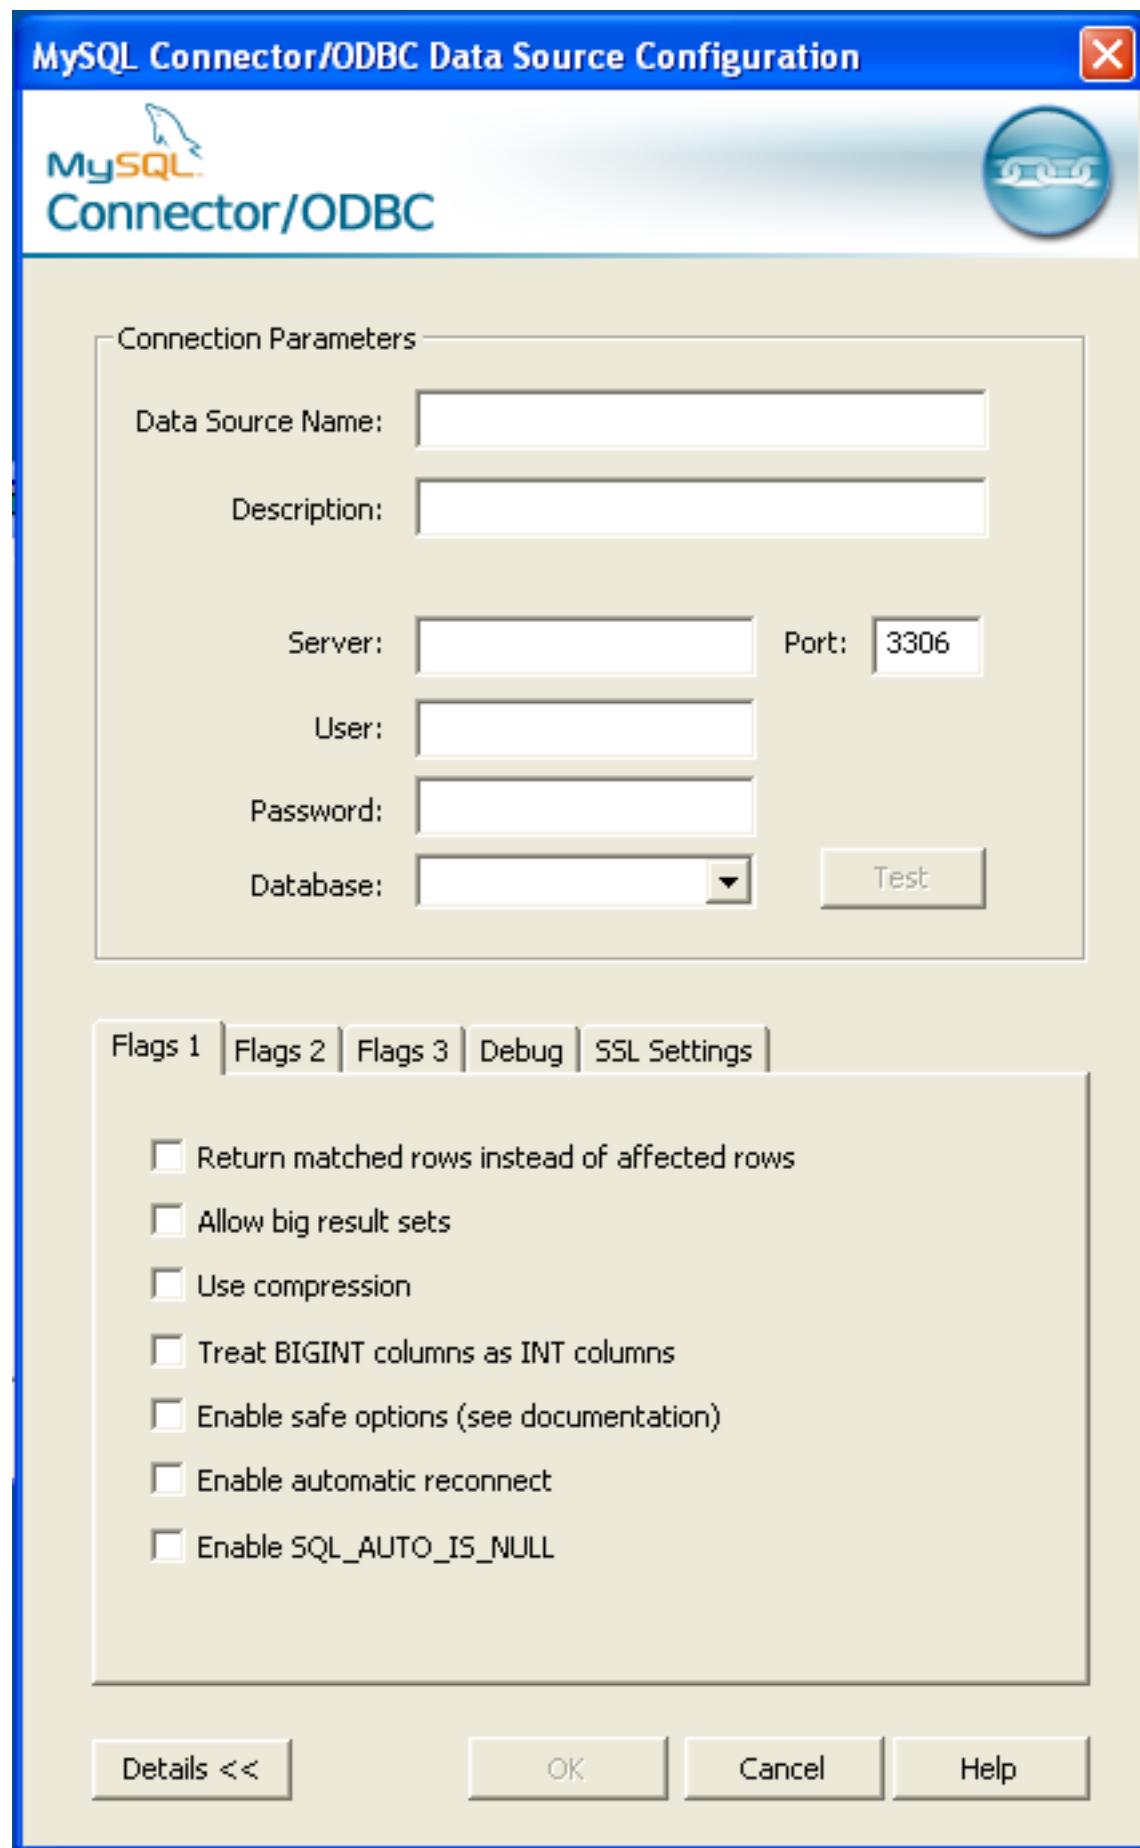

In the **DATA SOURCE NAME** box, enter the name of the data source you want to access. It can be any valid name that you choose.

5. In the **DESCRIPTION** box, enter some text to help identify the connection.
6. In the **SERVER** field, enter the name of the MySQL server host that you want to access. By default, it is `localhost`.
7. In the **USER** field, enter the user name to use for this connection.
8. In the **PASSWORD** field, enter the corresponding password for this connection.
9. The **DATABASE** pop-up should automatically populate with the list of databases that the user has permissions to access.
10. To communicate over a different TCP/IP port than the default (3306), change the value of the **PORT**.
11. Click **OK** to save the DSN.

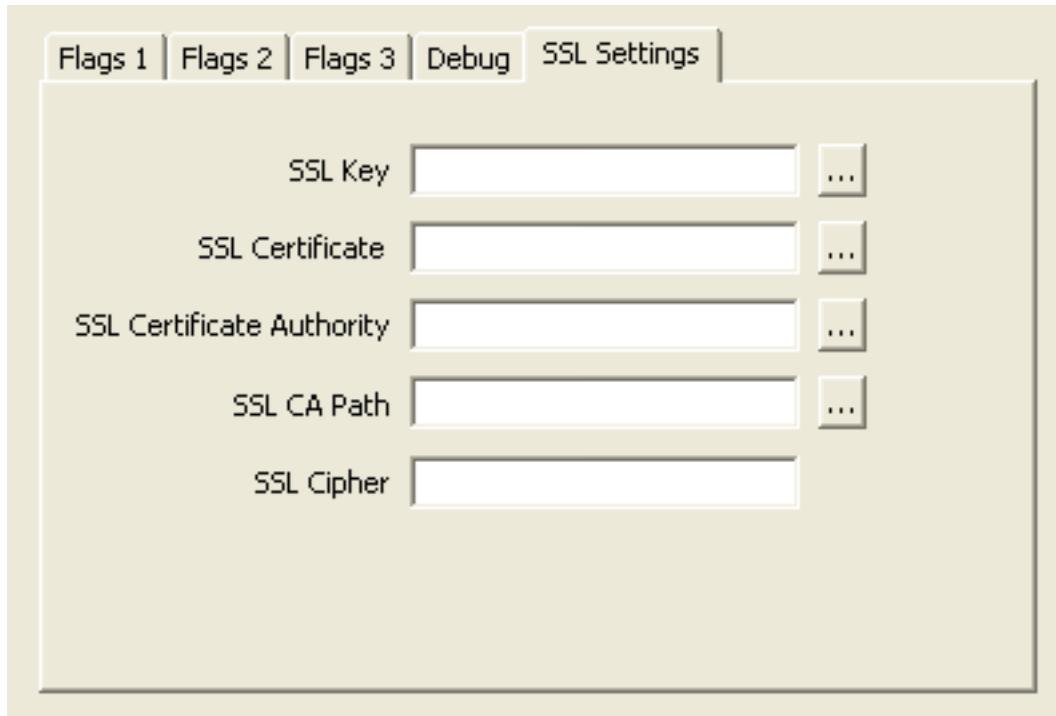

You can verify the connection using the parameters you have entered by clicking the **TEST** button. If the connection could be made successfully, you will be notified with a `Success; connection was made!` dialog.

You can configure a number of options for a specific DSN by using the **DETAILS** button.

The **DETAILS** button opens a tabbed display which enables you to set additional options:

- **FLAGS 1**, **FLAGS 2**, and **FLAGS 3** enable you to select the additional flags for the DSN connection. For more information on these flags, see [Section 21.1.4.2, “Connector/ODBC Connection Parameters”](#).
- **DEBUG** enables you to enable ODBC debugging to record the queries you execute through the DSN to the `myodbc.sql` file. For more information, see [Section 21.1.4.8, “Getting an ODBC Trace File”](#).
- **SSL SETTINGS** configures the additional options required for using the Secure Sockets Layer (SSL) when communicating with MySQL server. Note that you must have enabled SSL and configured the MySQL server with suitable certificates to communicate over SSL.

The ADVANCED tab enables you to configure Connector/ODBC connection parameters. Refer to [Section 21.1.4.2, “Connector/ODBC Connection Parameters”](#), for information about the meaning of these options.

### 21.1.4.3.3. Errors and Debugging

This section answers Connector/ODBC connection-related questions.

- While configuring a Connector/ODBC DSN, a **Could Not Load Translator or Setup Library** error occurs  
For more information, refer to [MS KnowledgeBase Article\(Q260558\)](#). Also, make sure you have the latest valid `ct13d32.dll` in your system directory.
- On Windows, the default `myodbc3.dll` is compiled for optimal performance. If you want to debug Connector/ODBC 3.51 (for example, to enable tracing), you should instead use `myodbc3d.dll`. To install this file, copy `myodbc3d.dll` over the installed `myodbc3.dll` file. Make sure to revert back to the release version of the driver DLL once you are done with the debugging because the debug version may cause performance issues. Note that the `myodbc3d.dll` isn't included in Connector/ODBC 3.51.07 through 3.51.11. If you are using one of these versions, you should copy that DLL from a previous version (for example, 3.51.06).

### 21.1.4.4. Configuring a Connector/ODBC DSN on Mac OS X

To configure a DSN on Mac OS X you can either use the `myodbc3i` utility, edit the `odbc.ini` file within the `Library/ODBC` directory of the user or the should use the ODBC Administrator. If you have Mac OS X 10.2 or earlier, refer to [Section 21.1.4.5, “Configuring a Connector/ODBC DSN on Unix”](#). Select whether you want to create a User DSN or a System DSN. If you want to add a System DSN, you may need to authenticate with the system. You must click the padlock and enter a user and password with administrator privileges.

For correct operation of ODBC Administrator, you should ensure that the `/Library/ODBC/odbc.ini` file used to set up ODBC connectivity and DSNs are writable by the `admin` group. If this file is not writable by this group then the ODBC Administrator may fail, or may appear to have worked but not generated the correct entry.

### Warning

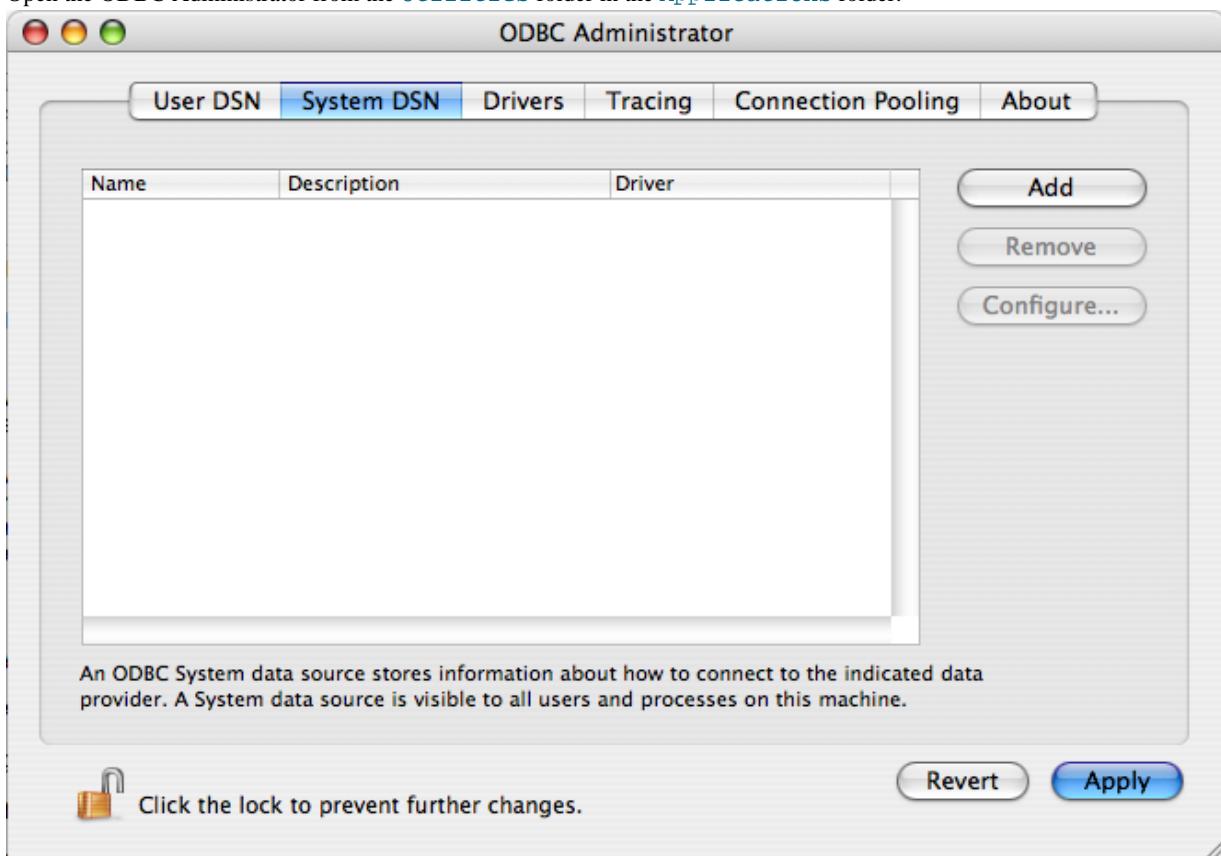

There are known issues with the OS X ODBC Administrator and Connector/ODBC that may prevent you from creating a DSN using this method. In this case you should use the command-line or edit the `odbc.ini` file directly. Note that existing DSNs or those that you create using the `myodbc3i` or `myodbc-installer` tool can still be checked and edited using ODBC Administrator.

To create a DSN using the `myodbc3i` utility, you need only specify the DSN type and the DSN connection string. For example:

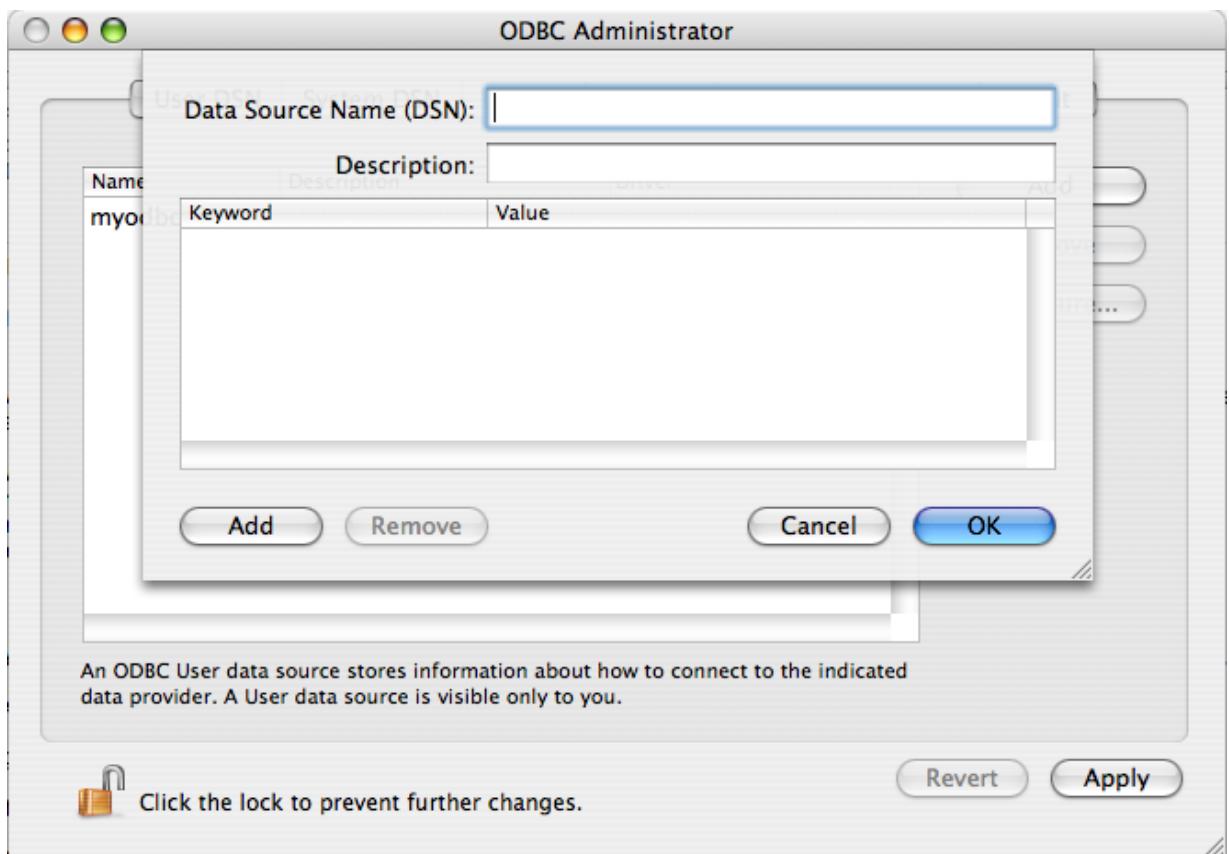

```
shell> myodbc3i -a -s -t "DSN=mydb;DRIVER=MySQL ODBC 3.51 Driver;SERVER=mysql;USER=username;PASSWORD=pass"
```

To use ODBC Administrator:

1. Open the ODBC Administrator from the `Utilities` folder in the `Applications` folder.

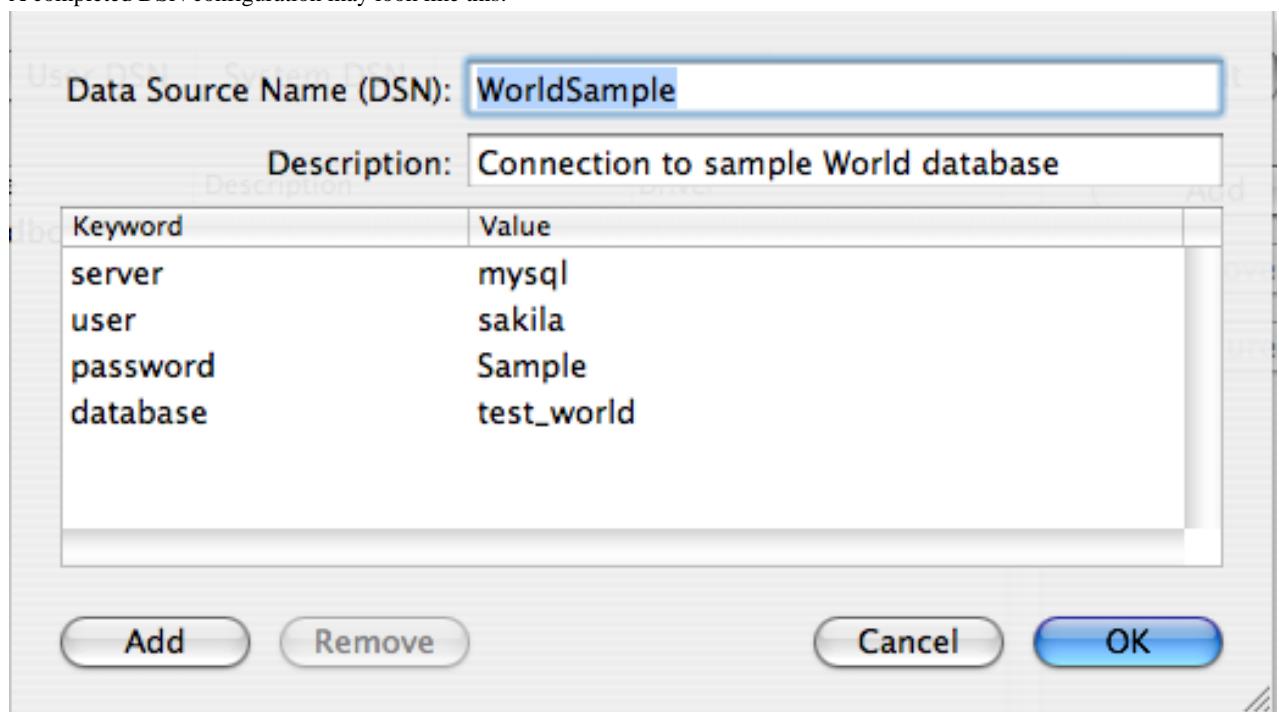

2. On the User DSN or System DSN panel, click ADD.
3. Select the Connector/ODBC driver and click OK.
4. You will be presented with the Data Source Name dialog. Enter The Data Source Name and an optional Description for the DSN.

5. Click ADD to add a new keyword/value pair to the panel. You should configure at least four pairs to specify the `server`, `username`, `password` and `database` connection parameters. See [Section 21.1.4.2, “Connector/ODBC Connection Parameters”](#).
6. Click OK to add the DSN to the list of configured data source names.

A completed DSN configuration may look like this:

You can configure other ODBC options in your DSN by adding further keyword/value pairs and setting the corresponding values. See [Section 21.1.4.2, “Connector/ODBC Connection Parameters”](#).

### 21.1.4.5. Configuring a Connector/ODBC DSN on Unix

On [Unix](#), you configure DSN entries directly in the `odbc.ini` file. Here is a typical `odbc.ini` file that configures `myodbc3` as the DSN name for Connector/ODBC 3.51:

```
; odbc.ini configuration for Connector/ODBC and Connector/ODBC 3.51 drivers

[ODBC Data Sources]
myodbc3 = MyODBC 3.51 Driver DSN

[myodbc3]
Driver = /usr/local/lib/libmyodbc3.so
Description = Connector/ODBC 3.51 Driver DSN
SERVER = localhost
PORT =
USER = root
Password =
Database = test
OPTION = 3
SOCKET =

[Default]
Driver = /usr/local/lib/libmyodbc3.so
Description = Connector/ODBC 3.51 Driver DSN
SERVER = localhost
PORT =
USER = root
Password =
Database = test
OPTION = 3
SOCKET =
```

Refer to the [Section 21.1.4.2, “Connector/ODBC Connection Parameters”](#), for the list of connection parameters that can be supplied.

#### Note

If you are using [unixODBC](#), you can use the following tools to set up the DSN:

- ODBCConfig GUI tool([HOWTO: ODBCConfig](#))
- `odbconfig`

In some cases when using [unixODBC](#), you might get this error:

```
Data source name not found and no default driver specified
```

If this happens, make sure the `ODBCINI` and `ODBCSYSINI` environment variables are pointing to the right `odbc.ini` file. For example, if your `odbc.ini` file is located in `/usr/local/etc`, set the environment variables like this:

```
export ODBCINI=/usr/local/etc/odbc.ini
export ODBCINI=/usr/local/etc
```

### 21.1.4.6. Connecting Without a Predefined DSN

You can connect to the MySQL server using `SQLDriverConnect`, by specifying the `DRIVER` name field. Here are the connection strings for Connector/ODBC using DSN-Less connections:

#### For Connector/ODBC 3.51:

```
ConnectionString = "DRIVER={MySQL ODBC 3.51 Driver};" \
 SERVER=localhost; \
 DATABASE=test; \
 USER=venu; \
 PASSWORD=venu; \
 OPTION=3;"
```

If your programming language converts backslash followed by whitespace to a space, it is preferable to specify the connection string as a single long string, or to use a concatenation of multiple strings that does not add spaces in between. For example:

```
ConnectionString = "DRIVER={MySQL ODBC 3.51 Driver};"
```

```
"SERVER=localhost;"
"DATABASE=test;"
"USER=venu;"
"PASSWORD=venu;"
"OPTION=3;"
```

**Note.** Note that on Mac OS X you may need to specify the full path to the Connector/ODBC driver library.

Refer to the [Section 21.1.4.2, “Connector/ODBC Connection Parameters”](#), for the list of connection parameters that can be supplied.

#### 21.1.4.7. ODBC Connection Pooling

Connection pooling enables the ODBC driver to re-use existing connections to a given database from a pool of connections, instead of opening a new connection each time the database is accessed. By enabling connection pooling you can improve the overall performance of your application by lowering the time taken to open a connection to a database in the connection pool.

For more information about connection pooling: <http://support.microsoft.com/default.aspx?scid=kb;EN-US;q169470>.

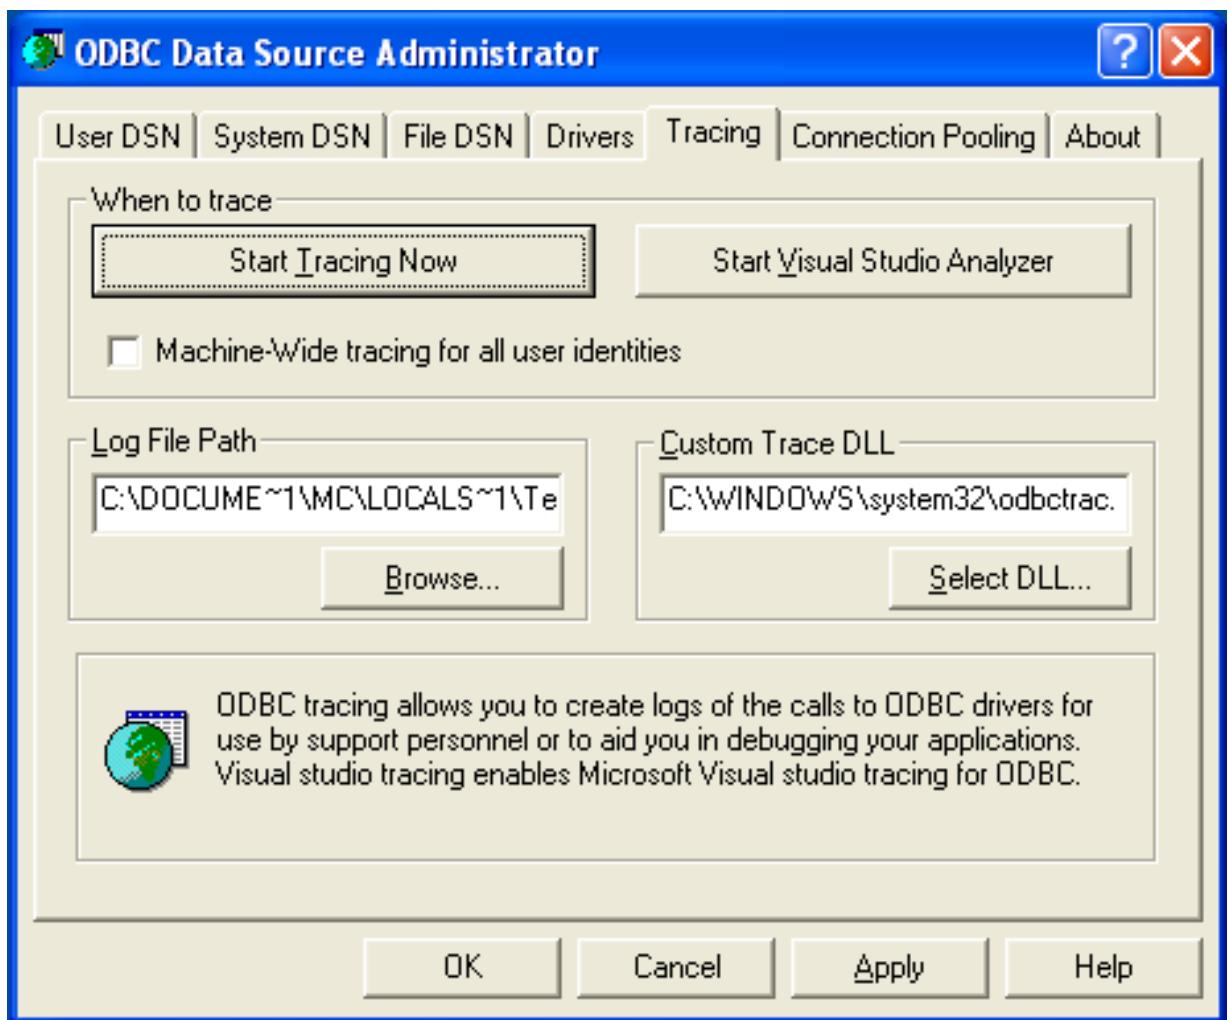

#### 21.1.4.8. Getting an ODBC Trace File

If you encounter difficulties or problems with Connector/ODBC, you should start by making a log file from the [ODBC Manager](#) and Connector/ODBC. This is called *tracing*, and is enabled through the ODBC Manager. The procedure for this differs for Windows, Mac OS X and Unix.

##### 21.1.4.8.1. Enabling ODBC Tracing on Windows

To enable the trace option on Windows:

1. The [Tracing](#) tab of the ODBC Data Source Administrator dialog box enables you to configure the way ODBC function calls are traced.

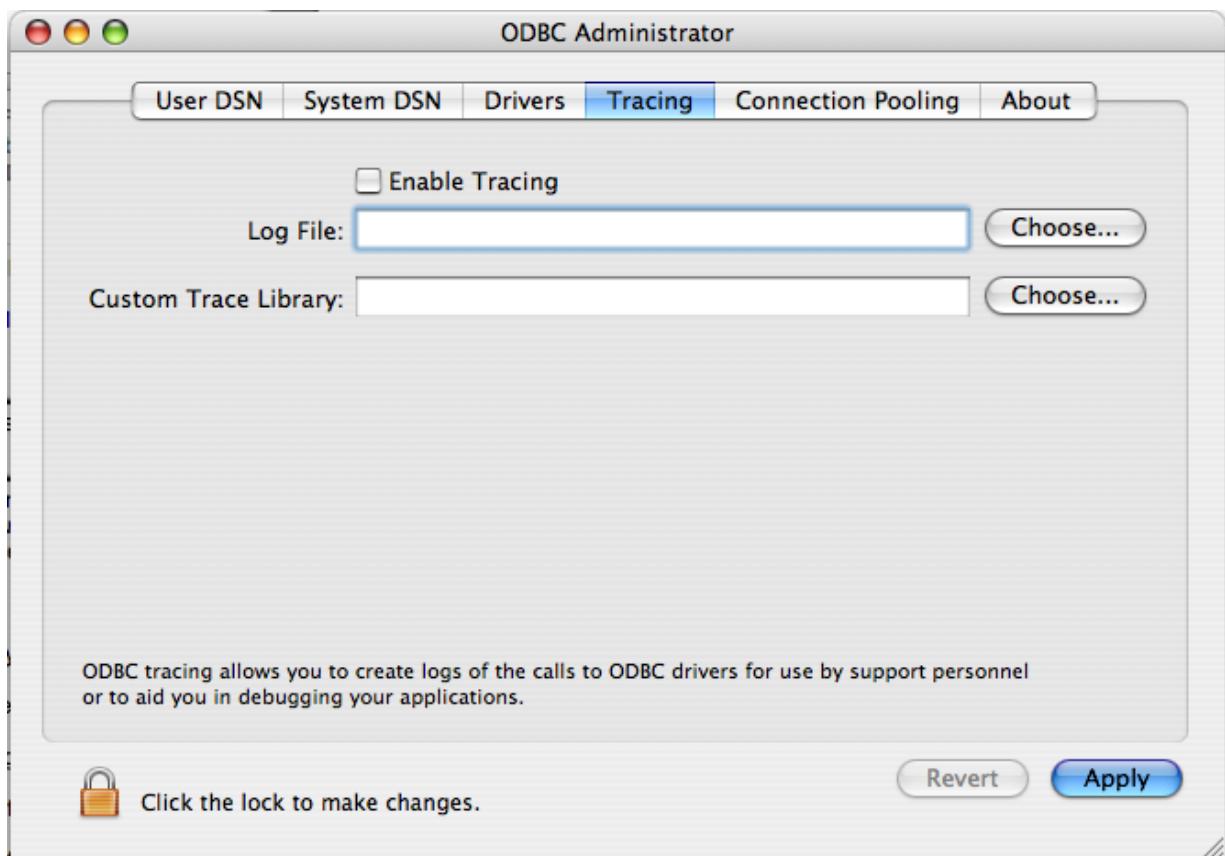

2. When you activate tracing from the [Tracing](#) tab, the [Driver Manager](#) logs all ODBC function calls for all subsequently run applications.
3. ODBC function calls from applications running before tracing is activated are not logged. ODBC function calls are recorded in a log file you specify.
4. Tracing ceases only after you click [Stop Tracing Now](#). Remember that while tracing is on, the log file continues to increase in size and that tracing affects the performance of all your ODBC applications.

#### **21.1.4.8.2. Enabling ODBC Tracing on Mac OS X**

To enable the trace option on Mac OS X 10.3 or later you should use the [Tracing](#) tab within ODBC Administrator .

1. Open the ODBC Administrator.
2. Select the [Tracing](#) tab.

3. Select the `Enable Tracing` checkbox.
4. Enter the location where you want to save the Tracing log. If you want to append information to an existing log file, click the CHOOSE... button.

#### 21.1.4.8.3. Enabling ODBC Tracing on Unix

To enable the trace option on Mac OS X 10.2 (or earlier) or Unix you must add the `trace` option to the ODBC configuration:

1. On Unix, you need to explicitly set the `Trace` option in the `ODBC.INI` file.

Set the tracing `ON` or `OFF` by using `TraceFile` and `Trace` parameters in `odbc.ini` as shown below:

```
TraceFile = /tmp/odbc.trace
Trace = 1
```

`TraceFile` specifies the name and full path of the trace file and `Trace` is set to `ON` or `OFF`. You can also use `1` or `YES` for `ON` and `0` or `NO` for `OFF`. If you are using `ODBCConfig` from `unixODBC`, then follow the instructions for tracing `unixODBC` calls at [HOWTO-ODBCConfig](#).

#### 21.1.4.8.4. Enabling a Connector/ODBC Log

To generate a Connector/ODBC log, do the following:

1. Within Windows, enable the `Trace Connector/ODBC` option flag in the Connector/ODBC connect/configure screen. The log is written to file `C:\myodbc.log`. If the trace option is not remembered when you are going back to the above screen, it means that you are not using the `myodbc.dll` driver, see [Section 21.1.4.3.3, “Errors and Debugging”](#).

On Mac OS X, Unix, or if you are using DSN-Less connection, then you need to supply `OPTION=4` in the connection string or set the corresponding keyword/value pair in the DSN.

2. Start your application and try to get it to fail. Then check the Connector/ODBC trace file to find out what could be wrong.

If you need help determining what is wrong, see [Section 21.1.8.1, “Connector/ODBC Community Support”](#).

## 21.1.5. Connector/ODBC Examples

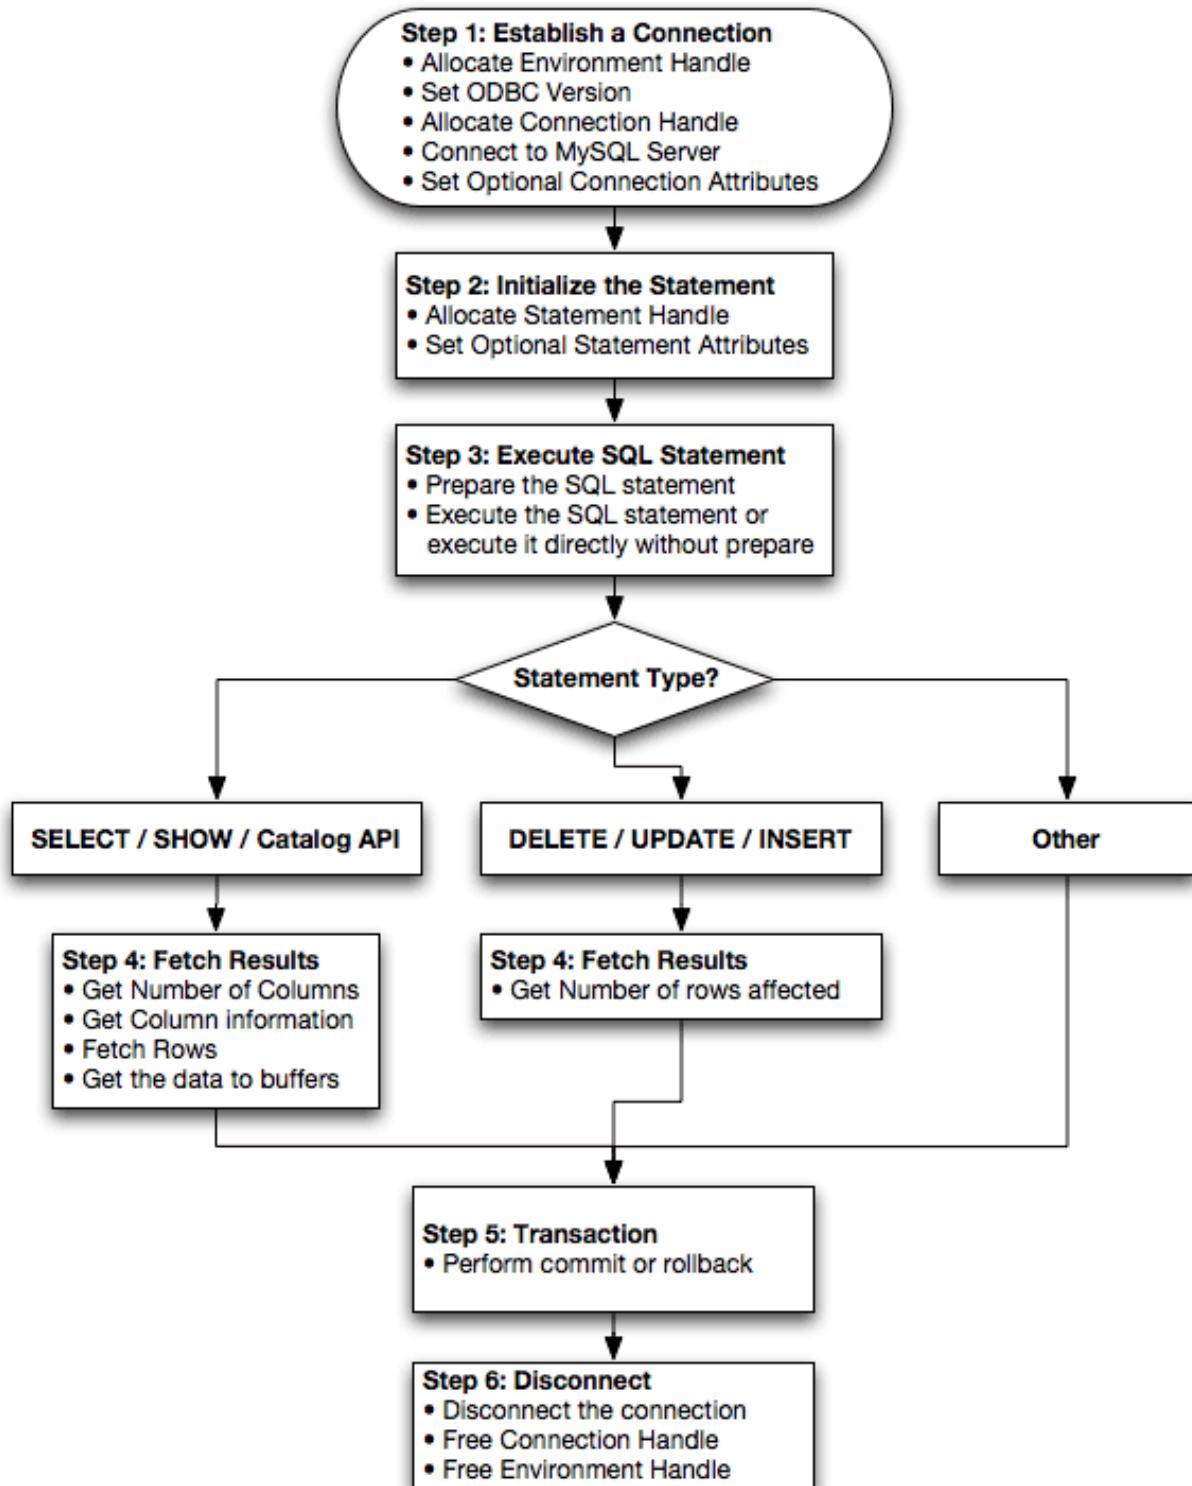

Once you have configured a DSN to provide access to a database, how you access and use that connection is dependent on the application or programming language. As ODBC is a standardized interface, any application or language that supports ODBC can use the DSN and connect to the configured database.

### 21.1.5.1. Basic Connector/ODBC Application Steps

Interacting with a MySQL server from an applications using the Connector/ODBC typically involves the following operations:

- Configure the Connector/ODBC DSN
- Connect to MySQL server
- Initialization operations
- Execute SQL statements
- Retrieve results
- Perform Transactions
- Disconnect from the server

Most applications use some variation of these steps. The basic application steps are shown in the following diagram:

### 21.1.5.2. Step-by-step Guide to Connecting to a MySQL Database through Connector/ODBC

A typical installation situation where you would install Connector/ODBC is when you want to access a database on a Linux or Unix host from a Windows machine.

As an example of the process required to set up access between two machines, the steps below take you through the basic steps. These instructions assume that you want to connect to system ALPHA from system BETA with a user name and password of `my-user` and `mypassword`.

On system ALPHA (the MySQL server) follow these steps:

1. Start the MySQL server.
2. Use `GRANT` to set up an account with a user name of `myuser` that can connect from system BETA using a password of `mypassword` to the database `test`:

```
GRANT ALL ON test.* to 'myuser'@'BETA' IDENTIFIED BY 'mypassword';
```

For more information about MySQL privileges, refer to [Section 5.5, “MySQL User Account Management”](#).

On system BETA (the Connector/ODBC client), follow these steps:

1. Configure a Connector/ODBC DSN using parameters that match the server, database and authentication information that you have just configured on system ALPHA.

Parameter	Value	Comment
DSN	remote_test	A name to identify the connection.
SERVER	ALPHA	The address of the remote server.
DATABASE	test	The name of the default database.
USER	myuser	The user name configured for access to this database.
PASSWORD	mypassword	The password for <code>myuser</code> .

2. Using an ODBC-capable application, such as Microsoft Office, connect to the MySQL server using the DSN you have just created. If the connection fails, use tracing to examine the connection process. See [Section 21.1.4.8, “Getting an ODBC Trace File”](#), for more information.

### 21.1.5.3. Connector/ODBC and Third-Party ODBC Tools

Once you have configured your Connector/ODBC DSN, you can access your MySQL database through any application that supports the ODBC interface, including programming languages and third-party applications. This section contains guides and help on using Connector/ODBC with various ODBC-compatible tools and applications, including Microsoft Word, Microsoft Excel and Adobe/Macromedia ColdFusion.

Connector/ODBC has been tested with the following applications.

Publisher	Application	Notes
Adobe	ColdFusion	Formerly Macromedia ColdFusion
Borland	C++ Builder	
	Builder 4	
	Delphi	
Business Objects	Crystal Reports	
Claris	Filemaker Pro	
Corel	Paradox	
Computer Associates	Visual Objects	Also known as CAVO
	AllFusion ERwin Data Modeler	
Gupta	Team Developer	Previously known as Centura Team Developer; Gupta SQL/Windows
Gensym	G2-ODBC Bridge	
Inline	iHTML	
Lotus	Notes	Versions 4.5 and 4.6
Microsoft	Access	
	Excel	
	Visio Enterprise	
	Visual C++	
	Visual Basic	

	ODBC.NET	Using C#, Visual Basic, C++
	FoxPro	
	Visual Interdev	
OpenOffice.org	OpenOffice.org	
Perl	DBD::ODBC	
Pervasive Software	DataJunction	
Sambar Technologies	Sambar Server	
SPSS	SPSS	
SoftVelocity	Clarion	
SQLExpress	SQLExpress for Xbase++	
Sun	StarOffice	
SunSystems	Vision	
Sybase	PowerBuilder	
	PowerDesigner	
theKompany.com	Data Architect	

If you know of any other applications that work with Connector/ODBC, please send mail to <[myodbc@lists.mysql.com](mailto:myodbc@lists.mysql.com)> about them.

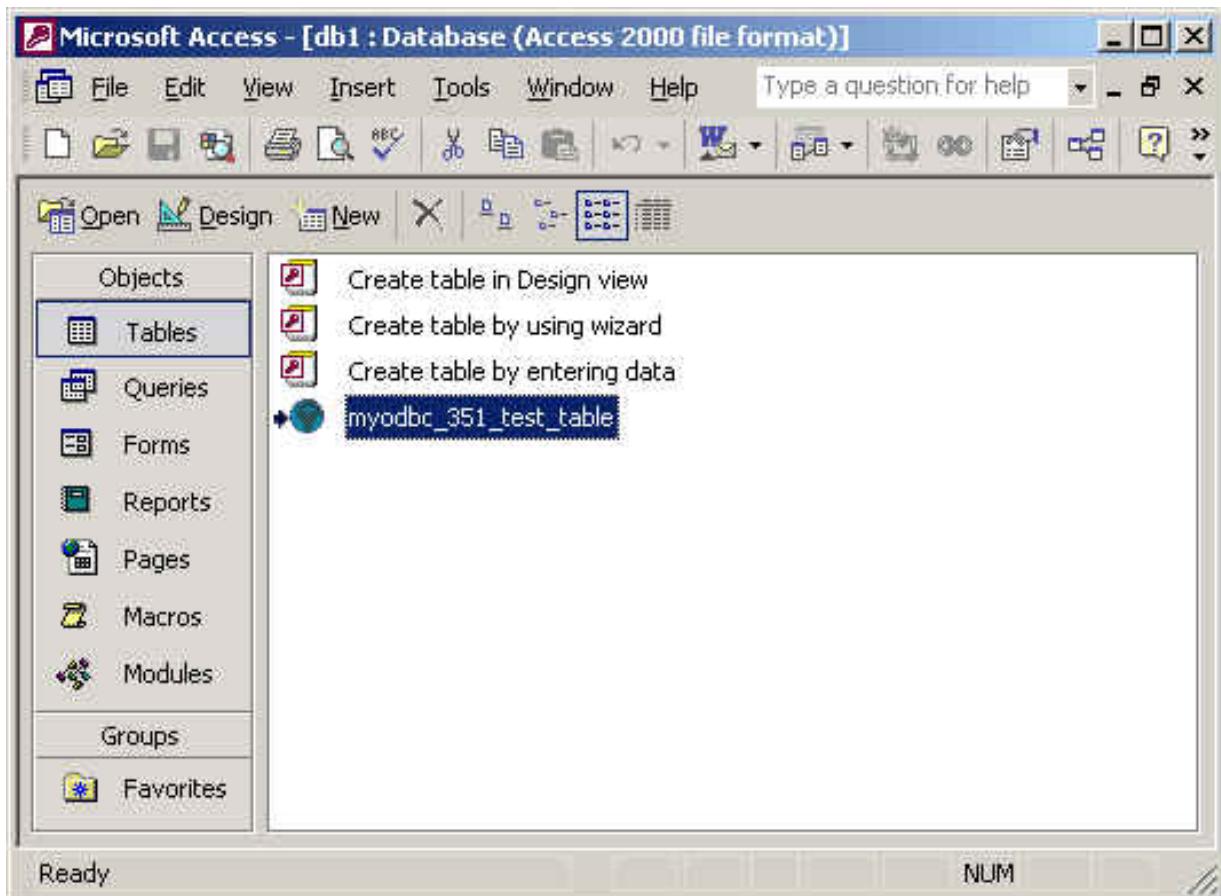

#### **21.1.5.4. Using Connector/ODBC with Microsoft Access**

You can use MySQL database with Microsoft Access using Connector/ODBC. The MySQL database can be used as an import source, an export source, or as a linked table for direct use within an Access application, so you can use Access as the front-end interface to a MySQL database.

##### **21.1.5.4.1. Exporting Access Data to MySQL**

To export a table of data from an Access database to MySQL, follow these instructions:

1. When you open an Access database or an Access project, a Database window appears. It displays shortcuts for creating new database objects and opening existing objects.

2. Click the name of the **table** or **query** you want to export, and then in the **File** menu, select **Export**.
3. In the **Export Object Type Object name To** dialog box, in the **Save As Type** box, select **ODBC Databases ()** as shown here:

4. In the **Export** dialog box, enter a name for the file (or use the suggested name), and then select **OK**.
5. The Select Data Source dialog box is displayed; it lists the defined data sources for any ODBC drivers installed on your computer. Click either the File Data Source or Machine Data Source tab, and then double-click the Connector/ODBC or Connector/ODBC 3.51 data source that you want to export to. To define a new data source for Connector/ODBC, please [Section 21.1.4.3, "Configuring a Connector/ODBC DSN on Windows"](#).

#### **Note**

Ensure that the information that you are exporting to the MySQL table is valid for the corresponding MySQL data types. Values that are outside of the supported range of the MySQL data type but valid within Access may trigger an “overflow” error during the export.

Microsoft Access connects to the MySQL Server through this data source and exports new tables and or data.

#### **21.1.5.4.2. Importing MySQL Data to Access**

To import a table or tables from MySQL to Access, follow these instructions:

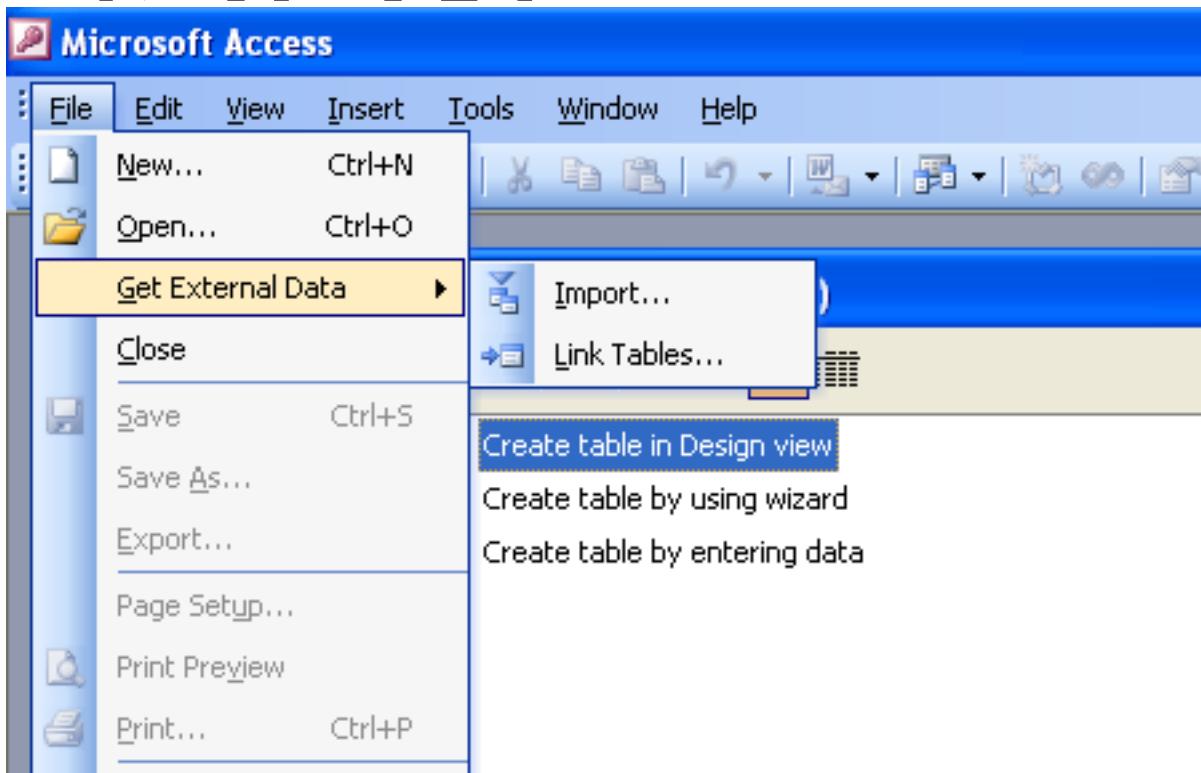

1. Open a database, or switch to the Database window for the open database.
2. To import tables, on the **File** menu, point to **Get External Data**, and then click **Import**.
3. In the **Import** dialog box, in the Files Of Type box, select **ODBC DATABASES ()**. The Select Data Source dialog box lists the defined data sources **THE SELECT DATA SOURCE** dialog box is displayed; it lists the defined data source names.
4. If the ODBC data source that you selected requires you to log on, enter your login ID and password (additional information might also be required), and then click **OK**.
5. Microsoft Access connects to the MySQL server through **ODBC data source** and displays the list of tables that you can **import**.
6. Click each table that you want to **import**, and then click **OK**.

#### **21.1.5.4.3. Using Microsoft Access as a Front-end to MySQL**

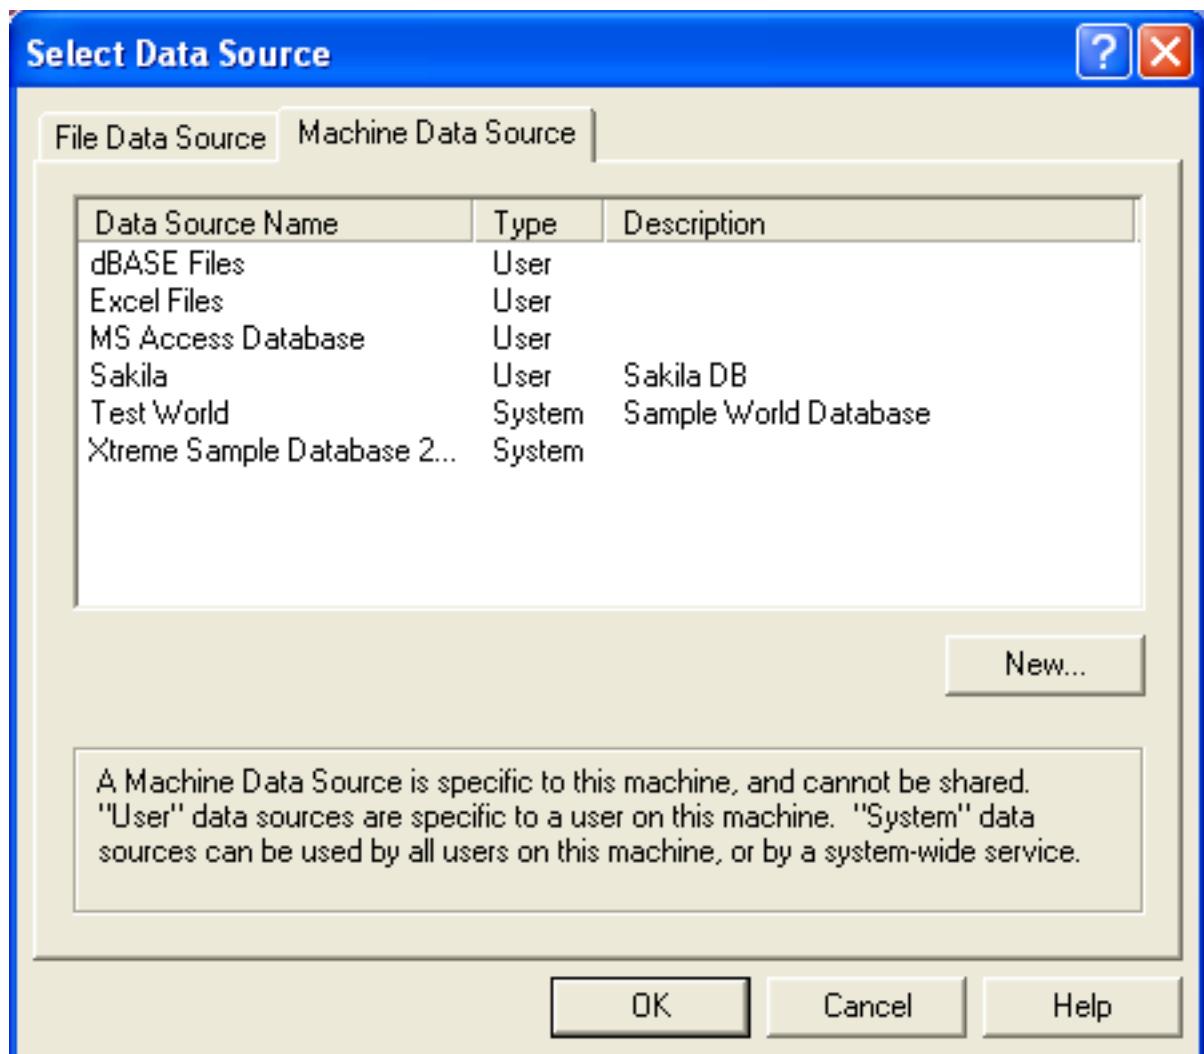

You can use Microsoft Access as a front end to a MySQL database by linking tables within your Microsoft Access database to tables that exist within your MySQL database. When a query is requested on a table within Access, ODBC is used to execute the queries on the MySQL database instead.

**To create a linked table:**

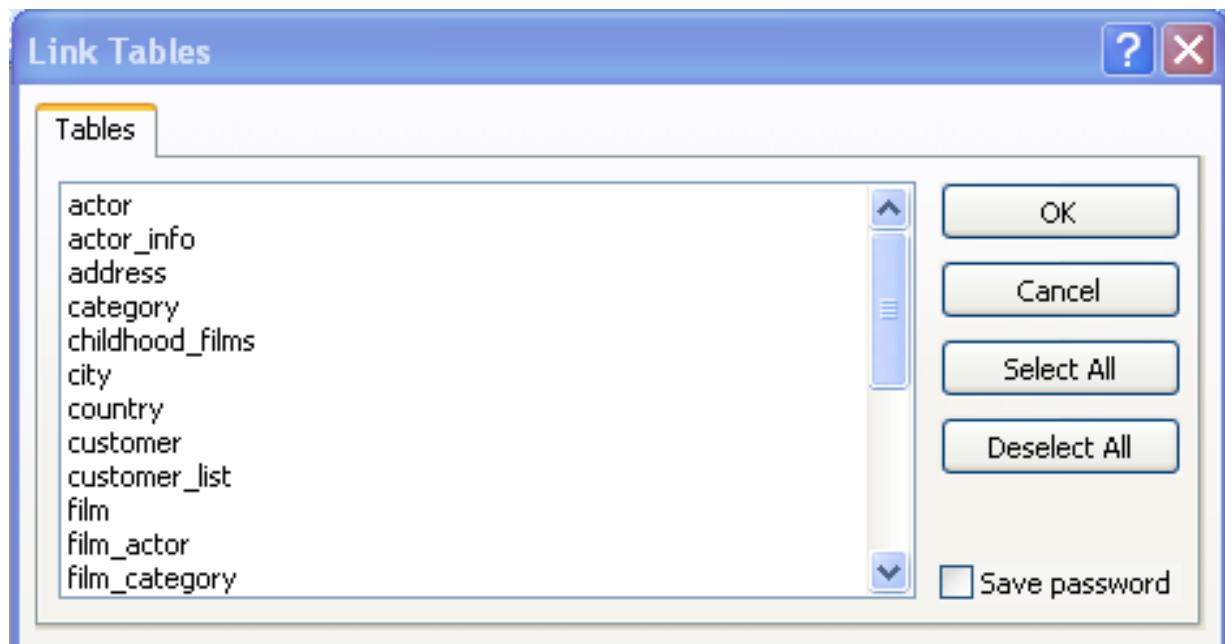

1. Open the Access database that you want to link to MySQL.
2. From the **FILE**, choose **GET EXTERNAL DATA->LINK TABLES**.

3. From the browser, choose **ODBC DATABASES ()** from the **FILES OF TYPE** pop-up.
4. In the **SELECT DATA SOURCE** window, choose an existing DSN, either from a **FILE DATA SOURCE** or **MACHINE DATA SOURCE**. You can also create a new DSN using the **NEW...** button. For more information on creating a DSN see [Section 21.1.4.3, "Configuring a Connector/ODBC DSN on Windows"](#).

- In the **LINK TABLES** dialog, select one or more tables from the MySQL database. A link will be created to each table that you select from this list.

6. If Microsoft Access is unable to determine the unique record identifier for a table automatically then it may ask you to confirm the column, or combination of columns, to be used to uniquely identify each row from the source table. Select the columns you want to use and click OK.

Once the process has been completed, you can now build interfaces and queries to the linked tables just as you would for any Access database.

Use the following procedure to view or to refresh links when the structure or location of a linked table has changed. The Linked Table Manager lists the paths to all currently linked tables.

**To view or refresh links:**

1. Open the database that contains links to MySQL tables.
2. On the **Tools** menu, point to **Add-ins (Database Utilities** in Access 2000 or newer), and then click **Linked Table Manager**.
3. Select the check box for the tables whose links you want to refresh.
4. Click **OK** to refresh the links.

Microsoft Access confirms a successful refresh or, if the table wasn't found, displays the **Select New Location of <table name>** dialog box in which you can specify its the table's new location. If several selected tables have moved to the new location that you specify, the Linked Table Manager searches that location for all selected tables, and updates all links in one step.

**To change the path for a set of linked tables:**

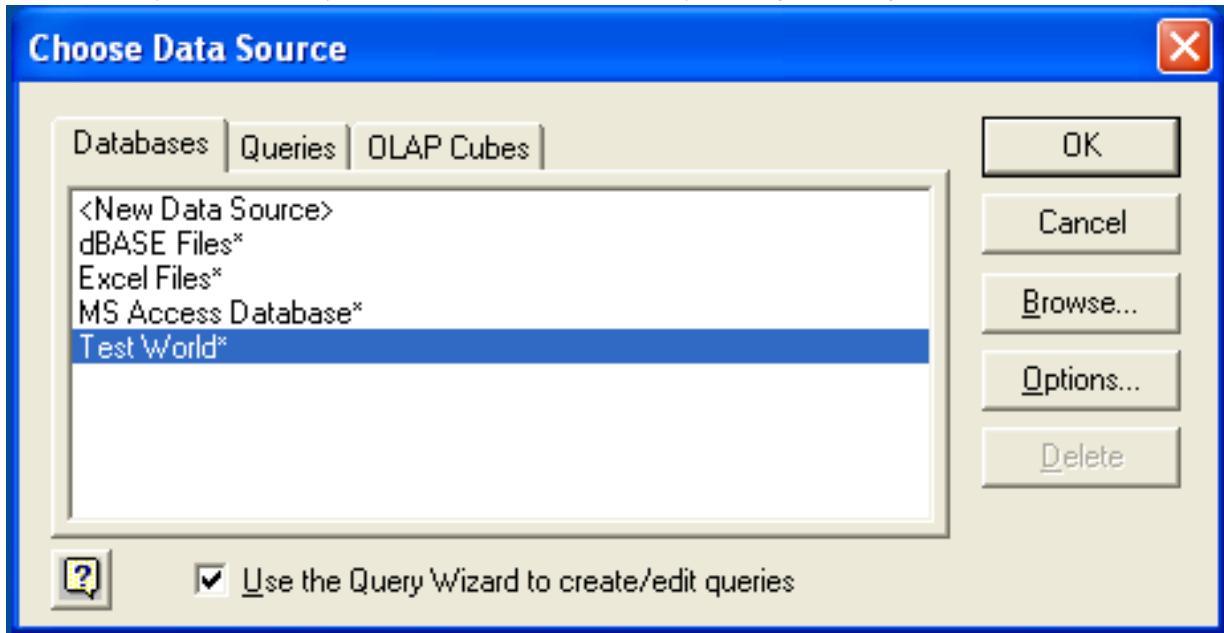

1. Open the database that contains links to tables.
2. On the **Tools** menu, point to **Add-ins (Database Utilities** in Access 2000 or newer), and then click **Linked Table Manager**.
3. Select the **Always Prompt For A New Location** check box.
4. Select the check box for the tables whose links you want to change, and then click **OK**.
5. In the **Select New Location of <table name>** dialog box, specify the new location, click **Open**, and then click **OK**.

## 21.1.5.5. Using Connector/ODBC with Microsoft Word or Excel

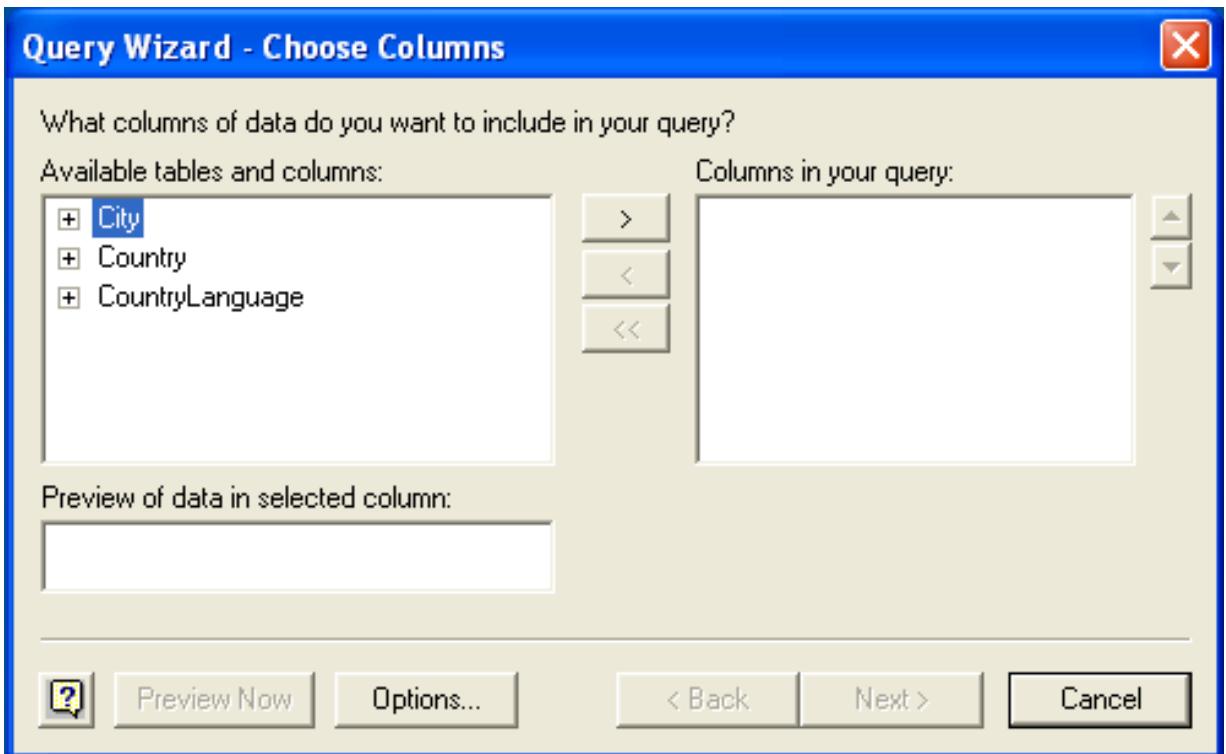

You can use Microsoft Word and Microsoft Excel to access information from a MySQL database using Connector/ODBC. Within Microsoft Word, this facility is most useful when importing data for mailmerge, or for tables and data to be included in reports. Within Microsoft Excel, you can execute queries on your MySQL server and import the data directly into an Excel Worksheet, presenting the data as a series of rows and columns.

With both applications, data is accessed and imported into the application using Microsoft Query , which enables you to execute a query though an ODBC source. You use Microsoft Query to build the SQL statement to be executed, selecting the tables, fields, selection criteria and sort order. For example, to insert information from a table in the World test database into an Excel spreadsheet, using the DSN samples shown in [Section 21.1.4, “Connector/ODBC Configuration”](#):

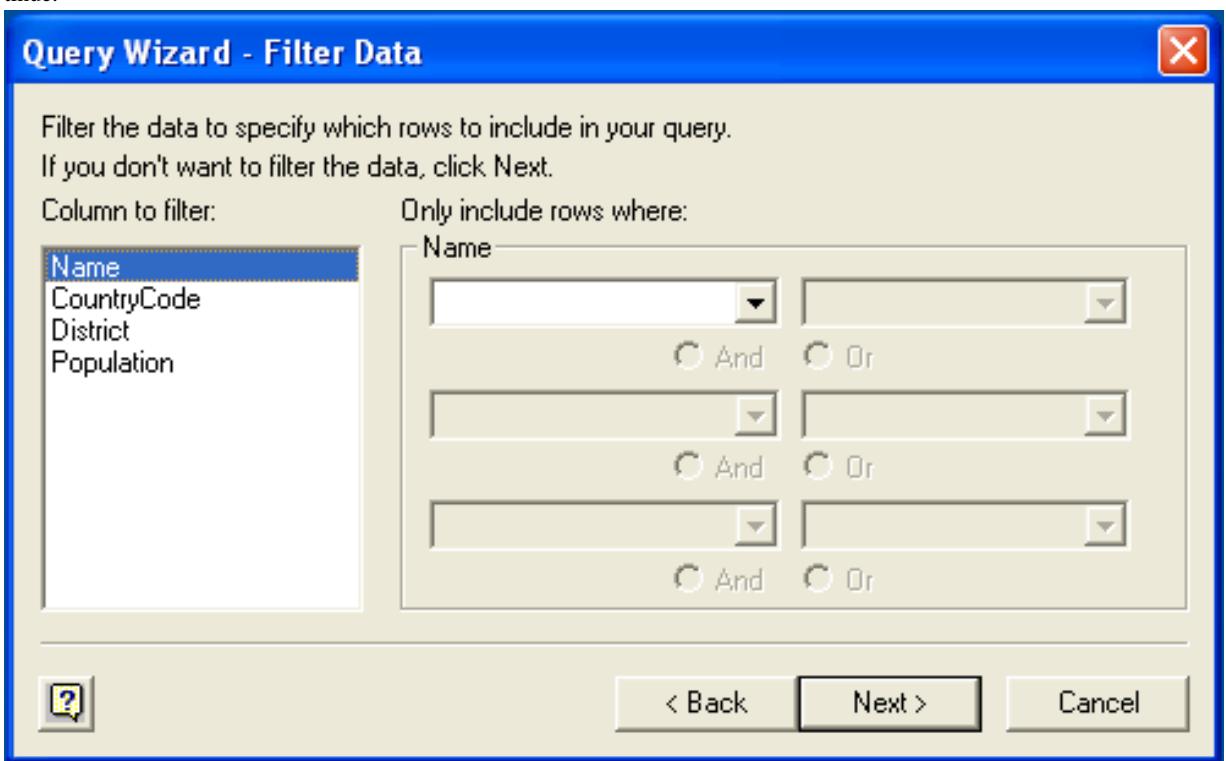

1. Create a new Worksheet.
2. From the [Data](#) menu, choose [Import External Data](#), and then select [New Database Query](#).
3. Microsoft Query will start. First, you need to choose the data source, by selecting an existing Data Source Name.

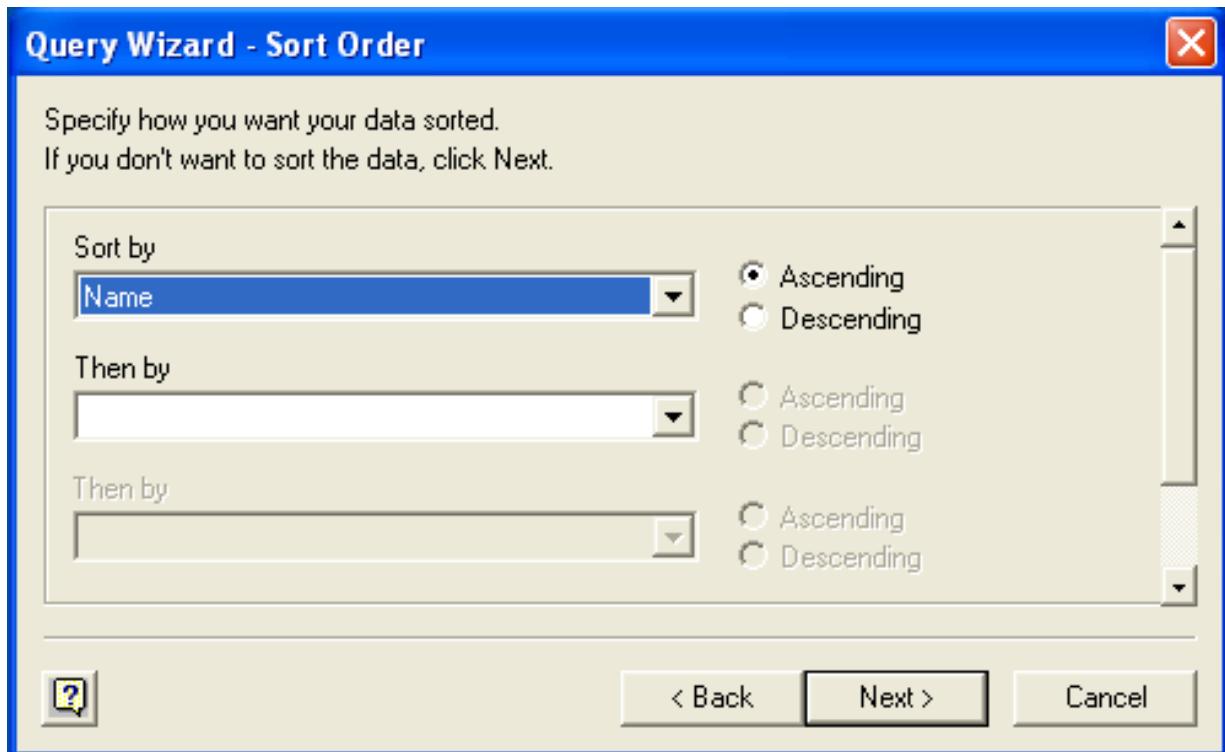

4. Within the [Query Wizard](#), you must choose the columns that you want to import. The list of tables available to the user configured through the DSN is shown on the left, the columns that will be added to your query are shown on the right. The columns you choose are equivalent to those in the first section of a [SELECT](#) query. Click [NEXT](#) to continue.

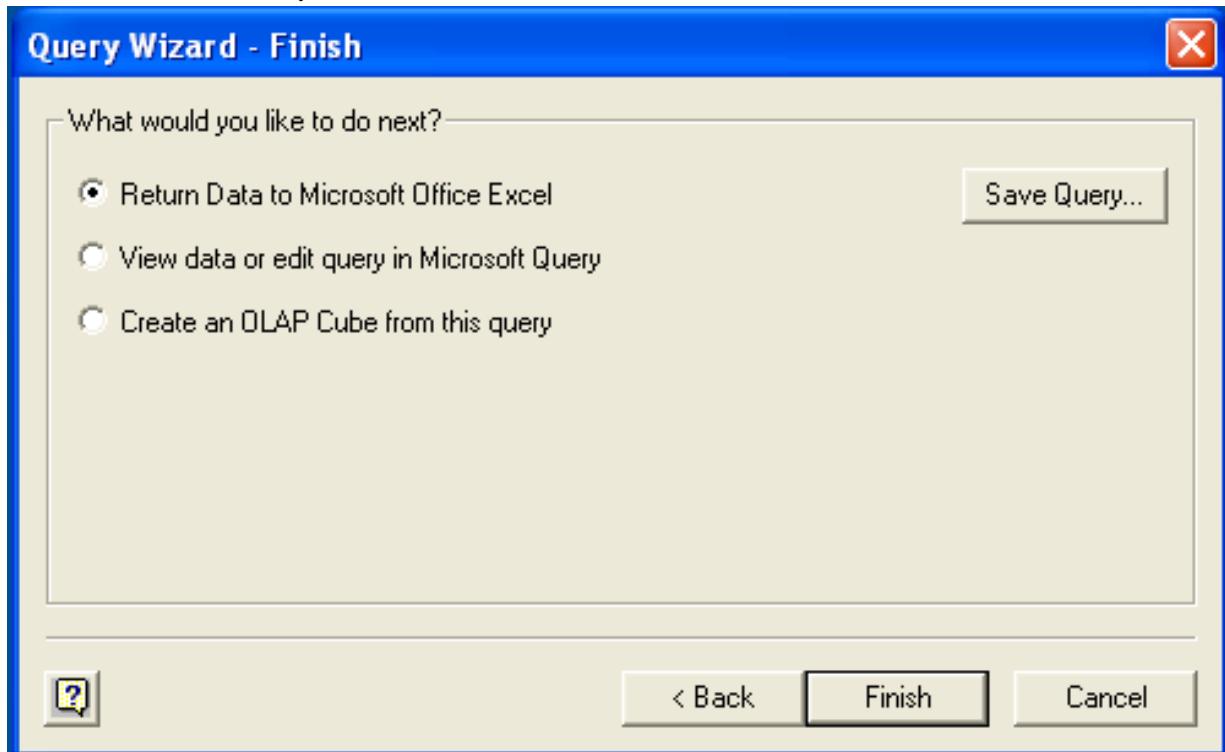

5. You can filter rows from the query (the equivalent of a `WHERE` clause) using the [Filter Data](#) dialog. Click NEXT to continue.

6. Select an (optional) sort order for the data. This is equivalent to using a `ORDER BY` clause in your SQL query. You can select up to three fields for sorting the information returned by the query. Click NEXT to continue.

7. Select the destination for your query. You can select to return the data Microsoft Excel, where you can choose a worksheet and cell where the data will be inserted; you can continue to view the query and results within Microsoft Query, where you can edit the SQL query and further filter and sort the information returned; or you can create an OLAP Cube from the query, which can then be used directly within Microsoft Excel. Click FINISH.

The same process can be used to import data into a Word document, where the data will be inserted as a table. This can be used for mail merge purposes (where the field data is read from a Word table), or where you want to include data and reports within a report or other document.

#### 21.1.5.6. Using Connector/ODBC with Crystal Reports

Crystal Reports can use an ODBC DSN to connect to a database from which you extract data and information for reporting purposes.

### Note

There is a known issue with certain versions of Crystal Reports where the application is unable to open and browse tables and fields through an ODBC connection. Before using Crystal Reports with MySQL, please ensure that you have updated to the latest version, including any outstanding service packs and hotfixes. For more information on this issue, see the [Business Objects Knowledgebase](#) for more information.

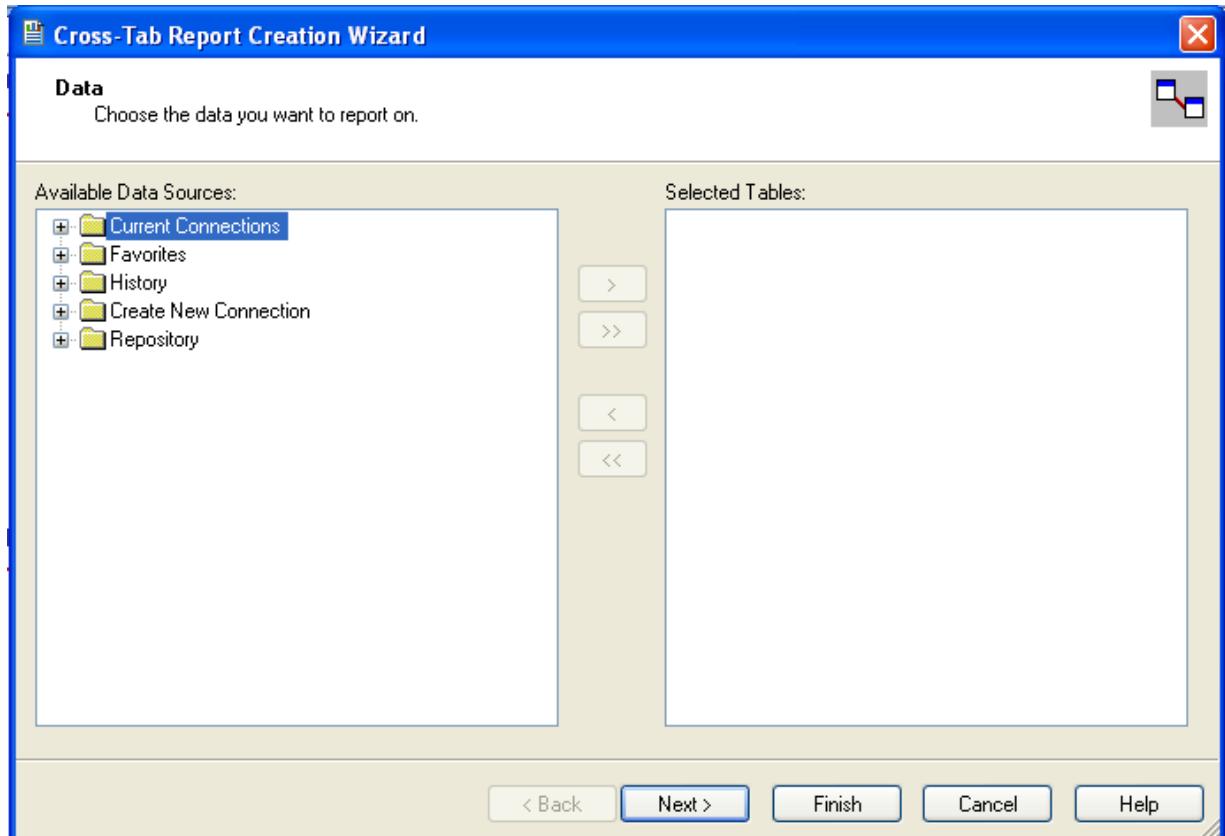

For example, to create a simple crosstab report within Crystal Reports XI, you should follow these steps:

1. Create a DSN using the [Data Sources \(ODBC\)](#) tool. You can either specify a complete database, including user name and password, or you can build a basic DSN and use Crystal Reports to set the user name and password.

For the purposes of this example, a DSN that provides a connection to an instance of the MySQL Sakila sample database has been created.

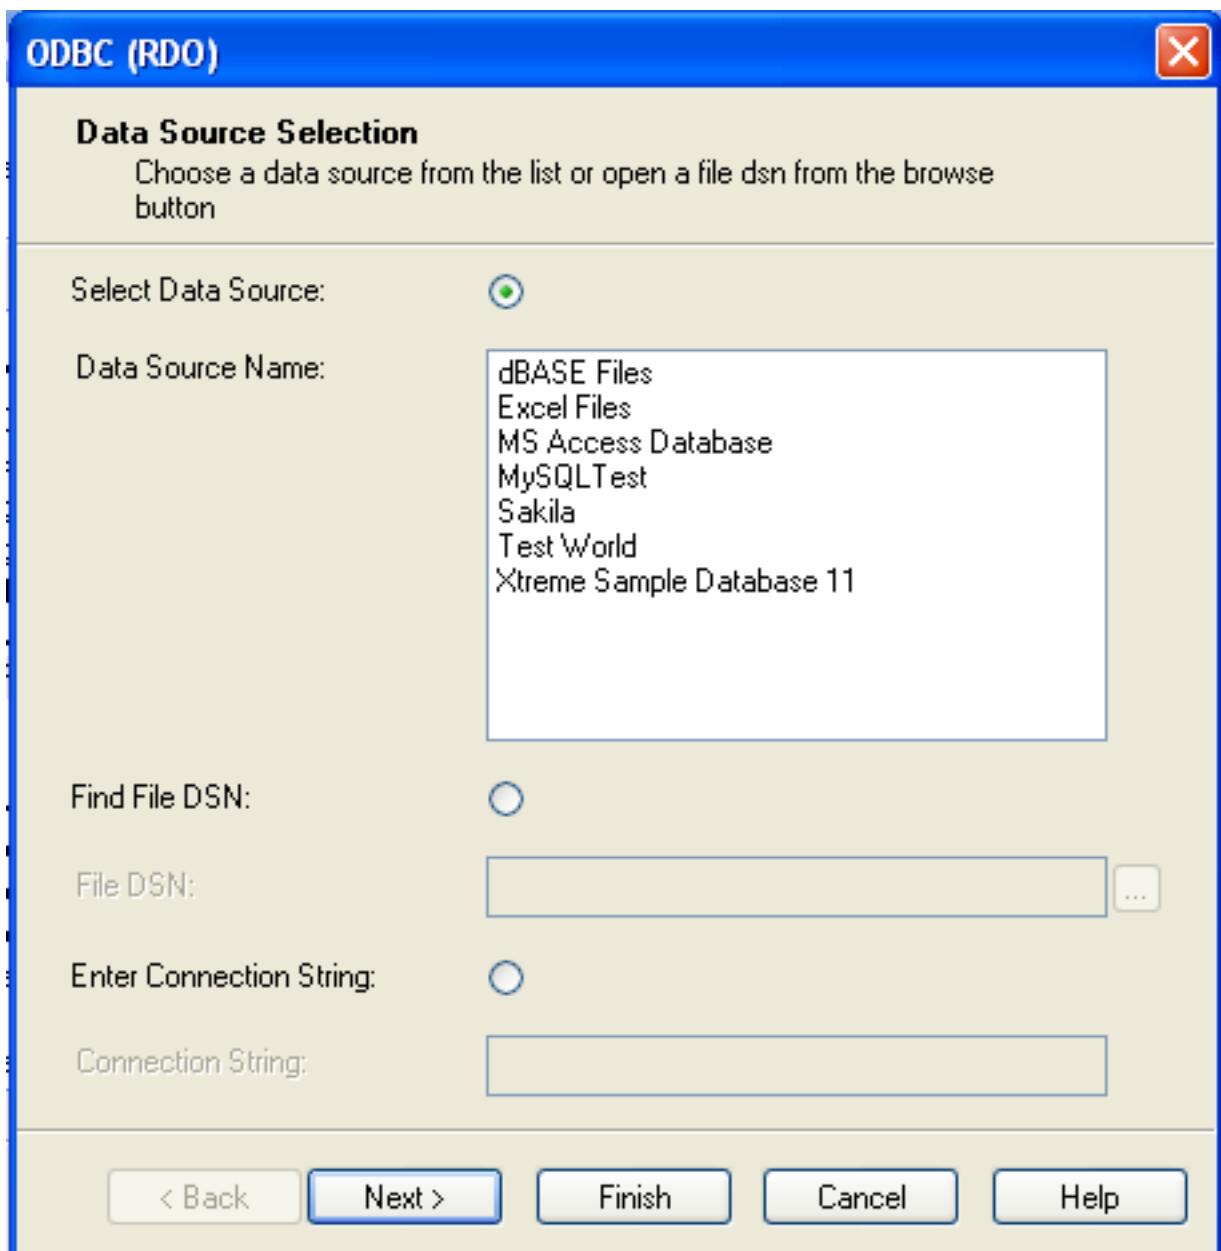

2. Open Crystal Reports and create a new project, or open an existing reporting project into which you want to insert data from your MySQL data source.
3. Start the Cross-Tab Report Wizard, either by clicking the option on the Start Page. Expand the **CREATE NEW CONNECTION** folder, then expand the **ODBC (RDO)** folder to obtain a list of ODBC data sources.

You will be asked to select a data source.

4. When you first expand the **ODBC (RDO)** folder you will be presented the Data Source Selection screen. From here you can select either a pre-configured DSN, open a file-based DSN or enter and manual connection string. For this example, the **SAKILA** DSN will be used.

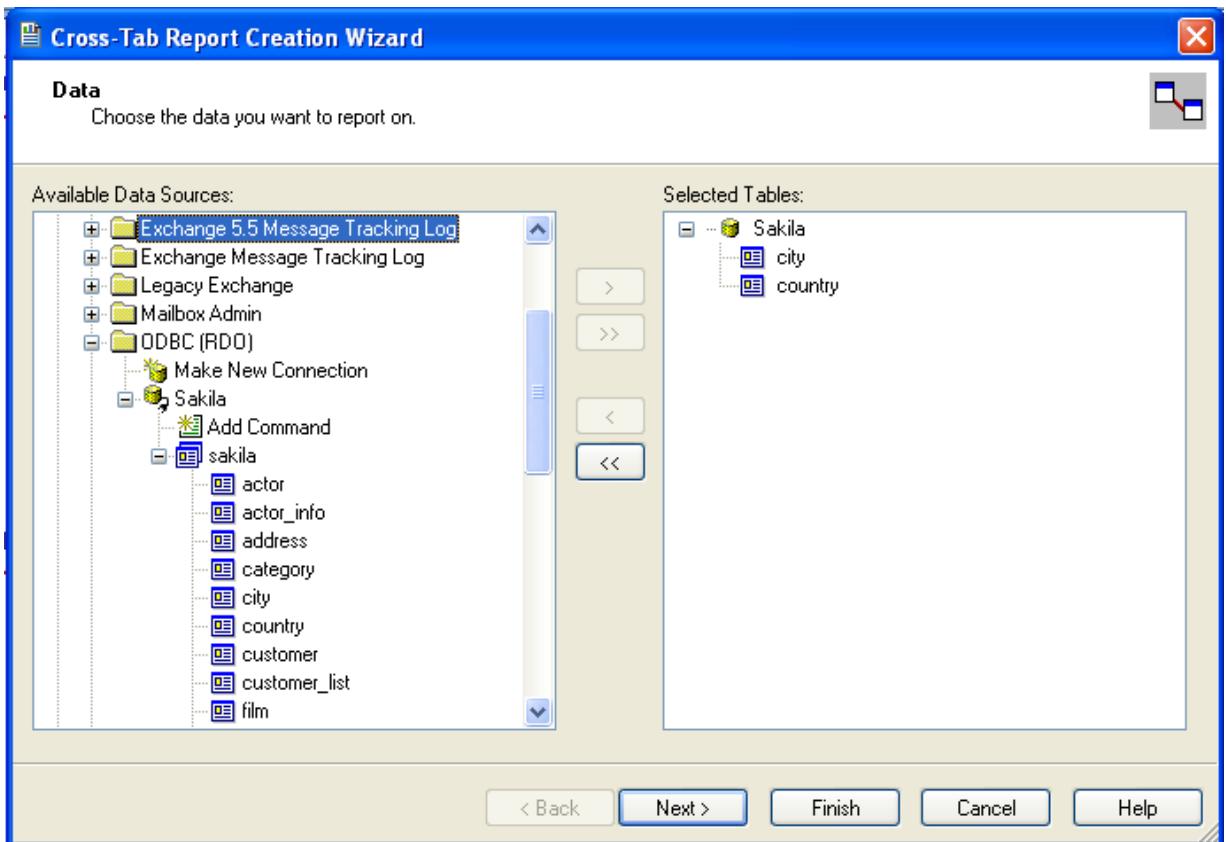

If the DSN contains a user name/password combination, or you want to use different authentication credentials, click **NEXT** to enter the user name and password that you want to use. Otherwise, click **FINISH** to continue the data source selection wizard.

5. You will be returned the Cross-Tab Report Creation Wizard. You now need to select the database and tables that you want to include in your report. For our example, we will expand the selected Sakila database. Click the `city` table and use the `>` button to add the table to the report. Then repeat the action with the `country` table. Alternatively you can select multiple tables and add them to the report.

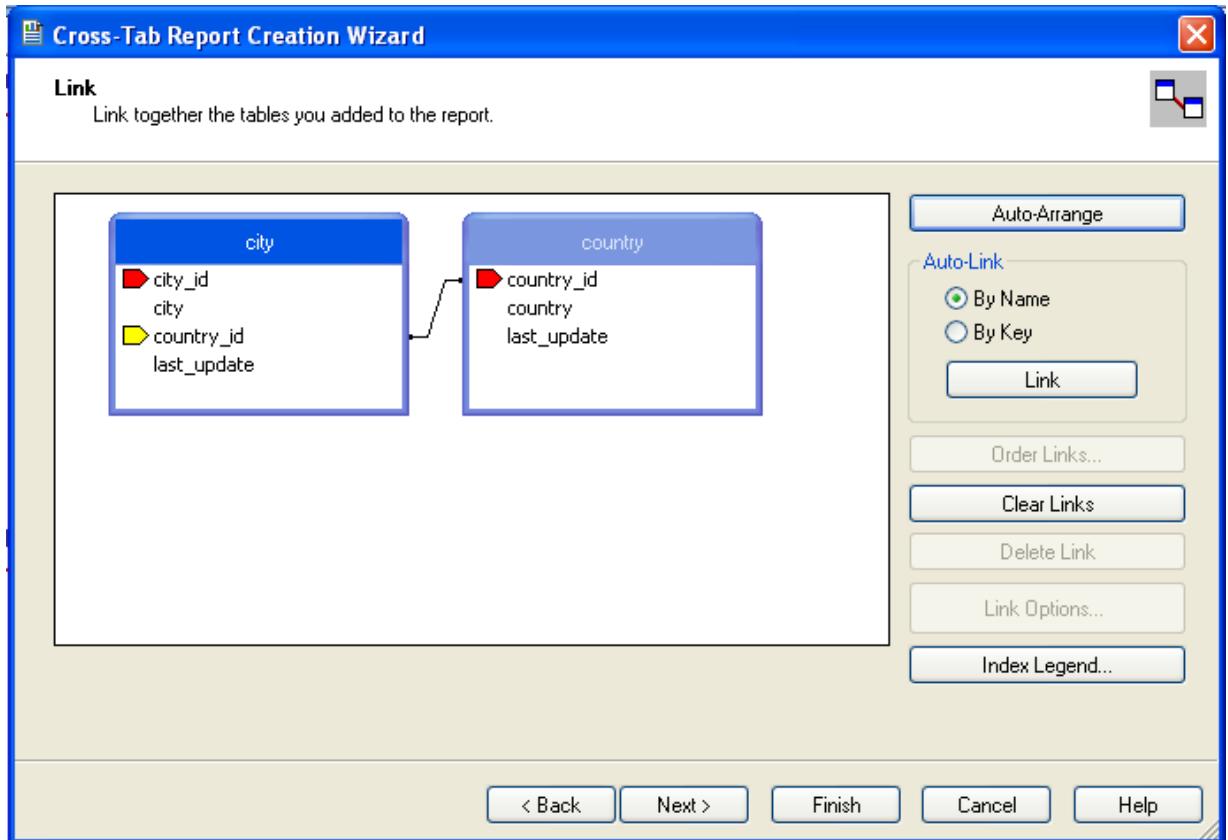

Finally, you can select the parent **SAKILA** resource and add of the tables to the report.

Once you have selected the tables you want to include, click **NEXT** to continue.

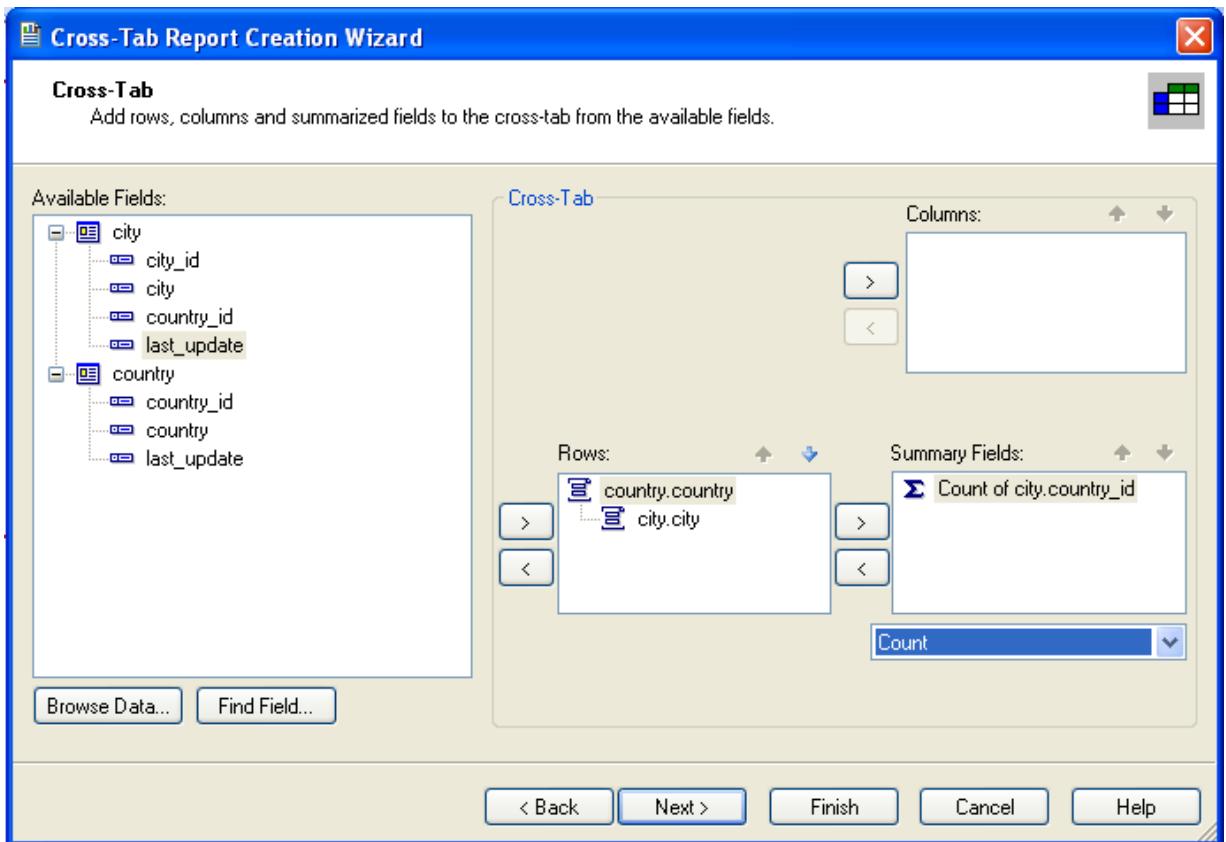

6. Crystal Reports will now read the table definitions and automatically identify the links between the tables. The identification of links between tables enables Crystal Reports to automatically lookup and summarize information based on all the tables in the database according to your query. If Crystal Reports is unable to perform the linking itself, you can manually create the links between fields in the tables you have selected.

Click **NEXT** to continue the process.

7. You can now select the columns and rows that you wish to include within the Cross-Tab report. Drag and drop or use the > buttons to add fields to each area of the report. In the example shown, we will report on cities, organized by country, incorporating a count of the number of cities within each country. If you want to browse the data, select a field and click the BROWSE DATA... button.

Click NEXT to create a graph of the results. Since we are not creating a graph from this data, click FINISH to generate the report.

8. The finished report will be shown, a sample of the output from the Sakila sample database is shown below.

		<b>Total</b>
<b>Total</b>		600
<b>Afghanistan</b>	<b>Total</b>	1
	<b>Kabul</b>	1
<b>Algeria</b>	<b>Total</b>	3
	<b>Batna</b>	1
	<b>Bchar</b>	1
	<b>Skikda</b>	1
<b>American Samoa</b>	<b>Total</b>	1
	<b>Tafuna</b>	1
<b>Angola</b>	<b>Total</b>	2
	<b>Benguela</b>	1
	<b>Namibe</b>	1
<b>Anguilla</b>	<b>Total</b>	1
	<b>South Hill</b>	1
<b>Argentina</b>	<b>Total</b>	13
	<b>Almirante Brow</b>	1

Once the ODBC connection has been opened within Crystal Reports, you can browse and add any fields within the available tables into your reports.

#### **21.1.5.7. Connector/ODBC Programming**

With a suitable ODBC Manager and the Connector/ODBC driver installed, any programming language or environment that can support ODBC should be able to connect to a MySQL database through Connector/ODBC.

This includes, but is certainly not limited to, Microsoft support languages (including Visual Basic, C# and interfaces such as ODBC.NET), Perl (through the DBI module, and the DBD::ODBC driver).

##### **21.1.5.7.1. Using Connector/ODBC with Visual Basic Using ADO, DAO and RDO**

This section contains simple examples of the use of MySQL ODBC 3.51 Driver with ADO, DAO and RDO.

### 21.1.5.7.1.1. ADO: rs.addNew, rs.delete, and rs.update

The following ADO (ActiveX Data Objects) example creates a table `my_ado` and demonstrates the use of `rs.addNew`, `rs.delete`, and `rs.update`.

```

Private Sub myodbc_ado_Click()
 Dim conn As ADODB.Connection
 Dim rs As ADODB.Recordset
 Dim fld As ADODB.Field
 Dim sql As String

 'connect to MySQL server using MySQL ODBC 3.51 Driver
 Set conn = New ADODB.Connection
 conn.ConnectionString = "DRIVER={MySQL ODBC 3.51 Driver};" _
 & "SERVER=localhost;" _
 & "DATABASE=test;" _
 & "UID=venu;PWD=venu; OPTION=3"

 conn.Open

 'create table
 conn.Execute "DROP TABLE IF EXISTS my_ado"
 conn.Execute "CREATE TABLE my_ado(id int not null primary key, name varchar(20), " _
 & "txt text, dt date, tm time, ts timestamp)"

 'direct insert
 conn.Execute "INSERT INTO my_ado(id,name,txt) values(1,100,'venu')"
 conn.Execute "INSERT INTO my_ado(id,name,txt) values(2,200,'MySQL')"
 conn.Execute "INSERT INTO my_ado(id,name,txt) values(3,300,'Delete')"

 Set rs = New ADODB.Recordset
 rs.CursorLocation = adUseServer

 'fetch the initial table ..
 rs.Open "SELECT * FROM my_ado", conn
 Debug.Print rs.RecordCount
 rs.MoveFirst
 Debug.Print String(50, "-") & "Initial my_ado Result Set " & String(50, "-")
 For Each fld In rs.Fields
 Debug.Print fld.Name,
 Next
 Debug.Print

 Do Until rs.EOF
 For Each fld In rs.Fields
 Debug.Print fld.Value,
 Next
 rs.MoveNext
 Debug.Print
 Loop
 rs.Close

 'rs insert
 rs.Open "select * from my_ado", conn, adOpenDynamic, adLockOptimistic
 rs.AddNew
 rs!Name = "Monty"
 rs!txt = "Insert row"
 rs.Update
 rs.Close

 'rs update
 rs.Open "SELECT * FROM my_ado"
 rs!Name = "update"
 rs!txt = "updated-row"
 rs.Update
 rs.Close

 'rs update second time..
 rs.Open "SELECT * FROM my_ado"
 rs!Name = "update"
 rs!txt = "updated-second-time"
 rs.Update
 rs.Close

 'rs delete
 rs.Open "SELECT * FROM my_ado"
 rs.MoveNext
 rs.MoveNext
 rs.Delete
 rs.Close

 'fetch the updated table ..
 rs.Open "SELECT * FROM my_ado", conn
 Debug.Print rs.RecordCount
 rs.MoveFirst
 Debug.Print String(50, "-") & "Updated my_ado Result Set " & String(50, "-")
 For Each fld In rs.Fields
 Debug.Print fld.Name,
 Next
 Debug.Print

 Do Until rs.EOF
 For Each fld In rs.Fields
 Debug.Print fld.Value,

```

```

Next
rs.MoveNext
Debug.Print
Loop
rs.Close
conn.Close
End Sub

```

### 21.1.5.7.1.2. DAO: rs.addNew, rs.update, and Scrolling

The following DAO (Data Access Objects) example creates a table `my_dao` and demonstrates the use of `rs.addNew`, `rs.update`, and result set scrolling.

```

Private Sub myodbc_dao_Click()
Dim ws As Workspace
Dim conn As Connection
Dim queryDef As queryDef
Dim str As String

'connect to MySQL using MySQL ODBC 3.51 Driver
Set ws = DBEngine.CreateWorkspace("", "venu", "venu", dbUseODBC)
str = "odbc;DRIVER={MySQL ODBC 3.51 Driver};" _
& "SERVER=localhost;" _
& "DATABASE=test;" _
& "UID=venu;PWD=venu; OPTION=3"
Set conn = ws.OpenConnection("test", dbDriverNoPrompt, False, str)

'Create table my_dao
Set queryDef = conn.CreateQueryDef("", "drop table if exists my_dao")
queryDef.Execute

Set queryDef = conn.CreateQueryDef("", "create table my_dao(Id INT AUTO_INCREMENT PRIMARY KEY, " _
& "Ts TIMESTAMP(14) NOT NULL, Name varchar(20), Id2 INT)")
queryDef.Execute

'Insert new records using rs.addNew
Set rs = conn.OpenRecordset("my_dao")
Dim i As Integer

For i = 10 To 15
rs.AddNew
rs!Name = "insert record" & i
rs!Id2 = i
rs.Update
Next i
rs.Close

'rs update..
Set rs = conn.OpenRecordset("my_dao")
rs.Edit
rs!Name = "updated-string"
rs.Update
rs.Close

'fetch the table back...
Set rs = conn.OpenRecordset("my_dao", dbOpenDynamic)
str = "Results:"
rs.MoveFirst
While Not rs.EOF
str = " " & rs!Id & " , " & rs!Name & ", " & rs!Ts & ", " & rs!Id2
Debug.Print "DATA:" & str
rs.MoveNext
Wend

'rs Scrolling
rs.MoveFirst
str = " FIRST ROW: " & rs!Id & " , " & rs!Name & ", " & rs!Ts & ", " & rs!Id2
Debug.Print str

rs.MoveLast
str = " LAST ROW: " & rs!Id & " , " & rs!Name & ", " & rs!Ts & ", " & rs!Id2
Debug.Print str

rs.MovePrevious
str = " LAST-1 ROW: " & rs!Id & " , " & rs!Name & ", " & rs!Ts & ", " & rs!Id2
Debug.Print str

'free all resources
rs.Close
queryDef.Close
conn.Close
ws.Close

End Sub

```

### 21.1.5.7.1.3. RDO: rs.addNew and rs.update

The following RDO (Remote Data Objects) example creates a table `my_rdo` and demonstrates the use of `rs.addNew` and `rs.update`.

```

Dim rs As rdoResultset
Dim cn As New rdoConnection
Dim cl As rdoColumn
Dim SQL As String

'cn.Connect = "DSN=test;"
cn.Connect = "DRIVER={MySQL ODBC 3.51 Driver};"
& "SERVER=localhost;_"
& "DATABASE=test;_"
& "UID=venu;PWD=venu; OPTION=3"

cn.CursorDriver = rdUseOdbc
cn.EstablishConnection rdDriverPrompt

'drop table my_rdo
SQL = "drop table if exists my_rdo"
cn.Execute SQL, rdExecDirect

'create table my_rdo
SQL = "create table my_rdo(id int, name varchar(20))"
cn.Execute SQL, rdExecDirect

'insert - direct
SQL = "insert into my_rdo values (100,'venu')"
cn.Execute SQL, rdExecDirect

SQL = "insert into my_rdo values (200,'MySQL')"
cn.Execute SQL, rdExecDirect

'rs insert
SQL = "select * from my_rdo"
Set rs = cn.OpenResultset(SQL, rdOpenStatic, rdConcurRowVer, rdExecDirect)
rs.AddNew
rs!id = 300
rs!Name = "Insert1"
rs.Update
rs.Close

'rs insert
SQL = "select * from my_rdo"
Set rs = cn.OpenResultset(SQL, rdOpenStatic, rdConcurRowVer, rdExecDirect)
rs.AddNew
rs!id = 400
rs!Name = "Insert 2"
rs.Update
rs.Close

'rs update
SQL = "select * from my_rdo"
Set rs = cn.OpenResultset(SQL, rdOpenStatic, rdConcurRowVer, rdExecDirect)
rs.Edit
rs!id = 999
rs!Name = "updated"
rs.Update
rs.Close

'fetch back...
SQL = "select * from my_rdo"
Set rs = cn.OpenResultset(SQL, rdOpenStatic, rdConcurRowVer, rdExecDirect)
Do Until rs.EOF
For Each cl In rs.rdoColumns
Debug.Print cl.Value,
Next
rs.MoveNext
Debug.Print
Loop
Debug.Print "Row count="; rs.RowCount

'close
rs.Close
cn.Close
End Sub

```

### 21.1.5.7.2. Using Connector/ODBC with .NET

This section contains simple examples that demonstrate the use of Connector/ODBC drivers with ODBC.NET.

#### 21.1.5.7.2.1. Using Connector/ODBC with ODBC.NET and C# (C sharp)

The following sample creates a table `my_odbc_net` and demonstrates its use in C#.

```

/***
 * @sample : mycon.cs
 * @purpose : Demo sample for ODBC.NET using Connector/ODBC
 * @author : Venu, <myodbc@lists.mysql.com>
 *
 * (C) Copyright MySQL AB, 1995-2006
 */

```

```

/* build command
*
* csc /t:exe
* /out:mycon.exe mycon.cs
* /r:Microsoft.Data.Odbc.dll
*/
using Console = System.Console;
using Microsoft.Data.Odbc;

namespace myodbc3
{
 class mycon
 {
 static void Main(string[] args)
 {
 try
 {
 //Connection string for Connector/ODBC 3.51
 string MyConString = "DRIVER={MySQL ODBC 3.51 Driver};" +
 "SERVER=localhost;" +
 "DATABASE=test;" +
 "UID=venu;" +
 "PASSWORD=venu;" +
 "OPTION=3";

 //Connect to MySQL using Connector/ODBC
 OdbcConnection MyConnection = new OdbcConnection(MyConString);
 MyConnection.Open();

 Console.WriteLine("\n !!! success, connected successfully !!!\n");

 //Display connection information
 Console.WriteLine("Connection Information:");
 Console.WriteLine("\tConnection String: " +
 MyConnection.ConnectionString);
 Console.WriteLine("\tConnection Timeout: " +
 MyConnection.ConnectionTimeout);
 Console.WriteLine("\tDatabase: " +
 MyConnection.Database);
 Console.WriteLine("\tDataSource: " +
 MyConnection.DataSource);
 Console.WriteLine("\tDriver: " +
 MyConnection.Driver);
 Console.WriteLine("\tServerVersion: " +
 MyConnection.ServerVersion);

 //Create a sample table
 OdbcCommand MyCommand =
 new OdbcCommand("DROP TABLE IF EXISTS my_odbc_net",
 MyConnection);
 MyCommand.ExecuteNonQuery();
 MyCommand.CommandText =
 "CREATE TABLE my_odbc_net(id int, name varchar(20), idb bigint)";
 MyCommand.ExecuteNonQuery();

 //Insert
 MyCommand.CommandText =
 "INSERT INTO my_odbc_net VALUES(10,'venu', 300)";
 Console.WriteLine("INSERT, Total rows affected: " +
 MyCommand.ExecuteNonQuery());

 //Insert
 MyCommand.CommandText =
 "INSERT INTO my_odbc_net VALUES(20,'mysql',400)";
 Console.WriteLine("INSERT, Total rows affected: " +
 MyCommand.ExecuteNonQuery());

 //Insert
 MyCommand.CommandText =
 "INSERT INTO my_odbc_net VALUES(20,'mysql',500)";
 Console.WriteLine("INSERT, Total rows affected: " +
 MyCommand.ExecuteNonQuery());

 //Update
 MyCommand.CommandText =
 "UPDATE my_odbc_net SET id=999 WHERE id=20";
 Console.WriteLine("Update, Total rows affected: " +
 MyCommand.ExecuteNonQuery());

 //COUNT(*)
 MyCommand.CommandText =
 "SELECT COUNT(*) as TRows FROM my_odbc_net";
 Console.WriteLine("Total Rows: " +
 MyCommand.ExecuteScalar());

 //Fetch
 MyCommand.CommandText = "SELECT * FROM my_odbc_net";
 OdbcDataReader MyDataReader;
 MyDataReader = MyCommand.ExecuteReader();
 while (MyDataReader.Read())
 {
 if(string.Compare(MyConnection.Driver,"myodbc3.dll") == 0) {
 //Supported only by Connector/ODBC 3.51
 Console.WriteLine("Data:" + MyDataReader.GetInt32(0) + " " +
 MyDataReader.GetString(1) + " " +
 MyDataReader.GetInt64(2));
 }
 }
 }
 }
 }
}

```

#### **21.1.5.7.2.2. Using Connector/ODBC with ODBC.NET and Visual Basic**

The following sample creates a table `my_vb_net` and demonstrates the use in VB.

```

@sample : myvb.vb
@purpose : Demo sample for ODBC.NET using Connector/ODBC
@author : Venu, <myodbc@lists.mysql.com>

(C) Copyright MySQL AB, 1995-2006

build command

vbc /target:exe
/out:myvb.exe
/r:Microsoft.Data.Odbc.dll
/r:System.dll
/r:System.Data.dll

Imports Microsoft.Data.Odbc
Imports System

Module myvb
 Sub Main()
 Try

 'Connector/ODBC 3.51 connection string
 Dim MyConString As String = "DRIVER={MySQL ODBC 3.51 Driver};;" & _
 "SERVER=localhost;" & _
 "DATABASE=test;" & _
 "UID=venu;" & _
 "PASSWORD=venu;" & _
 "OPTION=3;"

 'Connection
 Dim MyConnection As New OdbcConnection(MyConString)
 MyConnection.Open()

 Console.WriteLine("Connection State:::" & MyConnection.State.ToString)

 'Drop
 Console.WriteLine("Dropping table")
 Dim MyCommand As New OdbcCommand()
 MyCommand.Connection = MyConnection
 MyCommand.CommandText = "DROP TABLE IF EXISTS my_vb_net"
 MyCommand.ExecuteNonQuery()

 'Create
 Console.WriteLine("Creating....")
 MyCommand.CommandText = "CREATE TABLE my_vb_net(id int, name varchar(30))"
 MyCommand.ExecuteNonQuery()

 'Insert
 MyCommand.CommandText = "INSERT INTO my_vb_net VALUES(10,'venu')"
 Console.WriteLine("INSERT, Total rows affected:" & _
 MyCommand.ExecuteNonQuery())

 'Insert
 MyCommand.CommandText = "INSERT INTO my_vb_net VALUES(20,'mysql')"
 Console.WriteLine("INSERT, Total rows affected:" & _
 MyCommand.ExecuteNonQuery())
 End Try
 End Sub
End Module

```

```

' Insert
MyCommand.CommandText = "INSERT INTO my_vb_net VALUES(20,'mysql')"
Console.WriteLine("INSERT, Total rows affected:" & _
MyCommand.ExecuteNonQuery()

' Insert
MyCommand.CommandText = "INSERT INTO my_vb_net(id) VALUES(30)"
Console.WriteLine("INSERT, Total rows affected:" & _
MyCommand.ExecuteNonQuery()

'Update
MyCommand.CommandText = "UPDATE my_vb_net SET id=999 WHERE id=20"
Console.WriteLine("Update, Total rows affected:" & _
MyCommand.ExecuteNonQuery())

'COUNT(*)
MyCommand.CommandText = "SELECT COUNT(*) as TRows FROM my_vb_net"
Console.WriteLine("Total Rows:" & MyCommand.ExecuteScalar())

'Select
Console.WriteLine("Select * FROM my_vb_net")
MyCommand.CommandText = "SELECT * FROM my_vb_net"
Dim MyDataReader As OdbcDataReader
MyDataReader = MyCommand.ExecuteReader
While MyDataReader.Read
 If MyDataReader("name") Is DBNull.Value Then
 Console.WriteLine("id = " & _
 CStr(MyDataReader("id")) & " name = " & _
 "NULL")
 Else
 Console.WriteLine("id = " & _
 CStr(MyDataReader("id")) & " name = " & _
 CStr(MyDataReader("name")))
 End If
End While

'Catch ODBC Exception
Catch MyOdbcException As OdbcException
 Dim i As Integer
 Console.WriteLine(MyOdbcException.ToString)

'Catch program exception
Catch MyException As Exception
 Console.WriteLine(MyException.ToString)
End Try
End Sub

```

## 21.1.6. Connector/ODBC Reference

This section provides reference material for the Connector/ODBC API, showing supported functions and methods, supported MySQL column types and the corresponding native type in Connector/ODBC, and the error codes returned by Connector/ODBC when a fault occurs.

### 21.1.6.1. Connector/ODBC API Reference

This section summarizes ODBC routines, categorized by functionality.

For the complete ODBC API reference, please refer to the ODBC Programmer's Reference at <http://msdn.microsoft.com/en-us/library/ms714177.aspx>.

An application can call `SQLGetInfo` function to obtain conformance information about Connector/ODBC. To obtain information about support for a specific function in the driver, an application can call `SQLGetFunctions`.

#### Note

For backward compatibility, the Connector/ODBC 3.51 driver supports all deprecated functions.

The following tables list Connector/ODBC API calls grouped by task:

#### Connecting to a data source

Function name	C/ODBC 3.51	Standard	Purpose
<code>SQLAllocHandle</code>	Yes	ISO 92	Obtains an environment, connection, statement, or descriptor handle.
<code>SQLConnect</code>	Yes	ISO 92	Connects to a specific driver by data source name, user ID, and password.
<code>SQLDriverConnect</code>	Yes	ODBC	Connects to a specific driver by connection string or requests that the Driver Manager and driver display connection dialog boxes for the user.

<a href="#">SQLAllocEnv</a>	Yes	Deprecated	Obtains an environment handle allocated from driver.
<a href="#">SQLAllocConnect</a>	Yes	Deprecated	Obtains a connection handle

### Obtaining information about a driver and data source

Function name	C/ODBC 3.51	Standard	Purpose
<a href="#">SQLDataSources</a>	No	ISO 92	Returns the list of available data sources, handled by the Driver Manager
<a href="#">SQLDrivers</a>	No	ODBC	Returns the list of installed drivers and their attributes, handles by Driver Manager
<a href="#">SQLGetInfo</a>	Yes	ISO 92	Returns information about a specific driver and data source.
<a href="#">SQLGetFunctions</a>	Yes	ISO 92	Returns supported driver functions.
<a href="#">SQLGetTypeInfo</a>	Yes	ISO 92	Returns information about supported data types.

### Setting and retrieving driver attributes

Function name	C/ODBC 3.51	Standard	Purpose
<a href="#">SQLSetConnectAttr</a>	Yes	ISO 92	Sets a connection attribute.
<a href="#">SQLGetConnectAttr</a>	Yes	ISO 92	Returns the value of a connection attribute.
<a href="#">SQLSetConnectOption</a>	Yes	Deprecated	Sets a connection option
<a href="#">SQLGetConnectOption</a>	Yes	Deprecated	Returns the value of a connection option
<a href="#">SQLSetEnvAttr</a>	Yes	ISO 92	Sets an environment attribute.
<a href="#">SQLGetEnvAttr</a>	Yes	ISO 92	Returns the value of an environment attribute.
<a href="#">SQLSetStmtAttr</a>	Yes	ISO 92	Sets a statement attribute.
<a href="#">SQLGetStmtAttr</a>	Yes	ISO 92	Returns the value of a statement attribute.
<a href="#">SQLSetStmtOption</a>	Yes	Deprecated	Sets a statement option
<a href="#">SQLGetStmtOption</a>	Yes	Deprecated	Returns the value of a statement option

### Preparing SQL requests

Function name	C/ODBC 3.51	Standard	Purpose
<a href="#">SQLAllocStmt</a>	Yes	Deprecated	Allocates a statement handle
<a href="#">SQLPrepare</a>	Yes	ISO 92	Prepares an SQL statement for later execution.
<a href="#">SQLBindParameter</a>	Yes	ODBC	Assigns storage for a parameter in an SQL statement.
<a href="#">SQLGetCursorName</a>	Yes	ISO 92	Returns the cursor name associated with a statement handle.
<a href="#">SQLSetCursorName</a>	Yes	ISO 92	Specifies a cursor name.
<a href="#">SQLSetScrollOptions</a>	Yes	ODBC	Sets options that control cursor behavior.

### Submitting requests

Function name	C/ODBC 3.51	Standard	Purpose
<a href="#">SQLExecute</a>	Yes	ISO 92	Executes a prepared statement.
<a href="#">SQLExecDirect</a>	Yes	ISO 92	Executes a statement
<a href="#">SQLNativeSql</a>	Yes	ODBC	Returns the text of an SQL statement as translated by the driver.
<a href="#">SQLDescribeParam</a>	Yes	ODBC	Returns the description for a specific parameter in a statement.
<a href="#">SQLNumParams</a>	Yes	ISO 92	Returns the number of parameters in a statement.
<a href="#">SQLParamData</a>	Yes	ISO 92	Used in conjunction with <a href="#">SQLPutData</a> to supply parameter data at execution time. (Useful for long data values.)

<a href="#">SQLPutData</a>	Yes	ISO 92	Sends part or all of a data value for a parameter. (Useful for long data values.)
----------------------------	-----	--------	-----------------------------------------------------------------------------------

### Retrieving results and information about results

Function name	C/ODBC 3.51	Standard	Purpose
<a href="#">SQLRowCount</a>	Yes	ISO 92	Returns the number of rows affected by an insert, update, or delete request.
<a href="#">SQLNumResultCols</a>	Yes	ISO 92	Returns the number of columns in the result set.
<a href="#">SQLDescribeCol</a>	Yes	ISO 92	Describes a column in the result set.
<a href="#">SQLColAttribute</a>	Yes	ISO 92	Describes attributes of a column in the result set.
<a href="#">SQLColAttributes</a>	Yes	Deprecated	Describes attributes of a column in the result set.
<a href="#">SQLFetch</a>	Yes	ISO 92	Returns multiple result rows.
<a href="#">SQLFetchScroll</a>	Yes	ISO 92	Returns scrollable result rows.
<a href="#">SQLExtendedFetch</a>	Yes	Deprecated	Returns scrollable result rows.
<a href="#">SQLSetPos</a>	Yes	ODBC	Positions a cursor within a fetched block of data and enables an application to refresh data in the rowset or to update or delete data in the result set.
<a href="#">SQLBulkOperations</a>	Yes	ODBC	Performs bulk insertions and bulk bookmark operations, including update, delete, and fetch by bookmark.

### Retrieving error or diagnostic information

Function name	C/ODBC 3.51	Standard	Purpose
<a href="#">SQLError</a>	Yes	Deprecated	Returns additional error or status information
<a href="#">SQLGetDiagField</a>	Yes	ISO 92	Returns additional diagnostic information (a single field of the diagnostic data structure).
<a href="#">SQLGetDiagRec</a>	Yes	ISO 92	Returns additional diagnostic information (multiple fields of the diagnostic data structure).

### Obtaining information about the data source's system tables (catalog functions) item

Function name	C/ODBC 3.51	Standard	Purpose
<a href="#">SQLColumnPrivileges</a>	Yes	ODBC	Returns a list of columns and associated privileges for one or more tables.
<a href="#">SQLColumns</a>	Yes	X/Open	Returns the list of column names in specified tables.
<a href="#">SQLForeignKeys</a>	Yes	ODBC	Returns a list of column names that make up foreign keys, if they exist for a specified table.
<a href="#">SQLPrimaryKeys</a>	Yes	ODBC	Returns the list of column names that make up the primary key for a table.
<a href="#">SQLSpecialColumns</a>	Yes	X/Open	Returns information about the optimal set of columns that uniquely identifies a row in a specified table, or the columns that are automatically updated when any value in the row is updated by a transaction.
<a href="#">SQLStatistics</a>	Yes	ISO 92	Returns statistics about a single table and the list of indexes associated with the table.
<a href="#">SQLTablePrivileges</a>	Yes	ODBC	Returns a list of tables and the privileges associated with each table.
<a href="#">SQLTables</a>	Yes	X/Open	Returns the list of table names stored in a specific data source.

### Performing transactions

Function name	C/ODBC 3.51	Standard	Purpose
<a href="#">SQLTransact</a>	Yes	Deprecated	Commits or rolls back a transaction
<a href="#">SQLEndTran</a>	Yes	ISO 92	Commits or rolls back a transaction.

**Terminating a statement**

Function name	C/ODBC 3.51	Standard	Purpose
<a href="#">SQLFreeStmt</a>	Yes	ISO 92	Ends statement processing, discards pending results, and, optionally, frees all resources associated with the statement handle.
<a href="#">SQLCloseCursor</a>	Yes	ISO 92	Closes a cursor that has been opened on a statement handle.
<a href="#">SQLCancel</a>	Yes	ISO 92	Cancels an SQL statement.

**Terminating a connection**

Function name	C/ODBC 3.51	Standard	Purpose
<a href="#">SQLDisconnect</a>	Yes	ISO 92	Closes the connection.
<a href="#">SQLFreeHandle</a>	Yes	ISO 92	Releases an environment, connection, statement, or descriptor handle.
<a href="#">SQLFreeConnect</a>	Yes	Deprecated	Releases connection handle
<a href="#">SQLFreeEnv</a>	Yes	Deprecated	Releases an environment handle

**21.1.6.2. Connector/ODBC Data Types**

The following table illustrates how driver maps the server data types to default SQL and C data types.

Native Value	SQL Type	C Type
<code>bigint unsigned</code>	<code>SQL_BIGINT</code>	<code>SQL_C_UBIGINT</code>
<code>bigint</code>	<code>SQL_BIGINT</code>	<code>SQL_C_SBIGINT</code>
<code>bit</code>	<code>SQL_BIT</code>	<code>SQL_C_BIT</code>
<code>bit</code>	<code>SQL_CHAR</code>	<code>SQL_C_CHAR</code>
<code>blob</code>	<code>SQL_LONGVARBINARY</code>	<code>SQL_C_BINARY</code>
<code>bool</code>	<code>SQL_CHAR</code>	<code>SQL_C_CHAR</code>
<code>char</code>	<code>SQL_CHAR</code>	<code>SQL_C_CHAR</code>
<code>date</code>	<code>SQL_DATE</code>	<code>SQL_C_DATE</code>
<code>datetime</code>	<code>SQL_TIMESTAMP</code>	<code>SQL_C_TIMESTAMP</code>
<code>decimal</code>	<code>SQL_DECIMAL</code>	<code>SQL_C_CHAR</code>
<code>double precision</code>	<code>SQL_DOUBLE</code>	<code>SQL_C_DOUBLE</code>
<code>double</code>	<code>SQL_FLOAT</code>	<code>SQL_C_DOUBLE</code>
<code>enum</code>	<code>SQL_VARCHAR</code>	<code>SQL_C_CHAR</code>

### 21.1.6.3. Connector/ODBC Error Codes

The following tables lists the error codes returned by the driver apart from the server errors.

Native Code	SQLSTATE 2	SQLSTATE 3	Error Message
500	01000	01000	General warning
501	01004	01004	String data, right truncated
502	01S02	01S02	Option value changed
503	01S03	01S03	No rows updated/deleted
504	01S04	01S04	More than one row updated/deleted
505	01S06	01S06	Attempt to fetch before the result set returned the first row set
506	07001	07002	<code>SQLBindParameter</code> not used for all parameters
507	07005	07005	Prepared statement not a cursor-specification
508	07009	07009	Invalid descriptor index
509	08002	08002	Connection name in use
510	08003	08003	Connection does not exist
511	24000	24000	Invalid cursor state
512	25000	25000	Invalid transaction state
513	25S01	25S01	Transaction state unknown
514	34000	34000	Invalid cursor name
515	S1000	HY000	General driver defined error
516	S1001	HY001	Memory allocation error
517	S1002	HY002	Invalid column number
518	S1003	HY003	Invalid application buffer type
519	S1004	HY004	Invalid SQL data type
520	S1009	HY009	Invalid use of null pointer
521	S1010	HY010	Function sequence error
522	S1011	HY011	Attribute can not be set now
523	S1012	HY012	Invalid transaction operation code

524	S1013	HY013	Memory management error
525	S1015	HY015	No cursor name available
526	S1024	HY024	Invalid attribute value
527	S1090	HY090	Invalid string or buffer length
528	S1091	HY091	Invalid descriptor field identifier
529	S1092	HY092	Invalid attribute option identifier
530	S1093	HY093	Invalid parameter number
531	S1095	HY095	Function type out of range
532	S1106	HY106	Fetch type out of range
533	S1117	HY117	Row value out of range
534	S1109	HY109	Invalid cursor position
535	S1C00	HYC00	Optional feature not implemented
0	21S01	21S01	Column count does not match value count
0	23000	23000	Integrity constraint violation
0	42000	42000	Syntax error or access violation
0	42S02	42S02	Base table or view not found
0	42S12	42S12	Index not found
0	42S21	42S21	Column already exists
0	42S22	42S22	Column not found
0	08S01	08S01	Communication link failure

## 21.1.7. Connector/ODBC Notes and Tips

Here are some common notes and tips for using Connector/ODBC within different environments, applications and tools. The notes provided here are based on the experiences of Connector/ODBC developers and users.

### 21.1.7.1. Connector/ODBC General Functionality

This section provides help with common queries and areas of functionality in MySQL and how to use them with Connector/ODBC.

#### 21.1.7.1.1. Obtaining Auto-Increment Values

Obtaining the value of column that uses `AUTO_INCREMENT` after an `INSERT` statement can be achieved in a number of different ways. To obtain the value immediately after an `INSERT`, use a `SELECT` query with the `LAST_INSERT_ID()` function.

For example, using Connector/ODBC you would execute two separate statements, the `INSERT` statement and the `SELECT` query to obtain the auto-increment value.

```
INSERT INTO tbl (auto,text) VALUES(NULL,'text');
SELECT LAST_INSERT_ID();
```

If you do not require the value within your application, but do require the value as part of another `INSERT`, the entire process can be handled by executing the following statements:

```
INSERT INTO tbl (auto,text) VALUES(NULL,'text');
INSERT INTO tbl2 (id,text) VALUES(LAST_INSERT_ID(),'text');
```

Certain ODBC applications (including Delphi and Access) may have trouble obtaining the auto-increment value using the previous examples. In this case, try the following statement as an alternative:

```
SELECT * FROM tbl WHERE auto IS NULL;
```

This alternative method requires that `sql_auto_is_null` variable is not set to 0. See [Section 5.1.4, “Server System Variables”](#).

See also [Section 21.9.10.3, “How to Get the Unique ID for the Last Inserted Row”](#).

#### 21.1.7.1.2. Dynamic Cursor Support

Support for the `dynamic cursor` is provided in Connector/ODBC 3.51, but dynamic cursors are not enabled by default. You

can enable this function within Windows by selecting the `Enable Dynamic Cursor` checkbox within the ODBC Data Source Administrator.

On other platforms, you can enable the dynamic cursor by adding `32` to the `OPTION` value when creating the DSN.

### 21.1.7.1.3. Connector/ODBC Performance

The Connector/ODBC driver has been optimized to provide very fast performance. If you experience problems with the performance of Connector/ODBC, or notice a large amount of disk activity for simple queries, there are a number of aspects you should check:

- Ensure that `ODBC Tracing` is not enabled. With tracing enabled, a lot of information is recorded in the tracing file by the ODBC Manager. You can check, and disable, tracing within Windows using the TRACING panel of the ODBC Data Source Administrator. Within Mac OS X, check the TRACING panel of ODBC Administrator. See [Section 21.1.4.8, “Getting an ODBC Trace File”](#).
- Make sure you are using the standard version of the driver, and not the debug version. The debug version includes additional checks and reporting measures.
- Disable the Connector/ODBC driver trace and query logs. These options are enabled for each DSN, so make sure to examine only the DSN that you are using in your application. Within Windows, you can disable the Connector/ODBC and query logs by modifying the DSN configuration. Within Mac OS X and Unix, ensure that the driver trace (option value 4) and query logging (option value 524288) are not enabled.

### 21.1.7.1.4. Setting ODBC Query Timeout in Windows

For more information on how to set the query timeout on Microsoft Windows when executing queries through an ODBC connection, read the Microsoft knowledgebase document at <http://support.microsoft.com/default.aspx?scid=kb%3Ben-us%3B153756>.

### 21.1.7.2. Connector/ODBC Application Specific Tips

Most programs should work with Connector/ODBC, but for each of those listed here, there are specific notes and tips to improve or enhance the way you work with Connector/ODBC and these applications.

With all applications you should ensure that you are using the latest Connector/ODBC drivers, ODBC Manager and any supporting libraries and interfaces used by your application. For example, on Windows, using the latest version of Microsoft Data Access Components (MDAC) will improve the compatibility with ODBC in general, and with the Connector/ODBC driver.

#### 21.1.7.2.1. Using Connector/ODBC with Microsoft Applications

The majority of Microsoft applications have been tested with Connector/ODBC, including Microsoft Office, Microsoft Access and the various programming languages supported within ASP and Microsoft Visual Studio.

##### 21.1.7.2.1.1. Microsoft Access

To improve the integration between Microsoft Access and MySQL through Connector/ODBC:

- For all versions of Access, you should enable the Connector/ODBC `Return matching rows` option. For Access 2.0, you should additionally enable the `Simulate ODBC 1.0` option.
- You should have a `TIMESTAMP` column in all tables that you want to be able to update. For maximum portability, do not use a length specification in the column declaration (which is unsupported within MySQL in versions earlier than 4.1).
- You should have a primary key in each MySQL table you want to use with Access. If not, new or updated rows may show up as `#DELETED#`.
- Use only `DOUBLE` float fields. Access fails when comparing with single-precision floats. The symptom usually is that new or updated rows may show up as `#DELETED#` or that you cannot find or update rows.
- If you are using Connector/ODBC to link to a table that has a `BIGINT` column, the results are displayed as `#DELETED#`. The work around solution is:
  - Have one more dummy column with `TIMESTAMP` as the data type.
  - Select the `Change BIGINT columns to INT` option in the connection dialog in ODBC DSN Administrator.
  - Delete the table link from Access and re-create it.

Old records may still display as `#DELETED#`, but newly added/updated records are displayed properly.

- If you still get the error `Another user has changed your data` after adding a `TIMESTAMP` column, the following trick may help you:

Do not use a `table` data sheet view. Instead, create a form with the fields you want, and use that `form` data sheet view. You should set the `DefaultValue` property for the `TIMESTAMP` column to `NOW()`. It may be a good idea to hide the `TIMESTAMP` column from view so your users are not confused.

- In some cases, Access may generate SQL statements that MySQL cannot understand. You can fix this by selecting `"Query|SQL Specific|Pass-Through"` from the Access menu.
- On Windows NT, Access reports `BLOB` columns as `OLE OBJECTS`. If you want to have `MEMO` columns instead, you should change `BLOB` columns to `TEXT` with `ALTER TABLE`.
- Access cannot always handle the MySQL `DATE` column properly. If you have a problem with these, change the columns to `DATETIME`.
- If you have in Access a column defined as `BYTE`, Access tries to export this as `TINYINT` instead of `TINYINT UNSIGNED`. This gives you problems if you have values larger than 127 in the column.
- If you have very large (long) tables in Access, it might take a very long time to open them. Or you might run low on virtual memory and eventually get an `ODBC Query Failed` error and the table cannot open. To deal with this, select the following options:
  - Return Matching Rows (2)
  - Allow BIG Results (8).

These add up to a value of 10 (`OPTION=10`).

Some external articles and tips that may be useful when using Access, ODBC and Connector/ODBC:

- Read [How to Trap ODBC Login Error Messages in Access](#)
- Optimizing Access ODBC Applications
  - [Optimizing for Client/Server Performance](#)
  - [Tips for Converting Applications to Using ODBCDirect](#)
  - [Tips for Optimizing Queries on Attached SQL Tables](#)
- For a list of tools that can be used with Access and ODBC data sources, refer to <http://www.mysql.com/portal/software/convertors/> section for list of available tools.

### 21.1.7.2.1.2. Microsoft Excel and Column Types

If you have problems importing data into Microsoft Excel, particularly numeric, date, and time values, this is probably because of a bug in Excel, where the column type of the source data is used to determine the data type when that data is inserted into a cell within the worksheet. The result is that Excel incorrectly identifies the content and this affects both the display format and the data when it is used within calculations.

To address this issue, use the `CONCAT( )` function in your queries. The use of `CONCAT( )` forces Excel to treat the value as a string, which Excel will then parse and usually correctly identify the embedded information.

However, even with this option, some data may be incorrectly formatted, even though the source data remains unchanged. Use the `Format Cells` option within Excel to change the format of the displayed information.

### 21.1.7.2.1.3. Microsoft Visual Basic

To be able to update a table, you must define a primary key for the table.

Visual Basic with ADO cannot handle big integers. This means that some queries like `SHOW PROCESSLIST` do not work properly. The fix is to use `OPTION=16384` in the ODBC connect string or to select the `Change BIGINT columns to INT` option in the Connector/ODBC connect screen. You may also want to select the `Return matching rows` option.

#### 21.1.7.2.1.4. Microsoft Visual InterDev

If you have a `BIGINT` in your result, you may get the error `[Microsoft][ODBC Driver Manager] Driver does not support this parameter`. Try selecting the `Change BIGINT columns to INT` option in the Connector/ODBC connect screen.

#### 21.1.7.2.1.5. Visual Objects

You should select the `Don't optimize column widths` option.

#### 21.1.7.2.1.6. Microsoft ADO

When you are coding with the ADO API and Connector/ODBC, you need to pay attention to some default properties that aren't supported by the MySQL server. For example, using the `CursorLocation Property` as `adUseServer` returns a result of `-1` for the `RecordCount Property`. To have the right value, you need to set this property to `adUseClient`, as shown in the VB code here:

```
Dim myconn As New ADODB.Connection
Dim myrs As New Recordset
Dim mySQL As String
Dim myrows As Long

myconn.Open "DSN=MyODBCsample"
mySQL = "SELECT * from user"
myrs.Source = mySQL
Set myrs.ActiveConnection = myconn
myrs.CursorLocation = adUseClient
myrs.Open
myrows = myrs.RecordCount

myrs.Close
myconn.Close
```

Another workaround is to use a `SELECT COUNT(*)` statement for a similar query to get the correct row count.

To find the number of rows affected by a specific SQL statement in ADO, use the `RecordsAffected` property in the ADO execute method. For more information on the usage of execute method, refer to <http://msdn.microsoft.com/library/default.asp?url=/library/en-us/ado270/htm/mdmthcnexecute.asp>.

For information, see [ActiveX Data Objects\(ADO\) Frequently Asked Questions](#).

#### 21.1.7.2.1.7. Using Connector/ODBC with Active Server Pages (ASP)

You should select the `Return matching rows` option in the DSN.

For more information about how to access MySQL through ASP using Connector/ODBC, refer to the following articles:

- [Using MyODBC To Access Your MySQL Database Via ASP](#)
- [ASP and MySQL at DWAM.NT](#)

A Frequently Asked Questions list for ASP can be found at <http://support.microsoft.com/default.aspx?scid=/Support/ActiveServer/faq/data/adofaq.asp>.

#### 21.1.7.2.1.8. Using Connector/ODBC with Visual Basic (ADO, DAO and RDO) and ASP

Some articles that may help with Visual Basic and ASP:

- [MySQL BLOB columns and Visual Basic 6](#) by Mike Hillyer ([<mike@openwin.org>](mailto:<mike@openwin.org>)).
- [How to map Visual basic data type to MySQL types](#) by Mike Hillyer ([<mike@openwin.org>](mailto:<mike@openwin.org>)).

#### 21.1.7.2.2. Using Connector/ODBC with Borland Applications

With all Borland applications where the Borland Database Engine (BDE) is used, follow these steps to improve compatibility:

- Update to BDE 3.2 or newer.
- Enable the `Don't optimize column widths` option in the DSN.

- Enabled the `Return matching rows` option in the DSN.

### 21.1.7.2.2.1. Using Connector/ODBC with Borland Builder 4

When you start a query, you can use the `Active` property or the `Open` method. Note that `Active` starts by automatically issuing a `SELECT * FROM ...` query. That may not be a good thing if your tables are large.

### 21.1.7.2.2.2. Using Connector/ODBC with Delphi

Also, here is some potentially useful Delphi code that sets up both an ODBC entry and a BDE entry for Connector/ODBC. The BDE entry requires a BDE Alias Editor that is free at a Delphi Super Page near you. (Thanks to Bryan Brunton <[bryan@flesherfab.com](mailto:bryan@flesherfab.com)> for this):

```
fReg:= TRegistry.Create;
fReg.OpenKey('Software\ODBC\ODBC.INI\DocumentsFab', True);
fReg.WriteString('Database', 'Documents');
fReg.WriteString('Description', ' ');
fReg.WriteString('Driver', 'C:\WINNT\System32\myodbc.dll');
fReg.WriteString('Flag', '1');
fReg.WriteString('Password', '');
fReg.WriteString('Port', ' ');
fReg.WriteString('Server', 'xmark');
fReg.WriteString('User', 'winuser');
fReg.OpenKey('Software\ODBC\ODBC.INI\ODBC Data Sources', True);
fReg.WriteString('DocumentsFab', 'MySQL');
fReg.CloseKey;
fReg.Free;

Memo1.Lines.Add('DATABASE NAME=');
Memo1.Lines.Add('USER NAME=');
Memo1.Lines.Add('ODBC DSN=DocumentsFab');
Memo1.Lines.Add('OPEN MODE=READ/WRITE');
Memo1.Lines.Add('BATCH COUNT=200');
Memo1.Lines.Add('LANGDRIVER=');
Memo1.Lines.Add('MAX ROWS=-1');
Memo1.Lines.Add('SCHEMA CACHE DIR=');
Memo1.Lines.Add('SCHEMA CACHE SIZE=8');
Memo1.Lines.Add('SCHEMA CACHE TIME=-1');
Memo1.Lines.Add('SQLPASSTHRU MODE=SHARED AUTOCOMMIT');
Memo1.Lines.Add('SQLQRYMODE=');
Memo1.Lines.Add('ENABLE SCHEMA CACHE=FALSE');
Memo1.Lines.Add('ENABLE BCD=FALSE');
Memo1.Lines.Add('ROWSET SIZE=20');
Memo1.Lines.Add('BLOBS TO CACHE=64');
Memo1.Lines.Add('BLOB SIZE=32');

AliasEditor.Add('DocumentsFab', 'MySQL', Memo1.Lines);
```

### 21.1.7.2.2.3. Using Connector/ODBC with C++ Builder

Tested with BDE 3.0. The only known problem is that when the table schema changes, query fields are not updated. BDE, however, does not seem to recognize primary keys, only the index named `PRIMARY`, although this has not been a problem.

### 21.1.7.2.3. Using Connector/ODBC with ColdFusion

The following information is taken from the ColdFusion documentation:

Use the following information to configure ColdFusion Server for Linux to use the `unixODBC` driver with Connector/ODBC for MySQL data sources. You can download Connector/ODBC at <http://dev.mysql.com/downloads/connector/odbc/>.

ColdFusion version 4.5.1 enables you to use the ColdFusion Administrator to add the MySQL data source. However, the driver is not included with ColdFusion version 4.5.1. Before the MySQL driver appears in the ODBC data sources drop-down list, you must build and copy the Connector/ODBC driver to `/opt/coldfusion/lib/libmyodbc.so`.

The Contrib directory contains the program `mydsn-xxx.zip` which enables you to build and remove the DSN registry file for the Connector/ODBC driver on ColdFusion applications.

For more information and guides on using ColdFusion and Connector/ODBC, see the following external sites:

- [Troubleshooting Data Sources and Database Connectivity for Unix Platforms](#).

### 21.1.7.2.4. Using Connector/ODBC with OpenOffice.org

Open Office (<http://www.openoffice.org>) How-to: MySQL + OpenOffice. How-to: OpenOffice + MyODBC + unixODBC.

### 21.1.7.2.5. Using Connector/ODBC with Sambar Server

Sambar Server (<http://www.sambarserver.info>) How-to: MyODBC + SambarServer + MySQL.

### 21.1.7.2.6. Using Connector/ODBC with Pervasive Software DataJunction

You have to change it to output `VARCHAR` rather than `ENUM`, as it exports the latter in a manner that causes MySQL problems.

### 21.1.7.2.7. Using Connector/ODBC with SunSystems Vision

You should select the `Return matching rows` option.

### 21.1.7.3. Connector/ODBC Errors and Resolutions (FAQ)

The following section details some common errors and their suggested fix or alternative solution. If you are still experiencing problems, use the Connector/ODBC mailing list; see [Section 21.1.8.1, “Connector/ODBC Community Support”](#).

Many problems can be resolved by upgrading your Connector/ODBC drivers to the latest available release. On Windows, you should also make sure that you have the latest versions of the Microsoft Data Access Components (MDAC) installed.

#### Questions

- [22.1.7.3.1:](#) I have installed Connector/ODBC on Windows XP x64 Edition or Windows Server 2003 R2 x64. The installation completed successfully, but the Connector/ODBC driver does not appear in `ODBC Data Source Administrator`.
- [22.1.7.3.2:](#) When connecting or using the TEST button in `ODBC Data Source Administrator` I get error 10061 (Cannot connect to server)
- [22.1.7.3.3:](#) The following error is reported when using transactions: `Transactions are not enabled`
- [22.1.7.3.4:](#) Access reports records as `#DELETED#` when inserting or updating records in linked tables.
- [22.1.7.3.5:](#) How do I handle Write Conflicts or Row Location errors?
- [22.1.7.3.6:](#) Exporting data from Access 97 to MySQL reports a `Syntax Error`.
- [22.1.7.3.7:](#) Exporting data from Microsoft DTS to MySQL reports a `Syntax Error`.
- [22.1.7.3.8:](#) Using ODBC.NET with Connector/ODBC, while fetching empty string (0 length), it starts giving the `SQL_NO_DATA` exception.
- [22.1.7.3.9:](#) Using `SELECT COUNT(*) FROM tbl_name` within Visual Basic and ASP returns an error.
- [22.1.7.3.10:](#) Using the `AppendChunk()` or `GetChunk()` ADO methods, the `Multiple-step operation generated errors. Check each status value` error is returned.
- [22.1.7.3.11:](#) Access Returns `Another user had modified the record that you have modified` while editing records on a Linked Table.
- [22.1.7.3.12:](#) When linking an application directly to the Connector/ODBC library under Unix/Linux, the application crashes.
- [22.1.7.3.13:](#) Applications in the Microsoft Office suite are unable to update tables that have `DATE` or `TIMESTAMP` columns.
- [22.1.7.3.14:](#) When connecting Connector/ODBC 5.x (Beta) to a MySQL 4.x server, the error `1044 Access denied for user 'xxx'@'%' to database 'information_schema'` is returned.
- [22.1.7.3.15:](#) When calling `SQLTables`, the error `S1T00` is returned, but I cannot find this in the list of error numbers for Connector/ODBC.
- [22.1.7.3.16:](#) When linking to tables in Access 2000 and generating links to tables programmatically, rather than through the table designer interface, you may get errors about tables not existing.
- [22.1.7.3.17:](#) When I try to use batched statements, the execution of the batched statements fails.
- [22.1.7.3.18:](#) When connecting to a MySQL server using ADODB and Excel, occasionally the application fails to communicate with the server and the error `Got an error reading communication packets` appears in the error log.
- [22.1.7.3.19:](#) When using some applications to access a MySQL server using C/ODBC and outer joins, an error is reported regarding the Outer Join Escape Sequence.
- [22.1.7.3.20:](#) I can correctly store extended characters in the database (Hebrew/CJK) using C/ODBC 5.1, but when I retrieve the data, the text is not formatted correctly and I get garbled characters.

- [22.1.7.3.21](#): I have a duplicate MySQL Connector/ODBC entry within my **INSTALLED PROGRAMS** list, but I cannot delete one of them.
- [22.1.7.3.22](#): When submitting queries with parameter binding using `UPDATE`, my field values are being truncated to 255 characters.
- [22.1.7.3.23](#): Is it possible to disable data-at-execution using a flag?
- [22.1.7.3.24](#): When you call `SQLColumns()` for a table column that is `AUTO_INCREMENT`, the `NULLABLE` column of the result set is always `SQL_NULLABLE (1)`.

## Questions and Answers

### 22.1.7.3.1: I have installed Connector/ODBC on Windows XP x64 Edition or Windows Server 2003 R2 x64. The installation completed successfully, but the Connector/ODBC driver does not appear in ODBC Data Source Administrator.

This is not a bug, but is related to the way Windows x64 editions operate with the ODBC driver. On Windows x64 editions, the Connector/ODBC driver is installed in the `%SystemRoot%\SysWOW64` folder. However, the default `ODBC Data Source Administrator` that is available through the `Administrative Tools` or `Control Panel` in Windows x64 Editions is located in the `%SystemRoot%\system32` folder, and only searches this folder for ODBC drivers.

On Windows x64 editions, you should use the ODBC administration tool located at `%SystemRoot%\SysWOW64\odbcad32.exe`, this will correctly locate the installed Connector/ODBC drivers and enable you to create a Connector/ODBC DSN.

This issue was originally reported as [Bug#20301](#).

### 22.1.7.3.2: When connecting or using the TEST button in ODBC Data Source Administrator I get error 10061 (Cannot connect to server)

This error can be raised by a number of different issues, including server problems, network problems, and firewall and port blocking problems. For more information, see [Section B.5.2.2, “Can't connect to \[local\] MySQL server”](#).

### 22.1.7.3.3: The following error is reported when using transactions: Transactions are not enabled

This error indicates that you are trying to use transactions with a MySQL table that does not support transactions. Transactions are supported within MySQL when using the `InnoDB` database engine. In versions of MySQL before MySQL 5.1 you may also use the `BDB` engine.

You should check the following before continuing:

- Verify that your MySQL server supports a transactional database engine. Use `SHOW ENGINES` to obtain a list of the available engine types.
- Verify that the tables you are updating use a transaction database engine.
- Ensure that you have not enabled the `disable transactions` option in your DSN.

### 22.1.7.3.4: Access reports records as #DELETED# when inserting or updating records in linked tables.

If the inserted or updated records are shown as `#DELETED#` in the access, then:

- If you are using Access 2000, you should get and install the newest (version 2.6 or higher) Microsoft MDAC ([Microsoft Data Access Components](#)) from <http://support.microsoft.com/kb/110093>. This fixes a bug in Access that when you export data to MySQL, the table and column names aren't specified.

You should also get and apply the Microsoft Jet 4.0 Service Pack 5 (SP5) which can be found at [ht tp://support.microsoft.com/default.aspx?scid=kb;EN-US;q239114](http://support.microsoft.com/default.aspx?scid=kb;EN-US;q239114). This fixes some cases where columns are marked as `#DELETED#` in Access.

- For all versions of Access, you should enable the Connector/ODBC `Return matching rows` option. For Access 2.0, you should additionally enable the `Simulate ODBC 1.0` option.
- You should have a timestamp in all tables that you want to be able to update.
- You should have a primary key in the table. If not, new or updated rows may show up as `#DELETED#`.
- Use only `DOUBLE` float fields. Access fails when comparing with single-precision floats. The symptom usually is that new or

updated rows may show up as #DELETED# or that you cannot find or update rows.

- If you are using Connector/ODBC to link to a table that has a BIGINT column, the results are displayed as #DELETED. The work around solution is:
  - Have one more dummy column with TIMESTAMP as the data type.
  - Select the Change BIGINT columns to INT option in the connection dialog in ODBC DSN Administrator.
  - Delete the table link from Access and re-create it.

Old records still display as #DELETED#, but newly added/updated records are displayed properly.

#### 22.1.7.3.5: How do I handle Write Conflicts or Row Location errors?

If you see the following errors, select the Return Matching Rows option in the DSN configuration dialog, or specify OPTION=2, as the connection parameter:

```
Write Conflict. Another user has changed your data.
Row cannot be located for updating. Some values may have been changed
since it was last read.
```

#### 22.1.7.3.6: Exporting data from Access 97 to MySQL reports a Syntax Error.

This error is specific to Access 97 and versions of Connector/ODBC earlier than 3.51.02. Update to the latest version of the Connector/ODBC driver to resolve this problem.

#### 22.1.7.3.7: Exporting data from Microsoft DTS to MySQL reports a Syntax Error.

This error occurs only with MySQL tables using the TEXT or VARCHAR data types. You can fix this error by upgrading your Connector/ODBC driver to version 3.51.02 or higher.

#### 22.1.7.3.8: Using ODBC.NET with Connector/ODBC, while fetching empty string (0 length), it starts giving the SQL\_NO\_DATA exception.

You can get the patch that addresses this problem from <http://support.microsoft.com/default.aspx?scid=kb;EN-US;q319243>.

#### 22.1.7.3.9: Using SELECT COUNT(\*) FROM tbl\_name within Visual Basic and ASP returns an error.

This error occurs because the COUNT(\*) expression is returning a BIGINT, and ADO cannot make sense of a number this big. Select the Change BIGINT columns to INT option (option value 16384).

#### 22.1.7.3.10: Using the AppendChunk() or GetChunk() ADO methods, the Multiple-step operation generated errors. Check each status value error is returned.

The GetChunk() and AppendChunk() methods from ADO doesn't work as expected when the cursor location is specified as adUseServer. On the other hand, you can overcome this error by using adUseClient.

A simple example can be found from [http://www.dwam.net/iishelp/ado/docs/adomth02\\_4.htm](http://www.dwam.net/iishelp/ado/docs/adomth02_4.htm)

#### 22.1.7.3.11: Access Returns Another user had modified the record that you have modified while editing records on a Linked Table.

In most cases, this can be solved by doing one of the following things:

- Add a primary key for the table if one doesn't exist.
- Add a timestamp column if one doesn't exist.
- Only use double-precision float fields. Some programs may fail when they compare single-precision floats.

If these strategies do not help, you should start by making a log file from the ODBC manager (the log you get when requesting logs from ODBCADMIN) and a Connector/ODBC log to help you figure out why things go wrong. For instructions, see Section 21.1.4.8, "Getting an ODBC Trace File".

#### 22.1.7.3.12: When linking an application directly to the Connector/ODBC library under Unix/Linux, the application crashes.

Connector/ODBC 3.51 under Unix/Linux is not compatible with direct application linking. You must use a driver manager, such as iODBC or unixODBC to connect to an ODBC source.

**22.1.7.3.13: Applications in the Microsoft Office suite are unable to update tables that have `DATE` or `TIMESTAMP` columns.**

This is a known issue with Connector/ODBC. You must ensure that the field has a default value (rather than `NULL` and that the default value is nonzero (that is, the default value is not `0000-00-00 00:00:00`).

**22.1.7.3.14: When connecting Connector/ODBC 5.x (Beta) to a MySQL 4.x server, the error `1044 Access denied for user 'xxx'@'%' to database 'information_schema'` is returned.**

Connector/ODBC 5.x is designed to work with MySQL 5.0 or later, taking advantage of the `INFORMATION_SCHEMA` database to determine data definition information. Support for MySQL 4.1 is planned for the final release.

**22.1.7.3.15: When calling `SQLTables`, the error `S1T00` is returned, but I cannot find this in the list of error numbers for Connector/ODBC.**

The `S1T00` error indicates that a general timeout has occurred within the ODBC system and is not a MySQL error. Typically it indicates that the connection you are using is stale, the server is too busy to accept your request or that the server has gone away.

**22.1.7.3.16: When linking to tables in Access 2000 and generating links to tables programmatically, rather than through the table designer interface, you may get errors about tables not existing.**

There is a known issue with a specific version of the `msjet40.dll` that exhibits this issue. The version affected is 4.0.9025.0. Reverting to an older version will enable you to create the links. If you have recently updated your version, check your `WINDOWS` directory for the older version of the file and copy it to the drivers directory.

**22.1.7.3.17: When I try to use batched statements, the execution of the batched statements fails.**

Batched statement support was added in 3.51.18. Support for batched statements is not enabled by default. You must enable option `FLAG_MULTI_STATEMENTS`, value 67108864, or select the `ALLOW MULTIPLE STATEMENTS` flag within a GUI configuration.

**22.1.7.3.18: When connecting to a MySQL server using ADODB and Excel, occasionally the application fails to communicate with the server and the error `Got an error reading communication packets` appears in the error log.**

This error may be related to Keyboard Logger 1.1 from PanteraSoft.com, which is known to interfere with the network communication between MySQL Connector/ODBC and MySQL.

**22.1.7.3.19: When using some applications to access a MySQL server using C/ODBC and outer joins, an error is reported regarding the Outer Join Escape Sequence.**

This is a known issue with MySQL Connector/ODBC which is not correctly parsing the "Outer Join Escape Sequence", as per the specs at [Microsoft ODBC Specs](#). Currently, Connector/ODBC will return value > 0 when asked for `SQL_OJ_CAPABILITIES` even though no parsing takes place in the driver to handle the outer join escape sequence.

**22.1.7.3.20: I can correctly store extended characters in the database (Hebrew/CJK) using C/ODBC 5.1, but when I retrieve the data, the text is not formatted correctly and I get garbled characters.**

When using ASP and UTF8 characters you should add the following to your ASP files to ensure that the data returned is correctly encoded:

```
Response.CodePage = 65001
Response.CharSet = "utf-8"
```

**22.1.7.3.21: I have a duplicate MySQL Connector/ODBC entry within my INSTALLED PROGRAMS list, but I cannot delete one of them.**

This problem can occur when you upgrade an existing Connector/ODBC installation, rather than removing and then installing the updated version.

**Warning**

To fix the problem you should use any working uninstallers to remove existing installations and then may have to edit the contents of the registry. Make sure you have a backup of your registry information before attempting any editing of the registry contents.

**22.1.7.3.22: When submitting queries with parameter binding using `UPDATE`, my field values are being truncated to 255 characters.**

You should ensure that the `FLAG_BIG_PACKETS` option is set for your connection. This removes the 255 character limitation on bound parameters.

### 22.1.7.3.23: Is it possible to disable data-at-execution using a flag?

If you do not wish to use data-at-execution, simply remove the corresponding calls. For example:

```
SQLLEN ylen = SQL_LEN_DATA_AT_EXEC(10);
SQLBindCol(hstmt,2,SQL_C_BINARY, buf, 10, &hlen);
```

Would become:

```
SQLBindCol(hstmt,2,SQL_C_BINARY, buf, 10, NULL);
```

Note that in the call to `SQLBindCol()`, `&hlen` has been replaced by `NULL`.

For further information please refer to the [MSDN documentation](#) for `SQLBindCol()`.

### 22.1.7.3.24: When you call `SQLColumns()` for a table column that is `AUTO_INCREMENT`, the `NULLABLE` column of the result set is always `SQL_NULLABLE (1)`.

This is because MySQL reports the `DEFAULT` value for such a column as `NULL`. It means, if you insert a `NULL` value into the column, you will get the next integer value for the table's `auto_increment` counter.

## 21.1.8. Connector/ODBC Support

There are many different places where you can get support for using Connector/ODBC. You should always try the Connector/ODBC Mailing List or Connector/ODBC Forum. See [Section 21.1.8.1, “Connector/ODBC Community Support”](#), for help before reporting a specific bug or issue to MySQL.

### 21.1.8.1. Connector/ODBC Community Support

Oracle provides assistance to the user community by means of its mailing lists. For Connector/ODBC-related issues, you can get help from experienced users by using the [<myodbc@lists.mysql.com>](mailto:<myodbc@lists.mysql.com>) mailing list. Archives are available online at <http://lists.mysql.com/myodbc>.

For information about subscribing to MySQL mailing lists or to browse list archives, visit <http://lists.mysql.com/>. See [Section 1.6.1, “MySQL Mailing Lists”](#).

Community support from experienced users is also available through the [ODBC Forum](#). You may also find help from other users in the other MySQL Forums, located at <http://forums.mysql.com>. See [Section 1.6.2, “MySQL Community Support at the MySQL Forums”](#).

### 21.1.8.2. How to Report Connector/ODBC Problems or Bugs

If you encounter difficulties or problems with Connector/ODBC, you should start by making a log file from the [ODBC Manager](#) (the log you get when requesting logs from [ODBC ADMIN](#)) and Connector/ODBC. The procedure for doing this is described in [Section 21.1.4.8, “Getting an ODBC Trace File”](#).

Check the Connector/ODBC trace file to find out what could be wrong. You should be able to determine what statements were issued by searching for the string `>mysql_real_query` in the `myodbc.log` file.

You should also try issuing the statements from the `mysql` client program or from `admndemo`. This helps you determine whether the error is in Connector/ODBC or MySQL.

If you find out something is wrong, please only send the relevant rows (maximum 40 rows) to the `myodbc` mailing list. See [Section 1.6.1, “MySQL Mailing Lists”](#). Please never send the whole Connector/ODBC or ODBC log file!

You should ideally include the following information with the email:

- Operating system and version
- Connector/ODBC version
- ODBC Driver Manager type and version
- MySQL server version
- ODBC trace from Driver Manager
- Connector/ODBC log file from Connector/ODBC driver

- Simple reproducible sample

Remember that the more information you can supply to us, the more likely it is that we can fix the problem!

Also, before posting the bug, check the MyODBC mailing list archive at <http://lists.mysql.com/myodbc>.

If you are unable to find out what is wrong, the last option is to create an archive in `tar` or Zip format that contains a Connector/ODBC trace file, the ODBC log file, and a `README` file that explains the problem. You can send this to <ftp://ftp.mysql.com/pub/mysql/upload/>. Only MySQL engineers have access to the files you upload, and we are very discreet with the data.

If you can create a program that also demonstrates the problem, please include it in the archive as well.

If the program works with another SQL server, you should include an ODBC log file where you perform exactly the same SQL statements so that we can compare the results between the two systems.

Remember that the more information you can supply to us, the more likely it is that we can fix the problem.

### 21.1.8.3. How to Submit a Connector/ODBC Patch

You can send a patch or suggest a better solution for any existing code or problems by sending a mail message to [<myodbc@lists.mysql.com>](mailto:<myodbc@lists.mysql.com>).

### 21.1.8.4. Connector/ODBC Change History

The Connector/ODBC Change History (Changelog) is located with the main Changelog for MySQL. See [Section C.3, “MySQL Connector/ODBC \(MyODBC\) Change History”](#).

### 21.1.8.5. Credits

These are the developers that have worked on the Connector/ODBC and Connector/ODBC 3.51 Drivers from MySQL AB.

- Michael (Monty) Widenius
- Venu Anuganti
- Peter Harvey

## 21.2. MySQL Connector/.NET

Connector/.NET enables developers to easily create .NET applications that require secure, high-performance data connectivity with MySQL. It implements the required ADO.NET interfaces and integrates into ADO.NET aware tools. Developers can build applications using their choice of .NET languages. Connector/.NET is a fully managed ADO.NET driver written in 100% pure C#.

Connector/.NET includes full support for:

- Features provided by MySQL Server up to and including MySQL Server version 5.5.
- Large-packet support for sending and receiving rows and BLOBS up to 2 gigabytes in size.
- Protocol compression which enables compressing the data stream between the client and server.
- Support for connecting using TCP/IP sockets, named pipes, or shared memory on Windows.
- Support for connecting using TCP/IP sockets or Unix sockets on Unix.
- Support for the Open Source Mono framework developed by Novell.
- Fully managed, does not utilize the MySQL client library.

This document is intended as a user's guide to Connector/.NET and includes a full syntax reference. Syntax information is also included within the [Documentation.chm](#) file included with the Connector/.NET distribution.

If you are using MySQL 5.0 or later, and Visual Studio as your development environment, you may want also want to use the MySQL Visual Studio Plugin. The plugin acts as a DDEX (Data Designer Extensibility) provider, enabling you to use the data

design tools within Visual Studio to manipulate the schema and objects within a MySQL database. For more information, see [Section 21.2.3, “Connector/NET Visual Studio Integration”](#).

**Note**

Connector/NET 5.1.2 and later include the Visual Studio Plugin by default.

MySQL Connector/NET supports full versions of Visual Studio 2005, 2008, and 2010, although certain features are only available in Visual Studio 2010 when using MySQL Connector/NET version 6.3.2 and later. Note that MySQL Connector/NET does not currently support Express versions of Microsoft products, including Microsoft Visual Web Developer.

**Key topics:**

- For connection string properties when using the `MySqlConnection` class, see [Section 21.2.6, “Connector/NET Connection String Options Reference”](#).

## 21.2.1. Connector/NET Versions

There are several versions of Connector/NET available:

- Connector/NET 1.0 includes support for MySQL Server 4.0, 4.1, and 5.0 features, and full compatibility with the ADO.NET driver interface.

This version of Connector/NET is no longer supported.

- Connector/NET 5.0 includes support for MySQL Server 4.0, 4.1, 5.0 and 5.1 features. Connector/NET 5.0 also includes full support for the ADO.NET 2.0 interfaces and subclasses, includes support for the usage advisor and performance monitor (PerfMon) hooks.

This version of Connector/NET is no longer supported.

- Connector/NET 5.1 includes support for MySQL Server 4.0, 4.1, 5.0, 5.1, 5.4 and 5.5 features. Connector/NET 5.1 also includes support for a new membership/role provider, Compact Framework 2.0, a new stored procedure parser and improvements to `GetSchema`. Connector/NET 5.1 also includes the Visual Studio Plugin as a standard installable component.

This version of Connector/NET is no longer supported.

- Connector/NET 5.2 includes support for MySQL Server 4.1, 5.0, 5.1, 5.4, and 5.5 features. Connector/NET 5.2 also includes support for a new membership/role provider, Compact Framework 2.0, a new stored procedure parser and improvements to `GetSchema`. Connector/NET 5.2 also includes the Visual Studio Plugin as a standard installable component.

This version of Connector/NET is no longer supported.

- Connector/NET 6.0 includes support for MySQL Server 4.1, 5.0, 5.1, 5.4 and 5.5.

This version of Connector/NET is no longer supported.

- Connector/NET 6.1 includes support for MySQL Server 4.1, 5.0, 5.1, 5.4, and 5.5. Important new features include the MySQL Website Configuration Tool and a Session State Provider.

- Connector/NET 6.2 includes support for MySQL Server 4.1, 5.0, 5.1, 5.4, and 5.5. Important new features include a new logging system and client SSL certificates. Connector/NET 6.2 is currently available as a Beta release.

- Connector/NET 6.3 includes support for MySQL Server 5.0, 5.1, 5.4, and 5.5. Important new features include integration with Visual Studio 2010, such as availability of DDL T4 template for Entity Framework, and a custom MySQL SQL Editor. Other features include refactored transaction scope: Connector/NET now supports nested transactions in a scope where they use the same connection string. Connector/NET 6.3 is available as a Beta release.

The latest source code for Connector/NET can be downloaded from the MySQL public Subversion server. For further details see [Section 21.2.2.3, “Installing Connector/NET from the source code”](#).

The following table shows the .NET Framework version required, and MySQL Server version supported by Connector/NET:

Connector/NET version	ADO.NET version supported	.NET Framework version required	MySQL Server version supported	Currently supported
1.0	1.x	1.x	4.0, 4.1, 5.0	No

5.0	2.x+	2.x+	4.0, 4.1, 5.0	No
5.1	2.x+	2.x+	4.0, 4.1, 5.0, 5.1, 5.4, 5.5	No
5.2	2.x+	2.x+	4.1, 5.0, 5.1, 5.4, 5.5	No
6.0	2.x+	2.x+	4.1, 5.0, 5.1, 5.4, 5.5	Critical issues only
6.1	2.x+	2.x+	4.1, 5.0, 5.1, 5.4, 5.5	Yes
6.2	2.x+	2.x+	4.1, 5.0, 5.1, 5.4, 5.5	Yes
6.3	2.x+	2.x+, 4.x+ for VS 2010 support	5.0, 5.1, 5.4, 5.5	Yes

**Note**

Version numbers for MySQL products are formatted as X.Y.Z, where Z=0 indicates alpha, Z=1 indicates beta, and Z>=2 indicates GA. However, Windows tools (Control Panel, properties display) may show the version numbers as XX.YY.ZZ. For example, the official MySQL formatted version number 5.0.9 may be displayed by Windows tools as 5.00.09. The two versions are the same; only the number display format is different.

## 21.2.2. Connector/NET Installation

Connector/NET runs on any platform that supports the .NET framework. The .NET framework is primarily supported on recent versions of Microsoft Windows, and is supported on Linux through the Open Source Mono framework (see <http://www.mono-project.com>).

Connector/NET is available for download from <http://dev.mysql.com/downloads/connector/net/5.2.html>.

### 21.2.2.1. Installing Connector/NET on Windows

On Windows, installation is supported either through a binary installation process or by downloading a Zip file with the Connector/NET components.

Before installing, you should ensure that your system is up to date, including installing the latest version of the .NET Framework.

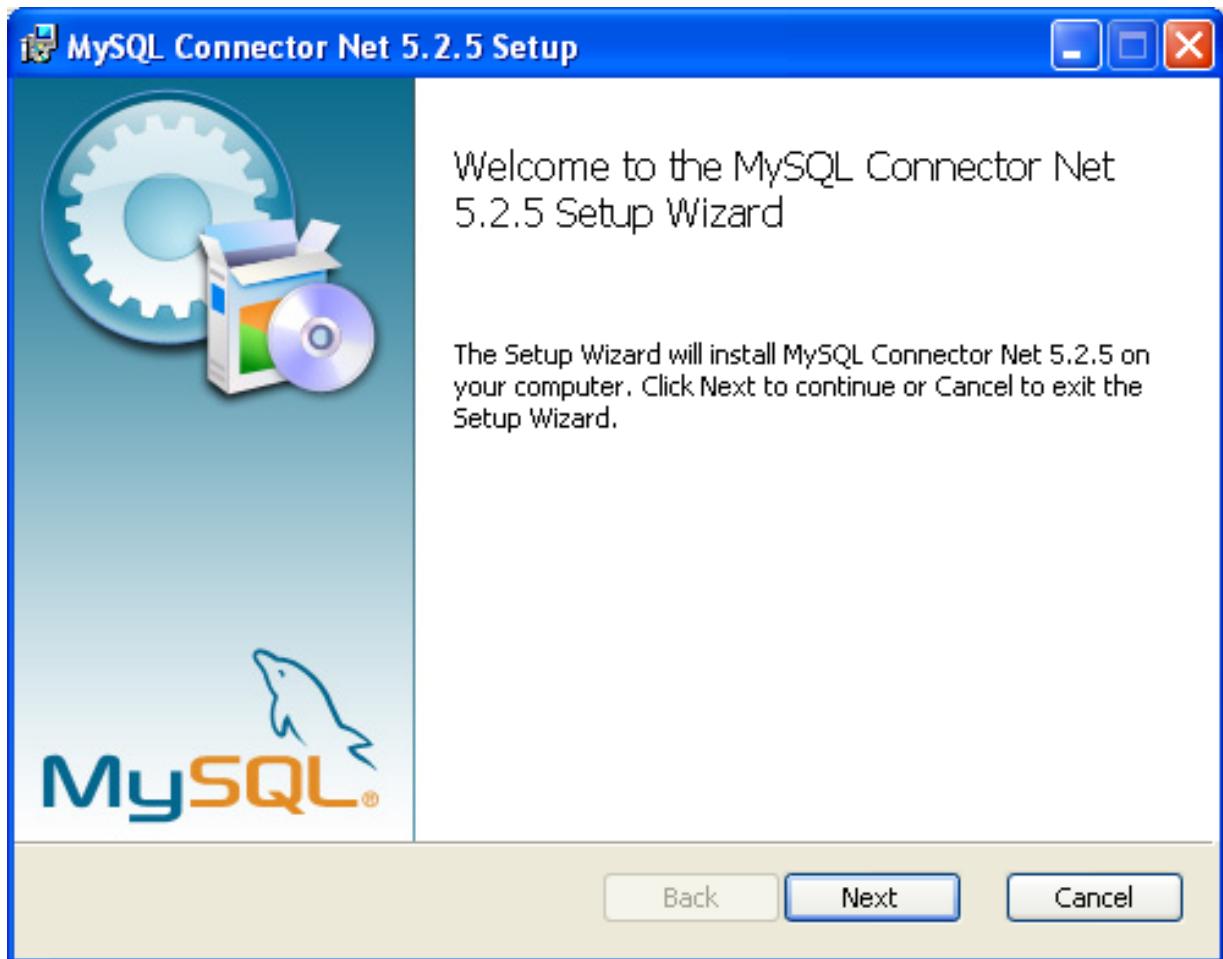

#### 21.2.2.1.1. Installing Connector/NET using the Installer

Using the installer is the most straightforward method of installing Connector/NET on Windows and the installed components include the source code, test code and full reference documentation.

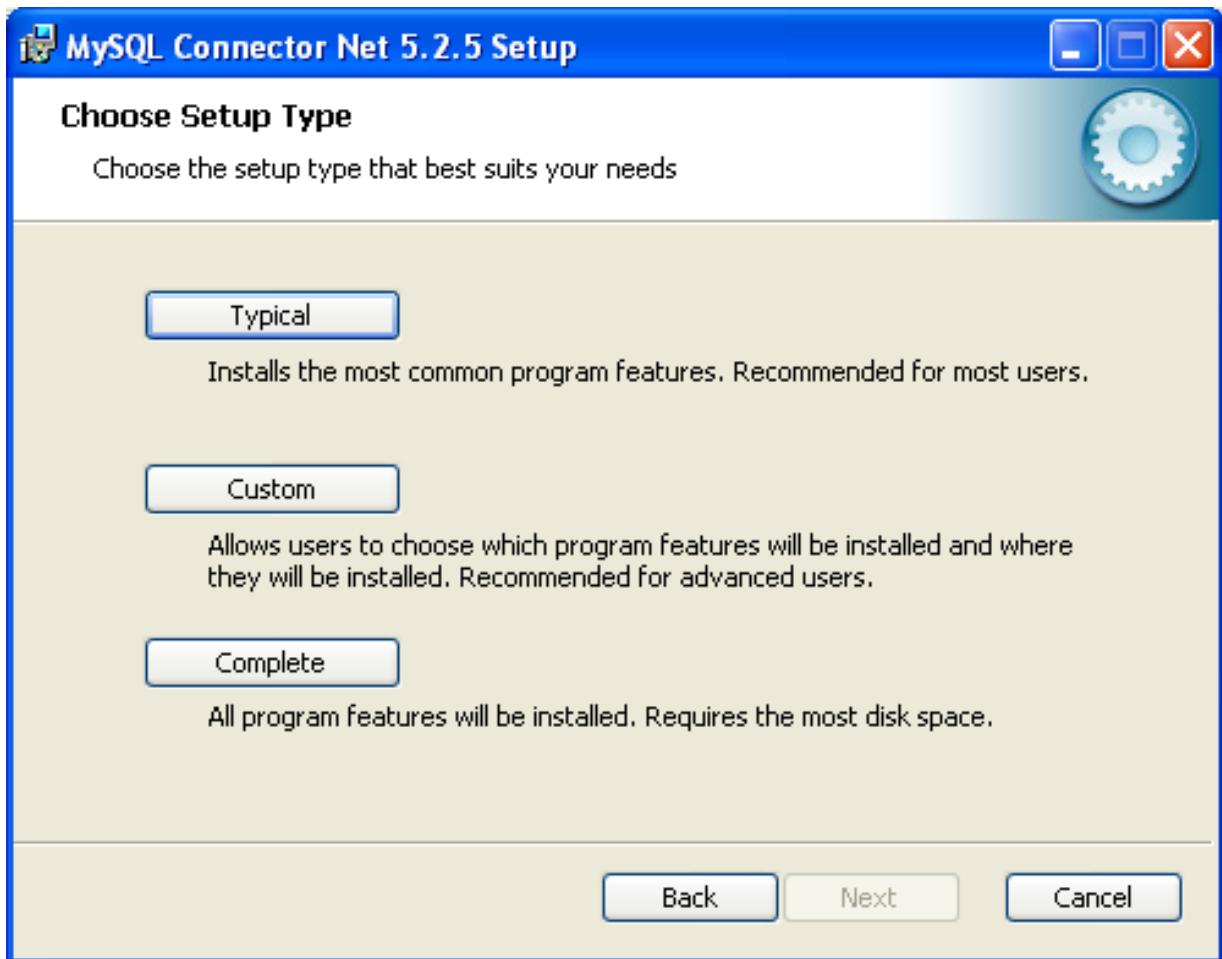

Connector/NET is installed through the use of a Windows Installer (`.msi`) installation package, which can be used to install Connector/NET on all Windows operating systems. The MSI package is contained within a ZIP archive named `mysql-connector-net-version.zip`, where `version` indicates the Connector/NET version.

To install Connector/NET:

1. Double-click the MSI installer file extracted from the Zip you downloaded. Click NEXT to start the installation.

2. You must choose the type of installation that you want to perform.

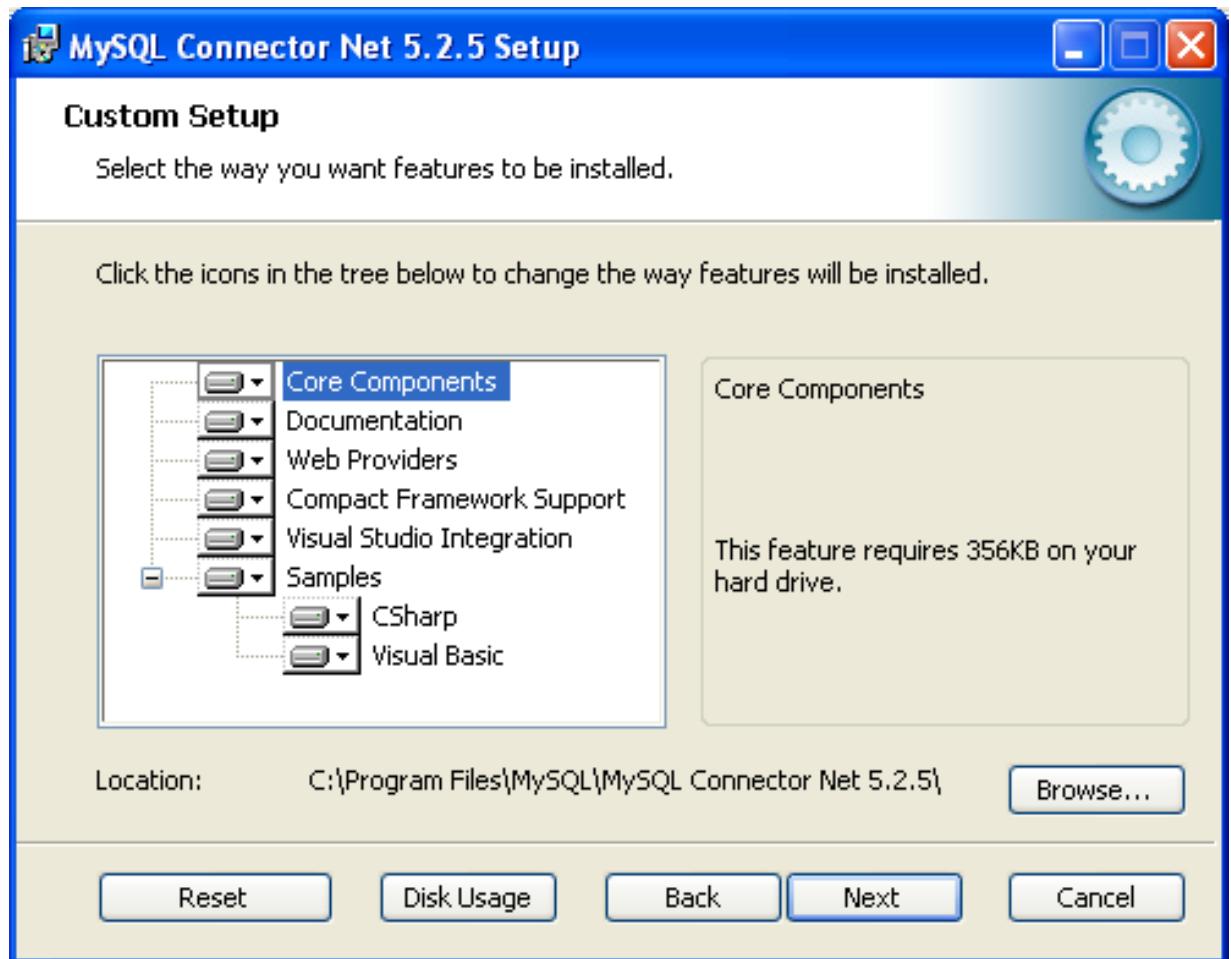

For most situations, the Typical installation will be suitable. Click the TYPICAL button and proceed to Step 5. A Complete installation installs all the available files. To conduct a Complete installation, click the COMPLETE button and proceed to step 5. If you want to customize your installation, including choosing the components to install and some installation options, click the CUSTOM button and proceed to Step 3.

The Connector/.NET installer will register the connector within the Global Assembly Cache (GAC) - this will make the Connector/.NET component available to all applications, not just those where you explicitly reference the Connector/.NET component. The installer will also create the necessary links in the Start menu to the documentation and release notes.

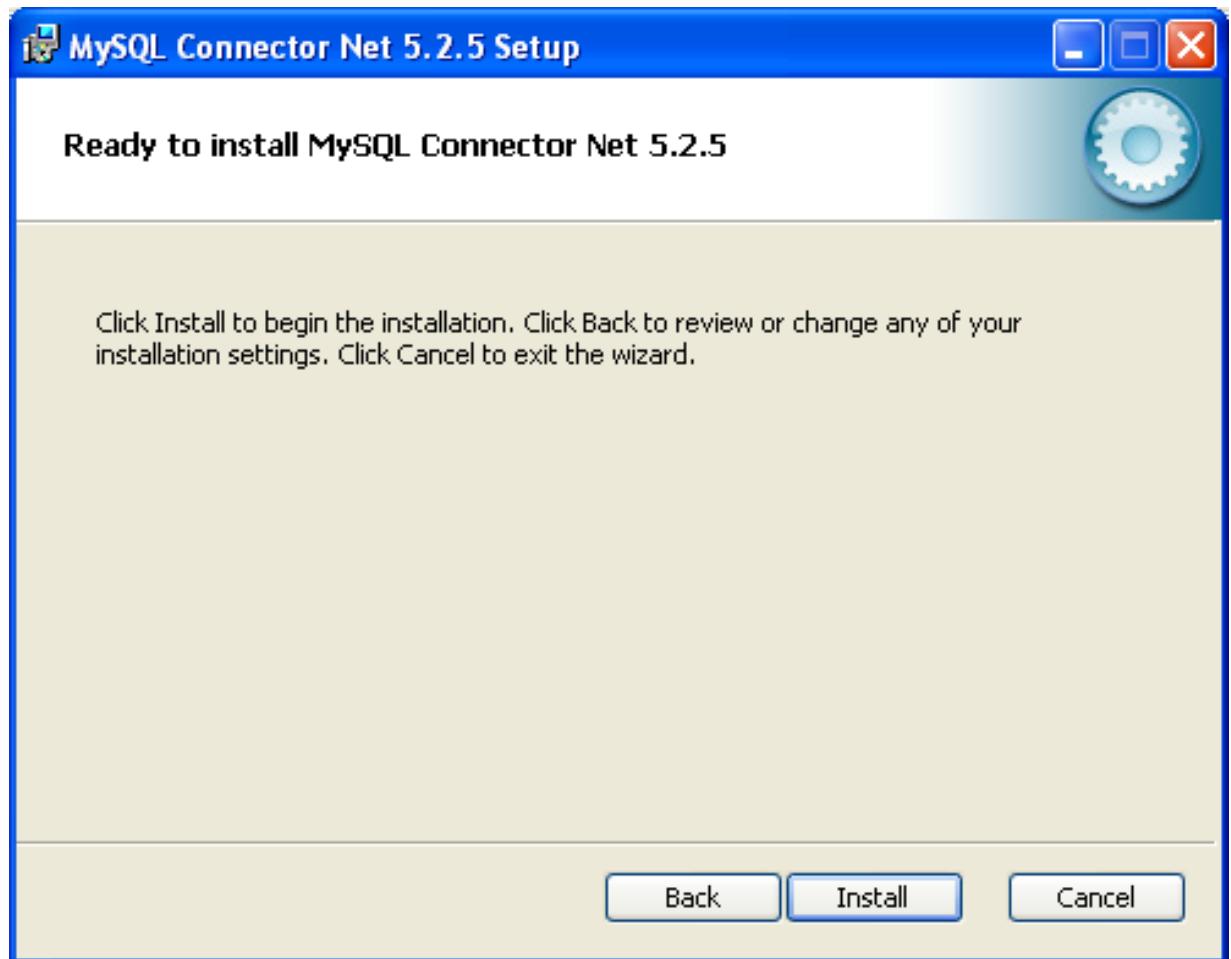

3. If you have chosen a custom installation, you can select the individual components that you want to install, including the core interface component, supporting documentation (a CHM file) samples and examples and the source code. Select the items, and their installation level, and then click NEXT to continue the installation.

#### Note

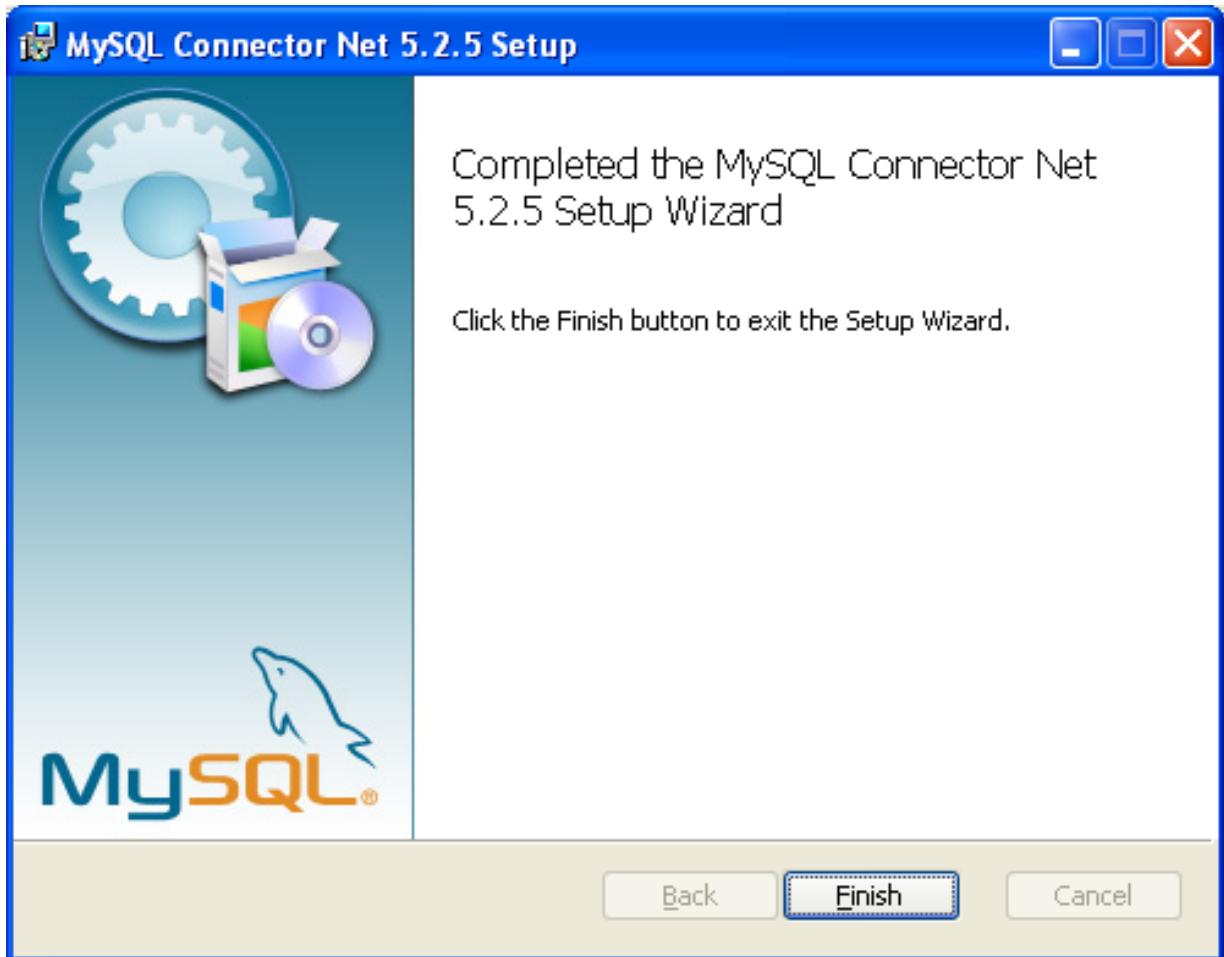

For Connector/.NET 1.0.8 or lower and Connector 5.0.4 and lower the installer will attempt to install binaries for both 1.x and 2.x of the .NET Framework. If you only have one version of the framework installed, the connector installation may fail. If this happens, you can choose the framework version to be installed through the custom installation step.

4. You will be given a final opportunity to confirm the installation. Click **INSTALL** to copy and install the files onto your machine.

5. Once the installation has been completed, click FINISH to exit the installer.

Unless you choose otherwise, Connector/NET is installed in `C:\Program Files\MySQL\MySQL Connector Net X.X.X`, where `X.X.X` is replaced with the version of Connector/NET you are installing. New installations do not overwrite existing versions of Connector/NET.

Depending on your installation type, the installed components will include some or all of the following components:

- `bin` - Connector/NET MySQL libraries for different versions of the .NET environment.
- `docs` - contains a CHM of the Connector/NET documentation.
- `samples` - sample code and applications that use the Connector/NET component.
- `src` - the source code for the Connector/NET component.

You may also use the `/quiet` or `/q` command-line option with the `msiexec` tool to install the Connector/NET package automatically (using the default options) with no notification to the user. Using this method the user cannot select options. Additionally, no prompts, messages or dialog boxes will be displayed.

```
C:\> msiexec /package connector-net.msi /quiet
```

To provide a progress bar to the user during automatic installation, use the `/passive` option.

#### **21.2.2.1.2. Installing Connector/NET using the Zip packages**

If you are having problems running the installer, you can download a Zip file without an installer as an alternative. That file is called `mysql-connector-net-version-noinstall.zip`. Once downloaded, you can extract the files to a location of your choice.

The file contains the following directories:

- **bin** - Connector/NET MySQL libraries for different versions of the .NET environment.
- **Docs** - contains a CHM of the Connector/NET documentation.
- **Samples** - sample code and applications that use the Connector/NET component.

Connector/NET 6.0.x has a different directory structure:

- **Assemblies** - contains a collection of DLLs that make up the connector functionality.
- **Documentation** - contains the Connector/NET documentation as a CHM file.
- **Samples** - sample code and applications that use the Connector/NET component.

There is also another Zip file available for download called [mysql-connector-net-version-src.zip](#). This file contains the source code distribution.

The file contains the following directories:

- **Documentation** - This folder contains the source files to build the documentation into the compiled HTML (CHM) format.
- **Installer** - This folder contains the source files to build the Connector/NET installer program.
- **MySql.Data** - This folder contains the source files for the core data provider.
- **MySql.VisualStudio** - This folder contains the source files for the Microsoft Visual Studio extensions.
- **MySql.Web** - This folder contains the source files for the web providers. This includes code for the membership provider, role provider and profile provider. These are used in ASP.NET web sites.
- **Samples** - This folder contains the source files for several example applications.
- **Tests** - This folder contains a spreadsheet listing test cases.
- **VisualStudio** - Contains resources used by the Visual Studio plug in.

Finally, you need to ensure that **MySql.Data.dll** is accessible to your program at build time (and run time). If using Microsoft Visual Studio you will need to add **MySql.Data** as a Reference to your project.

### 21.2.2.2. Installing Connector/NET on Unix with Mono

There is no installer available for installing the Connector/NET component on your Unix installation. Before installing, please ensure that you have a working Mono project installation. You can test whether your system has Mono installed by typing:

```
shell> mono --version
```

The version of the Mono JIT compiler will be displayed.

To compile C# source code you will also need to make sure a Mono C# compiler, is installed. Note that there are two Mono C# compilers available, **mcs**, which accesses the 1.0-profile libraries, and **gmcs**, which accesses the 2.0-profile libraries.

To install Connector/NET on Unix/Mono:

1. Download the [mysql-connector-net-version-noinstall.zip](#) and extract the contents to a directory of your choice, for example: `~/connector-net/`.
2. In the directory where you unzipped the connector to, change into the **bin** directory. Ensure the file **MySql.Data.dll** is present.
3. You must register the Connector/NET component, **MySql.Data**, in the Global Assembly Cache (GAC). In the current directory enter the **gacutil** command:

```
root-shell> gacutil /i MySql.Data.dll
```

This will register **MySql.Data** into the GAC. You can check this by listing the contents of [/usr/lib/mono/gac](#), where

you will find `MySql.Data` if the registration has been successful.

You are now ready to compile your application. You must ensure that when you compile your application you include the Connector/NET component using the `-r:` command-line option. For example:

```
shell> gmcs -r:System.dll -r:System.Data.dll -r:MySql.Data.dll HelloWorld.cs
```

Note, the assemblies that need to be referenced will depend on the requirements of the application, but applications using Connector/NET will need to provide `-r:MySql.Data` as a minimum.

You can further check your installation by running the compiled program, for example:

```
shell> mono HelloWorld.exe
```

### 21.2.2.3. Installing Connector/NET from the source code

#### Caution

You should read this section only if you are interested in helping us test our new code. If you just want to get Connector/NET up and running on your system, you should use a standard release distribution.

#### Obtaining the source code

To obtain the most recent development source tree, you first need to download and install Bazaar. You can obtain Bazaar from the [Bazaar VCS Website](#). Bazaar is supported by any platform that supports Python, and is therefore compatible with any Linux, Unix, Windows or Mac OS X host. Instructions for downloading and installing Bazaar on the different platforms are available on the Bazaar Web site.

The most recent development source tree is available from our public Subversion trees at <http://dev.mysql.com/tech-resources/sources.html>.

To checkout out the Connector/NET sources, change to the directory where you want the copy of the Connector/NET tree to be stored, then use the following command:

```
shell> bzr branch lp:connectornet/trunk
```

To download a specific version of Connector/NET, specify the version number instead of `trunk`. For example, to obtain a copy of the 6.0 version of the source tree:

```
shell> bzr branch lp:connectornet/6.0
```

Source packages are also available on the downloads page.

#### Building the source code on Windows

The following procedure can be used to build the connector on Microsoft Windows.

- Obtain the source code, either from the Subversion server, or through one of the prepared source code packages.
- Navigate to the root of the source code tree.
- A Microsoft Visual Studio 2005 solution file is available to build the connector, this is called `MySQL-VS2005.sln`. Click this file to load the solution into Visual Studio.
- Select BUILD, BUILD SOLUTION from the main menu to build the solution.

#### Building the source code on Unix

Support for building Connector/NET on Mono/Unix is currently not available.

### 21.2.3. Connector/NET Visual Studio Integration

When MySQL Connector/NET is installed on Microsoft Windows, Visual Studio integration components are also installed and initialized. This enables the developer to work seamlessly with MySQL Connector/NET in the familiar Visual Studio environment, as described in the following sections of the manual.

MySQL Connector/.NET supports Visual Studio versions 2005, 2008, and 2010. However, only MySQL Connector/.NET version 6.3 fully integrates with Visual Studio 2010, although applications using earlier versions of the connector can be built with the Visual Studio 2010 environment using .NET 2.x frameworks.

Visual Studio 2010 support was introduced with MySQL Connector/.NET 6.3.2. From version 6.3.2 the connector ships with both .NET 2.x and .NET 4.x versions of the entity framework support files, `mysql.data.ef.dll` and `mysql.visualstudio.dll`. The .NET 4.x versions need to be shipped to enable new integration features supported in Visual Studio 2010, including:

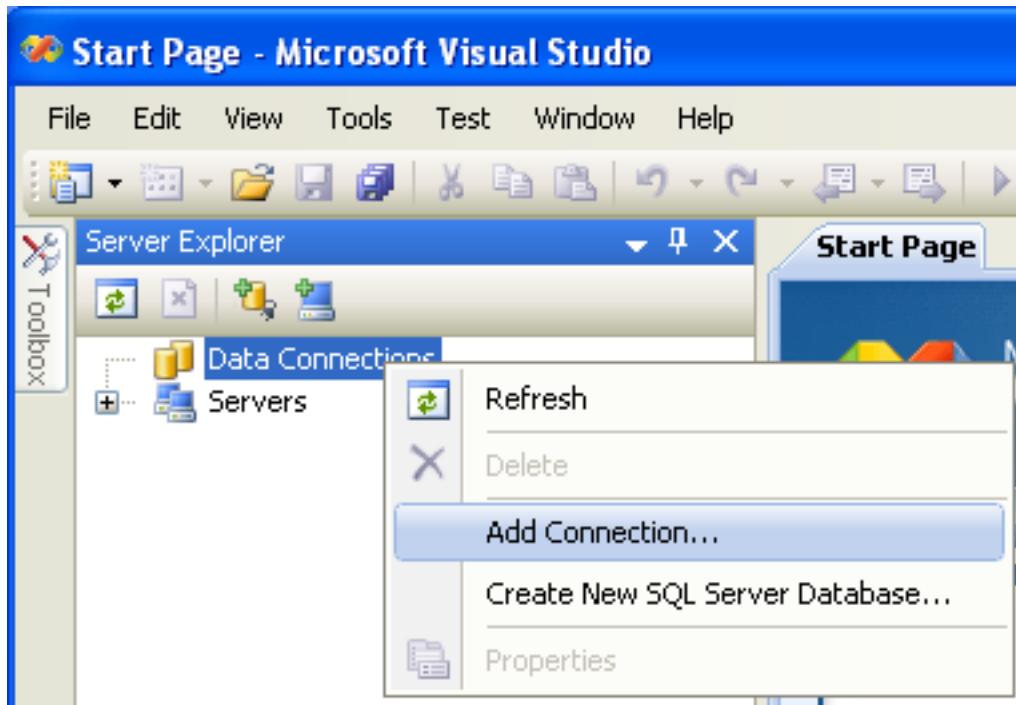

- New DDL T4 template for the Entity Framework (EF) - This enables developers to design an EF model from scratch and use the native Visual Studio 2010 facility to generate MySQL DDL from that model. This is done by creating the model, and with the model open, choosing the SSDLToMySQL template in the properties window. The correct DDL is then generated. The developer can then save this code as a `.mysql` file in their project and execute it against the MySQL server.
- New SQL Editor - A new SQL editor has been included that enables connections to servers to execute SQL. This is activated by creating a new file with a `.mysql` extension. A new template is also included to allow creation of this file type using the Visual Studio 2010 main menu item FILE, NEW. Note that the MySQL SQL Editor is also available in 2005 and 2008.

### 21.2.3.1. Making a connection

Once the connector is installed, you can use it to create, modify, and delete connections to MySQL databases. To create a connection with a MySQL database, perform the following steps:

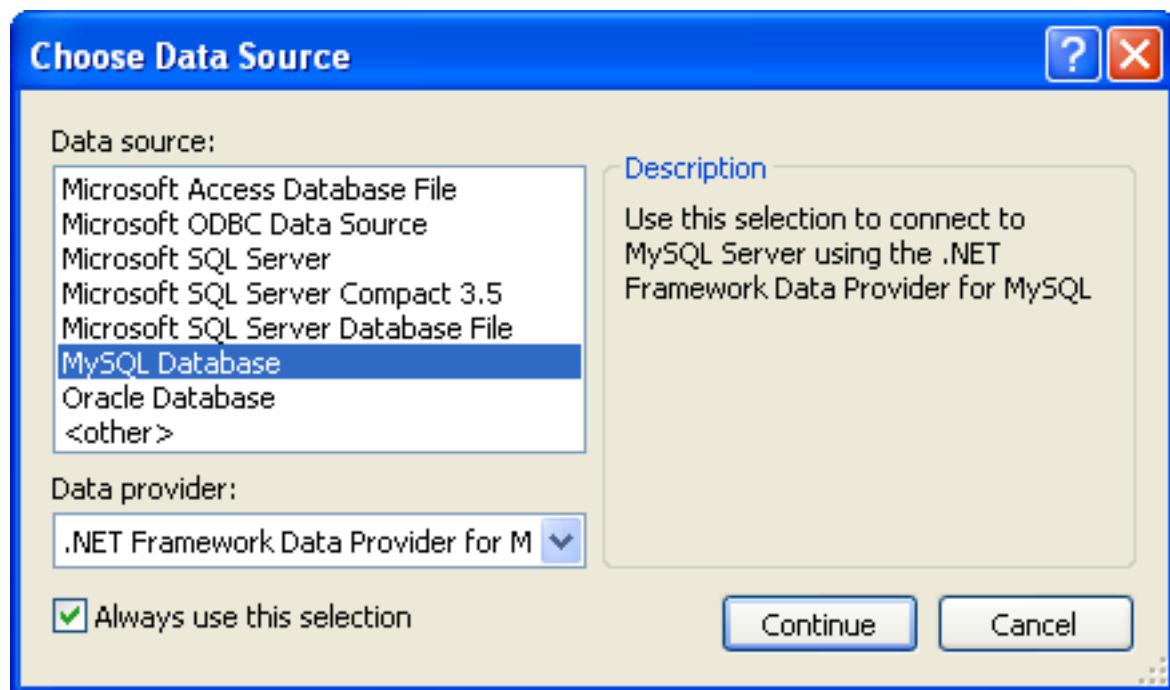

- Start Visual Studio, and open the Server Explorer window (VIEW, SERVER EXPLORER option in the main Visual Studio menu, or **Ctrl+W, L** hot keys).
- Right-click the Data Connections node, and choose the ADD CONNECTION... menu item.
- Add Connection dialog opens. Press the CHANGE button to choose MySQL Database as a data source.

**Figure 21.1. Add Connection Context Menu**

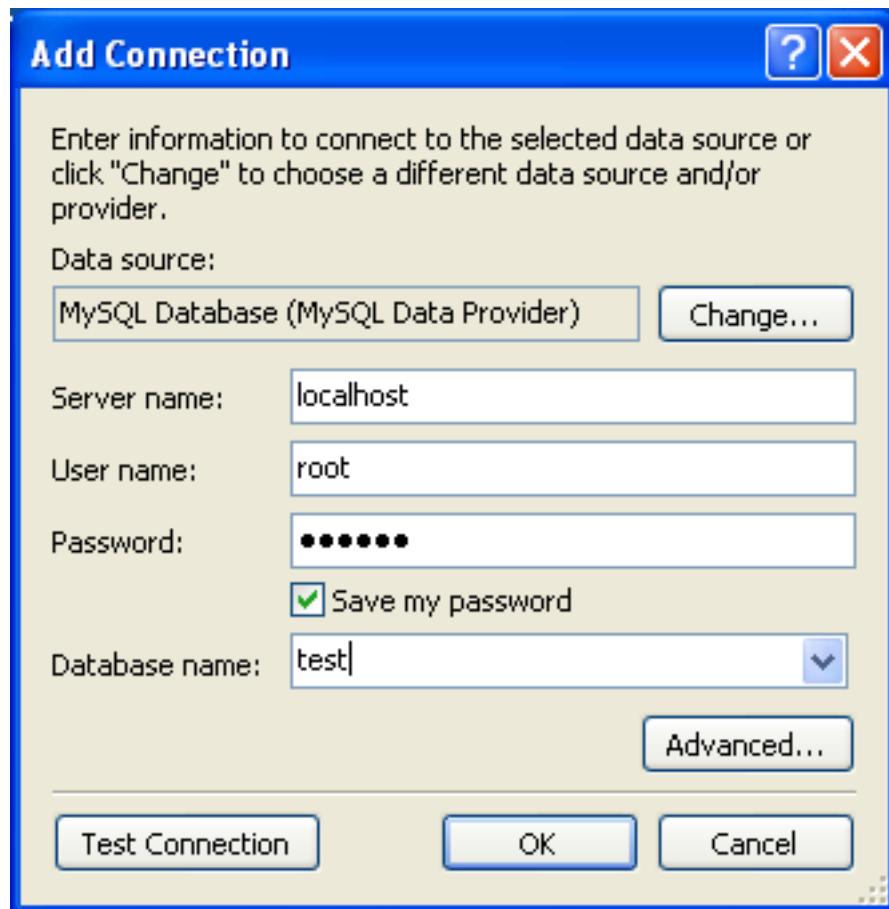

- Change Data Source dialog opens. Choose MySQL Database in the list of data sources (or the `<other>` option, if MySQL Database is absent), and then choose .NET Framework Data Provider for MySQL in the combo box of data providers.

**Figure 21.2. Choose Data Source**

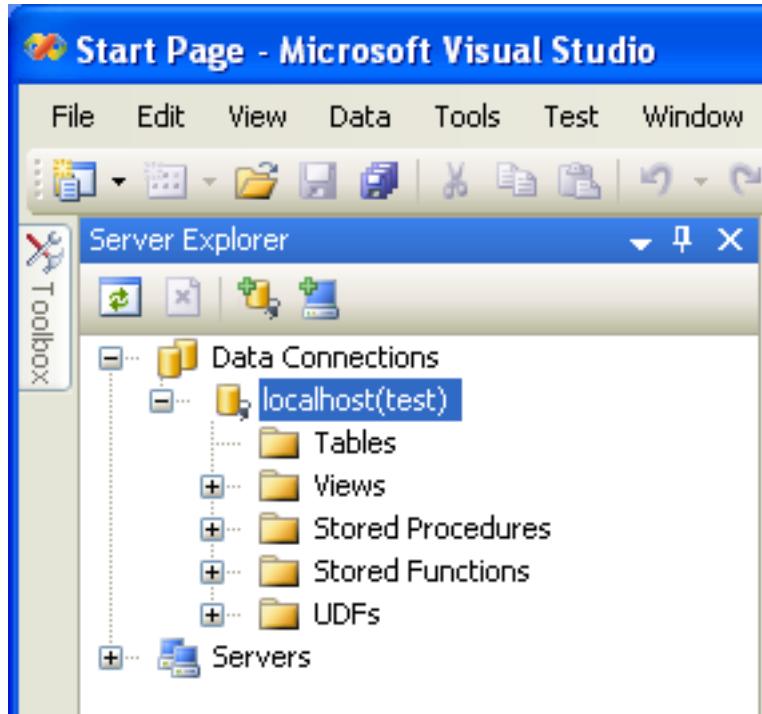

- Input the connection settings: the server host name (for example, localhost if the MySQL server is installed on the local machine), the user name, the password, and the default schema name. Note that you must specify the default schema name to open the connection.

**Figure 21.3. Add Connection Dialog**

- You can also set the port to connect with the MySQL server by pressing the ADVANCED button. To test connection with the MySQL server, set the server host name, the user name, and the password, and press the TEST CONNECTION button. If the test succeeds, the success confirmation dialog opens.
- After you set all settings and test the connection, press OK. The newly created connection is displayed in Server Explorer. Now you can work with the MySQL server through standard Server Explorer GUI.

**Figure 21.4. New Data Connection**

After the connection is successfully established, all settings are saved for future use. When you start Visual Studio for the next time, just open the connection node in Server Explorer to establish a connection to the MySQL server again.

To modify and delete a connection, use the Server Explorer context menu for the corresponding node. You can modify any of the settings just by overwriting the existing values with new ones. Note that the connection may be modified or deleted only if no active editor for its objects is opened: otherwise you may lose your data.

### 21.2.3.2. Editing Tables

Connector/Net contains a table editor, which enables the visual creation and modification of tables.

The Table Designer can be accessed through a mouse action on table-type node of Server Explorer. To create a new table, right-click the TABLES node (under the connection node) and choose the CREATE TABLE command from the context menu.

To modify an existing table, double-click the node of the table you wish to modify, or right-click this node and choose the DESIGN item from the context menu. Either of the commands opens the Table Designer.

The table editor is implemented in the manner of the well-known Query Browser Table Editor, but with minor differences.

**Figure 21.5. Editing New Table**

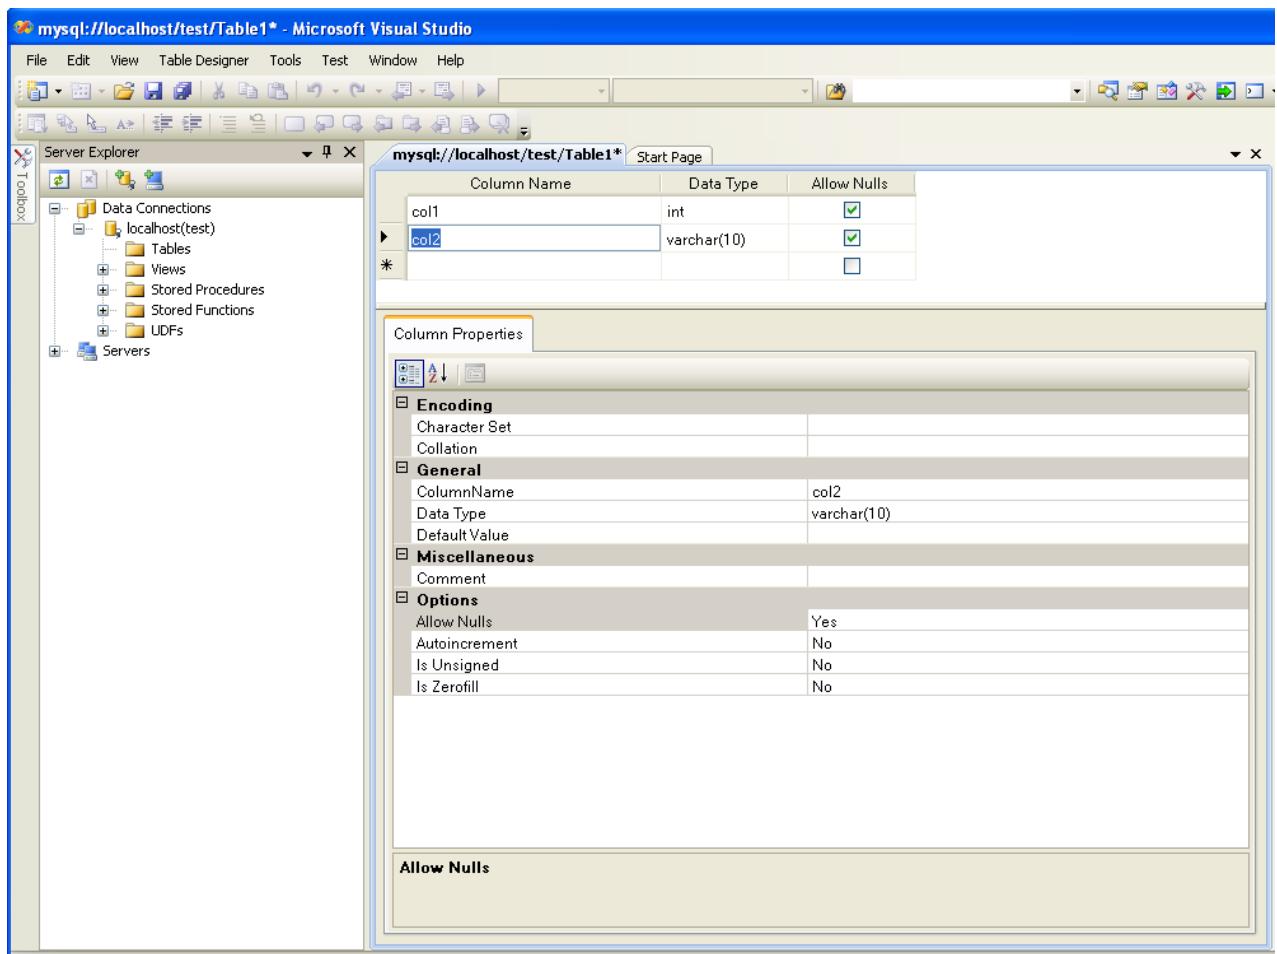

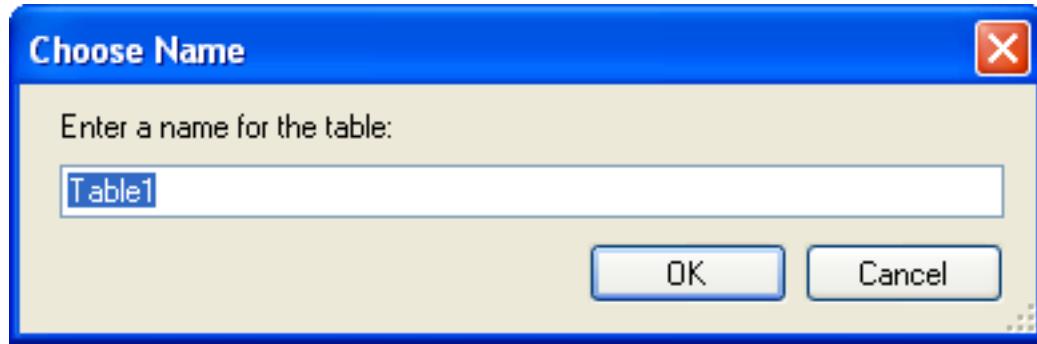

Table Designer consists of the following parts:

- Columns Editor - a data grid on top of the Table Designer. Use the Columns grid for column creation, modification, and deletion.
- Indexes tab - a tab on bottom of the Table Designer. Use the Indexes tab for indexes management.
- Foreign Keys tab - a tab on bottom of the Table Designer. Use the Foreign Keys tab for foreign keys management.
- Column Details tab - a tab on bottom of the Table Designer. Use the Column Details tab to set advanced column options.
- Properties window - a standard Visual Studio Properties window, where the properties of the edited table are displayed. Use the Properties window to set the table properties.

Each of these areas is discussed in more detail in subsequent sections.

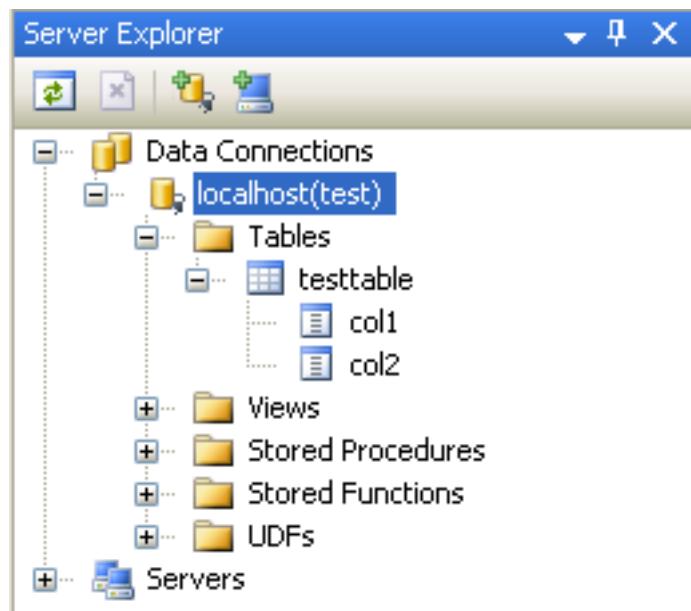

To save changes you have made in the Table Designer, use either SAVE or SAVE ALL button of the Visual Studio main toolbar, or just press **Ctrl+S**. If you have not already named the table you will be prompted to do so.

**Figure 21.6. Choose Table Name**

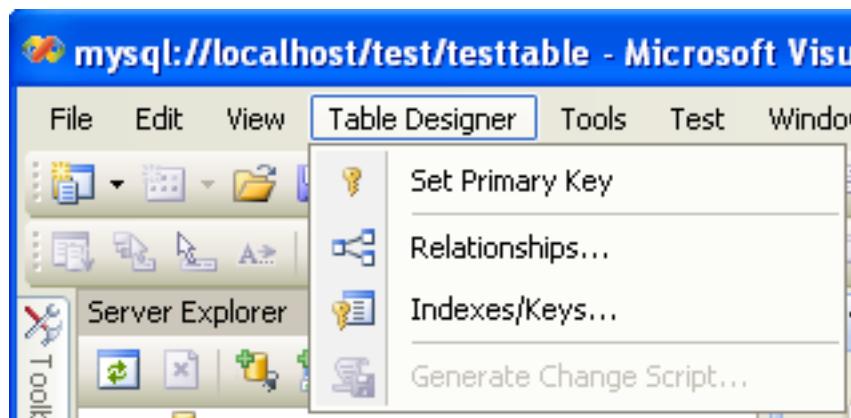

Once created you can view the table in the Server Explorer.

**Figure 21.7. Newly Created Table**

The Table Designer main menu enables you to set a Primary Key column, edit Relationships such as Foreign Keys, and create Indexes.

**Figure 21.8. Table Designer Main Menu**

#### 21.2.3.2.1. Column Editor

You can use the Column Editor to set or change the name, data type, default value, and other properties of a table column. To set

the focus to a needed cell of a grid, use the mouse click. Also you can move through the grid using **Tab** and **Shift+Tab** keys.

To set or change the name, data type, default value and comment of a column, activate the appropriate cell and type the desired value.

To set or unset flag-type column properties (**NOT NULL**, auto incremented, flags), check or uncheck the corresponding check boxes. Note that the set of column flags depends on its data type.

To reorder columns, index columns or foreign key columns in the Column Editor, select the whole column you wish to reorder by clicking the selector column on the left of the column grid. Then move the column by using **Ctrl+Up** (to move the column up) or **Ctrl+Down** (to move the column down) keys.

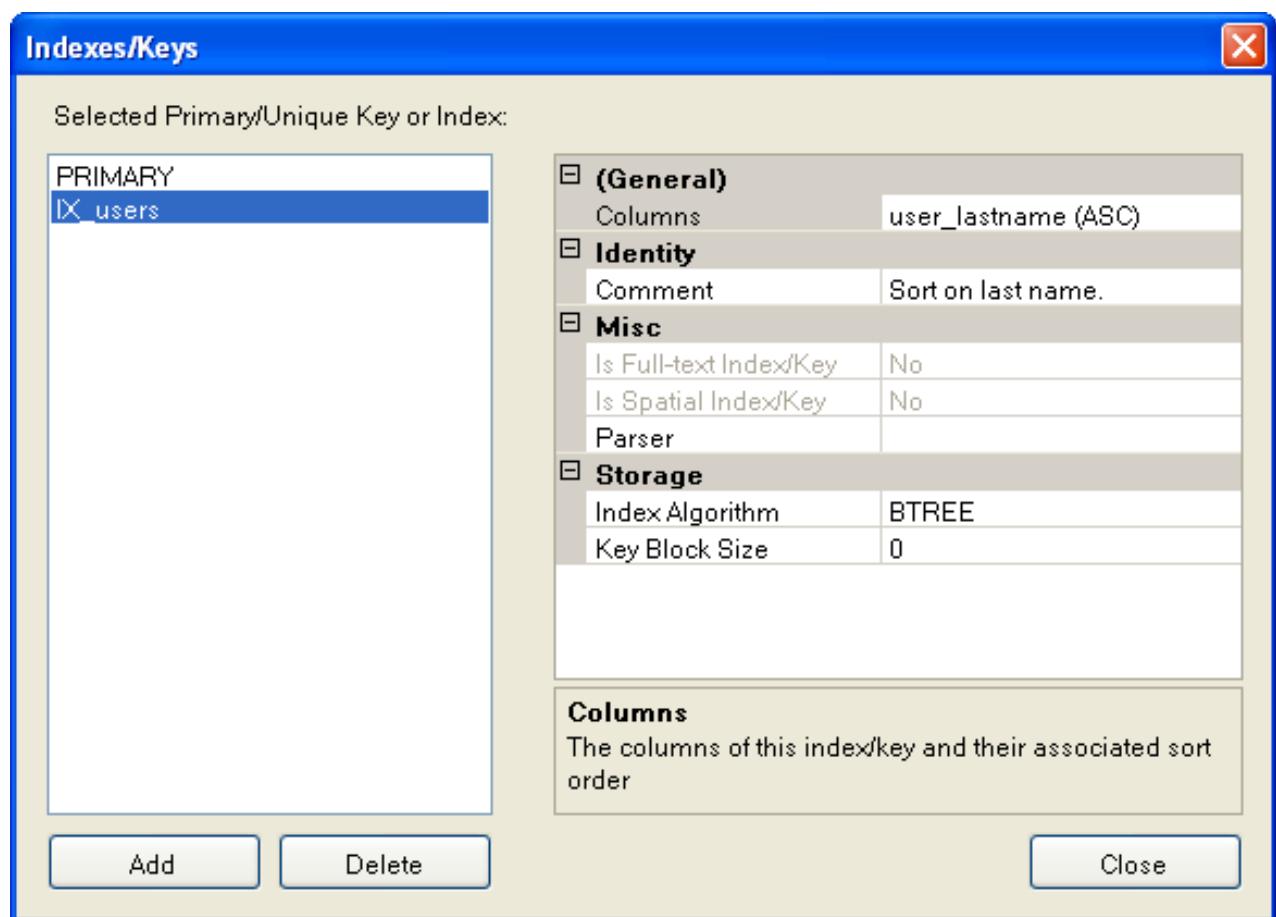

To delete a column, select it by clicking the selector column on the left of the column grid, then press the **Delete** button on a keyboard.

### 21.2.3.2.2. Editing Indexes

Indexes management is performed using the **INDEXES/KEYS** dialog.

To add an index, select **TABLE DESIGNER**, **INDEXES/KEYS...** from the main menu, and click **ADD** to add a new index. You can then set the index name, index kind, index type, and a set of index columns.

**Figure 21.9. Indexes Dialog**

To remove an index, select it in the list box on the left, and click the **DELETE** button.

To change index settings, select the needed index in the list box on the left. The detailed information about the index is displayed in the panel on the right hand side. Change the desired values.

### 21.2.3.2.3. Editing Foreign Keys

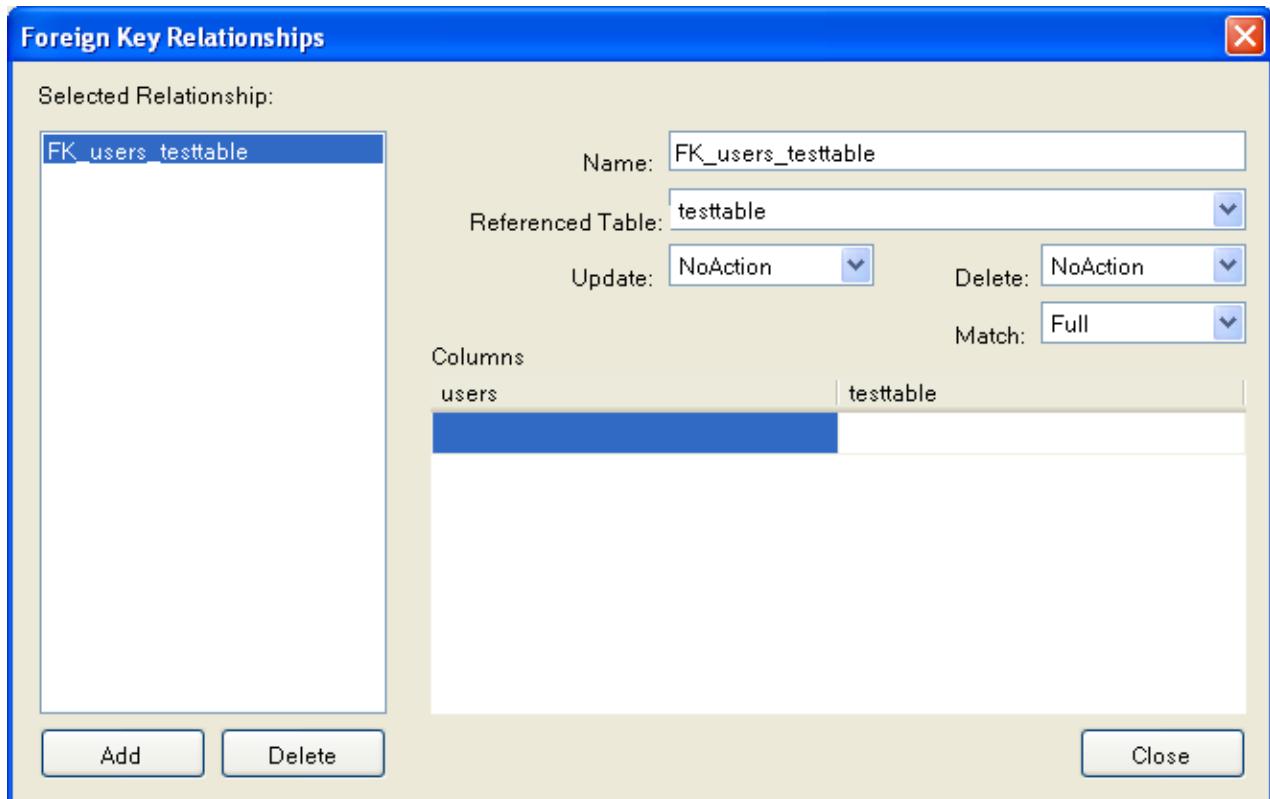

Foreign Keys management is performed using the **FOREIGN KEY RELATIONSHIPS** dialog.

To add a foreign key, select **TABLE DESIGNER, RELATIONSHIPS...** from the main menu. This displays the **FOREIGN KEY RELATIONSHIP** dialog. Click ADD. You can then set the foreign key name, referenced table name, foreign key columns, and actions upon update and delete.

To remove a foreign key, select it in the list box on the left, and click the **DELETE** button.

To change foreign key settings, select the required foreign key in the list box on the left. The detailed information about the foreign key is displayed in the right hand panel. Change the desired values.

**Figure 21.10. Foreign Key Relationships Dialog**

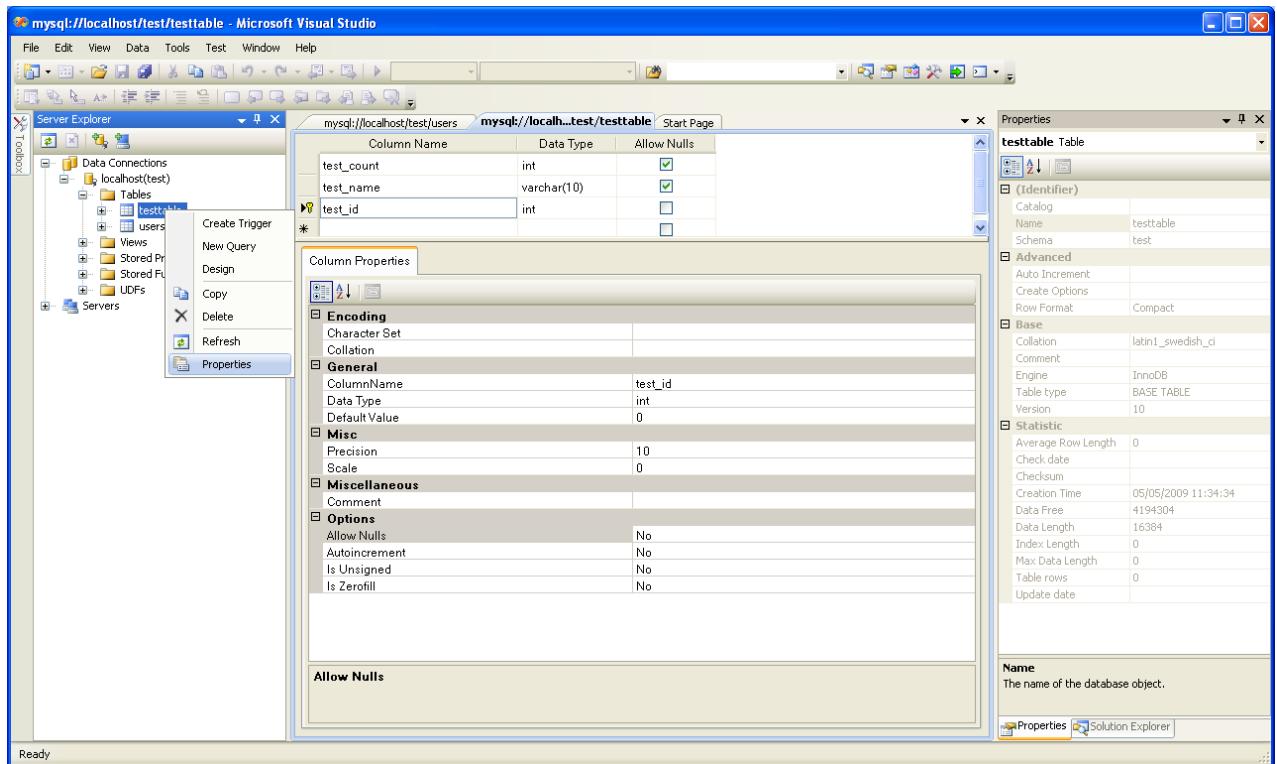

#### 21.2.3.2.4. Column Properties

The **COLUMN PROPERTIES** tab can be used to set column options. In addition to the general column properties presented in the Column Editor, in the **COLUMN PROPERTIES** tab you can set additional properties such as Character Set, Collation and Precision.

#### 21.2.3.2.5. Table Properties

To bring up Table Properties select the table and right-click to activate the context menu. Select **PROPERTIES**. The **TABLE PROPERTIES** dockable window will be displayed.

**Figure 21.11. Table Properties Menu Item**

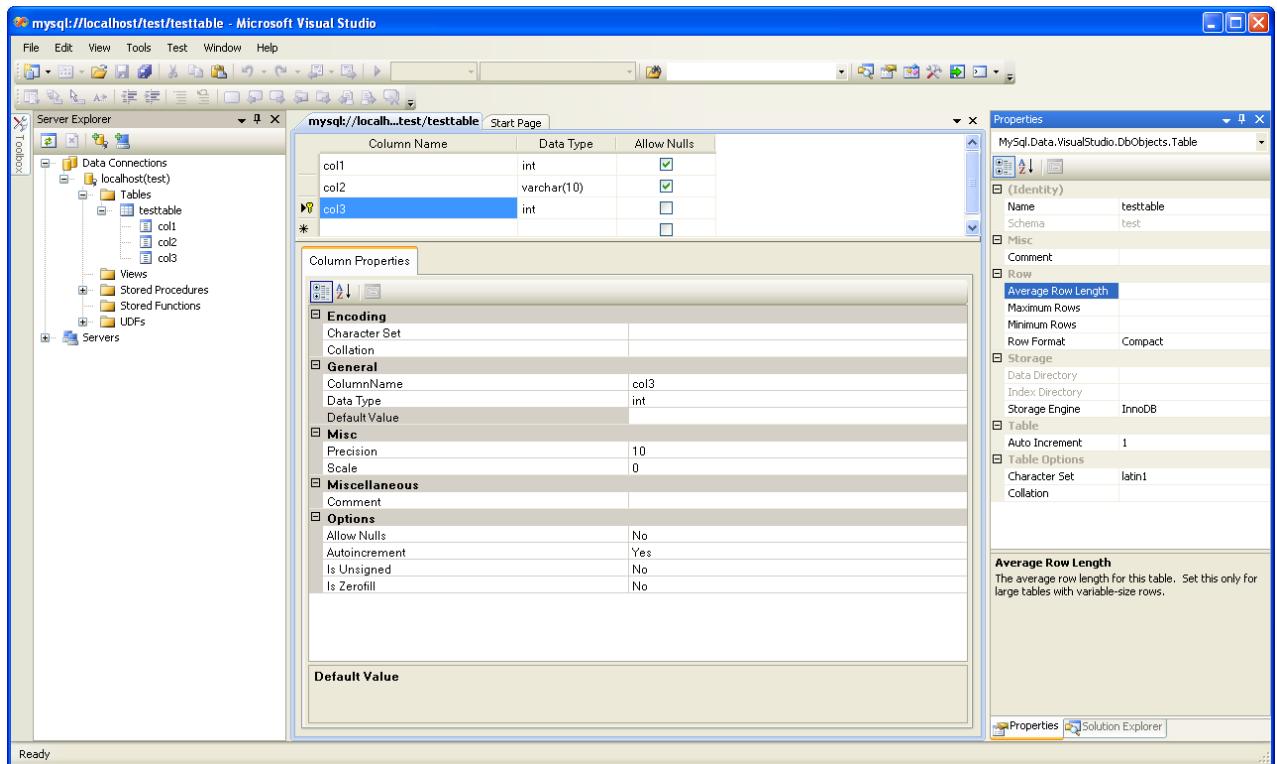

The following table properties can be set:

- Auto Increment
- Average Row Length
- Character Set
- Collation
- Comment
- Data Directory
- Index Directory
- Maximum Rows
- Minimum Rows
- Name
- Row Format
- Schema
- Storage Engine

The property **Schema** is read only.

**Figure 21.12. Table Properties**

### 21.2.3.3. Editing Views

To create a new view, right-click the Views node under the connection node in Server Explorer. From the node's context menu, choose the CREATE VIEW command. This command opens the SQL Editor.

**Figure 21.13. Editing View SQL**

```
mysql://localhost/world/View1 Start Page
CREATE VIEW View1
/*
(column1, column2)
*/
AS /* select statement */
```

You can then enter the SQL for your view.

**Figure 21.14. View SQL Added**

```
mysql://localhost/world/View1* Start Page
CREATE VIEW CityView AS SELECT ID, Name FROM City;
```

To modify an existing view, double-click a node of the view you wish to modify, or right-click this node and choose the ALTER VIEW command from a context menu. Either of the commands opens the SQL Editor.

All other view properties can be set in the Properties window. These properties are:

- Catalog
- Check Option

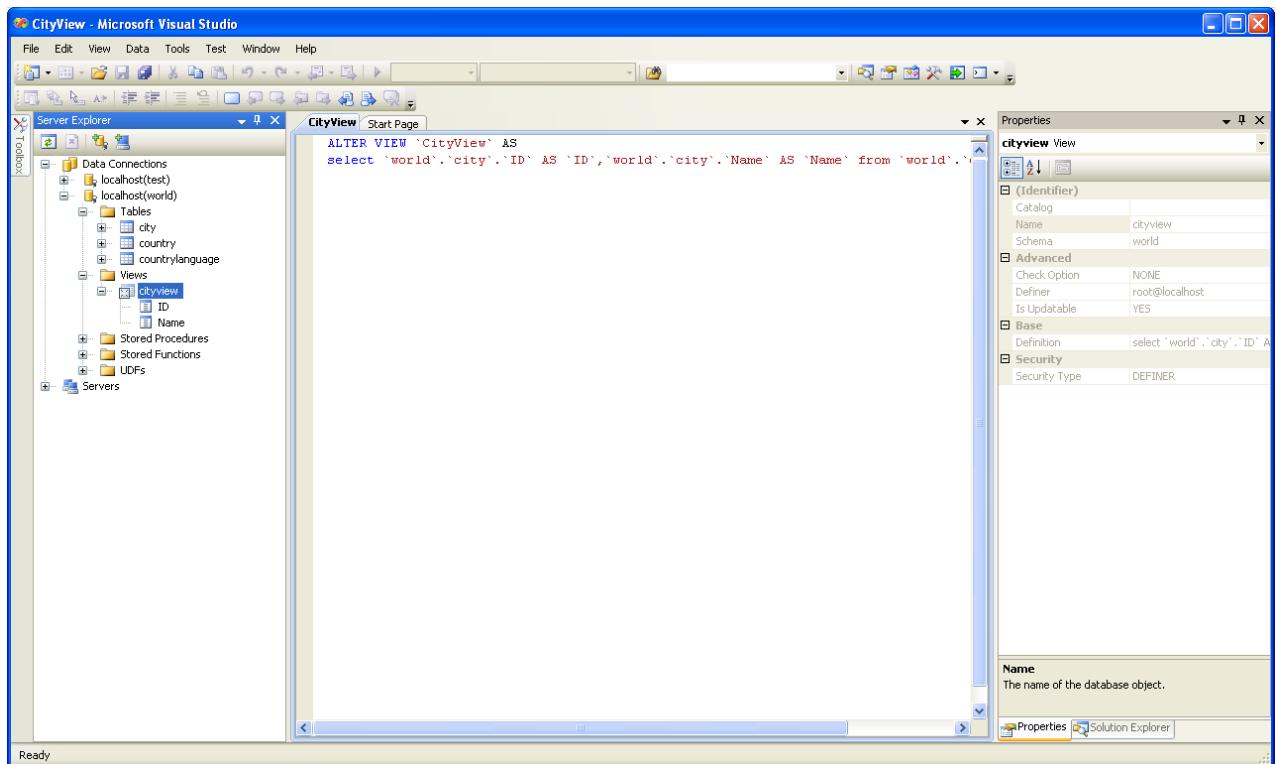

- Definer
- Definition
- Definer
- Is Updateable
- Name
- Schema
- Security Type

Some of these properties can have arbitrary text values, others accept values from a predefined set. In the latter case you set the desired value with an embedded combobox.

The properties **Is Updatable** and **Schema** are readonly.

To save changes you have made, use either **SAVE** or **SAVE ALL** buttons of the Visual Studio main toolbar, or just press **Ctrl+S**.

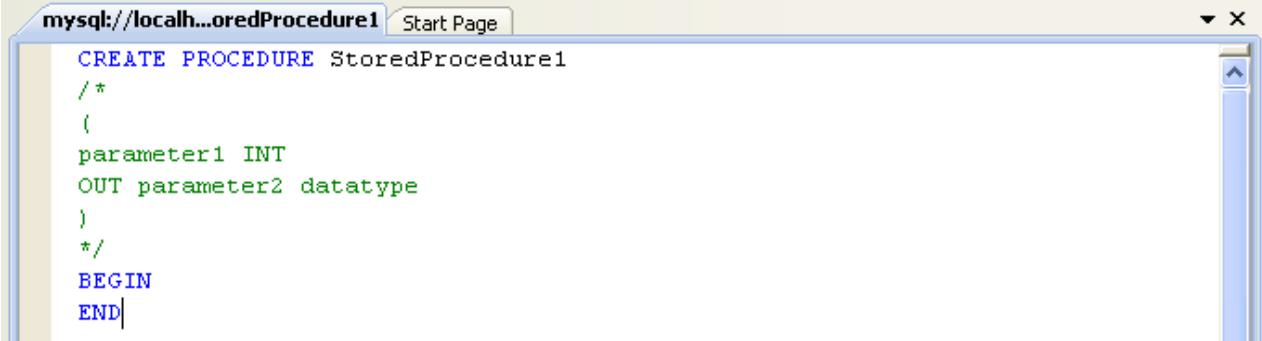

**Figure 21.15. View SQL Saved**

#### 21.2.3.4. Editing Stored Procedures and Functions

To create a new stored procedure, right-click the **STORED PROCEDURES** node under the connection node in Server Explorer. From the node's context menu, choose the **CREATE ROUTINE** command. This command opens the SQL Editor.

**Figure 21.16. Edit Stored Procedure SQL**

```
mysql://localhost...oredProcedure1 Start Page
CREATE PROCEDURE StoredProcedure1
/*
(
parameter1 INT
OUT parameter2 datatype
)
*/
BEGIN
END|
```

To create a new stored function, right-click the **FUNCTIONS** node under the connection node in Server Explorer. From the node's context menu, choose the **CREATE ROUTINE** command.

To modify an existing stored routine (procedure or function), double-click the node of the routine you wish to modify, or right-click this node and choose the **ALTER ROUTINE** command from the context menu. Either of the commands opens the SQL Editor.

To create or alter the routine definition using SQL Editor, type this definition in the SQL Editor using standard SQL. All other routine properties can be set in the Properties window. These properties are:

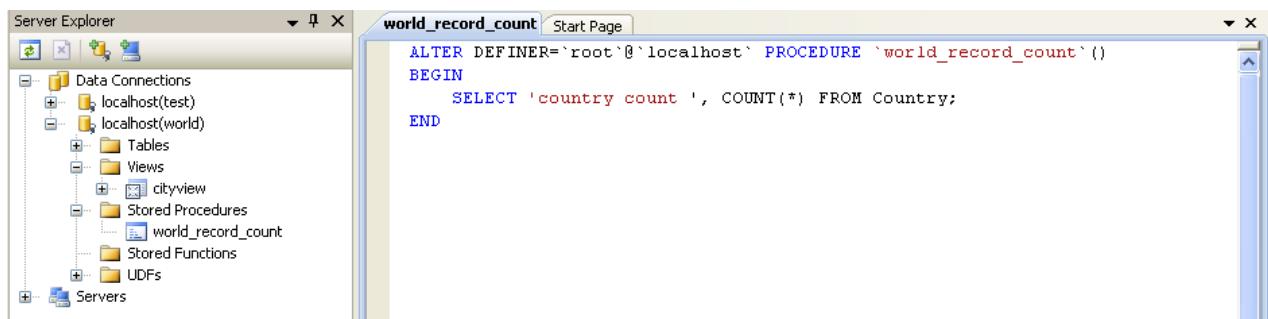

- Body
- Catalog
- Comment
- Creation Time
- Data Access
- Definer
- Definition
- External Name
- External Language
- Is Deterministic
- Last Modified
- Name
- Parameter Style
- Returns
- Schema
- Security Type
- Specific Name
- SQL Mode
- SQL Path
- Type

Some of these properties can have arbitrary text values, others accept values from a predefined set. In the latter case set the desired value using the embedded combo box.

You can also set all the options directly in the SQL Editor, using the standard **CREATE PROCEDURE** or **CREATE FUNCTION** statement. However, it is recommended to use the Properties window instead.

To save changes you have made, use either **SAVE** or **SAVE ALL** buttons of the Visual Studio main toolbar, or just press **Ctrl+S**.

**Figure 21.17. Stored Procedure SQL Saved**

### 21.2.3.5. Editing Triggers

To create a new trigger, right-click the node of the table, for which you wish to add a trigger. From the node's context menu, choose the **CREATE TRIGGER** command. This command opens the SQL Editor.

To modify an existing trigger, double-click the node of the trigger you wish to modify, or right-click this node and choose the **ALTER TRIGGER** command from the context menu. Either of the commands opens the SQL Editor.

To create or alter the trigger definition using SQL Editor, type the trigger statement in the SQL Editor using standard SQL.

#### Note

You should enter only the trigger statement, that is, the part of the **CREATE TRIGGER** query that is placed after the **FOR EACH ROW** clause.

All other trigger properties are set in the Properties window. These properties are:

- Definer
- Event Manipulation
- Name
- Timing

Some of these properties can have arbitrary text values, others accept values from a predefined set. In the latter case set the desired value using the embedded combo box.

The properties **Event**, **Table**, **Schema**, and **Server** in the Properties window are read only.

To save changes you have made, use either **SAVE** or **SAVE ALL** buttons of the Visual Studio main toolbar, or just press **Ctrl+S**. Before changes are saved, you will be asked to confirm the execution of the corresponding SQL query in a confirmation dialog.

### 21.2.3.6. Editing User Defined Functions (UDF)

To create a new User Defined Function (UDF), right-click the **UDFs** node under the connection node in Server Explorer. From the node's context menu, choose the **CREATE UDF** command. This command opens the UDF Editor.

To modify an UDF, double-click the node of the UDF you wish to modify, or right-click this node and choose the **ALTER UDF** command from the context menu. Either of the commands opens the UDF Editor.

The UDF editor enables you to set the following properties:

- Name
- So-name (DLL name)
- Return type

- Is Aggregate

There are text fields for both names, a combo box for the return type, and a check box to indicate if the UDF is aggregate. All these options are also accessible using the Properties window.

The property **Server** in the Properties window is read only.

To save changes you have made, use either **SAVE** or **SAVE ALL** buttons of the Visual Studio main toolbar, or just press **Ctrl+S**. Before changes are saved, you will be asked to confirm the execution of the corresponding SQL query in a confirmation dialog.

### 21.2.3.7. Cloning Database Objects

Tables, views, stored procedures, and functions can be cloned using the appropriate Clone command from the context menu: **CLONE TABLE**, **CLONE VIEW**, **CLONE ROUTINE**. The clone commands open the corresponding editor for a new object: the **TABLE EDITOR** for cloning a table, and the **SQL EDITOR** for cloning a view or a routine.

The editor is filled with values of the original object. You can modify these values in a usual manner.

To save the cloned object, use either Save or Save All buttons of the Visual Studio main toolbar, or just press **Ctrl+S**. Before changes are saved, you will be asked to confirm the execution of the corresponding SQL query in a confirmation dialog.

### 21.2.3.8. Dropping Database Objects

Tables, views, stored routines, triggers, and UDFs can be dropped with the appropriate Drop command selected from its context menu: **DROP TABLE**, **DROP VIEW**, **DROP ROUTINE**, **DROP TRIGGER**, **DROP UDF**.

You will be asked to confirm the execution of the corresponding drop query in a confirmation dialog.

Dropping of multiple objects is not supported.

### 21.2.3.9. Using the ADO.NET Entity Framework

Connector/.NET 6.0 introduced support for the ADO.NET Entity Framework. ADO.NET Entity Framework was included with .NET Framework 3.5 Service Pack 1, and Visual Studio 2008 Service Pack 1. ADO.NET Entity Framework was released on 11th August 2008.

ADO.NET Entity Framework provides an Object Relational Mapping (ORM) service, mapping the relational database schema to objects. The ADO.NET Entity Framework defines several layers, these can be summarized as:

- **Logical** - this layer defines the relational data and is defined by the Store Schema Definition Language (SSDL).
- **Conceptual** - this layer defines the .NET classes and is defined by the Conceptual Schema Definition Language (CSDL)
- **Mapping** - this layer defines the mapping from .NET classes to relational tables and associations, and is defined by Mapping Specification Language (MSL).

Connector/.NET integrates with Visual Studio 2008 to provide a range of helpful tools to assist the developer.

A full treatment of ADO.NET Entity Framework is beyond the scope of this manual. You are encouraged to review the [Microsoft ADO.NET Entity Framework documentation](#).

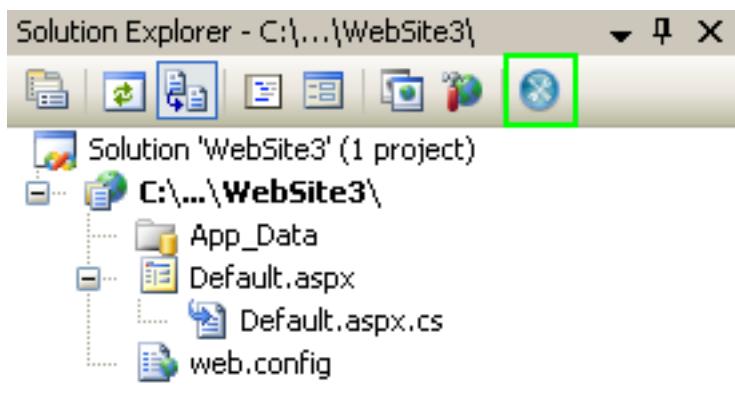

Tutorials on getting started with ADO.NET Entity Framework are available. See [Section 21.2.4.5, “Tutorial: Using an Entity Framework Entity as a Windows Forms Data Source”](#) and [Section 21.2.4.6, “Tutorial: Databinding in ASP.NET using LINQ on Entities”](#).

### 21.2.3.10. MySQL Website Configuration Tool

MySQL Connector/.NET 6.1 introduced the MySQL Website Configuration Tool. This is a facility available in Visual Studio that enables you to configure the Membership, Role, Session State and Profile Provider, without having to resort to editing configuration files. You simply run the tool, set your configuration options, and the tool will modify your `web.config` file accordingly.

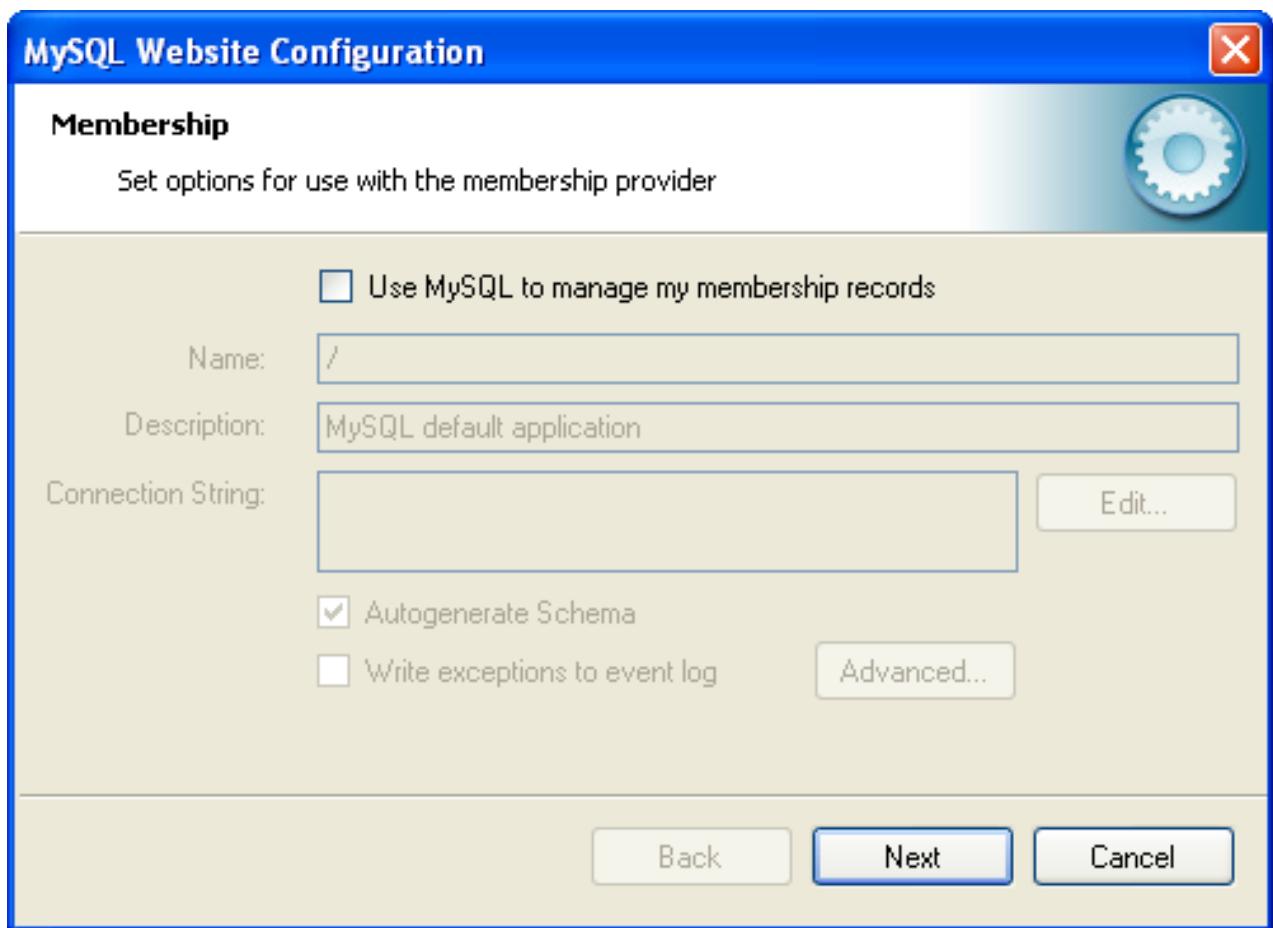

The MySQL Website Configuration Tool appears as a small icon on the Solution Explorer toolbar in Visual Studio, as shown by the following screenshot:

**Figure 21.18. MySQL Website Configuration Tool**

Clicking the Website Configuration Tool icon launches the wizard and displays the first screen:

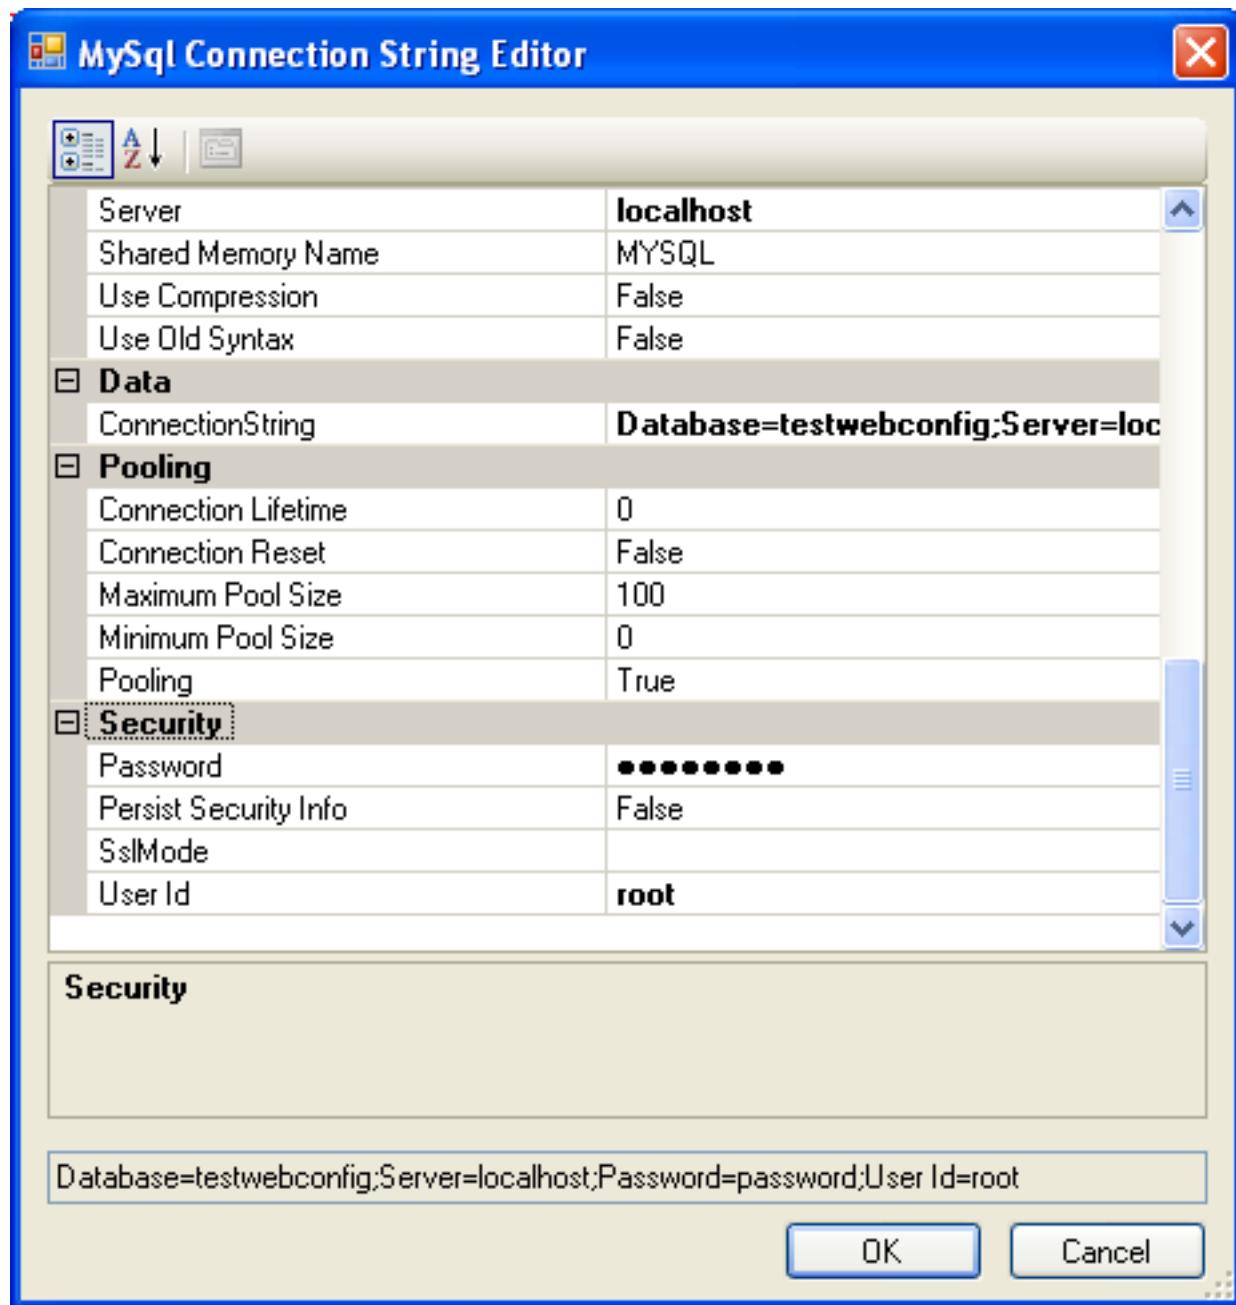

**Figure 21.19. MySQL Website Configuration Tool - Membership**

This allows you to enable use of the MySQL Membership Provider. Simply click the checkbox to enable this. You can now enter the name of the application that you are creating the configuration for. You can also enter a description for the application.

You can then click the EDIT... button to launch the Connection String Editor:

**Figure 21.20. MySQL Website Configuration Tool - Connection String Editor**

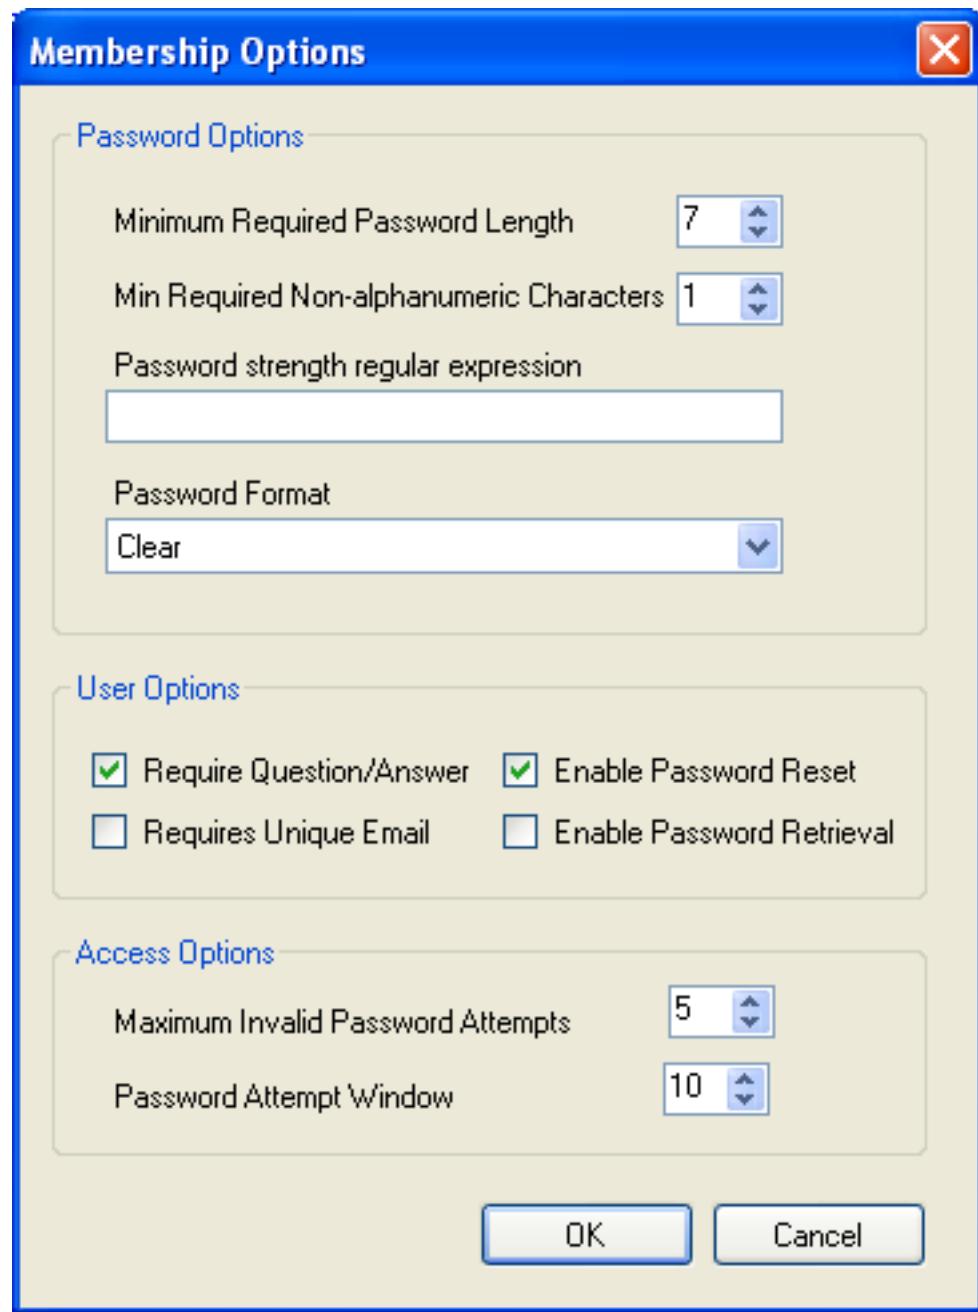

Note that if you have already defined a connection string for the providers manually in `web.config`, or previously using the tool, this will be automatically loaded and displayed, and can then be modified in this dialog.

You can also ensure that the necessary schema are created automatically for you by selecting the Autogenerate Schema checkbox. These schema are used to store membership information. The database used to storage is the one specified in the connection string.

You can also ensure that exceptions generated by the application will be written to the event log by selecting the **WRITE EXCEPTIONS TO EVENT LOG** checkbox.

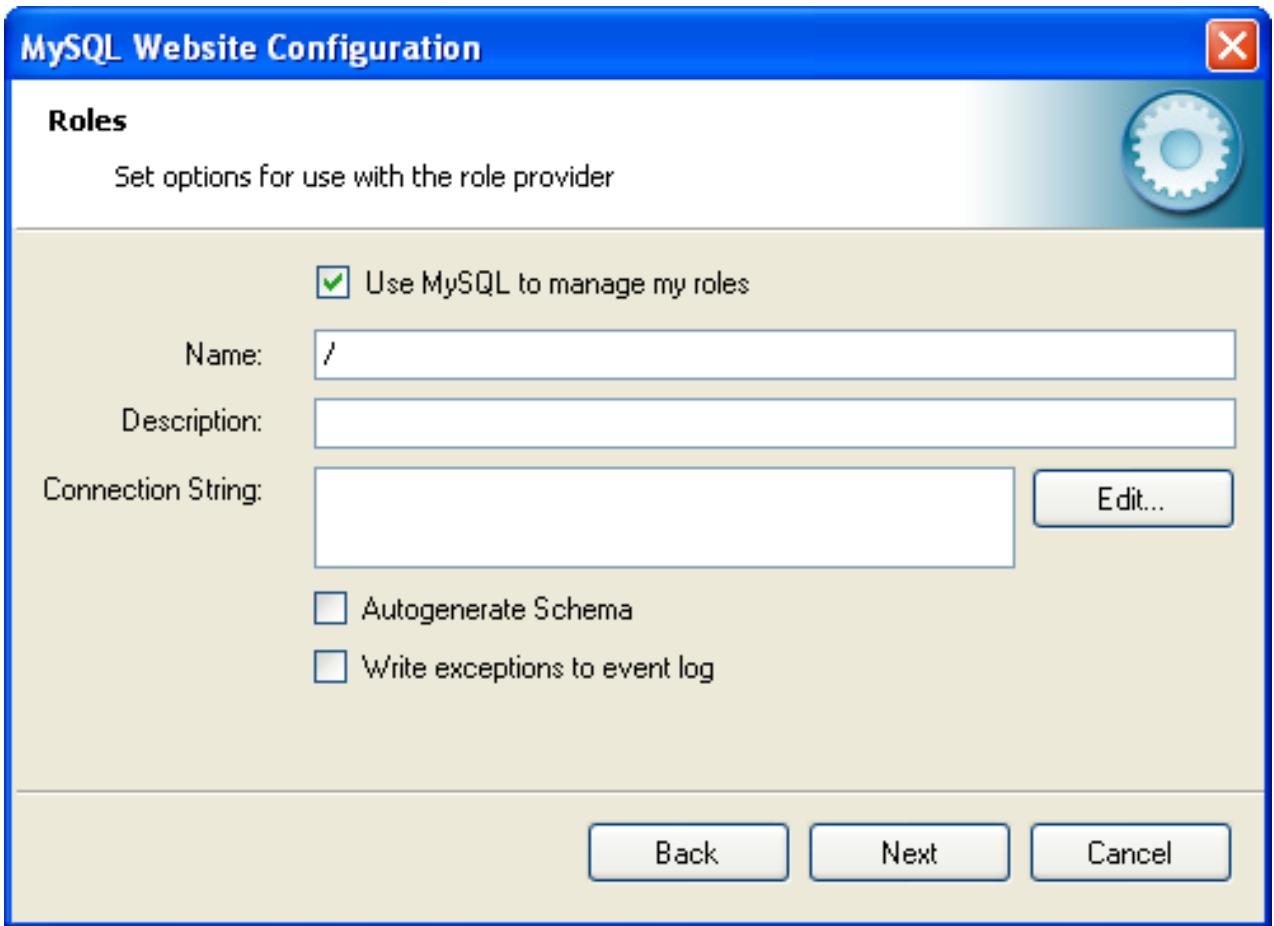

Clicking the ADVANCED... button launches a dialog that enables you to set Membership Options. These options dictate such variables as password length required when a user signs up, whether the password is encrypted and whether the user can reset their password or not.

**Figure 21.21. MySQL Website Configuration Tool - Advanced Options**

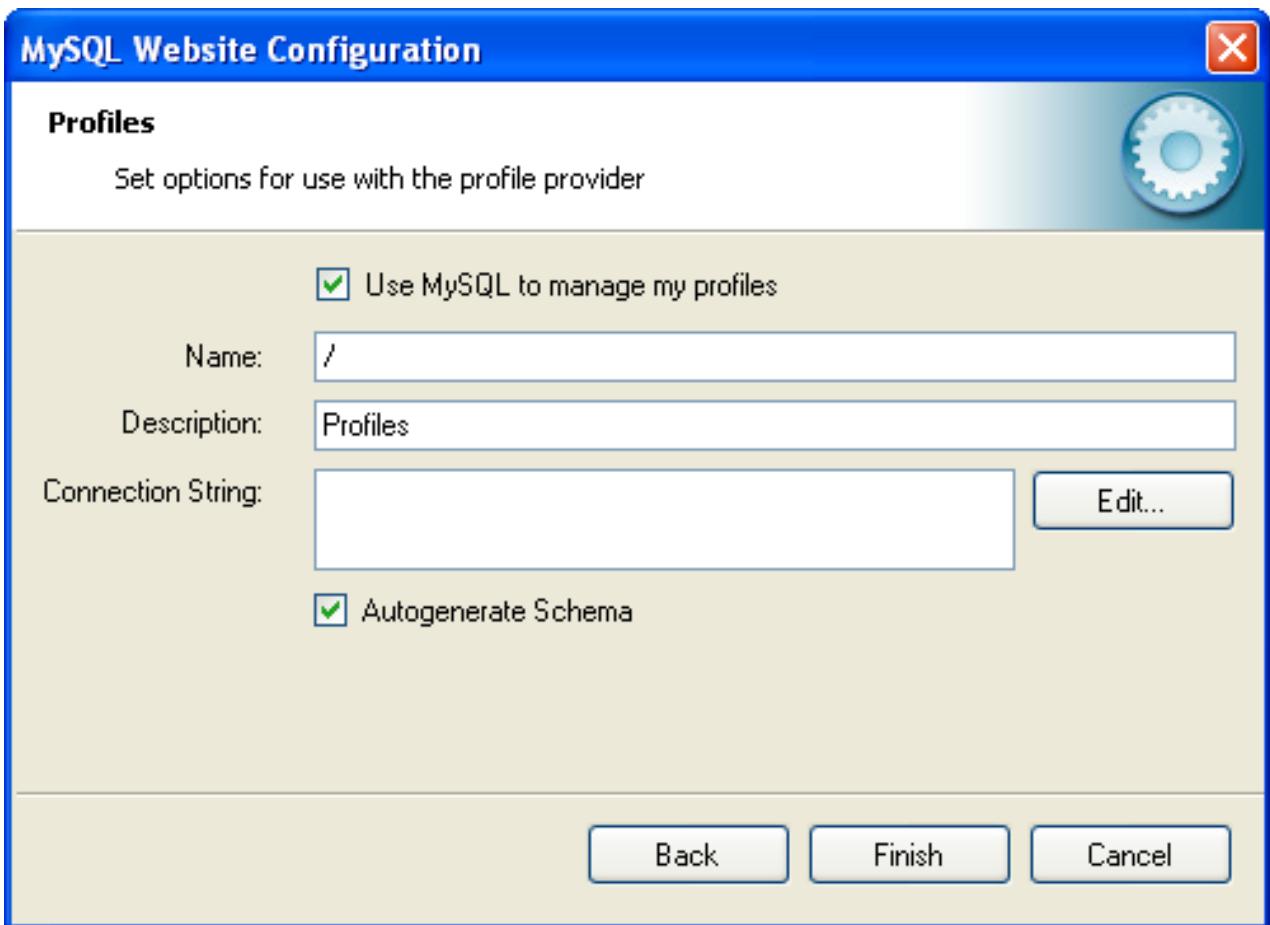

Once information has been set up as required for configuration of the Membership Provider the NEXT button can be clicked to display the Roles Provider screen:

**Figure 21.22. MySQL Website Configuration Tool - Roles**

Again the connection string can be edited, a description added and Autogenerate Schema can be enabled before clicking NEXT to go to the Profiles Provider screen:

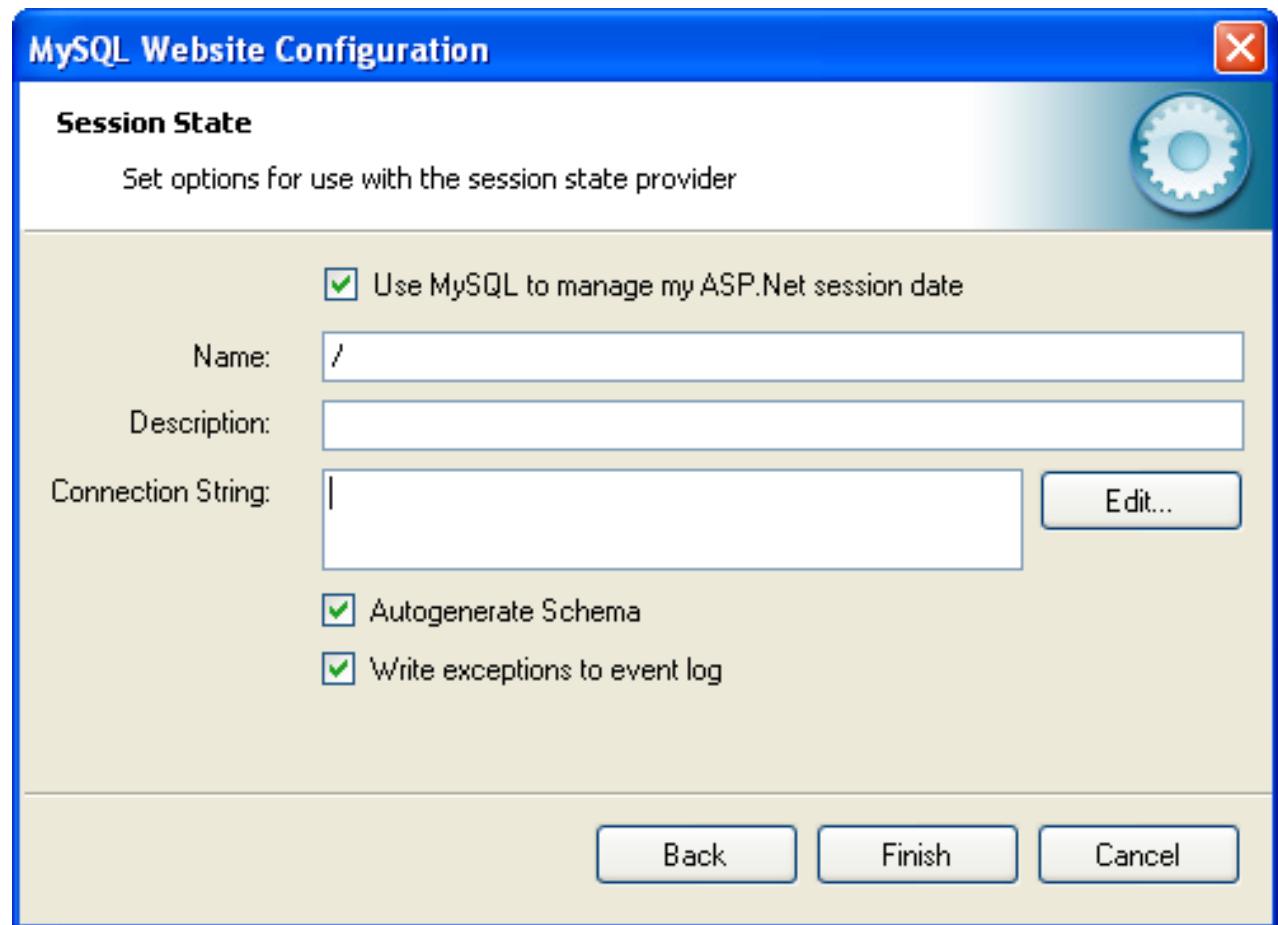

**Figure 21.23. MySQL Website Configuration Tool - Profiles**

This screen displays similar options to the previous screens.

Click NEXT to proceed to the Session State configuration page:

**Figure 21.24. MySQL Website Configuration Tool - Session State**

Once you have set up the Session State Provider as required, click FINISH to exit the wizard.

At this point it is necessary to select the Authentication Type to From Internet. This can be done by launching the ASP.NET Configuration Tool, and selecting the Security tab. Click the Select authentication type link and ensure that the From the internet radio button is selected. You can now examine the database you created to store membership information. All the necessary tables will have been created for you:

**Figure 21.25. MySQL Website Configuration Tool - Tables**

```

mysql> show tables;
Empty set (0.01 sec)

mysql> show tables;
Empty set (0.00 sec)

mysql> show tables;
+-----+
| Tables_in_testwebconfig |
+-----+
| my_aspnet_applications |
| my_aspnet_membership |
| my_aspnet_profiles |
| my_aspnet_roles |
| my_aspnet_schemaversion |
| my_aspnet_sessioncleanup |
| my_aspnet_sessions |
| my_aspnet_users |
| my_aspnet_usersinroles |
+-----+
9 rows in set (0.01 sec)

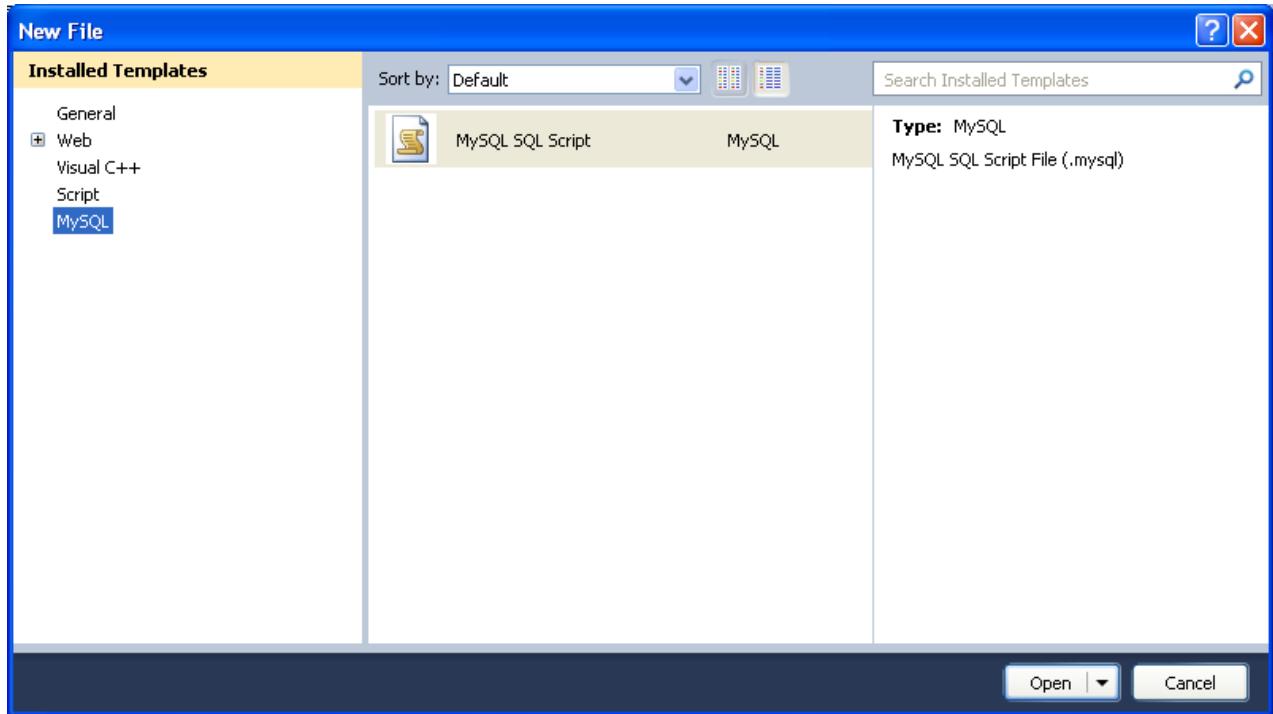

mysql>

```

### 21.2.3.11. MySQL SQL Editor

MySQL Connector/NET 6.3.2 introduced a new MySQL SQL Editor. The easiest way to invoke the editor is by selecting the NEW, FILE menu item from the Visual Studio main menu. This displays the **NEW FILE** dialog:

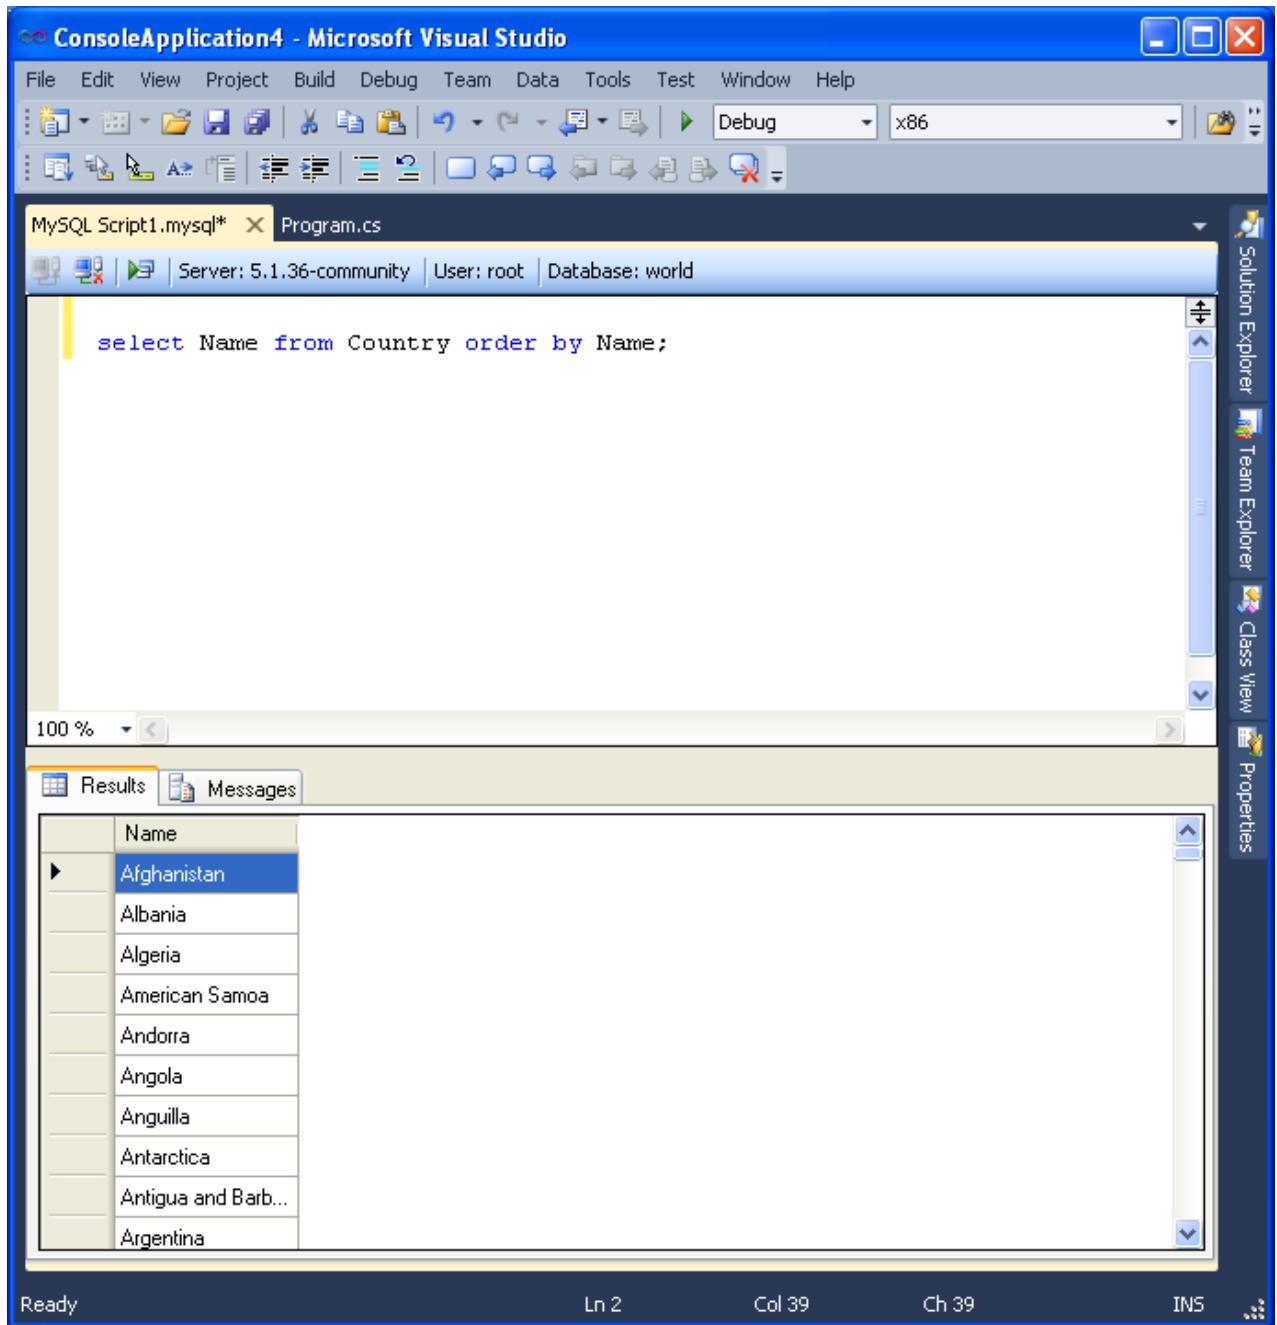

**Figure 21.26. MySQL SQL Editor - New File**

From the **NEW FILE** dialog select the MySQL template, and then double-click the **MySQL SQL SCRIPT** document, or click the **OPEN** button.

The MySQL SQL Editor will be displayed. You can now enter SQL code as required, or connect to a MySQL server. Click the **CONNECT TO MySQL** button in the MySQL SQL Editor toolbar. You can enter the connection details into the **CONNECT TO MySQL** dialog that is displayed. You can enter the server name, user id, password and database to connect to, or click the **ADVANCED** button to select other connection string options. Click the **CONNECT** button to connect to the MySQL server. It is now possible to execute your SQL code against the server by clicking the **RUN SQL** button on the toolbar.

**Figure 21.27. MySQL SQL Editor - Query**

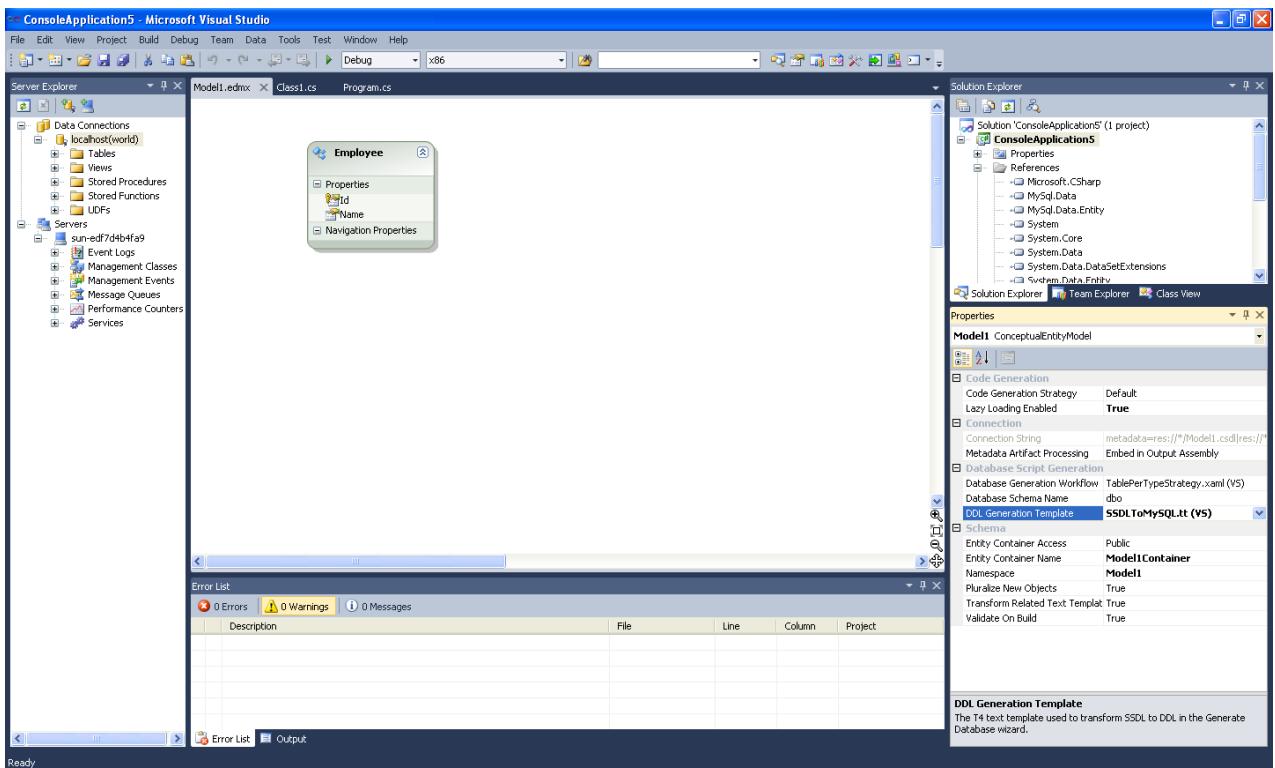

The results from any queries are displayed on the **RESULTS** tab. Any errors are displayed on the **MESSAGES** tab.

#### 21.2.3.12. DDL T4 Template Macro

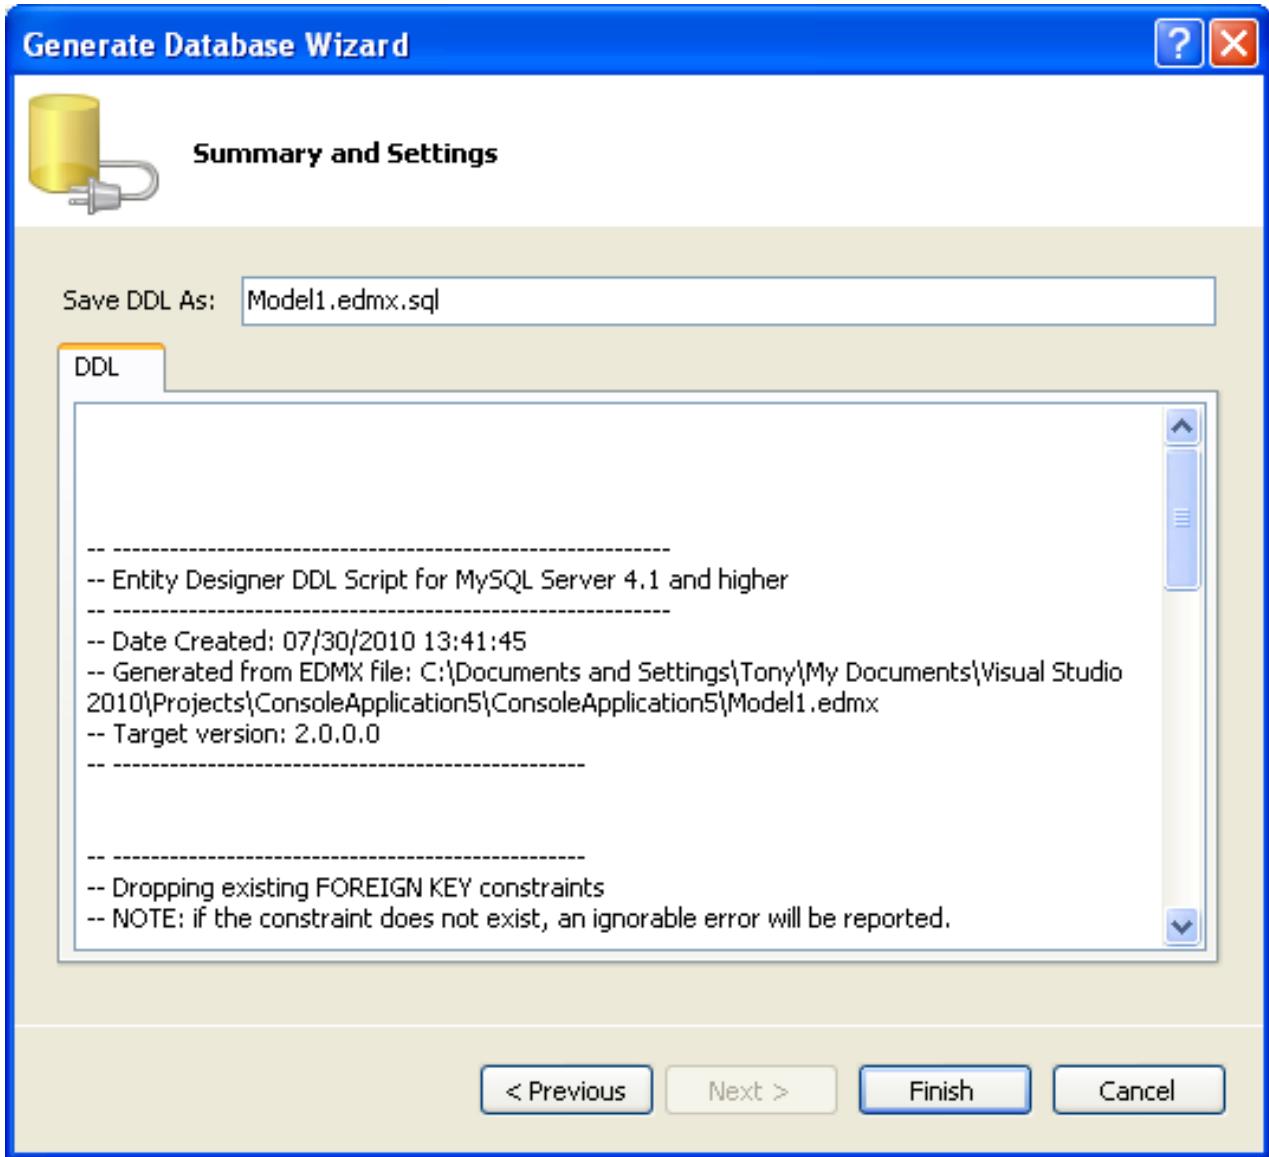

MySQL Connector/.NET 6.3 introduced the ability to convert an Entity Framework model to MySQL DDL code. Starting with a blank model, an entity model can be developed in Visual Studio's designer. Once the model has been created, the model's properties can be selected, and in the Database Script Generation category of the model's properties, the property **DDL GENERATION** can be found. The value **SSDLToMySQL.tt(VS)** can then be selected from the drop-down listbox.

**Figure 21.28. DDL T4 Template Macro - Model Properties**

Right-clicking the model design area will display a context-sensitive menu. Selecting **GENERATE DATABASE FROM MODEL** from the menu will display the **GENERATE DATABASE WIZARD**. The wizard can then be used to generate MySQL DDL code.

**Figure 21.29. DDL T4 Template Macro - Generate Database Wizard**

## 21.2.4. Connector/NET Tutorials

### 21.2.4.1. Tutorial: An Introduction to Connector/NET Programming

This section provides a gentle introduction to programming with Connector/NET. The example code is written in C#, and is designed to work on both Microsoft .NET Framework and Mono.

This tutorial is designed to get you up and running with Connector/NET as quickly as possible, it does not go into detail on any particular topic. However, the following sections of this manual describe each of the topics introduced in this tutorial in more detail. In this tutorial you are encouraged to type in and run the code, modifying it as required for your setup.

This tutorial assumes you have MySQL and Connector/NET already installed. It also assumes that you have installed the World example database, which can be downloaded from the [MySQL Documentation page](#). You can also find details on how to install the database on the same page.

#### Note

Before compiling the example code make sure that you have added References to your project as required. The References required are `System`, `System.Data` and `MySql.Data`.

#### 21.2.4.1.1. The MySqlConnection Object

For your Connector/NET application to connect to a MySQL database it needs to establish a connection. This is achieved through

the use of a `MySqlConnection` object.

The `MySqlConnection` constructor takes a connection string as one of its parameters. The connection string provides necessary information to make the connection to the MySQL database. The connection string is discussed more fully in [Section 21.2.5.1, “Connecting to MySQL Using Connector/NET”](#). A reference containing a list of supported connection string options can also be found in [Section 21.2.6, “Connector/NET Connection String Options Reference”](#).

The following code shows how to create a connection object.

```
using System;
using System.Data;

using MySql.Data;
using MySql.Data.MySqlClient;

public class Tutorial1
{
 public static void Main()
 {
 string connStr = "server=localhost;user=root;database=world;port=3306;password=*****";
 MySqlConnection conn = new MySqlConnection(connStr);
 try
 {
 Console.WriteLine("Connecting to MySQL...");
 conn.Open();
 // Perform database operations
 }
 catch (Exception ex)
 {
 Console.WriteLine(ex.ToString());
 }
 conn.Close();
 Console.WriteLine("Done.");
 }
}
```

When the `MySqlConnection` constructor is invoked it returns a connection object, which is used for subsequent database operations. The first operation in this example is to open the connection. This needs to be done before further operations take place. Before the application exits the connection to the database needs to be closed by calling `Close` on the connection object.

Sometimes an attempt to perform an `Open` on a connection object can fail, this will generate an exception that can be handled using standard exception handling code.

In this section you have learned how to create a connection to a MySQL database, and open and close the corresponding connection object.

#### 21.2.4.1.2. The `MySqlCommand` Object

Once a connection has been established with the MySQL database, the next step is to carry out the desired database operations. This can be achieved through the use of the `MySqlCommand` object.

You will see how to create a `MySqlCommand` object. Once it has been created there are three main methods of interest that you can call:

- **ExecuteReader** - used to query the database. Results are usually returned in a `MySqlDataReader` object, created by `ExecuteReader`.
- **ExecuteNonQuery** - used to insert and delete data.
- **ExecuteScalar** - used to return a single value.

Once a `MySqlCommand` object has been created, you will call one of the above methods on it to carry out a database operation, such as perform a query. The results are usually returned into a `MySqlDataReader` object, and then processed, for example the results might be displayed. The following code demonstrates how this could be done.

```
using System;
using System.Data;

using MySql.Data;
using MySql.Data.MySqlClient;

public class Tutorial2
{
 public static void Main()
 {
 string connStr = "server=localhost;user=root;database=world;port=3306;password=*****";
 MySqlConnection conn = new MySqlConnection(connStr);
 try
 {
```

```

Console.WriteLine("Connecting to MySQL...");
conn.Open();

string sql = "SELECT Name, HeadOfState FROM Country WHERE Continent='Oceania'";
MySqlCommand cmd = new MySqlCommand(sql, conn);
MySqlDataReader rdr = cmd.ExecuteReader();

while (rdr.Read())
{
 Console.WriteLine(rdr[0] + " -- " + rdr[1]);
}
rdr.Close();
}
catch (Exception ex)
{
 Console.WriteLine(ex.ToString());
}

conn.Close();
Console.WriteLine("Done.");
}
}

```

When a connection has been created and opened, the code then creates a `MySqlCommand` object. Note that the SQL query to be executed is passed to the `MySqlCommand` constructor. The `ExecuteReader` method is then used to generate a `MySqlReader` object. The `MySqlReader` object contains the results generated by the SQL executed on the command object. Once the results have been obtained in a `MySqlReader` object, the results can be processed. In this case the information is simply printed out as part of a `while` loop. Finally, the `MySqlReader` object is disposed of by running its `Close` method on it.

In the next example you will see how to use the `ExecuteNonQuery` method.

The procedure for performing an `ExecuteNonQuery` method call is simpler, as there is no need to create an object to store results. This is because `ExecuteNonQuery` is only used for inserting, updating and deleting data. The following example illustrates a simple update to the `Country` table:

```

using System;
using System.Data;

using MySql.Data;
using MySql.Data.MySqlClient;

public class Tutorial3
{
 public static void Main()
 {
 string connStr = "server=localhost;user=root;database=world;port=3306;password=*****;";
 MySqlConnection conn = new MySqlConnection(connStr);
 try
 {
 Console.WriteLine("Connecting to MySQL...");
 conn.Open();

 string sql = "INSERT INTO Country (Name, HeadOfState, Continent) VALUES ('Disneyland','Mickey Mouse', 'North America')";
 MySqlCommand cmd = new MySqlCommand(sql, conn);
 cmd.ExecuteNonQuery();
 }
 catch (Exception ex)
 {
 Console.WriteLine(ex.ToString());
 }

 conn.Close();
 Console.WriteLine("Done.");
 }
}

```

The query is constructed, the command object created and the `ExecuteNonQuery` method called on the command object. You can access your MySQL database with the MySQL Client program and verify that the update was carried out correctly.

Finally, you will see how the `ExecuteScalar` method can be used to return a single value. Again, this is straightforward, as a `MySqlDataReader` object is not required to store results, a simple variable will do. The following code illustrates how to use `ExecuteScalar`:

```

using System;
using System.Data;

using MySql.Data;
using MySql.Data.MySqlClient;

public class Tutorial4
{
 public static void Main()
 {
 string connStr = "server=localhost;user=root;database=world;port=3306;password=*****;";
 MySqlConnection conn = new MySqlConnection(connStr);
 try
 {

```

```

Console.WriteLine("Connecting to MySQL...");
conn.Open();

string sql = "SELECT COUNT(*) FROM Country";
MySqlCommand cmd = new MySqlCommand(sql, conn);
object result = cmd.ExecuteScalar();
if (result != null)
{
 int r = Convert.ToInt32(result);
 Console.WriteLine("Number of countries in the World database is: " + r);
}

}
catch (Exception ex)
{
 Console.WriteLine(ex.ToString());
}

conn.Close();
Console.WriteLine("Done.");
}
}

```

This example uses a simple query to count the rows in the Country table. The result is obtained by calling `ExecuteScalar` on the command object.

#### 21.2.4.1.3. Working with Decoupled Data

Previously, when using `MySqlDataReader`, the connection to the database was continually maintained, unless explicitly closed. It is also possible to work in a manner where a connection is only established when needed. For example, in this mode, a connection could be established to read a chunk of data, the data could then be modified by the application as required. A connection could then be reestablished only if and when the application needs to write data back to the database. This decouples the working data set from the database.

This decouple mode of working with data is supported by Connector/.NET. There are several parts involved in allowing this method to work:

- **Data Set** - The Data Set is the area in which data is loaded to read or modify it. A `DataSet` object is instantiated, which can store multiple tables of data.
- **Data Adapter** - The Data Adapter is the interface between the Data Set and the database itself. The Data Adapter is responsible for efficiently managing connections to the database, opening and closing them as required. The Data Adapter is created by instantiating an object of the `MySqlDataAdapter` class. The `MySqlDataAdapter` object has two main methods: `Fill` which reads data into the Data Set, and `Update`, which writes data from the Data Set to the database.
- **Command Builder** - The Command Builder is a support object. The Command Builder works in conjunction with the Data Adapter. When a `MySqlDataAdapter` object is created it is typically given an initial SELECT statement. From this SELECT statement the Command Builder can work out the corresponding INSERT, UPDATE and DELETE statements that would be required should the database need to be updated. To create the Command Builder an object of the class `MySqlCommandBuilder` is created.

Each of these classes will now be discussed in more detail.

##### Instantiating a DataSet object

A `DataSet` object can be created simply, as shown in the following example code snippet:

```

DataSet dsCountry;
...
dsCountry = new DataSet();

```

Although this creates the `DataSet` object it has not yet filled it with data. For that a Data Adapter is required.

##### Instantiating a MySqlDataAdapter object

The `MySqlDataAdapter` can be created as illustrated by the following example:

```

MySqlDataAdapter daCountry;
...
string sql = "SELECT Code, Name, HeadOfState FROM Country WHERE Continent='North America'";
daCountry = new MySqlDataAdapter (sql, conn);

```

Note, the `MySqlDataAdapter` is given the SQL specifying the data you wish to work with.

## Instantiating a MySqlCommandBuilder object

Once the `MySqlDataAdapter` has been created, it is necessary to generate the additional statements required for inserting, updating and deleting data. There are several ways to do this, but in this tutorial you will see how this can most easily be done with `MySqlCommandBuilder`. The following code snippet illustrates how this is done:

```
MySqlCommandBuilder cb = new MySqlCommandBuilder(daCountry);
```

Note that the `MySqlDataAdapter` object is passed as a parameter to the command builder.

## Filling the Data Set

To do anything useful with the data from your database, you need to load it into a Data Set. This is one of the jobs of the `MySqlDataAdapter` object, and is carried out with its `Fill` method. The following example code illustrates this:

```
DataSet dsCountry;
...
dsCountry = new DataSet();
...
daCountry.Fill(dsCountry, "Country");
```

Note the `Fill` method is a `MySqlDataAdapter` method, the Data Adapter knows how to establish a connection with the database and retrieve the required data, and then populates the Data Set when the `Fill` method is called. The second parameter “Country” is the table in the Data Set to update.

## Updating the Data Set

The data in the Data Set can now be manipulated by the application as required. At some point, changes to data will need to be written back to the database. This is achieved through a `MySqlDataAdapter` method, the `Update` method.

```
daCountry.Update(dsCountry, "Country");
```

Again, the Data Set and the table within the Data Set to update are specified.

## Working Example

The interactions between the `DataSet`, `MySqlDataAdapter` and `MySqlCommandBuilder` classes can be a little confusing, so their operation can perhaps be best illustrated by working code.

In this example, data from the World database is read into a Data Grid View control. Here, the data can be viewed and changed before clicking an update button. The update button then activates code to write changes back to the database. The code uses the principles explained above. The application was built using the Microsoft Visual Studio to place and create the user interface controls, but the main code that uses the key classes described above is shown below, and is portable.

```
using System;
using System.Collections.Generic;
using System.ComponentModel;
using System.Data;
using System.Drawing;
using System.Linq;
using System.Text;
using System.Windows.Forms;

using MySql.Data;
using MySql.Data.MySqlClient;

namespace WindowsFormsApplication5
{
 public partial class Form1 : Form
 {
 MySqlCommandAdapter daCountry;
 DataSet dsCountry;

 public Form1()
 {
 InitializeComponent();
 }

 private void Form1_Load(object sender, EventArgs e)
 {
 string connStr = "server=localhost;user=root;database=world;port=3306;password=*****";
 MySqlConnection conn = new MySqlConnection(connStr);
 try
 {
 label2.Text = "Connecting to MySQL...";

 string sql = "SELECT Code, Name, HeadOfState FROM Country WHERE Continent='North America'";
 daCountry = new MySqlDataAdapter(sql, conn);
 MySqlCommandBuilder cb = new MySqlCommandBuilder(daCountry);
```

```

 dsCountry = new DataSet();
 daCountry.Fill(dsCountry, "Country");
 dataGridView1.DataSource = dsCountry;
 dataGridView1.DataMember = "Country";
 }
 catch (Exception ex)
 {
 label2.Text = ex.ToString();
 }
}

private void button1_Click(object sender, EventArgs e)
{
 daCountry.Update(dsCountry, "Country");
 label2.Text = "MySQL Database Updated!";
}
}
}

```

The application running is shown below:

**Figure 21.30. World Database Application**

#### 21.2.4.1.4. Working with Parameters

This part of the tutorial shows you how to use parameters in your Connector/.NET application.

Although it is possible to build SQL query strings directly from user input, this is not advisable as it does not prevent erroneous or

malicious information being entered. It is safer to use parameters as they will be processed as field data only. For example, imagine the following query was contructed from user input:

```
string sql = "SELECT Name, HeadOfState FROM Country WHERE Continent = "+user_continent;
```

If the string `user_continent` came from a Text Box control, there would potentially be no control over the string entered by the user. The user could enter a string that generates a run time error, or in the worst case actually harms the system. When using parameters it is not possible to do this because a parameter is only ever treated as a field parameter, rather than an arbitrary piece of SQL code.

The same query written user a parameter for user input would be:

```
string sql = "SELECT Name, HeadOfState FROM Country WHERE Continent = @Continent";
```

Note that the parameter is preceded by an '@' symbol to indicate it is to be treated as a parameter.

As well as marking the position of the parameter in the query string, it is necessary to add a parameter to the Command object. This is illustrated by the following code snippet:

```
cmd.Parameters.AddWithValue("@Continent", "North America");
```

In this example the string "North America" is supplied as the parameter value statically, but in a more practical example it would come from a user input control.

A further example illustrates the complete process:

```
using System;
using System.Data;

using MySql.Data;
using MySql.Data.MySqlClient;

public class Tutorials5
{
 public static void Main()
 {
 string connStr = "server=localhost;user=root;database=world;port=3306;password=*****;";
 MySqlConnection conn = new MySqlConnection(connStr);
 try
 {
 Console.WriteLine("Connecting to MySQL...");
 conn.Open();

 string sql = "SELECT Name, HeadOfState FROM Country WHERE Continent=@Continent";
 MySqlCommand cmd = new MySqlCommand(sql, conn);

 Console.WriteLine("Enter a continent e.g. 'North America', 'Europe': ");
 string user_input = Console.ReadLine();

 cmd.Parameters.AddWithValue("@Continent", user_input);

 MySqlDataReader rdr = cmd.ExecuteReader();

 while (rdr.Read())
 {
 Console.WriteLine(rdr["Name"] + " --- " + rdr["HeadOfState"]);
 }
 rdr.Close();
 }
 catch (Exception ex)
 {
 Console.WriteLine(ex.ToString());
 }

 conn.Close();
 Console.WriteLine("Done.");
 }
}
```

In this part of the tutorial you have see how to use parameters to make your code more secure.

#### 21.2.4.1.5. Working with Stored Procedures

In this section you will see how to work with Stored Procedures. This section assumes you have a basic understanding of what a Stored Procedure is, and how to create one.

For the purposes of this tutorial, you will create a simple Stored Procedure to see how it can be called from Connector/.NET. In the MySQL Client program, connect to the World database and enter the following Stored Procedure:

```
DELIMITER //
CREATE PROCEDURE country_hos
```

```
(IN con CHAR(20))
BEGIN
 SELECT Name, HeadOfState FROM Country
 WHERE Continent = con;
END //
DELIMITER ;
```

Test the Stored Procedure works as expected by typing the following into the MySQL Client program:

```
CALL country_hos('Europe');
```

Note that The Stored Routine takes a single parameter, which is the continent you wish to restrict your search to.

Having confirmed that the Stored Procedure is present and correct you can now move on to seeing how it can be accessed from Connector/.NET.

Calling a Stored Procedure from your Connector/.NET application is similar to techniques you have seen earlier in this tutorial. A `MySqlCommand` object is created, but rather than taking a SQL query as a parameter it takes the name of the Stored Procedure to call. The `MySqlCommand` object also needs to be set to the type of Stored Procedure. This is illustrated by the following code snippet:

```
string rtn = "country_hos";
MySqlCommand cmd = new MySqlCommand(rtn, conn);
cmd.CommandType = CommandType.StoredProcedure;
```

In this case you also need to pass a parameter to the Stored Procedure. This can be achieved using the techniques seen in the previous section on parameters, [Section 21.2.4.1.4, “Working with Parameters”](#). This is shown in the following code snippet:

```
cmd.Parameters.AddWithValue("@con", "Europe");
```

The value of the parameter `@con` could more realistically have come from a user input control, but for simplicity it is set as a static string in this example.

At this point everything is set up and all that now needs to be done is to call the routine. This can be achieved using techniques also learned in earlier sections, but in this case the `ExecuteReader` method of the `MySqlCommand` object is used.

Complete working code for the Stored Procedure example is shown below:

```
using System;
using System.Data;

using MySql.Data;
using MySql.Data.MySqlClient;

public class Tutorial6
{
 public static void Main()
 {
 string connStr = "server=localhost;user=root;database=world;port=3306;password=*****;";
 MySqlConnection conn = new MySqlConnection(connStr);
 try
 {
 Console.WriteLine("Connecting to MySQL...");
 conn.Open();

 string rtn = "country_hos";
 MySqlCommand cmd = new MySqlCommand(rtn, conn);
 cmd.CommandType = CommandType.StoredProcedure;

 cmd.Parameters.AddWithValue("@con", "Europe");

 MySqlDataReader rdr = cmd.ExecuteReader();
 while (rdr.Read())
 {
 Console.WriteLine(rdr[0] + " --- " + rdr[1]);
 }
 rdr.Close();
 }
 catch (Exception ex)
 {
 Console.WriteLine(ex.ToString());
 }

 conn.Close();
 Console.WriteLine("Done.");
 }
}
```

In this section you have seen how to call a Stored Procedure from Connector/.NET. For the moment, this concludes our introductory tutorial on programming with Connector/.NET.

## 21.2.4.2. Tutorial: MySQL Connector/.NET ASP.NET Membership and Role Provider

Many web sites feature the facility for the user to create a user account. They can then log into the web site and enjoy a personalized experience. This requires that the developer creates database tables to store user information, along with code to gather and process this data. This represents a burden on the developer, and there is the possibility for security issues to creep into the developed code. However, ASP.NET 2.0 introduced the Membership system. This system is designed around the concept of Membership, Profile and Role Providers, which together provide all of the functionality to implement a user system, that previously would have to have been created by the developer from scratch.

Currently, MySQL Connector/.NET provides Membership, Role, Profile and Session State Providers.

This tutorial shows you how to set up your ASP.NET web application to use the MySQL Connector/.NET Membership and Role Providers. It assumes that you have MySQL Server installed, along with MySQL Connector/.NET and Microsoft Visual Studio. This tutorial was tested with MySQL Connector/.NET 6.0.4 and Microsoft Visual Studio 2008 Professional Edition. It is recommended you use 6.0.4 or above for this tutorial.

1. Create a new database in the MySQL Server using the MySQL Command Line Client program ([mysql](#)), or other suitable tool. It does not matter what name is used for the database, but it should be noted down so that it can be specified in the connection string constructed later in this tutorial. This database will contain the tables, automatically created for you later, used to store data about users and roles.
2. Create a new ASP.NET Web Site in Visual Studio. If you are not sure how to do this, refer to the following tutorial: [Section 21.2.4.6, “Tutorial: Databinding in ASP.NET using LINQ on Entities”](#), which demonstrates how to create a simple ASP.NET web site.
3. Add References to [MySql.Data](#) and [MySql.Web](#) to the web site project.
4. Locate the [machine.config](#) file on your system, which is the configuration file for the .NET Framework.
5. Search the [machine.config](#) file to find the membership provider [MySQLMembershipProvider](#).
6. Add the attribute [autogenerateschema="true"](#). The appropriate section should now resemble the following (note: for the sake of brevity some information has been excluded):

```
<membership>
 <providers>
 <add name="AspNetSqlMembershipProvider"
 type="System.Web.Security.SqlMembershipProvider"
 ...
 connectionStringName="LocalSqlServer"
 ... />
 <add name="MySQLMembershipProvider"
 autogenerateschema="true"
 type="MySql.Web.Security.MySQLMembershipProvider, MySql.Web, Version=6.0.4.0, Culture=neutral, PublicKeyToken"
 connectionStringName="LocalMySqlServer"
 ... />
 </providers>
</membership>
```

Note that the name for the connection string to be used to connect to the server that contains the membership database is [LocalMySqlServer](#).

The [autogenerateschema="true"](#) attribute will cause MySQL Connector/.NET to silently create, or upgrade, the schema on the database server, to contain the required tables for storing membership information.

7. It is now necessary to create the connection string referenced in the previous step. Load the web site's [web.config](#) file into Visual Studio.
8. Locate the section marked [<connectionStrings>](#). Add the following connection string information:

```
<connectionStrings>
 <remove name="LocalMySqlServer" />
 <add name="LocalMySqlServer"
 connectionString="Datasource=localhost;Database=users;uid=root;pwd=password;"
 providerName="MySql.Data.MySqlClient" />
</connectionStrings>
```

The database specified is the one created in the first step. You could alternatively have used an existing database.

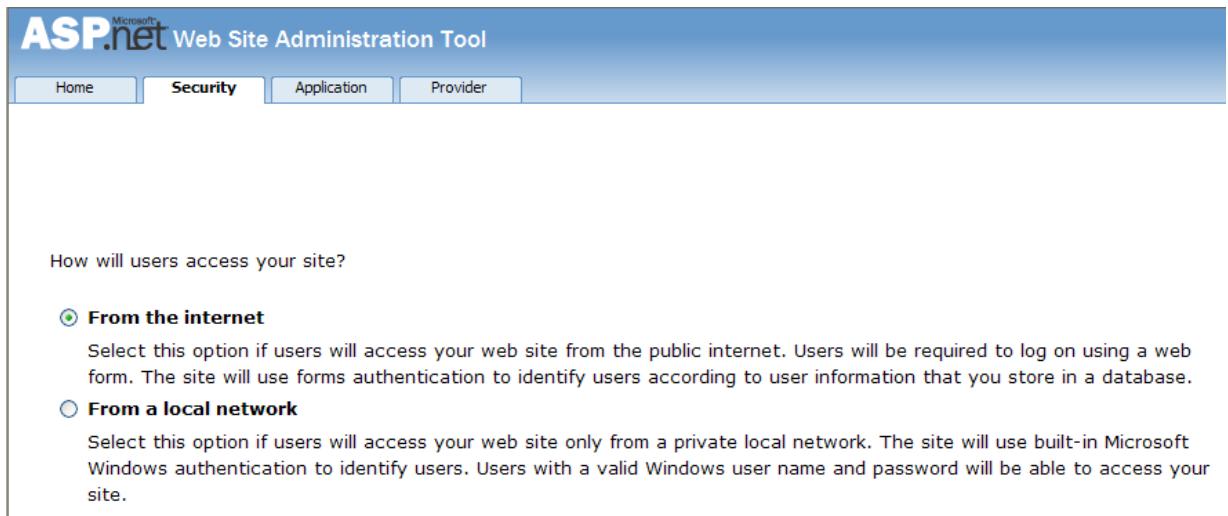

9. At this point build the solution to ensure no errors are present. This can be done by selecting [BUILD](#), [BUILD SOLUTION](#) from the main menu, or pressing [F6](#).
10. ASP.NET supports the concept of locally and remotely authenticated users. With local authentication the user is validated using their Windows credentials when they attempt to access the web site. This can be useful in an Intranet environment. With

remote authentication a user is prompted for their login details when accessing the web site, and these credentials are checked against the membership information stored in a database server such as MySQL Server. You will now see how to choose this form of authentication.

Start the ASP.NET Web Site Administration Tool. This can be done quickly by clicking the small hammer/Earth icon in the Solution Explorer. You can also launch this tool by selecting WEBSITE, ASP.NET CONFIGURATION from the main menu.

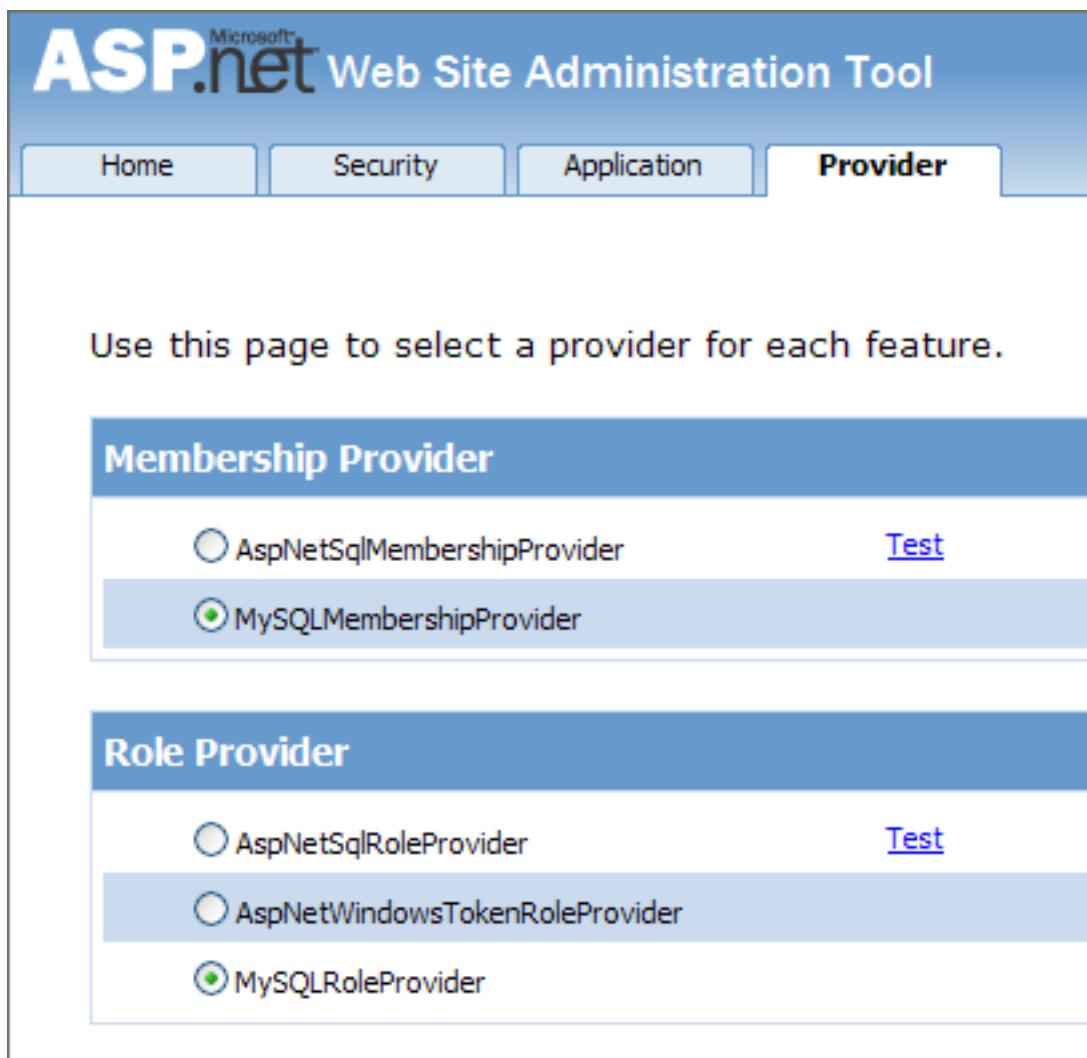

11. In the ASP.NET Web Site Administration Tool click the **SECURITY** tab.
12. Now click the **USER AUTHENTICATION TYPE** link.
13. Select the **FROM THE INTERNET** radio button. The web site will now need to provide a form to allow the user to enter their login details. These will be checked against membership information stored in the MySQL database.

**Figure 21.31. Authentication Type**

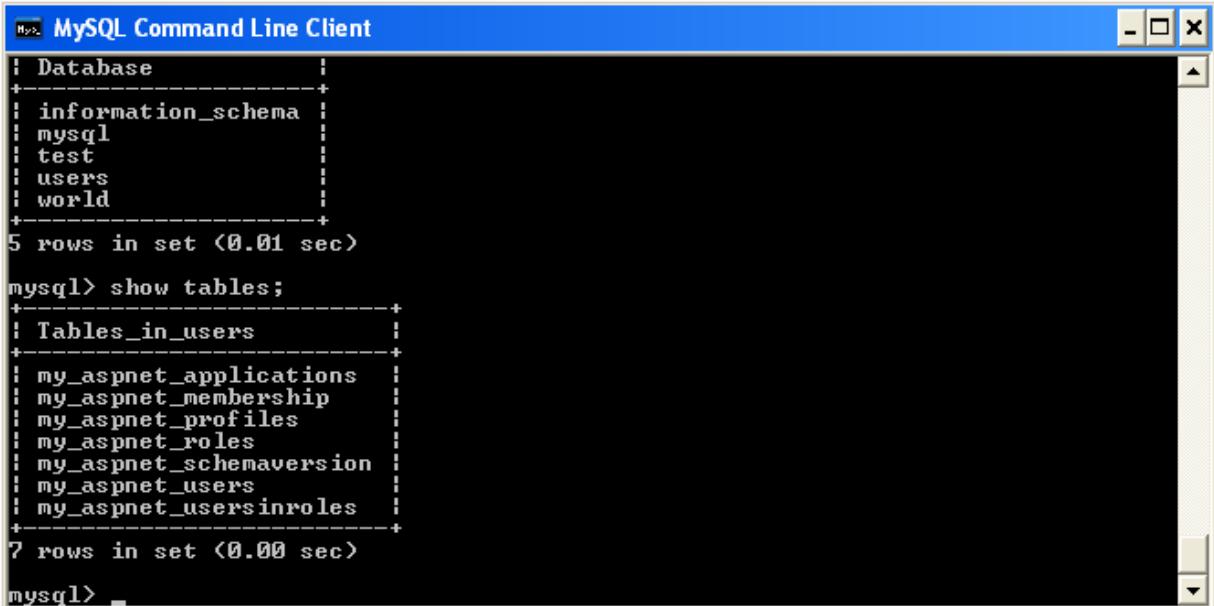

14. You now need to specify the Role and Membership Provider to be used. Click the **PROVIDER** tab.
15. Click the **SELECT A DIFFERENT PROVIDER FOR EACH FEATURE (ADVANCED)** link.
16. Now select the **MySQLMembershipProvider** and the **MySQLRoleProvider** radio buttons.

**Figure 21.32. Select Membership and Role Provider**

17. In Visual Studio rebuild the solution by selecting BUILD, REBUILD SOLUTION from the main menu.
18. Check that the necessary schema has been created. This can be achieved using the MySQL Command Line Client program.

**Figure 21.33. Membership and Role Provider Tables**

The screenshot shows the MySQL Command Line Client window. The title bar reads "MySQL Command Line Client". The main area displays two sets of command-line output:

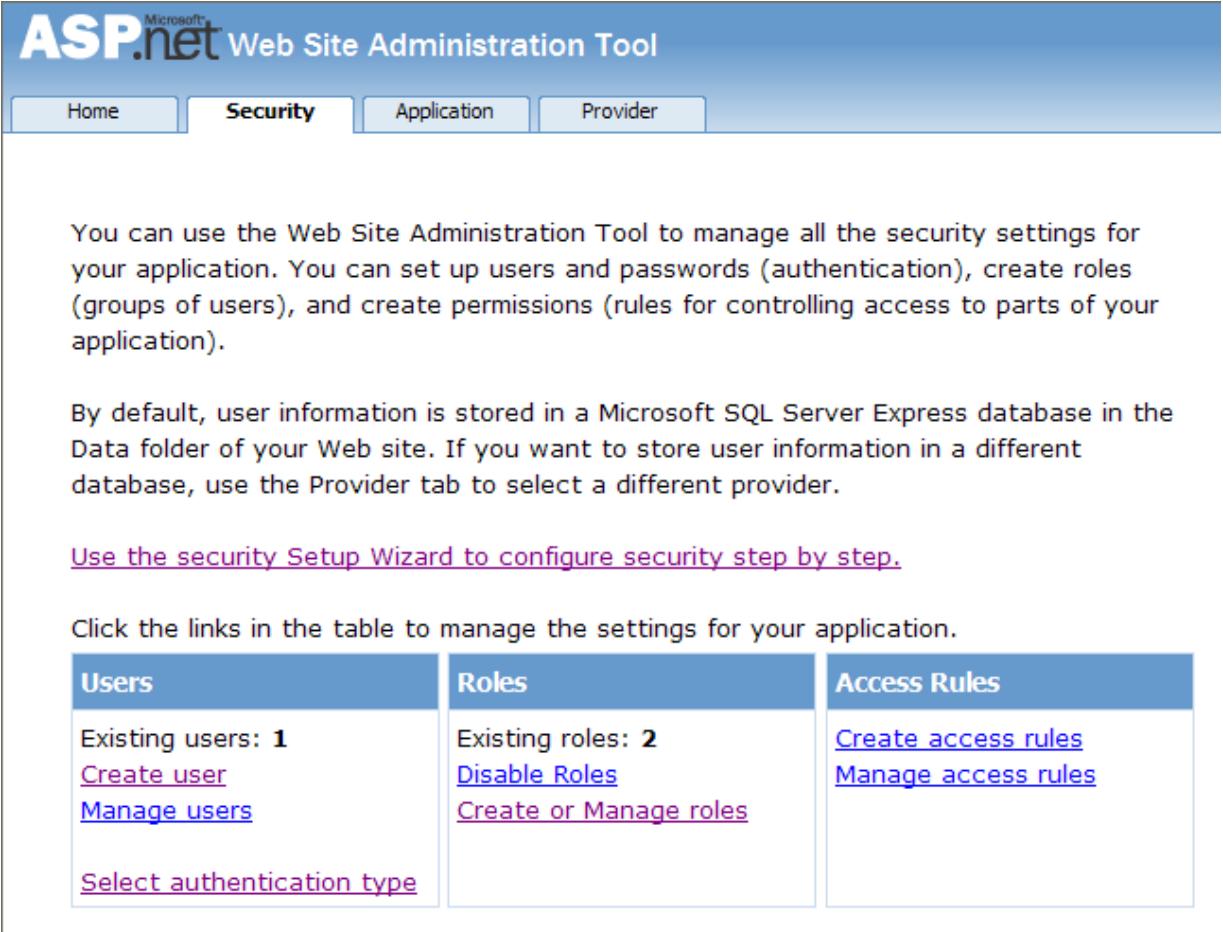

```
| Database |
+-----+
| information_schema |
| mysql |
| test |
| users |
| world |
+-----+
5 rows in set <0.01 sec>

mysql> show tables;
+-----+
| Tables_in_users |
+-----+
| my_aspnet_applications |
| my_aspnet_membership |
| my_aspnet_profiles |
| my_aspnet_roles |
| my_aspnet_schemaversion |
| my_aspnet_users |
| my_aspnet_usersinroles |
+-----+
7 rows in set <0.00 sec>

mysql>
```

19. Assuming all is present and correct you can now create users and roles for your web application. The easiest way to do this is with the ASP.NET Web Site Administration Tool. However, many web applications contain their own modules for creating roles and users. For simplicity the ASP.NET Web Site Administration Tool will be used in this tutorial.
20. In the ASP.NET Web Site Administration Tool, click the **SECURITY** tab. Now that both the Membership and Role Provider are enabled you will see links for creating roles and users. Click the **CREATE OR MANAGE ROLES** link.

**Figure 21.34. Security Tab**

The screenshot shows the ASP.NET Web Site Administration Tool interface. The title bar reads "ASP.net Microsoft Web Site Administration Tool". Below it is a navigation bar with four tabs: "Home", "Security" (which is selected and highlighted in blue), "Application", and "Provider". The main content area has the following text:

You can use the Web Site Administration Tool to manage all the security settings for your application. You can set up users and passwords (authentication), create roles (groups of users), and create permissions (rules for controlling access to parts of your application).

By default, user information is stored in a Microsoft SQL Server Express database in the Data folder of your Web site. If you want to store user information in a different database, use the Provider tab to select a different provider.

[Use the security Setup Wizard to configure security step by step.](#)

Click the links in the table to manage the settings for your application.

Users	Roles	Access Rules
Existing users: <b>1</b> <a href="#">Create user</a> <a href="#">Manage users</a>  <a href="#">Select authentication type</a>	Existing roles: <b>2</b> <a href="#">Disable Roles</a> <a href="#">Create or Manage roles</a>	<a href="#">Create access rules</a> <a href="#">Manage access rules</a>

21. You can now enter the name of a new Role and click ADD ROLE to create the new Role. Create new Roles as required.
22. Click the BACK button.
23. Click the **CREATE USER** link. You can now fill in information about the user to be created, and also allocate that user to one or more Roles.

**Figure 21.35. Create User**

Add a user by entering the user's ID, password, and e-mail address on this page.

Create User		Roles
Sign Up for Your New Account User Name: <input type="text" value="johndoe"/> Password: <input type="password" value="password"/> Confirm Password: <input type="password" value="password"/> E-mail: <input type="text" value="johndoe@example.com"/> Security Question: <input type="text" value="Statler and ..."/> Security Answer: <input type="text" value="Waldorf"/>		Select roles for this user: <input type="checkbox"/> Visitors <input checked="" type="checkbox"/> Admins
<input type="button" value="Create User"/>		
<input checked="" type="checkbox"/> Active User		

24. Using the MySQL Command Line Client program you can check that your database has been correctly populated with the Membership and Role data.

**Figure 21.36. Membership and Roles Table Contents**

```

MySQL Command Line Client
my_aspnet_roles
my_aspnet_schemaversion
my_aspnet_users
my_aspnet_usersinroles
7 rows in set <0.00 sec>

mysql> select * from my_aspnet_users;
+----+-----+-----+-----+-----+
| id | applicationId | name | isAnonymous | lastActivityDate |
+----+-----+-----+-----+-----+
| 1 | 1 | johndoe | 0 | 2009-07-14 17:17:25 |
+----+-----+-----+-----+-----+
1 row in set <0.01 sec>

mysql> select * from my_aspnet_roles;
+----+-----+-----+
| id | applicationId | name |
+----+-----+-----+
| 1 | 1 | Visitors |
| 2 | 1 | Admins |
+----+-----+-----+
2 rows in set <0.00 sec>

mysql> .

```

In this tutorial you have seen how to set up the MySQL Connector/.NET Membership and Role Providers for use in your ASP.NET web application.

### 21.2.4.3. Tutorial: MySQL Connector/.NET ASP.NET Session State Provider

MySQL Connector/.NET from version 6.1 has included a MySQL Session State Provider. This provider enables you to store session state in a MySQL database. The following tutorial shows you how to prepare to use the MySQL Session State Provider, and then store session data into the MySQL database. This tutorial uses Microsoft Visual Studio 2008 Professional Edition, MySQL Connector/.NET 6.1.1 and MySQL Server 5.1. This tutorial also assumes you have created an empty database, for example `test`, where you will store session data. You could do this using the MySQL Command Line Client tool.

1. In Visual Studio create a new ASP.NET web site. If you are not sure how to do this refer to the tutorial [Section 21.2.4.6, “Tutorial: Databinding in ASP.NET using LINQ on Entities”](#) which demonstrates how to do this.
2. Launch the MySQL MySQL Website Configuration tool. Due to a bug in 6.1.1 this may not appear unless you are connected to a server in the Server Explorer. If you are unfamiliar with the MySQL Website Configuration tool it is suggested that you first work through the following tutorial [Section 21.2.3.10, “MySQL Website Configuration Tool”](#).
3. Navigate through the wizard to the Session State page. Make sure the checkbox **USE MYSQL TO MANAGE MY ASP.NET SESSION DATA** is selected.
4. On the same page configure the connection string to the database that will contain your session data. This database can be empty as MySQL Connector/.NET will create the schema required to store session data.
5. Ensure that the checkbox **AUTOGGENERATE SCHEMA** is selected so that MySQL Connector/.NET will create the schema in your database to store the session data correctly.
6. Enter the name of your application.
7. Click FINISH. The MySQL Website Configuration tool will now update your application's `web.config` file with information about the connection string and default providers to be used. In this case we have selected the MySQL Session State Provider.

At this point you are ready to use the MySQL database to store session data. To test that the set up has worked you can write a simple program that uses session variables.

1. Open `Default.aspx.cs`. In the `Page_Load` method add the following code:

```
Session["SessionVariable1"] = "Test string";
```

2. Build your solution.
3. Run the solution (without debugging). When the application runs, the provider will autogenerate tables required in the database you chose when setting up the application.
4. Check that the schema was in fact created. Using the MySQL Command Line Client use the target database and then type `SHOW TABLES;`. You will see that MySQL Connector/.NET has created the required schema automatically, as we selected this to happen in the MySQL Website Configuration tool.
5. Now view the contents of these tables by typing `SELECT * FROM my_aspnet_sessions;` in the MySQL Command Line Client. This will display the session data our application used. Note that this is stored in binary format so some data may not display as expected.

At this point you have installed the Session State Provider and carried out a preliminary test of the installation. You will now work a bit more with the Session State Provider.

In this part of the tutorial you will set and retrieve a session variable. You can work with your existing project.

1. Select the `Default.aspx` and switch to Design View. Add a text box and three buttons. Change the text property for the buttons to “Store Session Variable”, “Clear Textbox”, and “Show Session Variable”. These will be `Button1`, `Button2` and `Button3` respectively. Build your solution to ensure that no errors have been introduced.
2. Still in the Design View, double-click `Button1`. Now to the `Button1_Click` event handler add code some the handler resembles the following:

```
protected void Button1_Click(object sender, EventArgs e)
{
 Session["SessionString"] = TextBox1.Text;
}
```

You have created a new Session variable accessed using the key “SessionString”. This will be set to the text that was entered into the text box when **Button1** is clicked.

3. In Design View double-click **Button2** to add its click event handler. This button needs to clear text from the text box. The code to do this is as follows:

```
protected void Button2_Click(object sender, EventArgs e)
{
 TextBox1.Text = "";
}
```

The code simply assigns an empty string to the **Text** property of the text box.

4. In the Design View double-click **Button3** and modify the click handler as follows:

```
protected void Button3_Click(object sender, EventArgs e)
{
 TextBox1.Text = (String)Session["SessionString"];
}
```

This will retrieve the session string and display it in the text box.

5. Now modify the **Page\_Load** method as follows:

```
protected void Page_Load(object sender, EventArgs e)
{
 if (!IsPostBack)
 {
 TextBox1.Text = "Enter some text";
 }
}
```

This ensures that when the page loads the text box **Text** property is reset.

6. Ensure that the solution is saved and then rebuild the solution.
7. Run the solution without debugging.
8. The form will be displayed. Enter some text into the text box. Now click STORE SESSION VARIABLE. At this point you have stored the string in a session variable.
9. Now click CLEAR TEXT to clear the text box.
10. Now click SHOW SESSION VARIABLE to retrieve and display the session variable.
11. Refresh the page to destroy the form and display a new form.
12. Click SHOW SESSION VARIABLE the text box will display the stored session variable, demonstrating that the refreshing the page does not destroy the session variable.

This illustrates that the session state data is not destroyed when a page is reloaded.

#### 21.2.4.4. Tutorial: MySQL Connector/.NET ASP.NET Profile Provider

This tutorial shows you how to use the MySQL Profile Provider to store user profile information in a MySQL database. The tutorial uses MySQL Connector/.NET 6.1.1, MySQL Server 5.1 and Microsoft Visual Studio 2008 Professional Edition.

Many modern web sites allow the user to create a personal profile. This requires a significant amount of code, but ASP.NET reduces this considerable by including the functionality in its Profile classes. The Profile Provider provides an abstraction between these classes and a data source. The MySQL Profile Provider enables profile data to be stored in a MySQL database. This enables the profile properties to be written to a persistent store, and be retrieved when required. The Profile Provider also enables profile data to be managed effectively, for example it enables profiles that have not been accessed since a specific date to be deleted.

The following steps show you how you can select the MySQL Profile Provider.

1. Create a new ASP.NET web project.
2. Select the MySQL Website Configuration tool. Due to a bug in 6.1.1 you may have to first connect to a server in Server Explorer before the tool's icon will display in the toolbar of the Solution Explorer.

3. In the MySQL Website Configuration tool navigate through the tool to the Profiles page.
4. Select the **USE MYSQL TO MANAGE MY PROFILES** checkbox.
5. Select the **AUTOGENERATE SCHEMA** checkbox.
6. Click the **EDIT...** button and configure a connection string for the database that will be used to store user profile information.
7. Navigate to the last page of the tool and click **FINISH** to save your changes and exit the tool.

At this point you are now ready to start using the MySQL Profile Provider. With the following steps you can carry out a preliminary test of your installation.

1. Open your **web.config** file.
2. Add a simple profile such as the following:

```
<system.web>
 <anonymousIdentification enabled="true"/>
 <profile defaultProvider="MySQLProfileProvider">
 ...
 <properties>
 <add name="Name" allowAnonymous="true"/>
 <add name="Age" allowAnonymous="true" type="System.UInt16"/>
 <group name="UI">
 <add name="Color" allowAnonymous="true" defaultValue="Blue"/>
 <add name="Style" allowAnonymous="true" defaultValue="Plain"/>
 </group>
 </properties>
 </profile>
 ...

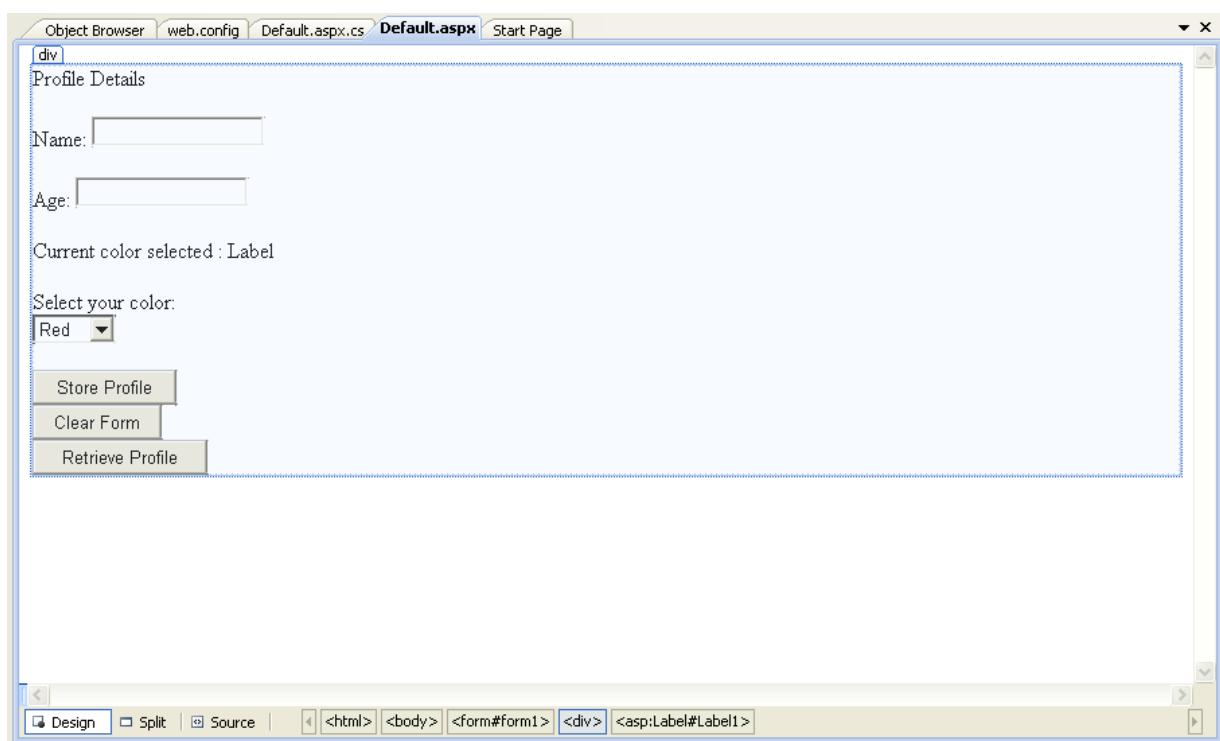

```

Note that **anonymousIdentification** has been set to true. This enables users who have not been authenticated to use profiles. They are identified by a GUID in a cookie rather than by user name.

Now that the simple profile has been defined in **web.config**, the next step is to write some code to test the profile.

1. In Design View design a simple page with the following controls:

**Figure 21.37. Simple Profile Application**

These will allow the user to enter some profile information. The user can also use the buttons to save their profile, clear the page, and restore their profile data.

2. In the Code View add code as follows:

```
...
protected void Page_Load(object sender, EventArgs e)
{
 if (!IsPostBack)
 {
 TextBox1.Text = Profile.Name;
 TextBox2.Text = Profile.Age.ToString();
 Label1.Text = Profile.UI.Color;
 }
}

// Store Profile
protected void Button1_Click(object sender, EventArgs e)
{
 Profile.Name = TextBox1.Text;
 Profile.Age = UInt16.Parse(TextBox2.Text);
}

// Clear Form
protected void Button2_Click(object sender, EventArgs e)
{
 TextBox1.Text = "";
 TextBox2.Text = "";
 Label1.Text = "";
}

// Retrieve Profile
protected void Button3_Click(object sender, EventArgs e)
{
 TextBox1.Text = Profile.Name;
 TextBox2.Text = Profile.Age.ToString();
 Label1.Text = Profile.UI.Color;
}

protected void DropDownList1_SelectedIndexChanged(object sender, EventArgs e)
{
 Profile.UI.Color = DropDownList1.SelectedValue;
}
...
```

3. Save all files and build the solution to check that no errors have been introduced.
4. Run the application.
5. Enter your name, age and select a color from the listbox. Now store this information in your profile by clicking STORE PROFILE. Note that if you do not select a color from the listbox your profile will use the default color **Blue** that was specified in the **web.config** file.
6. Click CLEAR FORM to clear text from the textboxes and the label that displays your chosen color.
7. Now click RETRIEVE PROFILE to restore your profile data from the MySQL database.
8. Now exit the browser to terminate the application.
9. Run the application again. Note that when the page loads your profile information is restored from the MySQL database.

In this tutorial you have seen how to using the MySQL Profile Provider with MySQL Connector/.NET.

#### 21.2.4.5. Tutorial: Using an Entity Framework Entity as a Windows Forms Data Source

In this tutorial you will learn how to create a Windows Forms Data Source from an Entity in an Entity Data Model. This tutorial assumes that you have installed the World example database, which can be downloaded from the [MySQL Documentation page](#). You can also find details on how to install the database on the same page. It will also be convenient for you to create a connection to the World database after it is installed. For instructions on how to do this see [Section 21.2.3.1, “Making a connection”](#).

##### Creating a new Windows Forms application

The first step is to create a new Windows Forms application.

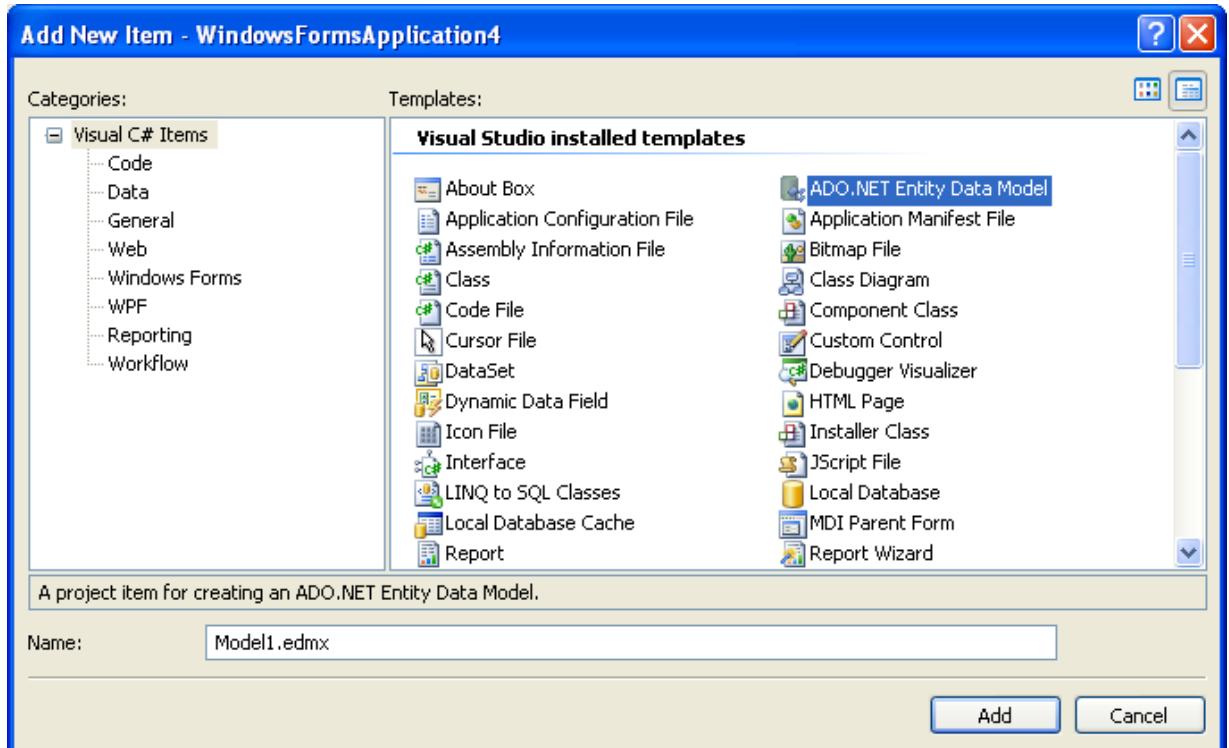

1. In Visual Studio, select **FILE**, **NEW**, **PROJECT** from the main menu.
2. Choose the **WINDOWS FORMS APPLICATION** installed template. Click **OK**. The solution is created.

### Adding an Entity Data Model

You will now add an Entity Data Model to your solution.

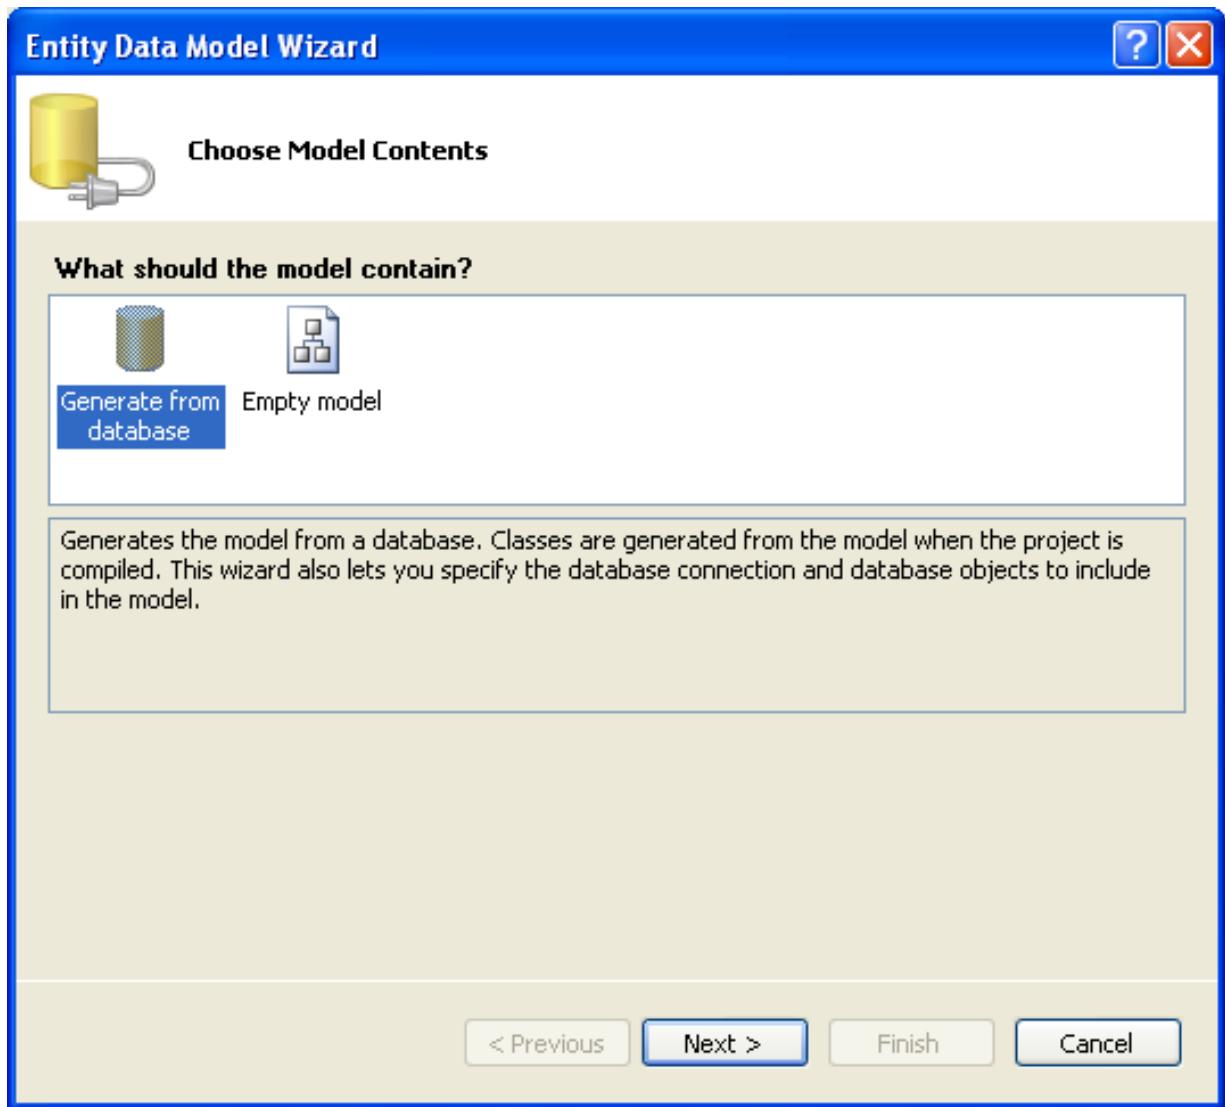

1. In the Solution Explorer, right-click your application and select **ADD, NEW ITEM...**. From **VISUAL STUDIO INSTALLED TEMPLATES** select **ADO.NET ENTITY DATA MODEL**. Click ADD.

**Figure 21.38. Add Entity Data Model**

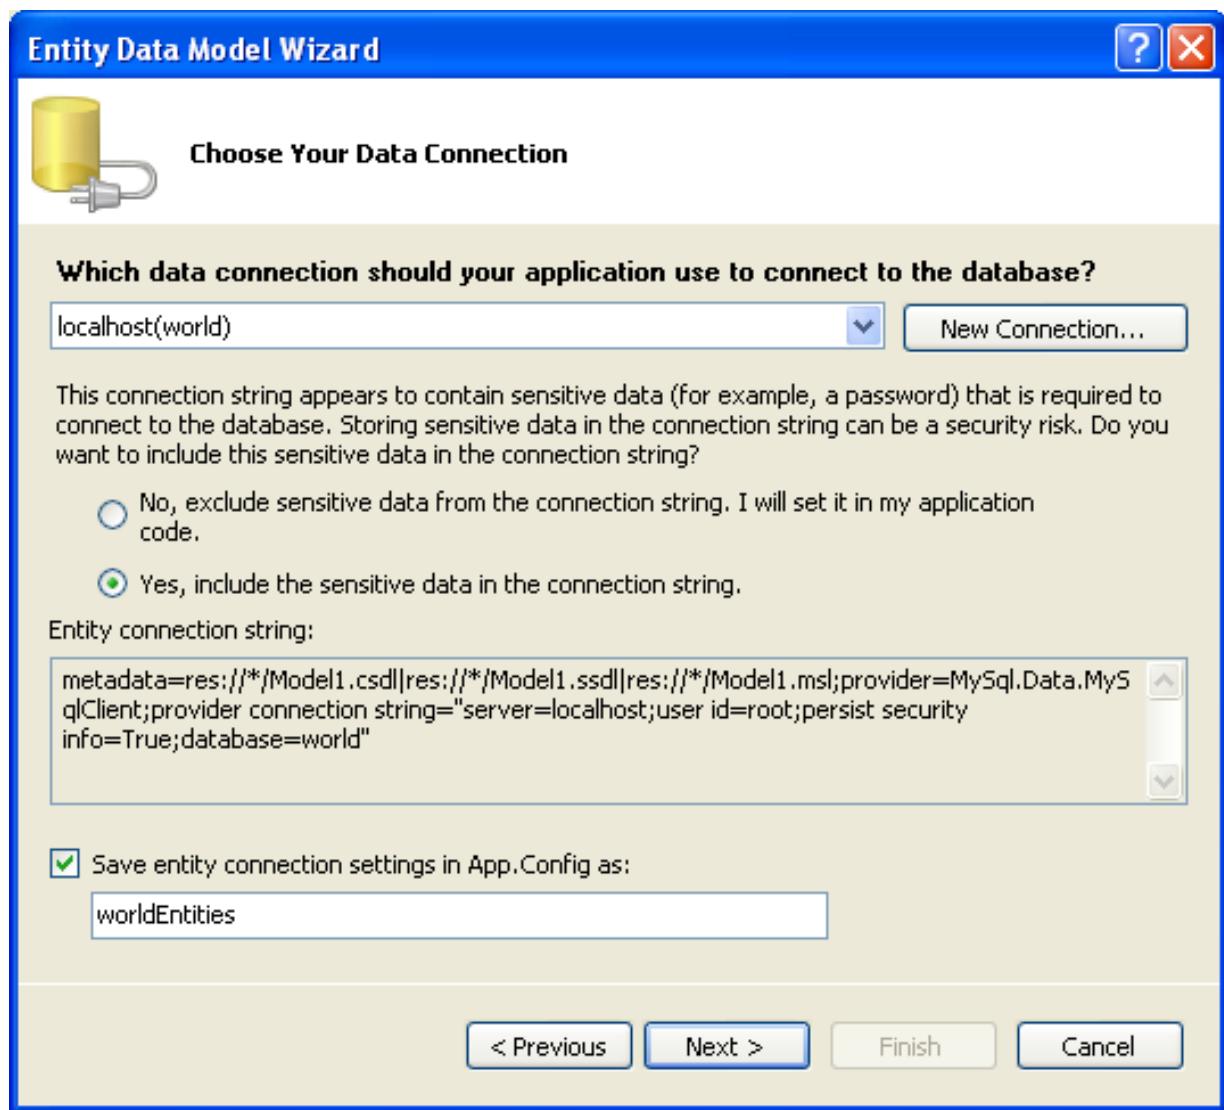

2. You will now see the Entity Data Model Wizard. You will use the wizard to generate the Entity Data Model from the world example database. Select the icon **GENERATE FROM DATABASE**. Click **NEXT**.

**Figure 21.39. Entity Data Model Wizard Screen 1**

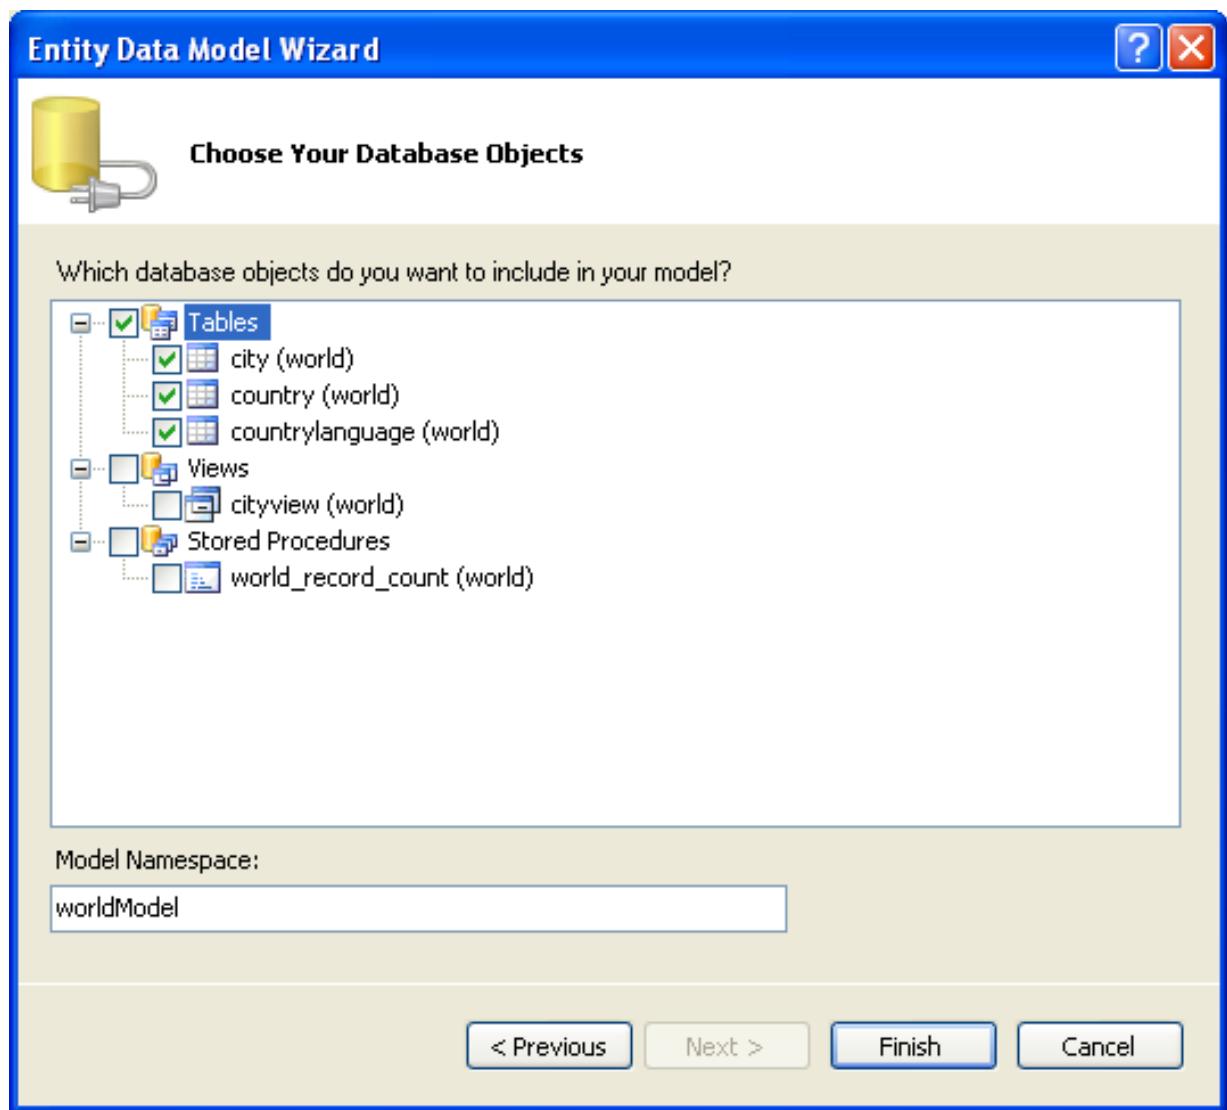

3. You can now select the connection you made earlier to the World database. If you have not already done so, you can create the new connection at this time by clicking NEW CONNECTION.... For further instructions on creating a connection to a database see [Section 21.2.3.1, "Making a connection"](#).

**Figure 21.40. Entity Data Model Wizard Screen 2**

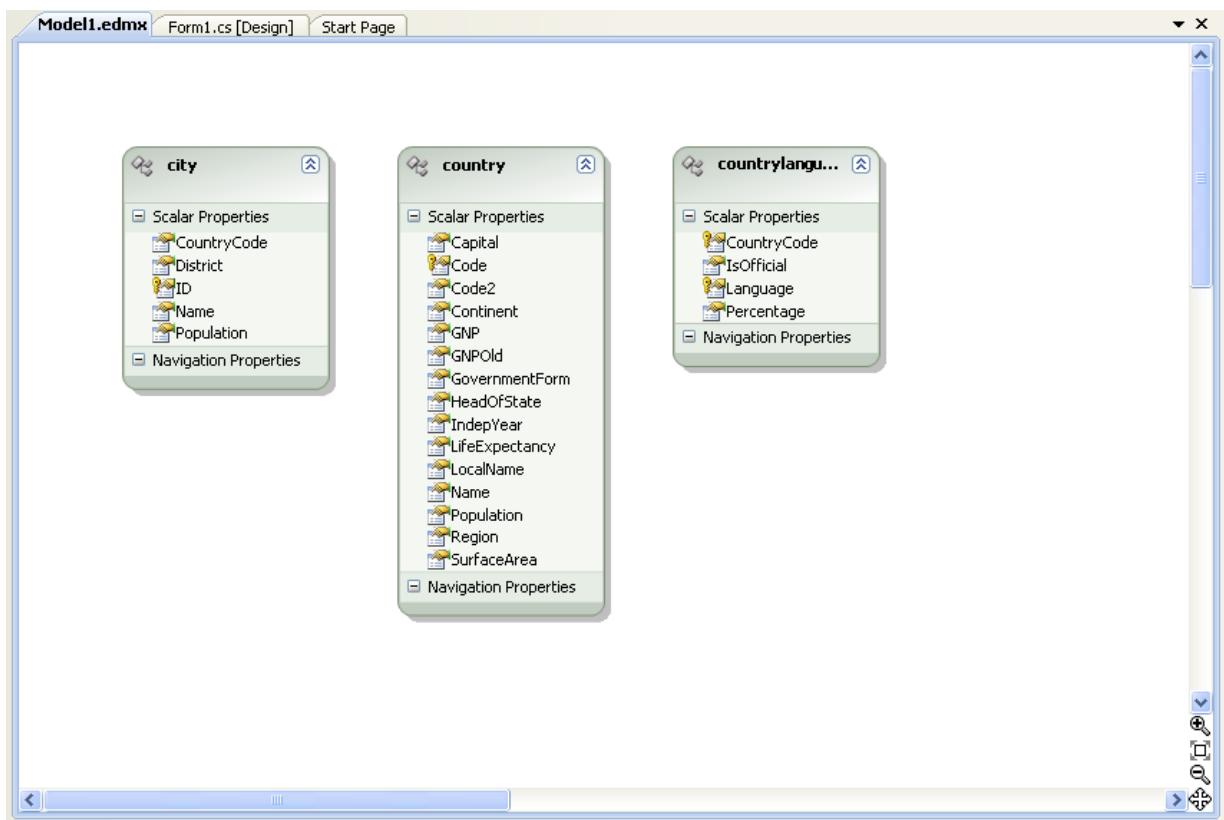

4. Make a note of the entity connection settings to be used in App.Config, as these will be used later to write the necessary control code.
5. Click NEXT.
6. The Entity Data Model Wizard connects to the database. You are then presented with a tree structure of the database. From this you can select the object you would like to include in your model. If you had created Views and Stored Routines these will be displayed along with any tables. In this example you just need to select the tables. Click FINISH to create the model and exit the wizard.

**Figure 21.41. Entity Data Model Wizard Screen 3**

- Visual Studio will generate the model and then display it.

**Figure 21.42. Entity Data Model Diagram**

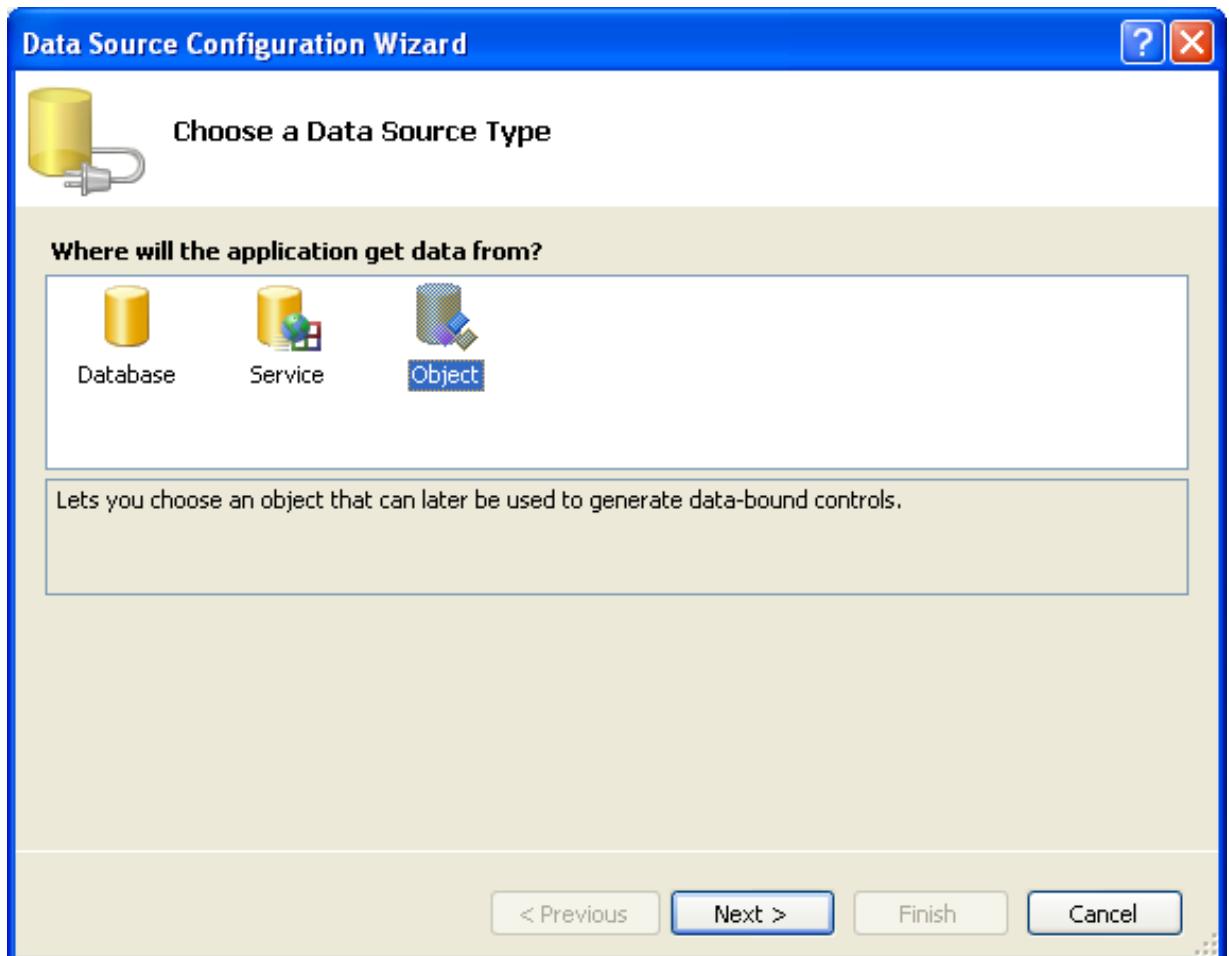

8. From the Visual Studio main menu select BUILD, BUILD SOLUTION, to ensure that everything compiles correctly so far.

#### Adding a new Data Source

You will now add a new Data Source to your project and see how it can be used to read and write to the database.

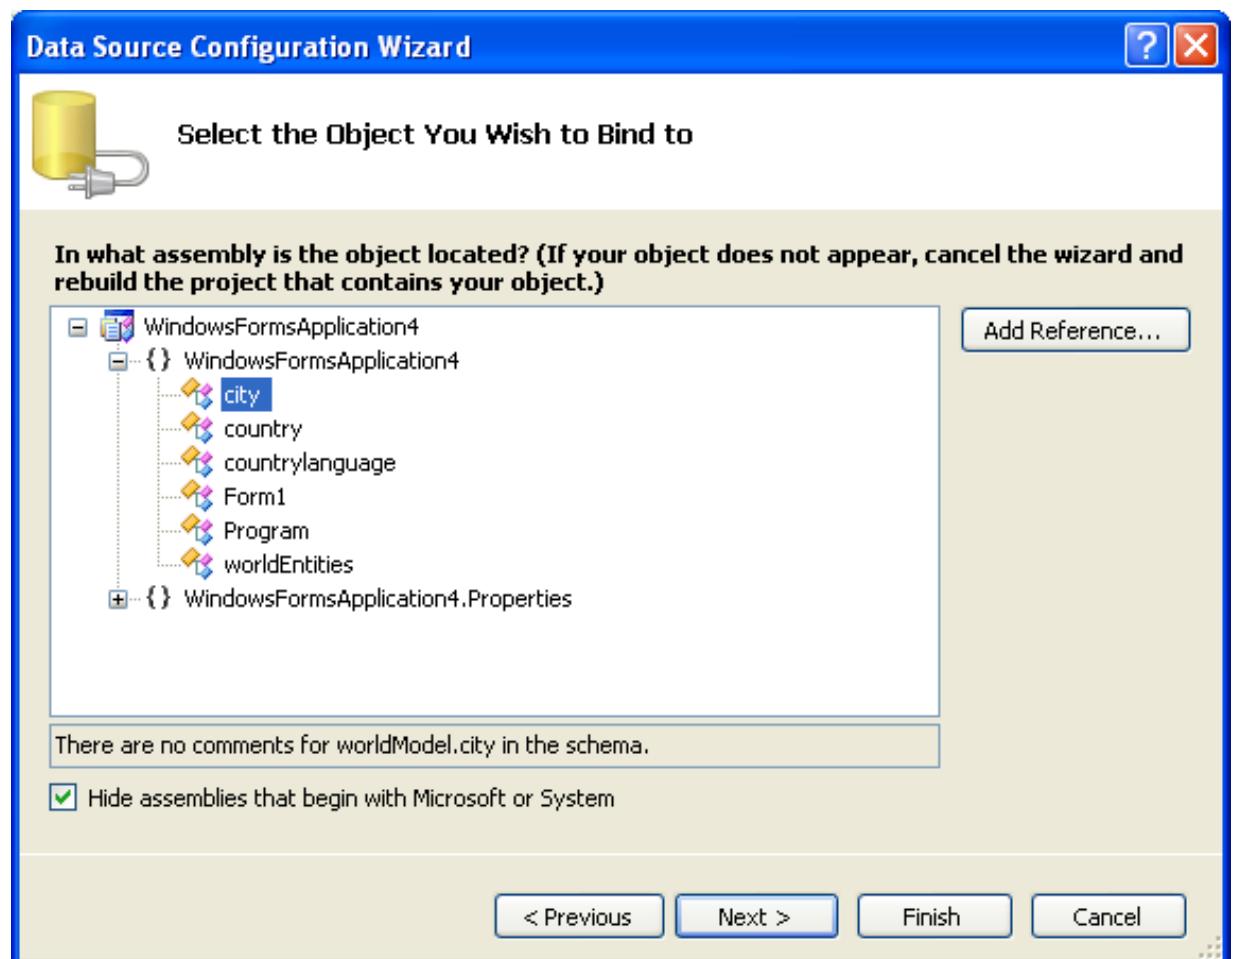

1. From the Visual Studio main menu select DATA, ADD NEW DATA SOURCE.... You will be presented with the Data Source Configuration Wizard.

**Figure 21.43. Entity Data Source Configuration Wizard Screen 1**

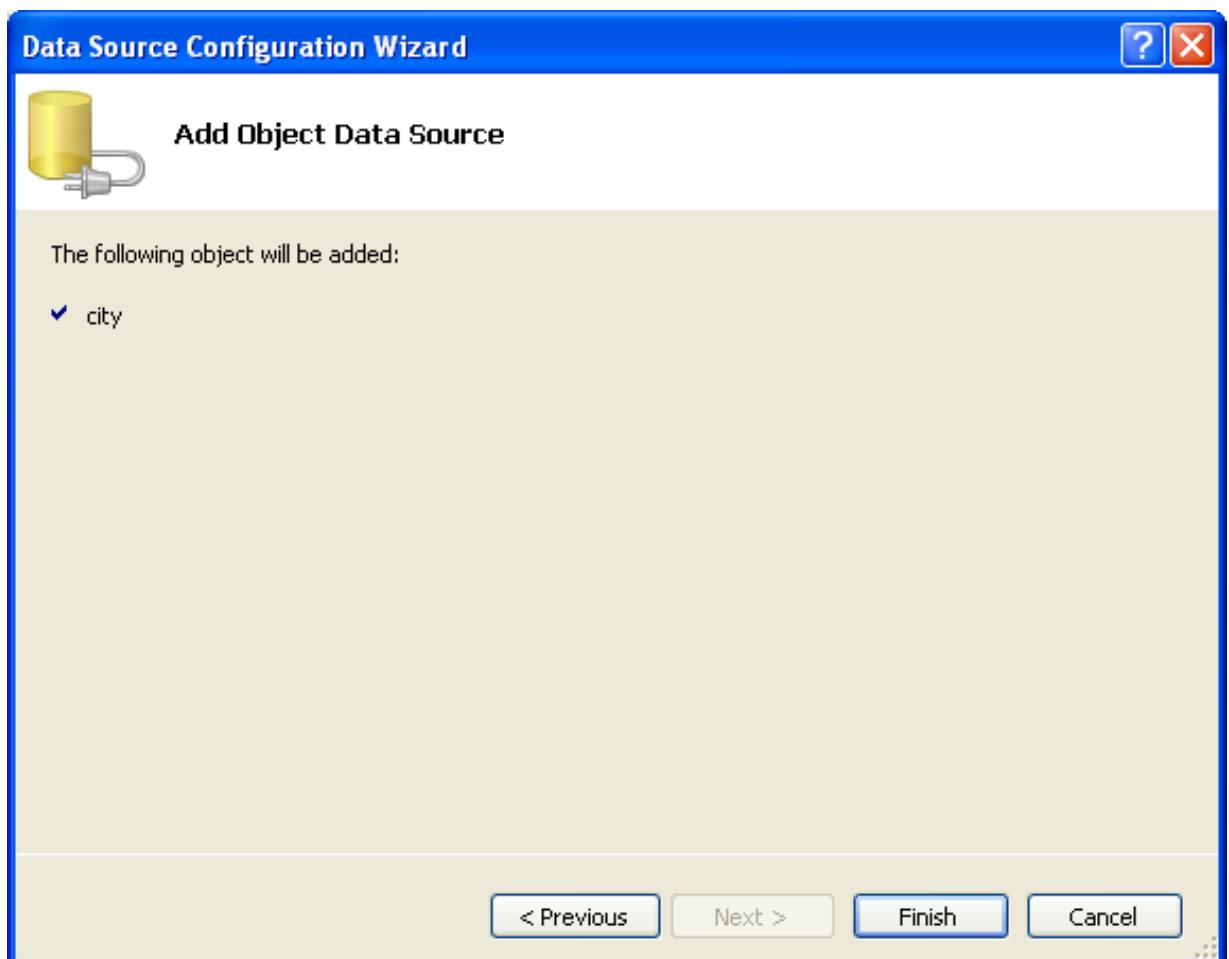

2. Select the **OBJECT** icon. Click **NEXT**.
3. You will now select the Object you wish to bind to. Expand the tree. In this tutorial you will select the city table. Once the city table has been selected click **NEXT**.

**Figure 21.44. Entity Data Source Configuration Wizard Screen 2**

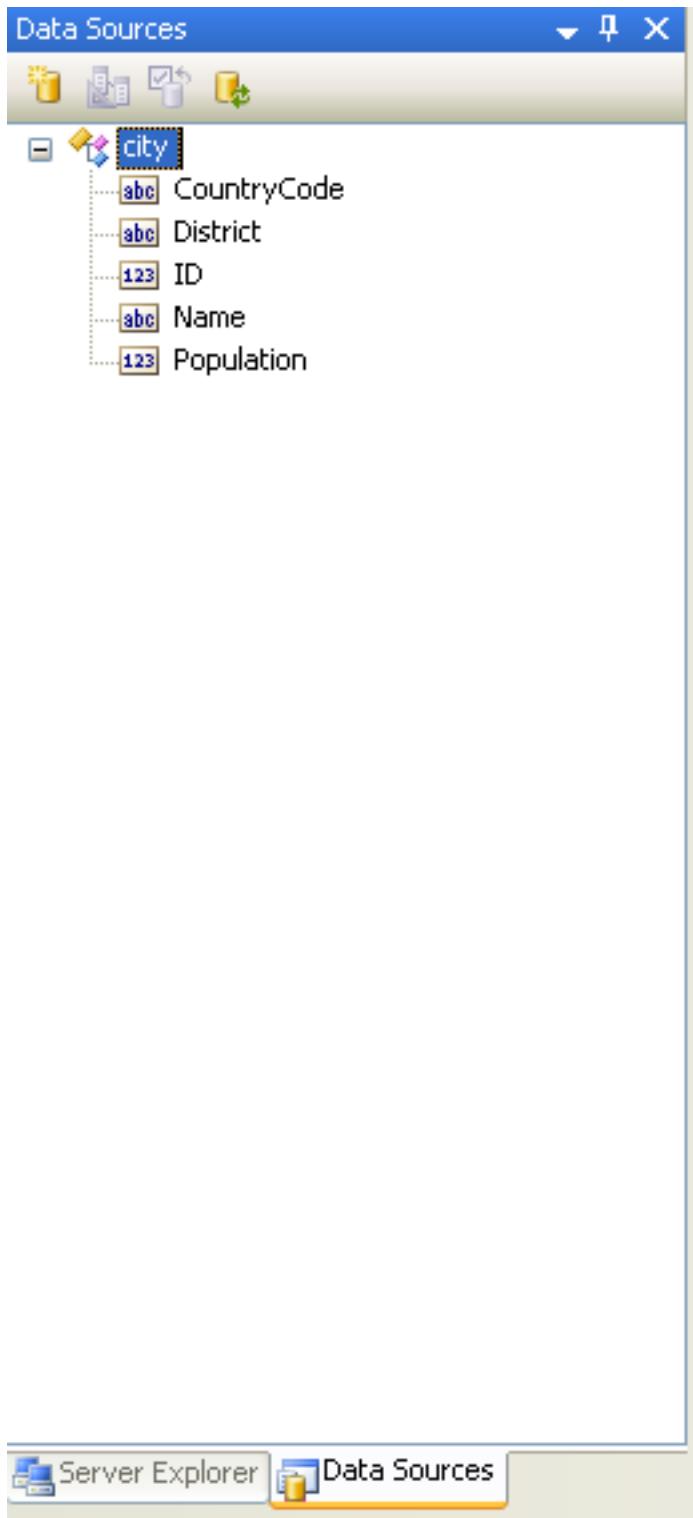

4. The wizard will confirm that the city object is to be added. Click FINISH.

**Figure 21.45. Entity Data Source Configuration Wizard Screen 3**

5. The city object will be display in the Data Sources panel. If the Data Sources panel is not displayed, select DATA, SHOW DATA SOURCES from the Visual Studio main menu. The docked panel will then be displayed.

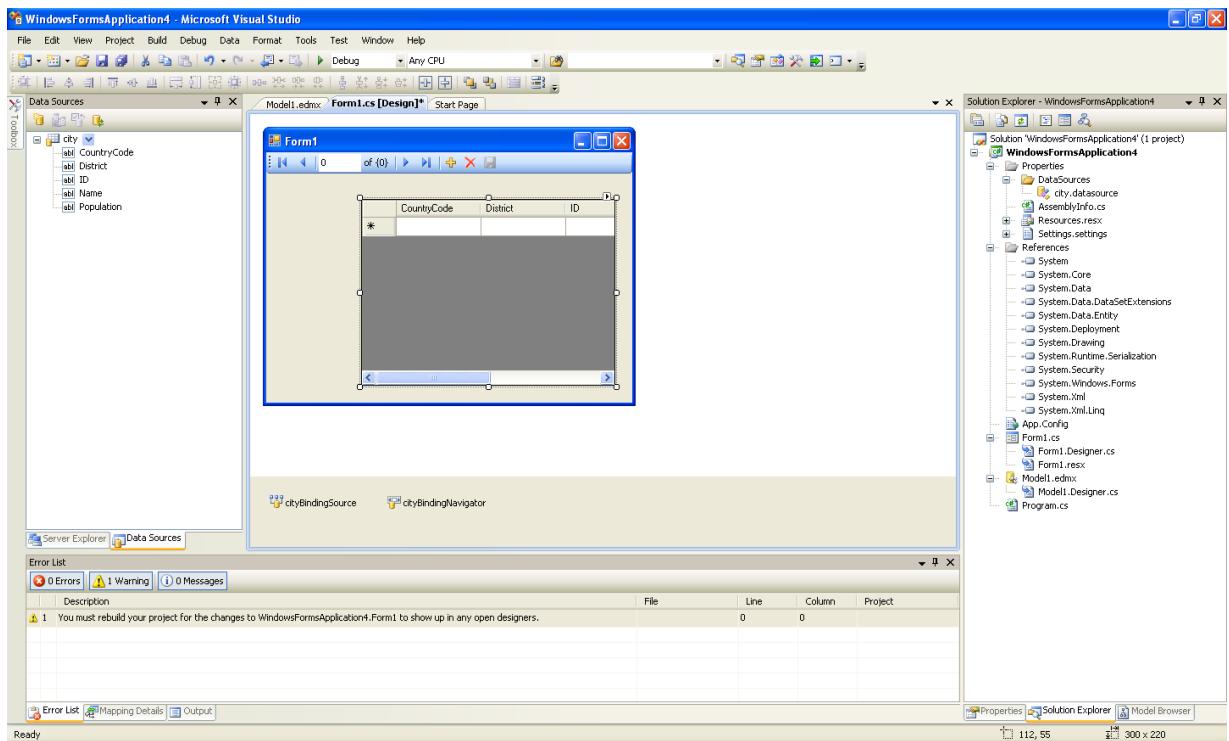

**Figure 21.46. Data Sources**

### Using the Data Source in a Windows Form

You will now learn how to use the Data Source in a Windows Form.

1. In the Data Sources panel select the Data Source you just created and drag and drop it onto the Form Designer. By default the Data Source object will be added as a Data Grid View control. Note that the Data Grid View control is bound to the `cityBindingSource` and the Navigator control is bound to `cityBindingNavigator`.

**Figure 21.47. Data Form Designer**

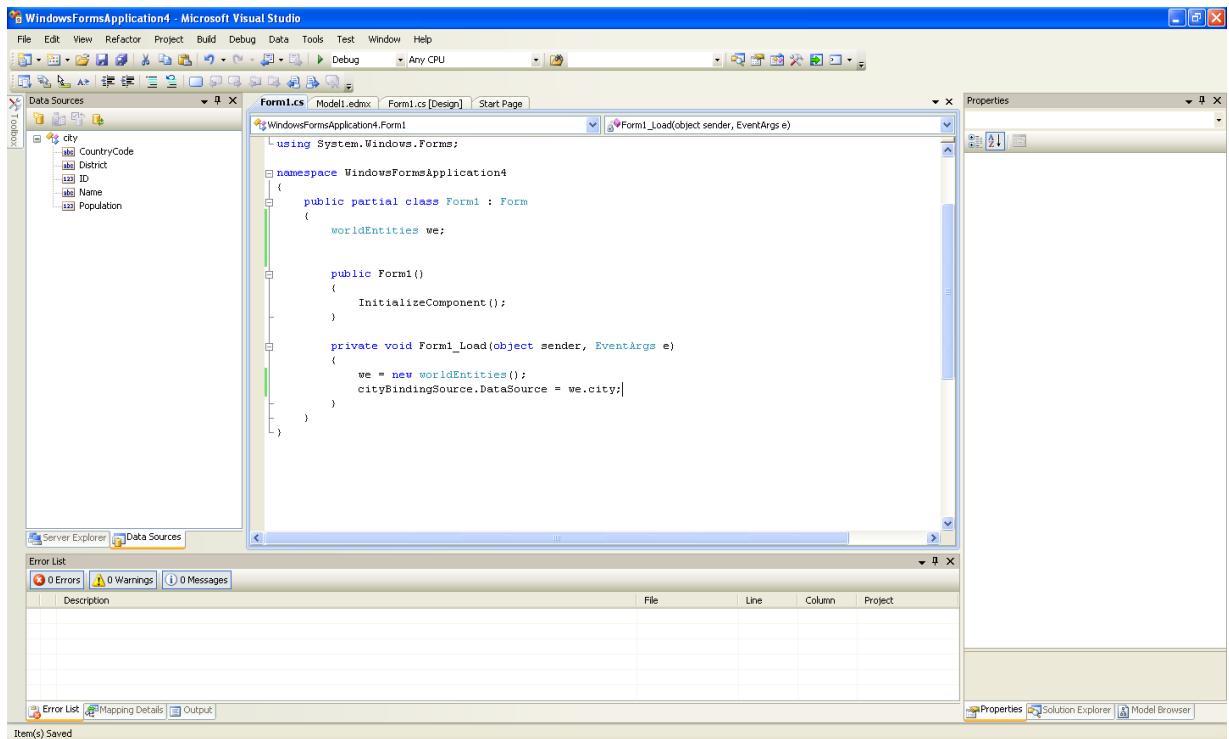

2. Save and rebuild the solution before continuing.

#### Adding Code to Populate the Data Grid View

You are now ready to add code to ensure that the Data Grid View control will be populated with data from the City database table.

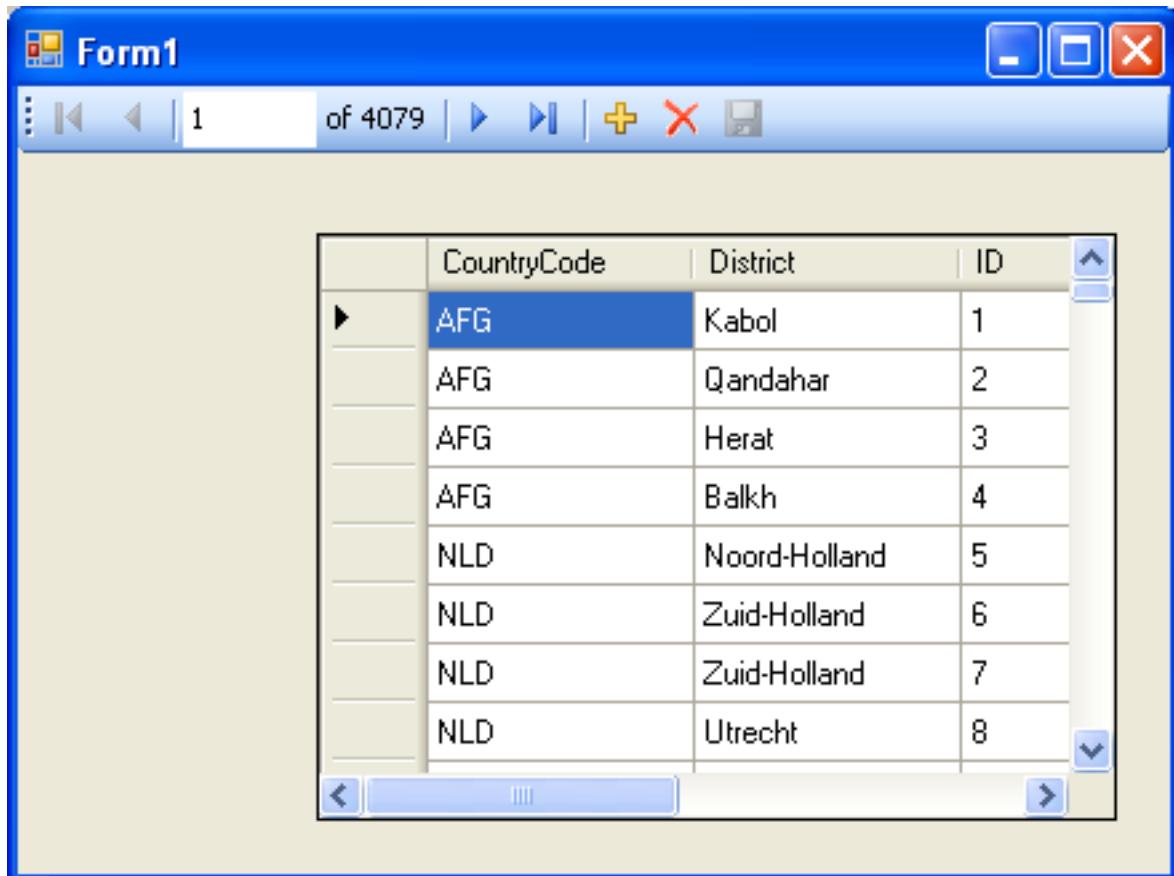

1. Double-click the form to access its code.
2. Add code to instantiate the Entity Data Model's EntityContainer object and retrieve data from the database to populate the control.

**Figure 21.48. Adding Code to the Form**

3. Save and rebuild the solution.
4. Run the solution. Ensure the grid is populated and you can navigate the database.

**Figure 21.49. The Populated Grid Control**

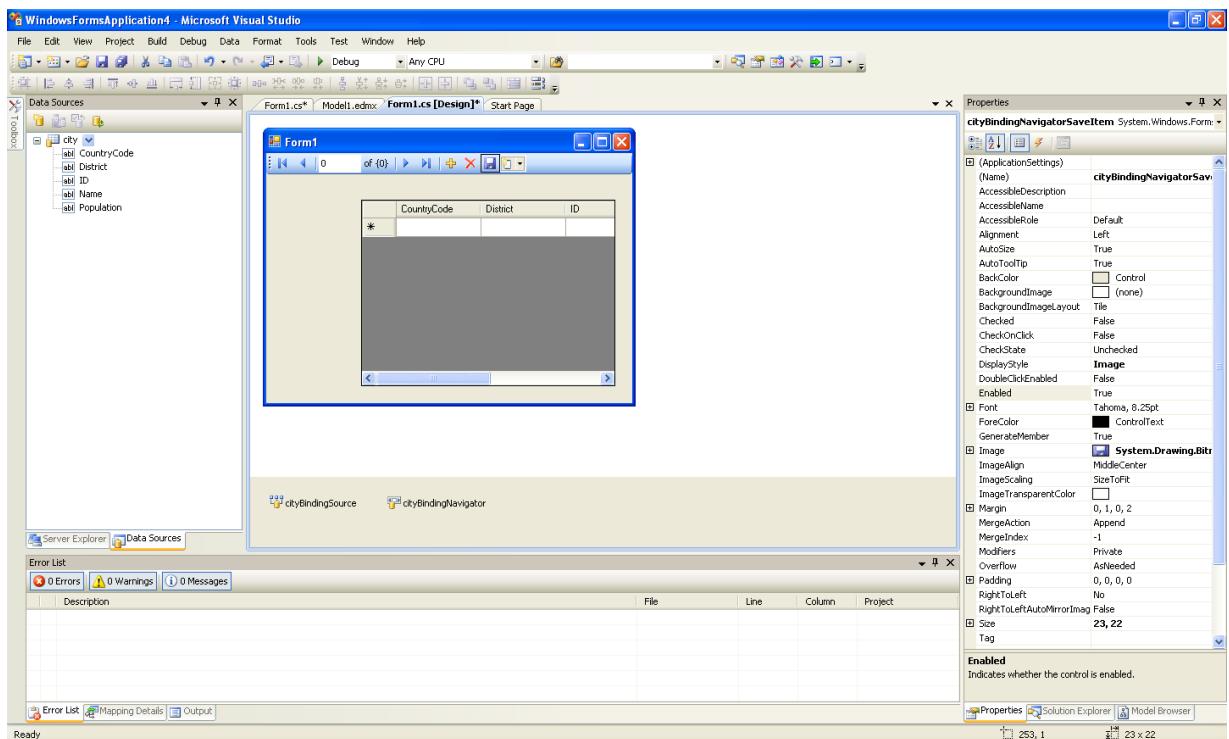

### Adding Code to Save Changes to the Database

You will now add code to enable you to save changes to the database.

The Binding source component ensures that changes made in the Data Grid View control are also made to the Entity classes bound to it. However, that data needs to be saved back from the entities to the database itself. This can be achieved by the enabling of the Save button in the Navigator control, and the addition of some code.

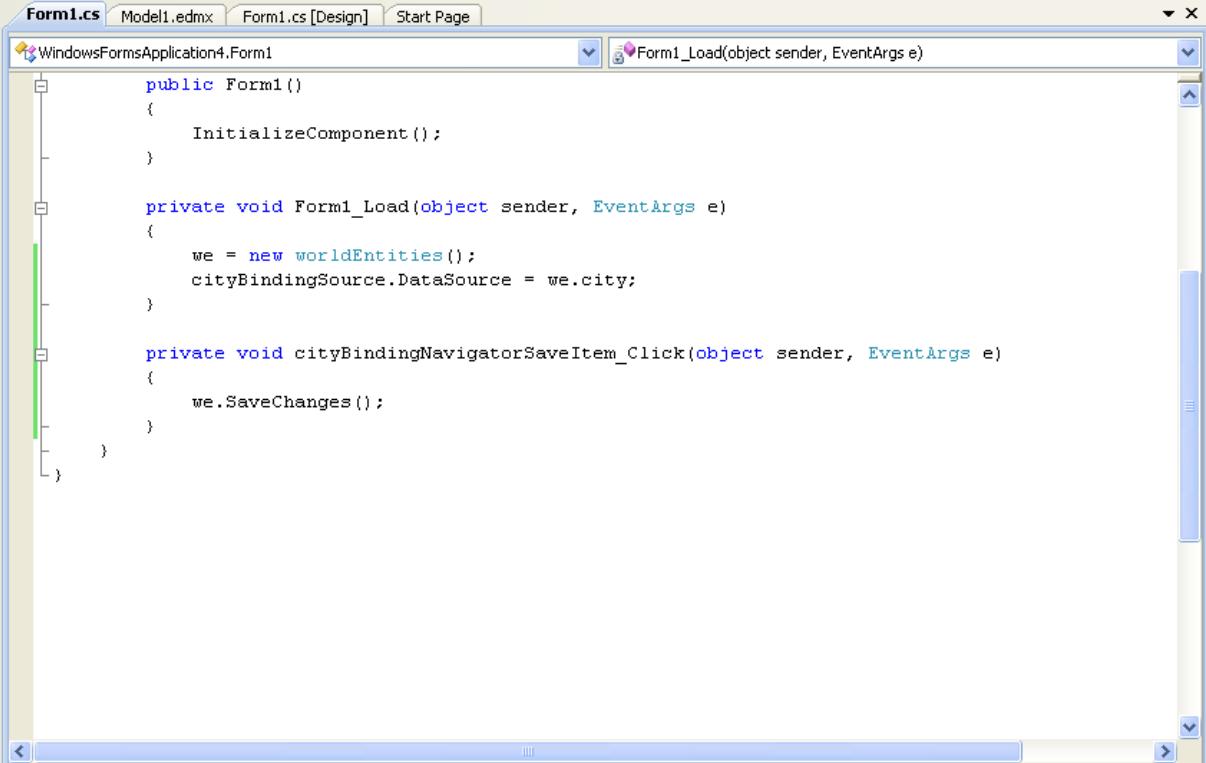

1. In the Form Designer, click the Save icon in the Form toolbar and ensure that its Enabled property is set to True.

**Figure 21.50. Save Button Enabled**

2. Double-click the Save icon in the Form toolbar to display its code.
3. You now need to add code to ensure that data is saved to the database when the save button is clicked in the application.

**Figure 21.51. Adding Save Code to the Form**

```

Form1.cs Model1.edmx Form1.cs [Design] Start Page
WindowsFormsApplication4.Form1 Form1_Load(object sender, EventArgs e)
public Form1()
{
 InitializeComponent();
}

private void Form1_Load(object sender, EventArgs e)
{
 we = new worldEntities();
 cityBindingSource.DataSource = we.city;
}

private void cityBindingNavigatorSaveItem_Click(object sender, EventArgs e)
{
 we.SaveChanges();
}

```

- Once the code has been added, save the solution and rebuild it. Run the application and verify that changes made in the grid are saved.

#### 21.2.4.6. Tutorial: Databinding in ASP.NET using LINQ on Entities

In this tutorial you create an ASP.NET web page that binds LINQ queries to entities using the Entity Framework mapping.

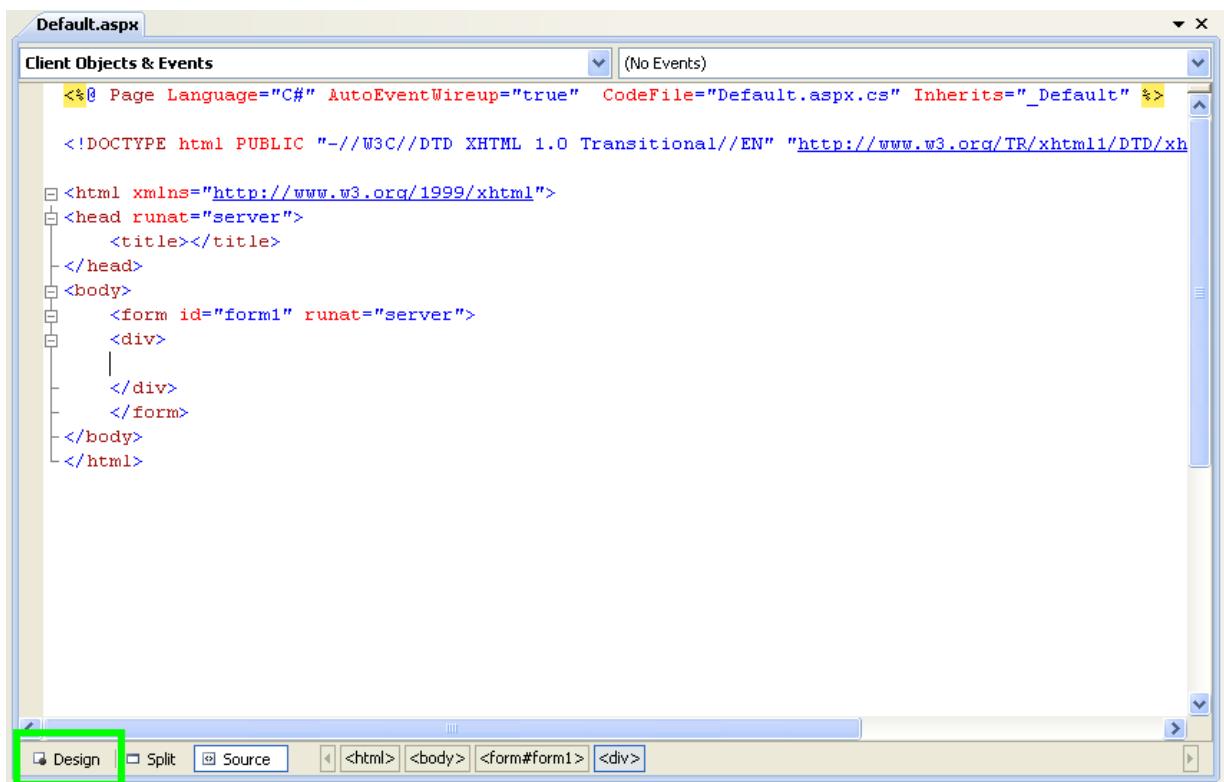

If you have not already done so, you should install the World example database prior to attempting this tutorial. Instructions on where to obtain the database and instructions on how to install it where given in the tutorial [Section 21.2.4.5, “Tutorial: Using an Entity Framework Entity as a Windows Forms Data Source”](#).

##### Creating an ASP.NET web site

In this part of the tutorial you will create an ASP.NET web site. The web site will use the World database. The main web page will feature a drop down list from which you can select a country, data about that country's cities will then be displayed in a grid view control.

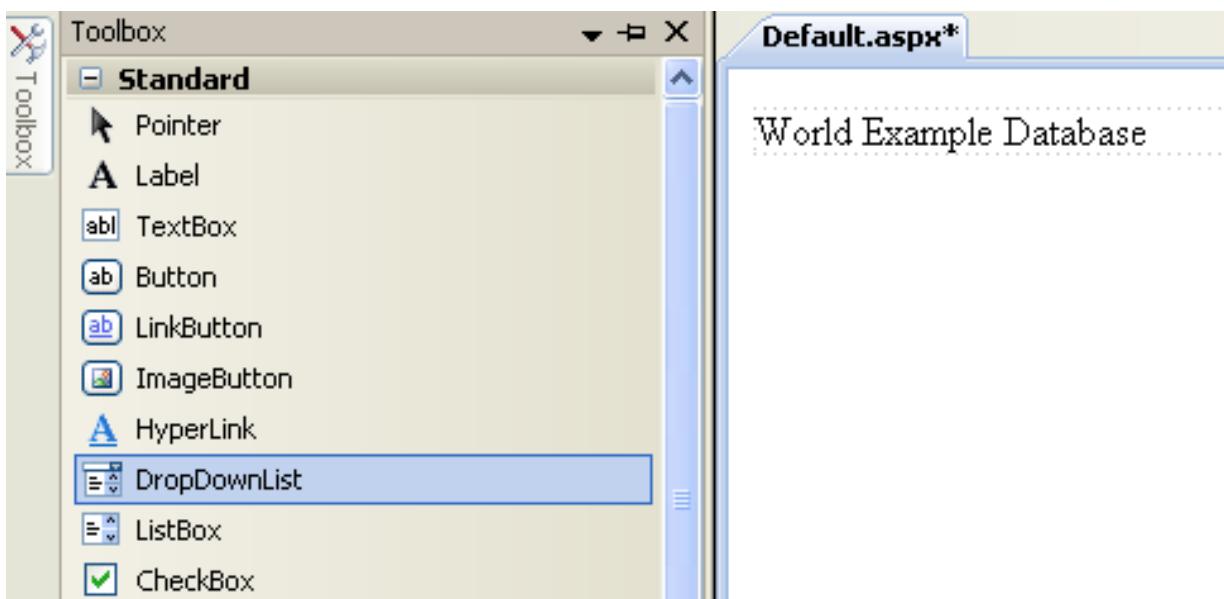

- From the Visual Studio main menu select **FILE, NEW, WEB SITE...**
- From the Visual Studio installed templates select **ASP.NET WEB SITE**. Click OK. You will be presented with the Source view of your web page by default.
- Click the Design view tab situated underneath the Source view panel.

**Figure 21.52. The Design Tab**

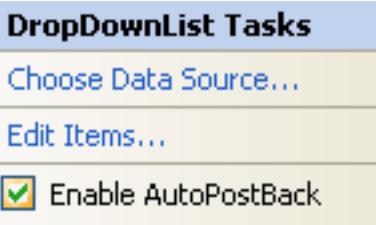

4. In the Design view panel, enter some text to decorate the blank web page.
5. Click Toolbox. From the list of controls select **DROPDOWNLIST**. Drag and drop the control to a location beneath the text on your web page.

**Figure 21.53. Drop Down List**

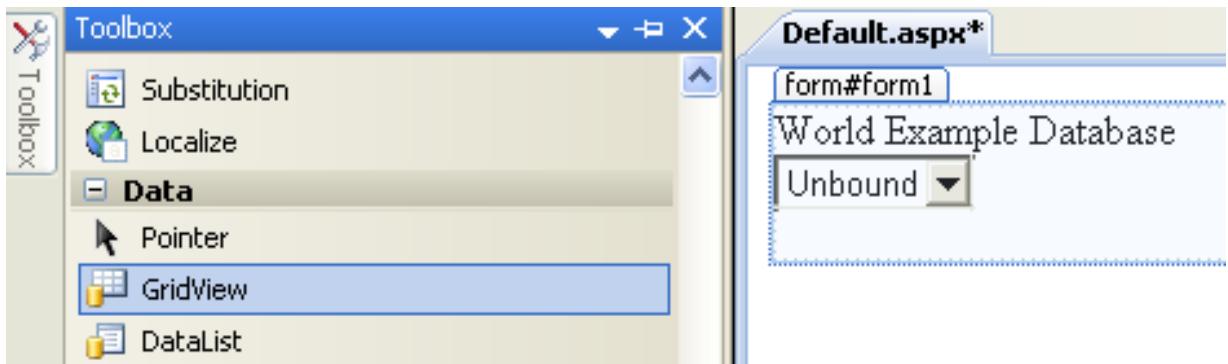

6. From the **DROPDOWNLIST** control's context menu, ensure that the **ENABLE AUTOPOSTBACK** check box is enabled. This will ensure the control's event handler is called when an item is selected. The user's choice will in turn be used to populate the **GRIDVIEW** control.

**Figure 21.54. Enable AutoPostBack**

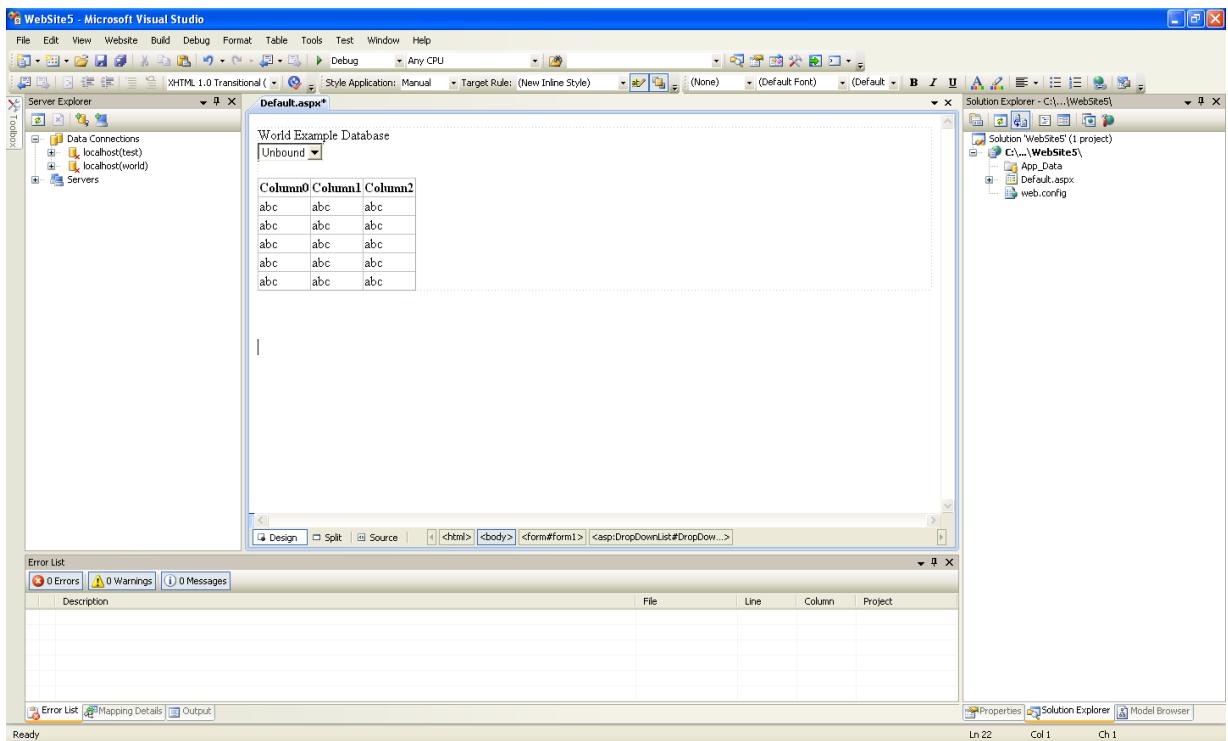

- From the Toolbox select the **GRIDVIEW** control.

**Figure 21.55. Grid View Control**

Drag and drop the Grid View control to a location just below the Drop Down List you already placed.

**Figure 21.56. Placed Grid View Control**

- At this point it is recommended that you save your solution, and build the solution to ensure that there are no errors.
- If you run the solution you will see that the text and drop down list are displayed, but the list is empty. Also, the grid view does not appear at all. Adding this functionality is described in the following sections.

At this stage you have a web site that will build, but further functionality is required. The next step will be to use the Entity Framework to create a mapping from the World database into entities that you can control programmatically.

### Creating an ADO.NET Entity Data Model

In this stage of the tutorial you will add an ADO.NET Entity Data Model to your project, using the World database at the storage level. The procedure for doing this is described in the tutorial [Section 21.2.4.5, “Tutorial: Using an Entity Framework Entity as a Windows Forms Data Source”](#), and so will not be repeated here.

### Populating a Drop Data List Box with using the results of a entity LINQ query

In this part of the tutorial you will write code to populate the DropDownList control. When the web page loads the data to populate the list will be achieved by using the results of a LINQ query on the model created previously.

1. In the Design view panel, double-click any blank area. This brings up the `Page_Load` method.
2. Modify the relevant section of code according to the following listing:

```
...
public partial class _Default : System.Web.UI.Page
{
 worldModel.worldEntities we;

 protected void Page_Load(object sender, EventArgs e)
 {
 we = new worldModel.worldEntities();

 if (!IsPostBack)
 {
 var countryQuery = from c in we.country
 orderby c.Name
 select new { c.Code, c.Name };
 DropDownList1.DataValueField = "Code";
 DropDownList1.DataTextField = "Name";
 DropDownList1.DataSource = countryQuery;
 DataBind();
 }
 }
...
}
```

Note that the list control only needs to be populated when the page first loads. The conditional code ensures that if the page is subsequently reloaded, the list control is not repopulated, which would cause the user selection to be lost.

3. Save the solution, build it and run it. You should see the list control has been populated. You can select an item, but as yet the grid view control does not appear.

At this point you have a working Drop Down List control, populated by a LINQ query on your entity data model.

### Populating a Grid View control using an entity LINQ query

In the last part of this tutorial you will populate the Grid View Control using a LINQ query on your entity data model.

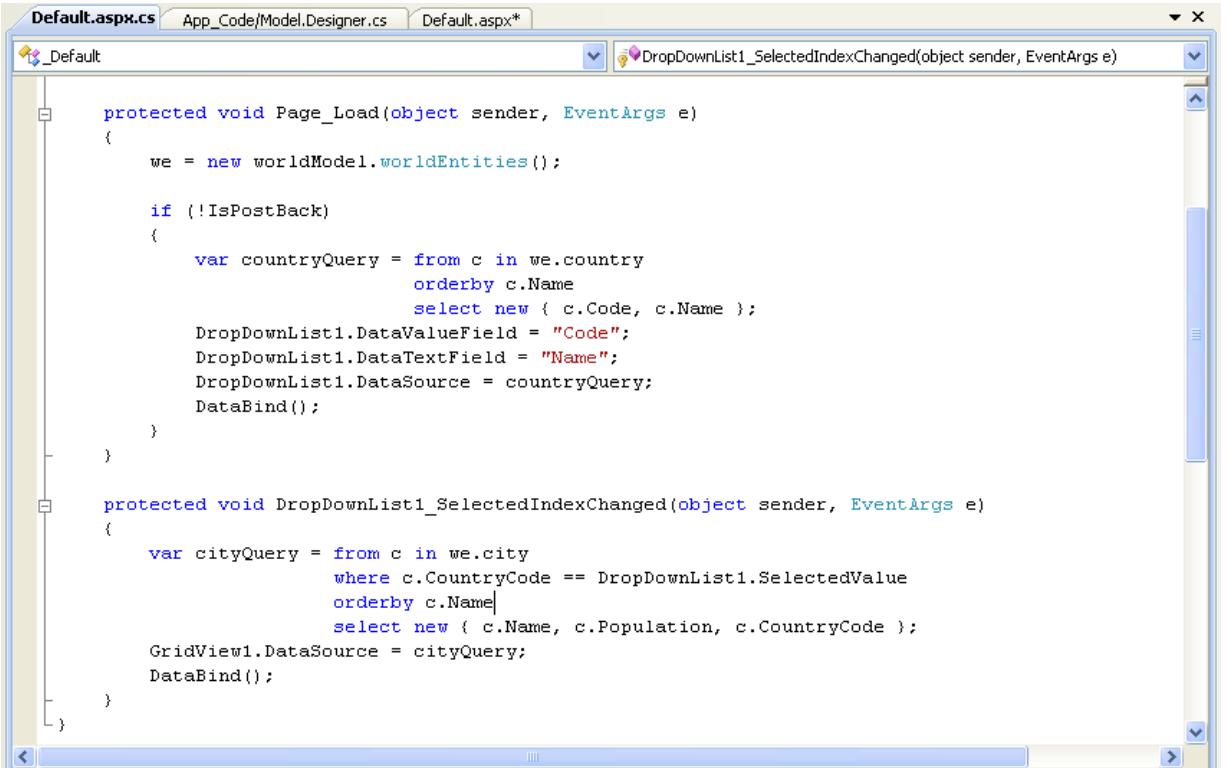

1. In the Design view, double-click the **DROPDOWNLIST** control. This causes its `SelectedIndexChanged` code to be displayed. This method is called when a user selects an item in the list control and thus fires an AutoPostBack event.
2. Modify the relevant section of code accordingly to the following listing:

```
...
protected void DropDownList1_SelectedIndexChanged(object sender, EventArgs e)
{
 var cityQuery = from c in we.city
 where c.CountryCode == DropDownList1.SelectedValue
 orderby c.Name
 select new { c.Name, c.Population, c.CountryCode };
 GridView1.DataSource = cityQuery;
 DataBind();
}
...
```

The grid view control is populated from the result of the LINQ query on the entity data model.

3. As a check compare your code to that shown in the following screenshot:

**Figure 21.57. Source Code**

The screenshot shows the Visual Studio IDE with the code editor open for the file Default.aspx.cs. The tab bar at the top has three tabs: Default.aspx.cs, App\_Code/Model.Designer.cs, and Default.aspx\*. The Default.aspx.cs tab is active. The code in the editor is as follows:

```
protected void Page_Load(object sender, EventArgs e)
{
 we = new worldModel.worldEntities();

 if (!IsPostBack)
 {
 var countryQuery = from c in we.country
 orderby c.Name
 select new { c.Code, c.Name };
 DropDownList1.DataValueField = "Code";
 DropDownList1.DataTextField = "Name";
 DropDownList1.DataSource = countryQuery;
 DataBind();
 }
}

protected void DropDownList1_SelectedIndexChanged(object sender, EventArgs e)
{
 var cityQuery = from c in we.city
 where c.CountryCode == DropDownList1.SelectedValue
 orderby c.Name
 select new { c.Name, c.Population, c.CountryCode };
 GridView1.DataSource = cityQuery;
 DataBind();
}
```

4. Save, build and run the solution. As you select a country you will see its cities are displayed in the grid view control.

**Figure 21.58. The Working Web Site**

The screenshot shows a Microsoft Internet Explorer browser window. The address bar displays the URL <http://localhost:1174/WebSite3/Default.aspx>. The main content area is titled "World Database Website". Below the title, there is a dropdown menu with the option "Belgium" selected. A table is displayed, showing data for cities in Belgium. The table has columns: Name, Population, and CountryCode. The data is as follows:

Name	Population	CountryCode
Antwerpen	446525	BEL
Brugge	116246	BEL
Bruxelles [Brussel]	133859	BEL
Charleroi	200827	BEL
Gent	224180	BEL
Liège	185639	BEL
Mons	90935	BEL
Namur	105419	BEL
Schaerbeek	105692	BEL

In this tutorial you have seen how to create an ASP.NET web site, you have also seen how you can access a MySQL database using LINQ queries on an entity data model.

#### 21.2.4.7. Tutorial: Using SSL with MySQL Connector/.NET

In this tutorial you will learn how you can use MySQL Connector/.NET to connect to a MySQL server configured to use SSL. Support for SSL client certificates was added with MySQL Connector/.NET 6.2.

MySQL Server uses the PEM format for certificates and private keys. This tutorial will use the test certificates from the server test suite by way of example. You can obtain the MySQL Server source code from [MySQL Downloads](#). The certificates can be found in the directory `./mysql-test/std_data`.

To carry out the steps in this tutorial you will also need to have Open SSL installed. This can be downloaded for Microsoft Windows at no charge from [Shining Light Productions](#).

Further details on the connection string options used in this tutorial can be found at [Section 21.2.6, “Connector/.NET Connection String Options Reference”](#).

##### Configuring the MySQL Server to use SSL

1. In the MySQL Server configuration file, set the SSL parameters as follows:

```
ssl-ca=path/to/repo/mysql-test/std_data/cacert.pem
ssl-cert=path/to/repo/mysql-test/std_data/server-cert.pem
ssl-key=path/to/repo/mysql-test/std_data/server-key.pem
```

Adjust the directories according to the location in which you installed the MySQL source code.

2. In this step you create a test user and set the user to require SSL.

Using the MySQL Command Line Client, connect as root and create the user `sslclient`.

3. To set privileges and requirements, issue the following command:

```
GRANT ALL PRIVILEGES ON *.* TO sslclient@'%' REQUIRE SSL;
```

### Creating a certificate file to use with the .NET client

1. The .NET client does not use the PEM file format, as .NET does not support this format natively. You will be using test client certificates from the same server repository, for the purposes of this example. You will need to convert these to PFX format first. This format is also known as PKCS#12. An article describing this procedure can be found at the [Citrix website](#). From the directory `server-repository-root/mysql-test/std_data`, issue the following command:

```
openssl pkcs12 -export -in client-cert.pem -inkey client-key.pem -certfile cacert.pem -out client.pfx
```

2. When asked for an export password, enter the password “pass”. The file `client.pfx` will be generated. This file is used in the remainder of the tutorial.

### Connecting to the server using a file-based certificate

1. You will use PFX file, `client.pfx` you created in the previous step to authenticate the client. The following example demonstrates how to connect using the `SSL Mode`, `CertificateFile` and `CertificatePassword` connection string options:

```
using (MySqlConnection connection = new MySqlConnection(
 "database=test;user=sslclient;" +
 "CertificateFile=H:\bzxr\mysql-trunk\mysqltest\std_data\client.pfx" +
 "CertificatePassword=pass;" +
 "SSL Mode=Required"))
{
 connection.Open();
}
```

The path to the certificate file will need to be changed to reflect your individual installation.

### Connecting to the server using a store-based certificate

1. The first step is to import the PFX file, `client.pfx`, into the Personal Store. Double-click the file in Windows explorer. This launches the Certificate Import Wizard.
2. Follow the steps dictated by the wizard, and when prompted for the password for the PFX file, enter “pass”.
3. Click FINISH to close the wizard and import the certificate into the personal store.

### Examine certificates in the Personal Store

1. Start the Microsoft Management Console by entering `mmc.exe` at a command prompt.
2. Select FILE, ADD/REMOVE SNAP-IN. Click ADD. Select **CERTIFICATES** from the list of available snap-ins in the dialog.
3. Click ADD button in the dialog, and select the **MY USER ACCOUNT** radio button. This is used for personal certificates.
4. Click the FINISH button.
5. Click OK to close the Add/Remove Snap-in dialog.
6. You will now have **CERTIFICATES – CURRENT USER** displayed in the left panel of the Microsoft Management Console. Expand the Certificates - Current User tree item and select **PERSONAL, CERTIFICATES**. The right-hand panel will display a certificate issued to MySQL. This is the certificate that was previously imported. Double-click the certificate to display its details.

7. After you have imported the certificate to the Personal Store, you can use a more succinct connection string to connect to the database, as illustrated by the following code:

```
using (MySqlConnection connection = new MySqlConnection(
 "database=test;user=sslclient;" +
 "Certificate Store Location=CurrentUser;" +
 "SSL Mode=Required"))
{
 connection.Open();
}
```

#### Certificate Thumbprint Parameter

If you have a large number of certificates in your store, and many have the same Issuer, this can be a source of confusion and result in the wrong certificate being used. To alleviate this situation, there is an optional Certificate Thumbprint parameter that can additionally be specified as part of the connection string. As mentioned before, you can double-click a certificate in the Microsoft Management Console to display the certificate's details. When the Certificate dialog is displayed click the **DETAILS** tab and scroll down to see the thumbprint. The thumbprint will typically be a number such as `□47 94 36 00 9a 40 f3 01 7a 14 5c f8 47 9e 76 94 d7 aa de f0`. This thumbprint can be used in the connection string, as the following code illustrates:

```
using (MySqlConnection connection = new MySqlConnection(
 "database=test;user=sslclient;" +
 "Certificate Store Location=CurrentUser;" +
 "Certificate Thumbprint=479436009a40f3017a145cf8479e7694d7aadef0;" +
 "SSL Mode=Required"))
{
 connection.Open();
}
```

Spaces in the thumbprint parameter are optional and the value is case-insensitive.

### 21.2.4.8. Tutorial: Using MySqlScript

In this tutorial you will learn how to use the [MySqlScript](#) class. This class enables you to execute a series of statements. Depending on the circumstances, this can be more convenient than using the [MySqlCommand](#) approach.

Further details of the [MySqlScript](#) class can be found in the reference documentation supplied with MySQL Connector/.NET.

If you wish to run the example programs in this tutorial, you will need to set up a simple test database and table. This can be achieved using the MySQL Command Line Client or MySQL Workbench. Commands for the MySQL Command Line Client are given here:

1. `CREATE DATABASE TestDB;`
2. `USE TestDB;`
3. `CREATE TABLE TestTable (id INT NOT NULL PRIMARY KEY AUTO_INCREMENT, name VARCHAR(100));`

The main method of the [MySqlScript](#) class is the [Execute](#) method. This method causes the script (sequence of statements) assigned to the [Query](#) property of the [MySqlScript](#) object to be executed. Note the [Query](#) property can be set through the [MySqlScript](#) constructor or using the [Query](#) property. [Execute](#) returns the number of statements executed.

The [MySqlScript](#) object will execute the specified script on the connection set using the [Connection](#) property. Again, this property can be set directly or through the [MySqlScript](#) constructor. The following code snippets illustrate this:

```
string sql = "SELECT * FROM TestTable";
...
MySqlScript script = new MySqlScript(conn, sql);
...
MySqlScript script = new MySqlScript();
script.Query = sql;
script.Connection = conn;
...
script.Execute();
```

The [MySqlScript](#) class has several events associated with it. There are:

1. Error - generated in an error occurs.
2. ScriptCompleted - generated when the script successfully completes execution.

3. StatementExecuted - generated after each statement is executed.

It is possible to assign event handlers to each of these events. These user-provided routines will be called back should the connected event occur. The following code shows how the event handlers are set up.

```
script.Error += new MySqlScriptErrorHandler(script_Error);
script.ScriptCompleted += new EventHandler(script_ScriptCompleted);
script.StatementExecuted += new MySqlStatementExecutedEventHandler(script_StatementExecuted);
```

In VisualStudio you can use tab completion to fill out stub routines for you, to save typing. To do this start by typing, for example, “script.Error +=”. Then press **TAB**, and then press **TAB** again. The assignment will be completed, and a stub event handler created. A complete working example is shown below:

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;

using System.Data;
using MySql.Data;
using MySql.Data.MySqlClient;

namespace MySqlScriptTest
{
 class Program
 {
 static void Main(string[] args)
 {
 string connStr = "server=localhost;user=root;database=TestDB;port=3306;password=*****;";
 MySqlConnection conn = new MySqlConnection(connStr);

 try
 {
 Console.WriteLine("Connecting to MySQL...");
 conn.Open();

 string sql = "INSERT INTO TestTable(name) VALUES ('Superman');" +
 "INSERT INTO TestTable(name) VALUES ('Batman');" +
 "INSERT INTO TestTable(name) VALUES ('Wolverine');" +
 "INSERT INTO TestTable(name) VALUES ('Storm');";

 MySqlScript script = new MySqlScript(conn, sql);

 script.Error += new MySqlScriptErrorHandler(script_Error);
 script.ScriptCompleted += new EventHandler(script_ScriptCompleted);
 script.StatementExecuted += new MySqlStatementExecutedEventHandler(script_StatementExecuted);

 int count = script.Execute();

 Console.WriteLine("Executed " + count + " statement(s).");
 Console.WriteLine("Delimiter: " + script.Delimiter);
 }
 catch (Exception ex)
 {
 Console.WriteLine(ex.ToString());
 }

 conn.Close();
 Console.WriteLine("Done.");
 }

 static void script_StatementExecuted(object sender, MySqlScriptEventArgs args)
 {
 Console.WriteLine("script_StatementExecuted");
 }

 static void script_ScriptCompleted(object sender, EventArgs e)
 {
 //EventArgs e will be EventArgs.Empty for this method
 Console.WriteLine("script_ScriptCompleted!");
 }

 static void script_Error(Object sender, MySqlScriptEventArgs args)
 {
 Console.WriteLine("script_Error: " + args.Exception.ToString());
 }
 }
}
```

Note that in the `script_ScriptCompleted` event handler, the `EventArgs` parameter `e` will be `EventArgs.Empty`. In the case of the `ScriptCompleted` event there is no additional data to be obtained, which is why the event object is `EventArgs`.

#### 21.2.4.8.1. Using Delimiters with MySqlScript

Depending on the nature of the script, you may need control of the delimiter used to separate the statements that will make up a

script. The most common example of this is where you have a multi-statement stored routine as part of your script. In this case if the default delimiter of “;” is used you will get an error when you attempt to execute the script. For example, consider the following stored routine:

```
CREATE PROCEDURE test_routine()
BEGIN
 SELECT name FROM TestTable ORDER BY name;
 SELECT COUNT(name) FROM TestTable;
END
```

This routine actually needs to be executed on the MySQL Server as a single statement. However, with the default delimiter of “;”, the [MySqlScript](#) class would interpret the above as two statements, the first being:

```
CREATE PROCEDURE test_routine()
BEGIN
 SELECT name FROM TestTable ORDER BY name;
```

Executing this as a statement would generate an error. To solve this problem [MySqlScript](#) supports the ability to set a different delimiter. This is achieved through the Delimiter property. For example, you could set the delimiter to “??”, in which case the above stored routine would no longer generate an error when executed. Multiple statements can be delimited in the script, so for example, you could have a three statement script such as:

```
string sql = "DROP PROCEDURE IF EXISTS test_routine??" +
 "CREATE PROCEDURE test_routine() " +
 "BEGIN " +
 "SELECT name FROM TestTable ORDER BY name;" +
 "SELECT COUNT(name) FROM TestTable;" +
 "END??" +
 "CALL test_routine();"
```

You can change the delimiter back at any point by setting the Delimiter property. The following code shows a complete working example:

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;

using MySql.Data;
using MySql.Data.MySqlClient;

namespace ConsoleApplication8
{
 class Program
 {
 static void Main(string[] args)
 {
 string connStr = "server=localhost;user=root;database=TestDB;port=3306;password=*****;";
 MySqlConnection conn = new MySqlConnection(connStr);

 try
 {
 Console.WriteLine("Connecting to MySQL...");
 conn.Open();

 string sql = "DROP PROCEDURE IF EXISTS test_routine??" +
 "CREATE PROCEDURE test_routine() " +
 "BEGIN " +
 "SELECT name FROM TestTable ORDER BY name;" +
 "SELECT COUNT(name) FROM TestTable;" +
 "END??" +
 "CALL test_routine();"

 MySqlScript script = new MySqlScript(conn);

 script.Query = sql;
 script.Delimiter = "?";
 int count = script.Execute();
 Console.WriteLine("Executed " + count + " statement(s)");
 script.Delimiter = ";";
 Console.WriteLine("Delimiter: " + script.Delimiter);
 Console.WriteLine("Query: " + script.Query);
 }
 catch (Exception ex)
 {
 Console.WriteLine(ex.ToString());
 }

 conn.Close();
 Console.WriteLine("Done.");
 }
 }
}
```

## 21.2.4.9. Tutorial: Generating MySQL DDL from an Entity Framework Model

In this tutorial you will learn how to create MySQL DDL from an Entity Framework model. You will need to use Visual Studio 2010 and MySQL Connector/NET 6.3 to carry out this tutorial.

1. Create a new console application in Visual Studio 2010.
2. Using the **SOLUTION EXPLORER** add a reference to [MySql.Data.Entity](#).
3. From the **SOLUTION EXPLORER** select ADD, NEW ITEM. In the **ADD NEW ITEM** dialog select **ONLINE TEMPLATES**. Select **ADO.NET ENTITY DATA MODEL** and click ADD. The **ENTITY DATA MODEL** dialog will be displayed.
4. In the **ENTITY DATA MODEL** dialog select **EMPTY MODEL**. Click FINISH. A blank model will be created.
5. Create a simple model. A single Entity will do for the purposes of this tutorial.
6. In the **PROPERTIES** panel select CONCEPTUALENTITYMODEL from the drop-down listbox.
7. In the **PROPERTIES** panel, locate the **DDL GENERATION TEMPLATE** in the category **DATABASE SCRIPT GENERATION**.
8. For the **DDL GENERATION** property select SSDLToMySQL.tt(VS) from the drop-down listbox.
9. Save the solution.
10. Right-click an empty space in the model design area. The context-sensitive menu will be displayed.
11. From the context-sensitive menu select GENERATE DATABASE FROM MODEL. The **GENERATE DATABASE WIZARD** dialog will be displayed.
12. In the **GENERATE DATABASE WIZARD** dialog select an existing connection, or create a new connection to a server. Select an appropriate radio button to show or hide sensitive data. For the purposes of this tutorial you can select **YES** (although you may not want to do this for commercial applications).
13. Click **NEXT**. MySQL compatible DDL code will be generated. Click **FINISH** to exit the wizard.

You have seen how to create MySQL DDL code from an Entity Framework model.

## 21.2.5. Connector/NET Programming

Connector/NET comprises several classes that are used to connect to the database, execute queries and statements, and manage query results.

The following are the major classes of Connector/NET:

- [MySqlCommand](#): Represents an SQL statement to execute against a MySQL database.
- [MySqlCommandBuilder](#): Automatically generates single-table commands used to reconcile changes made to a DataSet with the associated MySQL database.
- [MySqlConnection](#): Represents an open connection to a MySQL Server database.
- [MySqlDataAdapter](#): Represents a set of data commands and a database connection that are used to fill a data set and update a MySQL database.
- [MySqlDataReader](#): Provides a means of reading a forward-only stream of rows from a MySQL database.
- [MySqlException](#): The exception that is thrown when MySQL returns an error.
- [MySqlHelper](#): Helper class that makes it easier to work with the provider.
- [MySqlTransaction](#): Represents an SQL transaction to be made in a MySQL database.

In the following sections you will learn about some common use cases for Connector/NET, including BLOB handling, date handling, and using Connector/NET with common tools such as Crystal Reports.

### 21.2.5.1. Connecting to MySQL Using Connector/NET

#### Introduction

All interaction between a .NET application and the MySQL server is routed through a `MySqlConnection` object. Before your application can interact with the server, a `MySqlConnection` object must be instanced, configured, and opened.

Even when using the `MySqlHelper` class, a `MySqlConnection` object is created by the helper class.

In this section, we will describe how to connect to MySQL using the `MySqlConnection` object.

## 21.2.5.2. Creating a Connection String

The `MySqlConnection` object is configured using a connection string. A connection string contains sever key/value pairs, separated by semicolons. Each key/value pair is joined with an equal sign.

The following is a sample connection string:

```
Server=127.0.0.1;Uid=root;Pwd=12345;Database=test;
```

In this example, the `MySqlConnection` object is configured to connect to a MySQL server at `127.0.0.1`, with a user name of `root` and a password of `12345`. The default database for all statements will be the `test` database.

The following options are available:

### Note

Using the '@' symbol for parameters is now the preferred approach although the old pattern of using '?' is still supported.

Please be aware however that using '@' can cause conflicts when user variables are also used. To help with this situation please see the documentation on the `Allow User Variables` connection string option, which can be found here: [Section 21.2.5.2, “Creating a Connection String”](#). The `Old Syntax` connection string option has now been deprecated.

## 21.2.5.2.1. Opening a Connection

Once you have created a connection string it can be used to open a connection to the MySQL server.

The following code is used to create a `MySqlConnection` object, assign the connection string, and open the connection.

Visual Basic Example

```
Dim conn As New MySql.Data.MySqlClient.MySqlConnection
Dim myConnectionString as String

myConnectionString = "server=127.0.0.1;" _
 & "uid=root;" _
 & "pwd=12345;" _
 & "database=test;"

Try
 conn.ConnectionString = myConnectionString
 conn.Open()

Catch ex As MySql.Data.MySqlClient.MySqlException
 MessageBox.Show(ex.Message)
End Try
```

C# Example

```
MySql.Data.MySqlClient.MySqlConnection conn;
string myConnectionString;

myConnectionString = "server=127.0.0.1;uid=root;" +
 "pwd=12345;database=test;";

try
{
 conn = new MySql.Data.MySqlClient.MySqlConnection();
 conn.ConnectionString = myConnectionString;
 conn.Open();
}
catch (MySql.Data.MySqlClient.MySqlException ex)
{
 MessageBox.Show(ex.Message);
}
```

You can also pass the connection string to the constructor of the `MySqlConnection` class:

### Visual Basic Example

```
Dim myConnectionString as String
myConnectionString = "server=127.0.0.1;" _
 & "uid=root;" _
 & "pwd=12345;" _
 & "database=test;"

Try
 Dim conn As New MySql.Data.MySqlClient.MySqlConnection(myConnectionString)
 conn.Open()
Catch ex As MySql.Data.MySqlClient.MySqlException
 MessageBox.Show(ex.Message)
End Try
```

### C# Example

```
MySql.Data.MySqlClient.MySqlConnection conn;
string myConnectionString;

myConnectionString = "server=127.0.0.1;uid=root;" +
 "pwd=12345;database=test;";

try
{
 conn = new MySql.Data.MySqlClient.MySqlConnection(myConnectionString);
 conn.Open();
}
catch (MySql.Data.MySqlClient.MySqlException ex)
{
 MessageBox.Show(ex.Message);
}
```

Once the connection is open it can be used by the other Connector/.NET classes to communicate with the MySQL server.

#### 21.2.5.2.2. Handling Connection Errors

Because connecting to an external server is unpredictable, it is important to add error handling to your .NET application. When there is an error connecting, the `MySqlConnection` class will return a `MySqlException` object. This object has two properties that are of interest when handling errors:

- `Message`: A message that describes the current exception.
- `Number`: The MySQL error number.

When handling errors, you can adapt your application's response based on the error number. The two most common error numbers when connecting are as follows:

- `0`: Cannot connect to server.
- `1045`: Invalid user name and/or password.

The following code shows how to adapt the application's response based on the actual error:

### Visual Basic Example

```
Dim myConnectionString as String
myConnectionString = "server=127.0.0.1;" _
 & "uid=root;" _
 & "pwd=12345;" _
 & "database=test;"

Try
 Dim conn As New MySql.Data.MySqlClient.MySqlConnection(myConnectionString)
 conn.Open()
Catch ex As MySql.Data.MySqlClient.MySqlException
 Select Case ex.Number
 Case 0
 MessageBox.Show("Cannot connect to server. Contact administrator")
 Case 1045
 MessageBox.Show("Invalid username/password, please try again")
 End Select
End Try
```

### C# Example

```
MySql.Data.MySqlClient.MySqlConnection conn;
string myConnectionString;

myConnectionString = "server=127.0.0.1;uid=root;" +
 "pwd=12345;database=test;";

try
{
 conn = new MySql.Data.MySqlClient.MySqlConnection(myConnectionString);
 conn.Open();
}
catch (MySql.Data.MySqlClient.MySqlException ex)
{
 switch (ex.Number)
 {
 case 0:
 MessageBox.Show("Cannot connect to server. Contact administrator");
 case 1045:
 MessageBox.Show("Invalid username/password, please try again");
 }
}
```

### Important

Note that if you are using multilanguage databases you must specify the character set in the connection string. If you do not specify the character set, the connection defaults to the `latin1` charset. You can specify the character set as part of the connection string, for example:

```
MySqlConnection myConnection = new MySqlConnection("server=127.0.0.1;uid=root;" +
 "pwd=12345;database=test;Charset=latin1;");
```

## 21.2.5.2.3. Using GetSchema on a Connection

The `GetSchema()` method of the connection object can be used to retrieve schema information about the database currently connected to. The schema information is returned in the form of a `DataTable`. The schema information is organised into a number of collections. Different forms of the `GetSchema()` method can be used depending on the information required. There are three forms of the `GetSchema()` method:

- `GetSchema()` - This call will return a list of available collections.
- `GetSchema(String)` - This call returns information about the collection named in the string parameter. If the string “`MetaDataCollections`” is used then a list of all available collections is returned. This is the same as calling `GetSchema()` without any parameters.
- `GetSchema(String, String[])` - In this call the first string parameter represents the collection name, and the second parameter represents a string array of restriction values. Restriction values limit the amount of data that will be returned. Restriction values are explained in more detail in the [Microsoft .NET documentation](#).

### 21.2.5.2.3.1. Collections

The collections can be broadly grouped into two types: collections that are common to all data providers, and collections specific to a particular provider.

#### Common

The following collections are common to all data providers:

- `MetaDataCollections`
- `DataSourceInformation`
- `DataTypes`
- `Restrictions`
- `ReservedWords`

#### Provider-specific

The following are the collections currently provided by MySQL Connector/NET, in addition to the common collections above:

- Databases
- Tables
- Columns
- Users
- Foreign Keys
- IndexColumns
- Indexes
- Foreign Key Columns
- UDF
- Views
- ViewColumns
- Procedure Parameters
- Procedures
- Triggers

### Example Code

A list of available collections can be obtained using the following code:

```
using System;
using System.Data;
using System.Text;
using MySql.Data;
using MySql.Data.MySqlClient;

namespace ConsoleApplication2
{
 class Program
 {

 private static void DisplayData(System.Data.DataTable table)
 {
 foreach (System.Data DataRow row in table.Rows)
 {
 foreach (System.Data DataColumn col in table.Columns)
 {
 Console.WriteLine("{0} = {1}", col.ColumnName, row[col]);
 }
 Console.WriteLine("=====");
 }
 }

 static void Main(string[] args)
 {

 string connStr = "server=localhost;user=root;database=world;port=3306;password=*****";
 MySqlConnection conn = new MySqlConnection(connStr);

 try
 {
 Console.WriteLine("Connecting to MySQL...");
 conn.Open();

 DataTable table = conn.GetSchema("MetaDataCollections");
 //DataTable table = conn.GetSchema("UDF");
 DisplayData(table);

 conn.Close();
 }
 catch (Exception ex)
 {
 Console.WriteLine(ex.ToString());
 }
 Console.WriteLine("Done.");
 }
 }
}
```

Further information on the `GetSchema()` method and schema collections can be found in the [Microsoft .NET documentation](#).

### 21.2.5.3. Using MySqlCommand

A MySqlCommand has the `CommandText` and  `CommandType` properties associated with it. The `CommandText` will be handled differently depending on the setting of  `CommandType`.  `CommandType` can be one of:

1. Text - A SQL text command (default)
2. StoredProcedure - The name of a Stored Procedure
3. TableDirect - The name of a table (new in Connector/NET 6.2)

The default  `CommandType`, `Text`, is used for executing queries and other SQL commands. Some example of this can be found in the following section [Section 21.2.4.1.2, “The MySqlCommand Object”](#).

If  `CommandType` is set to  `StoredProcedure`,  `CommandText` should be set to the name of the Stored Procedure to access.

If  `CommandType` is set to  `TableDirect`, all rows and columns of the named table will be returned when you call one of the  `Execute` methods. In effect, this command performs a  `SELECT *` on the table specified. The  `CommandText` property is set to the name of the table you wish to query. This is illustrated by the following code snippet:

```
...
MySqlCommand cmd = new MySqlCommand();
cmd.CommandText = "mytable";
cmd.Connection = someConnection;
cmd.CommandType = CommandType.TableDirect;
SqlDataReader reader = cmd.ExecuteReader();
while (reader.Read())
{
 Console.WriteLine(reader[0], reader[1]...);
}
...
```

Examples of using the  `CommandType` of  `StoredProcedure` can be found in the section [Section 21.2.5.6, “Accessing Stored Procedures with Connector/NET”](#).

Commands can have a timeout associated with them. This is useful as you may not want a situation were a command takes up an excessive amount of time. A timeout can be set using the  `CommandTimeout` property. The following code snippet sets a timeout of one minute:

```
MySqlCommand cmd = new MySqlCommand();
cmd.CommandTimeout = 60;
```

The default value is 30 secs. A value of 0 indicates an indefinite wait and should be avoided. Note the default command timeout can be changed using the connection string option `Default Command Timeout`.

Prior to MySQL Connector/NET 6.2,  `MySqlCommand.CommandTimeout` included user processing time, that is processing time not related to direct use of the connector. Timeout was implemented through a .NET Timer, that triggered after  `CommandTimeout` seconds. This timer consumed a thread.

MySQL Connector/NET 6.2 introduced timeouts that are aligned with how Microsoft handles  `SqlCommand.CommandTimeout`. This property is the cumulative timeout for all network reads and writes during command execution or processing of the results. A timeout can still occur in the  `MySqlReader.Read` method after the first row is returned, and does not include user processing time, only IO operations. The 6.2 implementation uses the underlying stream timeout facility, so is more efficient in that it does not require the additional timer thread as was the case with the previous implementation.

Further details on this can be found in the relevant [Microsoft documentation](#).

### 21.2.5.4. Using Connector/NET with Connection Pooling

The Connector/NET supports connection pooling. This is enabled by default, but can be turned off using connection string options. See [Section 21.2.5.2, “Creating a Connection String”](#) for further information.

Connection pooling works by keeping the native connection to the server live when the client disposes of a  `MySqlConnection`. Subsequently, if a new  `MySqlConnection` object is opened, it will be created from the connection pool, rather than creating a new native connection. This improves performance.

To work as designed, it is best to let the connection pooling system manage all connections. You should not create a globally accessible instance of  `MySqlConnection` and then manually open and close it. This interferes with the way the pooling works and

can lead to unpredictable results or even exceptions.

One approach that simplifies things is to avoid manually creating a `MySqlConnection` object. Instead use the overloaded methods that take a connection string as an argument. Using this approach, Connector/NET will automatically create, open, close and destroy connections, using the connection pooling system for best performance.

Typed Datasets and the `MembershipProvider` and `RoleProvider` classes use this approach. Most classes that have methods that take a `MySqlConnection` as an argument, also have methods that take a connection string as an argument. This includes `MySqlDataAdapter`.

Instead of manually creating `MySqlCommand` objects, you can use the static methods of the `MySqlHelper` class. These take a connection string as an argument, and they fully support connection pooling.

Starting with MySQL Connector/NET 6.2, there is a background job that runs every three minutes and removes connections from pool that have been idle (unused) for more than three minutes. The pool cleanup frees resources on both client and server side. This is because on the client side every connection uses a socket, and on the server side every connection uses a socket and a thread.

Prior to this change, connections were never removed from the pool, and the pool always contained the peak number of open connections. For example, a web application that peaked at 1000 concurrent database connections would consume 1000 threads and 1000 open sockets at the server, without ever freeing up those resources from the connection pool. Note, connections, no matter how old, will not be closed if the number of connections in the pool is less than or equal to the value set by the `Min Pool Size` connection string parameter.

## 21.2.5.5. Using the Connector/NET with Prepared Statements

### Introduction

As of MySQL 4.1, it is possible to use prepared statements with Connector/NET. Use of prepared statements can provide significant performance improvements on queries that are executed more than once.

Prepared execution is faster than direct execution for statements executed more than once, primarily because the query is parsed only once. In the case of direct execution, the query is parsed every time it is executed. Prepared execution also can provide a reduction of network traffic because for each execution of the prepared statement, it is necessary only to send the data for the parameters.

Another advantage of prepared statements is that it uses a binary protocol that makes data transfer between client and server more efficient.

### 21.2.5.5.1. Preparing Statements in Connector/NET

To prepare a statement, create a command object and set the `.CommandText` property to your query.

After entering your statement, call the `.Prepare` method of the `MySqlCommand` object. After the statement is prepared, add parameters for each of the dynamic elements in the query.

After you enter your query and enter parameters, execute the statement using the `.ExecuteNonQuery()`, `.ExecuteScalar()`, or `.ExecuteReader` methods.

For subsequent executions, you need only modify the values of the parameters and call the execute method again, there is no need to set the `.CommandText` property or redefine the parameters.

#### Visual Basic Example

```
Dim conn As New MySqlConnection
Dim cmd As New MySqlCommand

conn.ConnectionString = strConnection

Try
 conn.Open()
 cmd.Connection = conn

 cmd.CommandText = "INSERT INTO myTable VALUES(NULL, @number, @text)"
 cmd.Prepare()

 cmd.Parameters.AddWithValue("@number", 1)
 cmd.Parameters.AddWithValue("@text", "One")

 For i = 1 To 1000
 cmd.Parameters("@number").Value = i
 cmd.Parameters("@text").Value = "A string value"

 cmd.ExecuteNonQuery()
 Next
Catch ex As MySqlException
 MessageBox.Show("Error " & ex.Number & " has occurred: " & ex.Message, "Error", MessageBoxButtons.OK, MessageBoxIcon.Error)
End Try
```

### C# Example

```

MySql.Data.MySqlClient.MySqlConnection conn;
MySql.Data.MySqlClient.MySqlCommand cmd;

conn = new MySql.Data.MySqlClient.MySqlConnection();
cmd = new MySql.Data.MySqlClient.MySqlCommand();

conn.ConnectionString = strConnection;

try
{
 conn.Open();
 cmd.Connection = conn;

 cmd.CommandText = "INSERT INTO myTable VALUES(NULL, @number, @text)";
 cmd.Prepare();

 cmd.Parameters.AddWithValue("@number", 1);
 cmd.Parameters.AddWithValue("@text", "One");

 for (int i=1; i <= 1000; i++)
 {
 cmd.Parameters["@number"].Value = i;
 cmd.Parameters["@text"].Value = "A string value";

 cmd.ExecuteNonQuery();
 }
}
catch (MySql.Data.MySqlClient.MySqlException ex)
{
 MessageBox.Show("Error " + ex.Number + " has occurred: " + ex.Message,
 "Error", MessageBoxButtons.OK, MessageBoxIcon.Error);
}

```

## 21.2.5.6. Accessing Stored Procedures with Connector/.NET

### Introduction

With the release of MySQL version 5 the MySQL server now supports stored procedures with the SQL 2003 stored procedure syntax.

A stored procedure is a set of SQL statements that can be stored in the server. Once this has been done, clients do not need to keep reissuing the individual statements but can refer to the stored procedure instead.

Stored procedures can be particularly useful in situations such as the following:

- When multiple client applications are written in different languages or work on different platforms, but need to perform the same database operations.
- When security is paramount. Banks, for example, use stored procedures for all common operations. This provides a consistent and secure environment, and procedures can ensure that each operation is properly logged. In such a setup, applications and users would not get any access to the database tables directly, but can only execute specific stored procedures.

Connector/.NET supports the calling of stored procedures through the `MySqlCommand` object. Data can be passed in and out of a MySQL stored procedure through use of the `MySqlCommand.Parameters` collection.

### Note

When you call a stored procedure, the command object makes an additional `SELECT` call to determine the parameters of the stored procedure. You must ensure that the user calling the procedure has the `SELECT` privilege on the `mysql.proc` table to enable them to verify the parameters. Failure to do this will result in an error when calling the procedure.

This section will not provide in-depth information on creating Stored Procedures. For such information, please refer to <http://dev.mysql.com/doc/mysql/en/stored-routines.html>.

A sample application demonstrating how to use stored procedures with Connector/.NET can be found in the `Samples` directory of your Connector/.NET installation.

### 21.2.5.6.1. Using Stored Routines from Connector/.NET

Stored procedures in MySQL can be created using a variety of tools. First, stored procedures can be created using the `mysql` command-line client. Second, stored procedures can be created using MySQL Workbench. Finally, stored procedures can be created using the `.ExecuteNonQuery` method of the `MySqlCommand` object.

It should be noted that, unlike the command-line and GUI clients, you are not required to specify a special delimiter when creating stored procedures in Connector/NET.

To call a stored procedure using Connector/NET, you create a `MySqlCommand` object and pass the stored procedure name as the `.CommandText` property. You then set the `. CommandType` property to `CommandType.StoredProcedure`.

After the stored procedure is named, you create one `MySqlCommand` parameter for every parameter in the stored procedure. `IN` parameters are defined with the parameter name and the object containing the value, `OUT` parameters are defined with the parameter name and the data type that is expected to be returned. All parameters need the parameter direction defined.

After defining the parameters, you call the stored procedure by using the `MySqlCommand.ExecuteNonQuery()` method.

Once the stored procedure is called, the values of the output parameters can be retrieved by using the `.Value` property of the `MySqlConnector.Parameters` collection.

### Note

When a stored procedure is called using `MySqlCommand.ExecuteReader`, and the stored procedure has output parameters, the output parameters are only set after the `MySqlDataReader` returned by `ExecuteReader` is closed.

The following C# example code demonstrates the use of stored procedures. It assumes the database 'employees' has already been created:

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;

using System.Data;
using MySql.Data;
using MySql.Data.MySqlClient;

namespace UsingStoredRoutines
{
 class Program
 {
 static void Main(string[] args)
 {
 MySqlConnection conn = new MySqlConnection();
 conn.ConnectionString = "server=localhost;user=root;database=employees;port=3306;password=*****";
 MySqlCommand cmd = new MySqlCommand();

 try
 {
 Console.WriteLine("Connecting to MySQL...");
 conn.Open();
 cmd.Connection = conn;
 cmd.CommandText = "DROP PROCEDURE IF EXISTS add_emp";
 cmd.ExecuteNonQuery();
 cmd.CommandText = "DROP TABLE IF EXISTS emp";
 cmd.ExecuteNonQuery();
 cmd.CommandText = "CREATE TABLE emp (empno INT UNSIGNED NOT NULL AUTO_INCREMENT PRIMARY KEY, first_name VARCHAR(20), last_name VARCHAR(20), bday DATETIME)";
 cmd.ExecuteNonQuery();

 cmd.CommandText = "CREATE PROCEDURE add_emp(" +
 "IN fname VARCHAR(20), IN lname VARCHAR(20), IN bday DATETIME, OUT empno INT)" +
 "BEGIN INSERT INTO emp(first_name, last_name, birthdate) " +
 "VALUES(fname, lname, DATE(bday)); SET empno = LAST_INSERT_ID(); END";

 cmd.ExecuteNonQuery();
 }
 catch (MySqlException ex)
 {
 Console.WriteLine("Error " + ex.Number + " has occurred: " + ex.Message);
 }
 conn.Close();
 Console.WriteLine("Connection closed.");
 try
 {
 Console.WriteLine("Connecting to MySQL...");
 conn.Open();
 cmd.Connection = conn;

 cmd.CommandText = "add_emp";
 cmd.CommandType = CommandType.StoredProcedure;

 cmd.Parameters.AddWithValue("@lname", "Jones");
 cmd.Parameters["@lname"].Direction = ParameterDirection.Input;

 cmd.Parameters.AddWithValue("@fname", "Tom");
 cmd.Parameters["@fname"].Direction = ParameterDirection.Input;

 cmd.Parameters.AddWithValue("@bday", "1940-06-07");
 cmd.Parameters["@bday"].Direction = ParameterDirection.Input;

 cmd.Parameters.AddWithValue("@empno", MySqlDbType.Int32);
 cmd.Parameters["@empno"].Direction = ParameterDirection.Output;
 }
 }
 }
}
```

```
 cmd.ExecuteNonQuery();

 Console.WriteLine("Employee number: " + cmd.Parameters["@empno"].Value);
 Console.WriteLine("Birthday: " + cmd.Parameters["@bdy"].Value);
 }
 catch (MySql.Data.MySqlClient.MySqlException ex)
 {
 Console.WriteLine("Error " + ex.Number + " has occurred: " + ex.Message);
 }
 conn.Close();
 Console.WriteLine("Done.");
}
}
```

The following code shows the same application in Visual Basic:

```

Imports System
Imports System.Collections.Generic
Imports System.Linq
Imports System.Text

Imports System.Data
Imports MySql.Data
Imports MySql.Data.MySqlClient

Module Module1

Sub Main()
 Dim conn As New MySqlConnection()
 conn.ConnectionString = "server=localhost;user=root;database=world;port=3306;password=*****;"
 Dim cmd As New MySqlCommand()

 Try
 Console.WriteLine("Connecting to MySQL...")
 conn.Open()
 cmd.Connection = conn
 cmd.CommandText = "DROP PROCEDURE IF EXISTS add_emp"
 cmd.ExecuteNonQuery()
 cmd.CommandText = "DROP TABLE IF EXISTS emp"
 cmd.ExecuteNonQuery()
 cmd.CommandText = "CREATE TABLE emp (empno INT UNSIGNED NOT NULL AUTO_INCREMENT PRIMARY KEY, first_name VARCHAR(20), last_name VARCHAR(20), bday DATE, salary DECIMAL(10,2), hire_date DATE)"
 cmd.ExecuteNonQuery()

 cmd.CommandText = "CREATE PROCEDURE add_emp(" & "IN fname VARCHAR(20), IN lname VARCHAR(20), IN bday DATE, IN salary DECIMAL(10,2))"
 cmd.ExecuteNonQuery()
 Catch ex As MySqlException
 Console.WriteLine(("Error " & ex.Number & " has occurred: ") + ex.Message)
 End Try
 conn.Close()
 Console.WriteLine("Connection closed.")

 Try
 Console.WriteLine("Connecting to MySQL...")
 conn.Open()
 cmd.Connection = conn

 cmd.CommandText = "add_emp"
 cmd.CommandType = CommandType.StoredProcedure

 cmd.Parameters.AddWithValue("@lname", "Jones")
 cmd.Parameters("@lname").Direction = ParameterDirection.Input

 cmd.Parameters.AddWithValue("@fname", "Tom")
 cmd.Parameters("@fname").Direction = ParameterDirection.Input

 cmd.Parameters.AddWithValue("@bday", "1940-06-07")
 cmd.Parameters("@bday").Direction = ParameterDirection.Input

 cmd.Parameters.AddWithValue("@empno", MySqlDbType.Int32)
 cmd.Parameters("@empno").Direction = ParameterDirection.Output

 cmd.ExecuteNonQuery()

 Console.WriteLine("Employee number: " & cmd.Parameters("@empno").Value)
 Console.WriteLine("Birthday: " & cmd.Parameters("@bday").Value)
 Catch ex As MySql.Data.MySqlClient.MySqlException
 Console.WriteLine(("Error " & ex.Number & " has occurred: ") + ex.Message)
 End Try
 conn.Close()
 Console.WriteLine("Done.")

End Sub

End Module

```

#### **21.2.5.7. Handling BLOB Data With Connector/NET**

## Introduction

One common use for MySQL is the storage of binary data in `BLOB` columns. MySQL supports four different `BLOB` data types: `TINYBLOB`, `BLOB`, `MEDIUMBLOB`, and `LONGBLOB`.

Data stored in a `BLOB` column can be accessed using Connector/NET and manipulated using client-side code. There are no special requirements for using Connector/NET with `BLOB` data.

Simple code examples will be presented within this section, and a full sample application can be found in the `Samples` directory of the Connector/NET installation.

### 21.2.5.7.1. Preparing the MySQL Server

The first step is using MySQL with `BLOB` data is to configure the server. Let's start by creating a table to be accessed. In my file tables, I usually have four columns: an `AUTO_INCREMENT` column of appropriate size (`UNSIGNED SMALLINT`) to serve as a primary key to identify the file, a `VARCHAR` column that stores the file name, an `UNSIGNED MEDIUMINT` column that stores the size of the file, and a `MEDIUMBLOB` column that stores the file itself. For this example, I will use the following table definition:

```
CREATE TABLE file(
 file_id SMALLINT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
 file_name VARCHAR(64) NOT NULL,
 file_size MEDIUMINT UNSIGNED NOT NULL,
 file MEDIUMBLOB NOT NULL);
```

After creating a table, you may need to modify the `max_allowed_packet` system variable. This variable determines how large of a packet (that is, a single row) can be sent to the MySQL server. By default, the server will only accept a maximum size of 1MB from our client application. If you do not intend to exceed 1MB, this should be fine. If you do intend to exceed 1MB in your file transfers, this number has to be increased.

The `max_allowed_packet` option can be modified using MySQL Administrator's Startup Variables screen. Adjust the Maximum permitted option in the Memory section of the Networking tab to an appropriate setting. After adjusting the value, click the `APPLY CHANGES` button and restart the server using the `Service Control` screen of MySQL Administrator. You can also adjust this value directly in the `my.cnf` file (add a line that reads `max_allowed_packet=xxM`), or use the `SET max_allowed_packet=xxM;` syntax from within MySQL.

Try to be conservative when setting `max_allowed_packet`, as transfers of `BLOB` data can take some time to complete. Try to set a value that will be adequate for your intended use and increase the value if necessary.

### 21.2.5.7.2. Writing a File to the Database

To write a file to a database we need to convert the file to a byte array, then use the byte array as a parameter to an `INSERT` query.

The following code opens a file using a `FileStream` object, reads it into a byte array, and inserts it into the `file` table:

#### Visual Basic Example

```
Dim conn As New MySqlConnection
Dim cmd As New MySqlCommand

Dim SQL As String

Dim FileSize As UInt32
Dim rawData() As Byte
Dim fs As FileStream

conn.ConnectionString = "server=127.0.0.1;" _
 & "uid=root;" _
 & "pwd=12345;" _
 & "database=test"

Try
 fs = New FileStream("c:\image.png", FileMode.Open, FileAccess.Read)
 FileSize = fs.Length

 rawData = New Byte(FileSize) {}
 fs.Read(rawData, 0, FileSize)
 fs.Close()

 conn.Open()

 SQL = "INSERT INTO file VALUES(NULL, @FileName, @FileSize, @File)"

 cmd.Connection = conn
 cmd.CommandText = SQL
 cmd.Parameters.AddWithValue("@FileName", strFileName)
 cmd.Parameters.AddWithValue("@FileSize", FileSize)
 cmd.Parameters.AddWithValue("@File", rawData)

 cmd.ExecuteNonQuery()

 MessageBox.Show("File Inserted into database successfully!", _
 "Success!", MessageBoxButtons.OK, MessageBoxIcon.Asterisk)
```

```

 conn.Close()
Catch ex As Exception
 MessageBox.Show("There was an error: " & ex.Message, "Error", _
 MessageBoxButtons.OK, MessageBoxIcon.Error)
End Try

```

### C# Example

```

MySql.Data.MySqlClient.MySqlConnection conn;
MySql.Data.MySqlClient.MySqlCommand cmd;

conn = new MySql.Data.MySqlClient.MySqlConnection();
cmd = new MySql.Data.MySqlClient.MySqlCommand();

string SQL;
UInt32 FileSize;
byte[] rawData;
FileStream fs;

conn.ConnectionString = "server=127.0.0.1;uid=root;" +
 "pwd=12345;database=test;";

try
{
 fs = new FileStream(@"c:\image.png", FileMode.Open, FileAccess.Read);
 FileSize = fs.Length;

 rawData = new byte[FileSize];
 fs.Read(rawData, 0, FileSize);
 fs.Close();

 conn.Open();

 SQL = "INSERT INTO file VALUES(NULL, @FileName, @FileSize, @File)";

 cmd.Connection = conn;
 cmd.CommandText = SQL;
 cmd.Parameters.AddWithValue("@FileName", strFileName);
 cmd.Parameters.AddWithValue("@FileSize", FileSize);
 cmd.Parameters.AddWithValue("@File", rawData);

 cmd.ExecuteNonQuery();

 MessageBox.Show("File Inserted into database successfully!",
 "Success!", MessageBoxButtons.OK, MessageBoxIcon.Asterisk);

 conn.Close();
}
catch (MySql.Data.MySqlClient.MySqlException ex)
{
 MessageBox.Show("Error " + ex.Number + " has occurred: " + ex.Message,
 "Error", MessageBoxButtons.OK, MessageBoxIcon.Error);
}

```

The `Read` method of the `FileStream` object is used to load the file into a byte array which is sized according to the `Length` property of the `FileStream` object.

After assigning the byte array as a parameter of the `MySqlCommand` object, the `ExecuteNonQuery` method is called and the BLOB is inserted into the `file` table.

### 21.2.5.7.3. Reading a BLOB from the Database to a File on Disk

Once a file is loaded into the `file` table, we can use the `MySqlDataReader` class to retrieve it.

The following code retrieves a row from the `file` table, then loads the data into a `FileStream` object to be written to disk:

#### Visual Basic Example

```

Dim conn As New MySqlConnection
Dim cmd As New MySqlCommand
Dim myData As MySqlDataReader
Dim SQL As String
Dim rawData() As Byte
Dim FileSize As UInt32
Dim fs As FileStream

conn.ConnectionString = "server=127.0.0.1;" _
 & "uid=root;" _
 & "pwd=12345;" _
 & "database=test"

SQL = "SELECT file_name, file_size, file FROM file"

Try
 conn.Open()

```

```

cmd.Connection = conn
cmd.CommandText = SQL

myData = cmd.ExecuteReader

If Not myData.HasRows Then Throw New Exception("There are no BLOBs to save")

myData.Read()

FileSize = myData.GetUInt32(myData.GetOrdinal("file_size"))
rawData = New Byte[FileSize] {}

myData.GetBytes(myData.GetOrdinal("file"), 0, rawData, 0, FileSize)

fs = New FileStream("C:\newfile.png", FileMode.OpenOrCreate, FileAccess.Write)
fs.Write(rawData, 0, FileSize)
fs.Close()

MessageBox.Show("File successfully written to disk!", "Success!", MessageBoxButtons.OK, MessageBoxIcon.Asterisk)

myData.Close()
conn.Close()
Catch ex As Exception
 MessageBox.Show("There was an error: " & ex.Message, "Error", MessageBoxButtons.OK, MessageBoxIcon.Error)
End Try

```

### C# Example

```

MySql.Data.MySqlClient.MySqlConnection conn;
MySql.Data.MySqlClient.MySqlCommand cmd;
MySql.Data.MySqlClient.MySqlDataReader myData;

conn = new MySql.Data.MySqlClient.MySqlConnection();
cmd = new MySql.Data.MySqlClient.MySqlCommand();

string SQL;
UInt32 FileSize;
byte[] rawData;
FileStream fs;

conn.ConnectionString = "server=127.0.0.1;uid=root;" +
 "pwd=12345;database=test";

SQL = "SELECT file_name, file_size, file FROM file";

try
{
 conn.Open();

 cmd.Connection = conn;
 cmd.CommandText = SQL;

 myData = cmd.ExecuteReader();

 if (! myData.HasRows)
 throw new Exception("There are no BLOBs to save");

 myData.Read();

 FileSize = myData.GetUInt32(myData.GetOrdinal("file_size"));
 rawData = new byte[FileSize];

 myData.GetBytes(myData.GetOrdinal("file"), 0, rawData, 0, FileSize);

 fs = new FileStream(@"C:\newfile.png", FileMode.OpenOrCreate, FileAccess.Write);
 fs.Write(rawData, 0, FileSize);
 fs.Close();

 MessageBox.Show("File successfully written to disk!",
 "Success!", MessageBoxButtons.OK, MessageBoxIcon.Asterisk);

 myData.Close();
 conn.Close();
}
catch (MySql.Data.MySqlClient.MySqlException ex)
{
 MessageBox.Show("Error " + ex.Number + " has occurred: " + ex.Message,
 "Error", MessageBoxButtons.OK, MessageBoxIcon.Error);
}

```

After connecting, the contents of the `file` table are loaded into a `MySqlDataReader` object. The `GetBytes` method of the `MySqlDataReader` is used to load the BLOB into a byte array, which is then written to disk using a `FileStream` object.

The `GetOrdinal` method of the `MySqlDataReader` can be used to determine the integer index of a named column. Use of the `GetOrdinal` method prevents errors if the column order of the `SELECT` query is changed.

## 21.2.5.8. Using Connector/.NET with Crystal Reports

## Introduction

Crystal Reports is a common tool used by Windows application developers to perform reporting and document generation. In this section we will show how to use Crystal Reports XI with MySQL and Connector/NET.

### 21.2.5.8.1. Creating a Data Source

When creating a report in Crystal Reports there are two options for accessing the MySQL data while designing your report.

The first option is to use Connector/ODBC as an ADO data source when designing your report. You will be able to browse your database and choose tables and fields using drag and drop to build your report. The disadvantage of this approach is that additional work must be performed within your application to produce a data set that matches the one expected by your report.

The second option is to create a data set in VB.NET and save it as XML. This XML file can then be used to design a report. This works quite well when displaying the report in your application, but is less versatile at design time because you must choose all relevant columns when creating the data set. If you forget a column you must re-create the data set before the column can be added to the report.

The following code can be used to create a data set from a query and write it to disk:

#### Visual Basic Example

```
Dim myData As New DataSet
Dim conn As New MySqlConnection
Dim cmd As New MySqlCommand
Dim myAdapter As New MySqlDataAdapter

conn.ConnectionString = "server=127.0.0.1;" +
 & "uid=root;" +
 & "pwd=12345;" +
 & "database=world"

Try
 conn.Open()
 cmd.CommandText = "SELECT city.name AS cityName, city.population AS CityPopulation, " +
 & "country.name, country.population, country.continent " +
 & "FROM country, city ORDER BY country.continent, country.name"
 cmd.Connection = conn

 myAdapter.SelectCommand = cmd
 myAdapter.Fill(myData)

 myData.WriteXml("C:\dataset.xml", XmlWriteMode.WriteSchema)
Catch ex As Exception
 MessageBox.Show(ex.Message, "Report could not be created", MessageBoxButtons.OK, MessageBoxIcon.Error)
End Try
```

#### C# Example

```
DataSet myData = new DataSet();
MySql.Data.MySqlClient.MySqlConnection conn;
MySql.Data.MySqlClient.MySqlCommand cmd;
MySql.Data.MySqlClient.MySqlDataAdapter myAdapter;

conn = new MySql.Data.MySqlClient.MySqlConnection();
cmd = new MySql.Data.MySqlClient.MySqlCommand();
myAdapter = new MySql.Data.MySqlClient.MySqlDataAdapter();

conn.ConnectionString = "server=127.0.0.1;uid=root;" +
 "pwd=12345;database=test;";

try
{
 cmd.CommandText = "SELECT city.name AS cityName, city.population AS CityPopulation, " +
 "country.name, country.population, country.continent " +
 "FROM country, city ORDER BY country.continent, country.name";
 cmd.Connection = conn;

 myAdapter.SelectCommand = cmd;
 myAdapter.Fill(myData);

 myData.WriteXml(@"C:\dataset.xml", XmlWriteMode.WriteSchema);
}
catch (MySql.Data.MySqlClient.MySqlException ex)
{
 MessageBox.Show(ex.Message, "Report could not be created",
 MessageBoxButtons.OK, MessageBoxIcon.Error);
}
```

The resulting XML file can be used as an ADO.NET XML datasource when designing your report.

If you choose to design your reports using Connector/ODBC, it can be downloaded from [dev.mysql.com](http://dev.mysql.com).

### 21.2.5.8.2. Creating the Report

For most purposes the Standard Report wizard should help with the initial creation of a report. To start the wizard, open Crystal Reports and choose the New > Standard Report option from the File menu.

The wizard will first prompt you for a data source. If you are using Connector/ODBC as your data source, use the OLEDB provider for ODBC option from the OLE DB (ADO) tree instead of the ODBC (RDO) tree when choosing a data source. If using a saved data set, choose the ADO.NET (XML) option and browse to your saved data set.

The remainder of the report creation process is done automatically by the wizard.

After the report is created, choose the Report Options... entry of the File menu. Un-check the Save Data With Report option. This prevents saved data from interfering with the loading of data within our application.

### 21.2.5.8.3. Displaying the Report

To display a report we first populate a data set with the data needed for the report, then load the report and bind it to the data set. Finally we pass the report to the crViewer control for display to the user.

The following references are needed in a project that displays a report:

- CrystalDecisions.CrystalReports.Engine
- CrystalDecisions.ReportSource
- CrystalDecisions.Shared
- CrystalDecisions.Windows.Forms

The following code assumes that you created your report using a data set saved using the code shown in [Section 21.2.5.8.1, "Creating a Data Source"](#), and have a crViewer control on your form named `myViewer`.

#### Visual Basic Example

```
Imports CrystalDecisions.CrystalReports.Engine
Imports System.Data
Imports MySql.Data.MySqlClient

Dim myReport As New ReportDocument
Dim myData As New DataSet
Dim conn As New MySqlConnection
Dim cmd As New MySqlCommand
Dim myAdapter As New MySqlDataAdapter

conn.ConnectionString = _
 "server=127.0.0.1;" _
 & "uid=root;" _
 & "pwd=12345;" _
 & "database=test"

Try
 conn.Open()

 cmd.CommandText = "SELECT city.name AS cityName, city.population AS CityPopulation, " _
 & "country.name, country.population, country.continent " _
 & "FROM country, city ORDER BY country.continent, country.name"
 cmd.Connection = conn

 myAdapter.SelectCommand = cmd
 myAdapter.Fill(myData)

 myReport.Load(".\world_report.rpt")
 myReport.SetDataSource(myData)
 myViewer.ReportSource = myReport
Catch ex As Exception
 MessageBox.Show(ex.Message, "Report could not be created", MessageBoxButtons.OK, MessageBoxIcon.Error)
End Try
```

#### C# Example

```
using CrystalDecisions.CrystalReports.Engine;
using System.Data;
using MySql.Data.MySqlClient;

ReportDocument myReport = new ReportDocument();
DataSet myData = new DataSet();
MySql.Data.MySqlClient.MySqlConnection conn;
MySql.Data.MySqlClient.MySqlCommand cmd;
MySql.Data.MySqlClient.MySqlDataAdapter myAdapter;
```

```

conn = new MySql.Data.MySqlClient.MySqlConnection();
cmd = new MySql.Data.MySqlClient.MySqlCommand();
myAdapter = new MySql.Data.MySqlClient.MySqlDataAdapter();

conn.ConnectionString = "server=127.0.0.1;uid=root;" +
 "pwd=12345;database=test;";

try
{
 cmd.CommandText = "SELECT city.name AS cityName, city.population AS CityPopulation, " +
 "country.name, country.population, country.continent " +
 "FROM country, city ORDER BY country.continent, country.name";
 cmd.Connection = conn;

 myAdapter.SelectCommand = cmd;
 myAdapter.Fill(myData);

 myReport.Load(@"..\world_report.rpt");
 myReport.SetDataSource(myData);
 myViewer.ReportSource = myReport;
}
catch (MySql.Data.MySqlClient.MySqlException ex)
{
 MessageBox.Show(ex.Message, "Report could not be created",
 MessageBoxButtons.OK, MessageBoxIcon.Error);
}

```

A new data set is generated using the same query used to generate the previously saved data set. Once the data set is filled, a ReportDocument is used to load the report file and bind it to the data set. The ReportDocument is passed as the ReportSource of the crViewer.

This same approach is taken when a report is created from a single table using Connector/ODBC. The data set replaces the table used in the report and the report is displayed properly.

When a report is created from multiple tables using Connector/ODBC, a data set with multiple tables must be created in our application. This enables each table in the report data source to be replaced with a report in the data set.

We populate a data set with multiple tables by providing multiple **SELECT** statements in our MySqlCommand object. These **SELECT** statements are based on the SQL query shown in Crystal Reports in the Database menu's Show SQL Query option. Assume the following query:

```

SELECT `country`.'Name', `country`.'Continent', `country`.'Population', `city`.'Name', `city`.'Population'
FROM `world`.`country` LEFT OUTER JOIN `world`.`city` ON `country`.'Code' = `city`.'CountryCode'
ORDER BY `country`.'Continent', `country`.'Name', `city`.'Name'

```

This query is converted to two **SELECT** queries and displayed with the following code:

#### Visual Basic Example

```

Imports CrystalDecisions.CrystalReports.Engine
Imports System.Data
Imports MySql.Data.MySqlClient

Dim myReport As New ReportDocument
Dim myData As New DataSet
Dim conn As New MySqlConnection
Dim cmd As New MySqlCommand
Dim myAdapter As New MySqlDataAdapter

conn.ConnectionString = "server=127.0.0.1;" _
 & "uid=root;" _
 & "pwd=12345;" _
 & "database=world"

Try
 conn.Open()
 cmd.CommandText = "SELECT name, population, countrycode FROM city ORDER BY countrycode, name;" _
 & "SELECT name, population, code, continent FROM country ORDER BY continent, name"
 cmd.Connection = conn

 myAdapter.SelectCommand = cmd
 myAdapter.Fill(myData)

 myReport.Load(".\world_report.rpt")
 myReport.Database.Tables(0).SetDataSource(myData.Tables(0))
 myReport.Database.Tables(1).SetDataSource(myData.Tables(1))
 myViewer.ReportSource = myReport
Catch ex As Exception
 MessageBox.Show(ex.Message, "Report could not be created", MessageBoxButtons.OK, MessageBoxIcon.Error)
End Try

```

#### C# Example

```

using CrystalDecisions.CrystalReports.Engine;
using System.Data;
using MySql.Data.MySqlClient;

```

```

ReportDocument myReport = new ReportDocument();
DataSet myData = new DataSet();
MySql.Data.MySqlClient.MySqlConnection conn;
MySql.Data.MySqlClient.MySqlCommand cmd;
MySql.Data.MySqlClient.MySqlDataAdapter myAdapter;

conn = new MySql.Data.MySqlClient.MySqlConnection();
cmd = new MySql.Data.MySqlClient.MySqlCommand();
myAdapter = new MySql.Data.MySqlClient.MySqlDataAdapter();

conn.ConnectionString = "server=127.0.0.1;uid=root;" +
 "pwd=12345;database=test;";

try
{
 cmd.CommandText = "SELECT name, population, countrycode FROM city ORDER " +
 "BY countrycode, name; SELECT name, population, code, continent FROM " +
 "country ORDER BY continent, name";
 cmd.Connection = conn;

 myAdapter.SelectCommand = cmd;
 myAdapter.Fill(myData);

 myReport.Load(@"..\world_report.rpt");
 myReport.Database.Tables(0).SetDataSource(myData.Tables(0));
 myReport.Database.Tables(1).SetDataSource(myData.Tables(1));
 myViewer.ReportSource = myReport;
}
catch (MySql.Data.MySqlClient.MySqlException ex)
{
 MessageBox.Show(ex.Message, "Report could not be created",
 MessageBoxButtons.OK, MessageBoxIcon.Error);
}

```

It is important to order the `SELECT` queries in alphabetic order, as this is the order the report will expect its source tables to be in. One `SetDataSource` statement is needed for each table in the report.

This approach can cause performance problems because Crystal Reports must bind the tables together on the client-side, which will be slower than using a pre-saved data set.

## 21.2.5.9. Handling Date and Time Information in Connector/.NET

### Introduction

MySQL and the .NET languages handle date and time information differently, with MySQL allowing dates that cannot be represented by a .NET data type, such as `'0000-00-00 00:00:00'`. These differences can cause problems if not properly handled.

In this section we will demonstrate how to properly handle date and time information when using Connector/.NET.

### 21.2.5.9.1. Problems when Using Invalid Dates

The differences in date handling can cause problems for developers who use invalid dates. Invalid MySQL dates cannot be loaded into native .NET `DateTime` objects, including `NULL` dates.

Because of this issue, .NET `DataSet` objects cannot be populated by the `Fill` method of the `MySqlDataAdapter` class as invalid dates will cause a `System.ArgumentOutOfRangeException` exception to occur.

### 21.2.5.9.2. Restricting Invalid Dates

The best solution to the date problem is to restrict users from entering invalid dates. This can be done on either the client or the server side.

Restricting invalid dates on the client side is as simple as always using the .NET `DateTime` class to handle dates. The `DateTime` class will only allow valid dates, ensuring that the values in your database are also valid. The disadvantage of this is that it is not useful in a mixed environment where .NET and non .NET code are used to manipulate the database, as each application must perform its own date validation.

Users of MySQL 5.0.2 and higher can use the new `traditional` SQL mode to restrict invalid date values. For information on using the `traditional` SQL mode, see [Section 5.1.7, “Server SQL Modes”](#).

### 21.2.5.9.3. Handling Invalid Dates

Although it is strongly recommended that you avoid the use of invalid dates within your .NET application, it is possible to use invalid dates by means of the `MySqlDateTime` data type.

The `MySqlDateTime` data type supports the same date values that are supported by the MySQL server. The default behavior of

Connector/NET is to return a .NET DateTime object for valid date values, and return an error for invalid dates. This default can be modified to cause Connector/NET to return `MySqlDateTime` objects for invalid dates.

To instruct Connector/NET to return a `MySqlDateTime` object for invalid dates, add the following line to your connection string:

```
Allow Zero Datetime=True
```

Please note that the use of the `MySqlDateTime` class can still be problematic. The following are some known issues:

1. Data binding for invalid dates can still cause errors (zero dates like 0000-00-00 do not seem to have this problem).
2. The `ToString` method return a date formatted in the standard MySQL format (for example, `2005-02-23 08:50:25`). This differs from the `ToString` behavior of the .NET DateTime class.
3. The `MySqlDateTime` class supports NULL dates, while the .NET DateTime class does not. This can cause errors when trying to convert a MySQLDate to a DateTime if you do not check for NULL first.

Because of the known issues, the best recommendation is still to use only valid dates in your application.

#### 21.2.5.9.4. Handling NULL Dates

The .NET `DateTime` data type cannot handle `NULL` values. As such, when assigning values from a query to a `DateTime` variable, you must first check whether the value is in fact `NULL`.

When using a `MySqlDataReader`, use the `.IsDBNull` method to check whether a value is `NULL` before making the assignment:

Visual Basic Example

```
If Not myReader.IsDBNull(myReader.GetOrdinal("mytime")) Then
 myTime = myReader.GetDateTime(myReader.GetOrdinal("mytime"))
Else
 myTime = DateTime.MinValue
End If
```

C# Example

```
if (! myReader.IsDBNull(myReader.GetOrdinal("mytime")))
 myTime = myReader.GetDateTime(myReader.GetOrdinal("mytime"));
else
 myTime = DateTime.MinValue;
```

`NULL` values will work in a data set and can be bound to form controls without special handling.

#### 21.2.5.10. ASP.NET Provider Model

MySQL Connector/NET provides support for the ASP.NET 2.0 provider model. This model enables application developers to focus on the business logic of their application instead of having to recreate such boilerplate items as membership and roles support.

MySQL Connector/NET supplies the following providers:

- Membership Provider
- Role Provider
- Profile Provider
- Session State Provider (MySQL Connector/NET 6.1 and later)

The following tables show the supported providers, their default provider and the corresponding MySQL provider.

##### Membership Provider

Default Provider	MySQL Provider
System.Web.Security.SqlMembershipProvider	MySQL.Web.Security.MySQLMembershipProvider

**Role Provider**

<b>Default Provider</b>	<b>MySQL Provider</b>
System.Web.Security.SqlRoleProvider	MySQL.Web.Security.MySQLRoleProvider

**Profile Provider**

<b>Default Provider</b>	<b>MySQL Provider</b>
System.Web.Profile.SqlProfileProvider	MySQL.Web.Profile.MySQLProfileProvider

**SessionState Provider**

<b>Default Provider</b>	<b>MySQL Provider</b>
System.Web.SessionState.InProcSessionStateStore	MySQL.Web.SessionState.MySqlSessionStateStore

**Note**

The MySQL Session State provider uses slightly different capitalization on the class name compared to the other MySQL providers.

**Installing The Providers**

The installation of Connector/Net 5.1 or later will install the providers and register them in your machine's .NET configuration file, `machine.config`. The additional entries created will result in the `system.web` section appearing similar to the following code:

```
<system.web>
 <processModel autoConfig="true" />
 <httpHandlers />
 <membership>
 <providers>
 <add name="AspNetSqlMembershipProvider" type="System.Web.Security.SqlMembershipProvider, System.Web, Version=2.0.0.0, Culture=neutral, PublicKeyToken=b03f5f7f1434493e" />
 <add name="MySQLMembershipProvider" type="MySQL.Web.Security.MySQLMembershipProvider, MySql.Web, Version=6.1.1.0, Culture=neutral, PublicKeyToken=c5687fc4b0d60ed1" />
 </providers>
 </membership>
 <profile>
 <providers>
 <add name="AspNetSqlProfileProvider" connectionStringName="LocalSqlServer" applicationName="/" type="System.Web.Profile.SqlProfileProvider, System.Web, Version=2.0.0.0, Culture=neutral, PublicKeyToken=b03f5f7f1434493e" />
 <add name="MySQLProfileProvider" type="MySQL.Web.Profile.MySQLProfileProvider, MySql.Web, Version=6.1.1.0, Culture=neutral, PublicKeyToken=c5687fc4b0d60ed1" />
 </providers>
 </profile>
 <roleManager>
 <providers>
 <add name="AspNetSqlRoleProvider" connectionStringName="LocalSqlServer" applicationName="/" type="System.Web.Security.SqlRoleProvider, System.Web, Version=2.0.0.0, Culture=neutral, PublicKeyToken=b03f5f7f1434493e" />
 <add name="AspNetWindowsTokenRoleProvider" applicationName="/" type="System.Web.Security.WindowsTokenRoleProvider, System.Web, Version=2.0.0.0, Culture=neutral, PublicKeyToken=b03f5f7f1434493e" />
 <add name="MySQLRoleProvider" type="MySQL.Web.Security.MySQLRoleProvider, MySql.Web, Version=6.1.1.0, Culture=neutral, PublicKeyToken=c5687fc4b0d60ed1" />
 </providers>
 </roleManager>
</system.web>
```

Each provider type can have multiple provider implementations. The default provider can also be set here using the `defaultProvider` attribute, but usually this is set in the `web.config` file either manually or by using the ASP.NET configuration tool.

At time of writing the `MySqlSessionStateStore` is not added to `machine.config` at install time, and so you would need to add the following:

```
<sessionState>
 <providers>
 <add name="MySqlSessionStateStore" type="MySQL.Web.SessionState.MySqlSessionStateStore, MySql.Web, Version=6.1.1.0, Culture=neutral, PublicKeyToken=c5687fc4b0d60ed1" />
 </providers>
</sessionState>
```

It should be pointed out that the SessionState Provider uses the `customProvider` attribute, rather than `defaultProvider`, to set the provider as the default. A typical `web.config` file might contain:

```
<system.web>
 <membership defaultProvider="MySQLMembershipProvider" />
 <roleManager defaultProvider="MySQLRoleProvider" />
 <profile defaultProvider="MySQLProfileProvider" />
 <sessionState customProvider="MySqlSessionStateStore" />
 <compilation debug="false">
 ...
 </compilation>
</system.web>
```

This sets the MySQL Providers as the defaults to be used in this web application.

The providers are implemented in the file `mysql.web.dll` and this file can be found in your MySQL Connector/NET installation folder. There is no need to run any type of SQL script to set up the database schema as the providers create and maintain the proper schema automatically.

### Using The Providers

The easiest way to start using the providers is to use the ASP.NET configuration tool that is available on the Solution Explorer toolbar when you have a website project loaded.

In the web pages that open you will be able to select the MySQL membership and roles providers by indicating that you want to pick a custom provider for each area.

When the provider is installed, it creates a dummy connection string named `LocalMySqlServer`. This has to be done so that the provider will work in the ASP.NET configuration tool. However, you will want to override this connection string in your `web.config` file. You do this by first removing the dummy connection string and then adding in the proper one, as shown in the following example:

```
<connectionStrings>
 <remove name="LocalMySqlServer"/>
 <add name="LocalMySqlServer" connectionString="server=xxx;uid=xxx;pwd=xxx;database=xxx;" />
</connectionStrings>
```

Note the database you want to connect to must be specified.

Rather than manually editing configuration files it is recommended that you use the MySQL Website Configuration tool to config your desired provider setup. From MySQL Connector/NET 6.1.1 onwards all providers can be selected and configured from this wizard. The tool will modify your `website.config` file to the desired configuration. A tutorial on doing this is available in the following section [Section 21.2.3.10, “MySQL Website Configuration Tool”](#).

A tutorial demonstrating how to use the Membership and Role Providers can be found in the following section [Section 21.2.4.2, “Tutorial: MySQL Connector/NET ASP.NET Membership and Role Provider”](#).

### Deployment

To use the providers on a production server you will need to distribute the `MySql.Data` and the `MySql.Web` assemblies and either register them in the remote systems Global Assembly Cache or keep them in your application's `bin/` directory.

## 21.2.5.11. Binary/Nonbinary Issues

There are certain situations where MySQL will return incorrect metadata about one or more columns. More specifically, the server will sometimes report that a column is binary when it is not and vice versa. In these situations, it becomes practically impossible for the connector to be able to correctly identify the correct metadat.

Some examples of situations that may return incorrect metadata are:

- Execution of `SHOW PROCESSLIST`. Some of the columns will be returned as binary even though they only hold string data.
- When a temp table is used to process a resultset, some columns may be returned with incorrect binary flags.
- Some server functions such `DATE_FORMAT` will incorrectly return the column as binary.

With the availability of `BINARY` and `VARBINARY` data types it is important that we respect the metadata returned by the sever. However, we are aware that some existing applications may break with this change so we are creating a connection string option to enable or disable it. By default, Connector/Net 5.1 will respect the binary flags returned by the server. This will mean that you may need to make small changes to your application to accomodate this change.

In the event that the changes required to your application would be too large, you can add 'respect binary flags=false' to your connection string. This will cause the connector to use the prior behavior. In a nutshell, that behavior was that any column that is marked as string, regardless of binary flags, will be returned as string. Only columns that are specifically marked as a `BLOB` will be returned as `BLOB`.

## 21.2.5.12. Character Sets

### Treating Binary Blobs As UTF8

MySQL doesn't currently support 4 byte UTF8 sequences. This makes it difficult to represent some multi-byte languages such as Japanese. To try and alleviate this, Connector/Net now supports a mode where binary blobs can be treated as strings.

To do this, you set the 'Treat Blobs As UTF8' connection string keyword to yes. This is all that needs to be done to enable conversion of all binary blobs to UTF8 strings. If you wish to convert only some of your blob columns, then you can make use of the 'BlobAsUTF8IncludePattern' and 'BlobAsUTF8ExcludePattern' keywords. These should be set to the regular expression pattern that matches the column names you wish to include or exclude respectively.

One thing to note is that the regular expression patterns can both match a single column. When this happens, the include pattern is applied before the exclude pattern. The result, in this case, would be that the column would be excluded. You should also be aware that this mode does not apply to columns of type `BINARY` or `VARBINARY` and also do not apply to nonbinary `BLOB` columns.

Currently this mode only applies to reading strings out of MySQL. To insert 4-byte UTF8 strings into blob columns you will need to use the .NET `Encoding.GetBytes` function to convert your string to a series of bytes. You can then set this byte array as a parameter for a `BLOB` column.

### 21.2.5.13. Working with medium trust

.NET applications operate under a given trust level. Normal desktop applications operate under full trust while web applications that are hosted in shared environments are normally run under the medium trust level. Some hosting providers host shared applications in their own app pools and allow the application to run under full trust, but this seems to be the exception rather than the rule.

Connector/Net versions prior to 5.0.8 and 5.1.3 were not compatible with medium trust hosting. Starting with these versions, Connector/Net can be used under medium trust hosting that has been modified to allow the use of sockets for communication. By default, medium trust does not include `SocketPermission`. Connector/Net uses sockets to talk with the MySQL server so it is required that a new trust level be created that is an exact clone of medium trust but that has `SocketPermission` added.

### 21.2.5.14. Using the MySQL Connector/.NET Trace Source Object

MySQL Connector/.NET 6.2 introduced support for .NET 2.0 compatible tracing, using `TraceSource` objects.

The .NET 2.0 tracing architecture consists of four main parts:

- *Source* - This is the originator of the trace information. The source is used to send trace messages. The name of the source provided by MySQL Connector/.NET is `mysql`.
- *Switch* - This defines the level of trace information to emit. Typically, this is specified in the `app.config` file, so that it is not necessary to recompile an application to change the trace level.
- *Listener* - Trace listeners define where the trace information will be written to. Supported listeners include, for example, the Visual Studio Output window, the Windows Event Log, and the console.
- *Filter* - Filters can be attached to listeners. Filters determine the level of trace information that will be written. While a switch defines the level of information that will be written to all listeners, a filter can be applied on a per-listener basis, giving finer grained control of trace information.

To use tracing a `TraceSource` object first needs to be created. To create a `TraceSource` object in MySQL Connector/.NET you would use code similar to the following:

```
TraceSource ts = new TraceSource("mysql");
```

To enable trace messages you also need to configure a trace switch. There are three main switch classes, `BooleanSwitch`, `SourceSwitch`, and `TraceSwitch`. Trace switches also have associated with them a trace level enumeration, these are `Off`, `Error`, `Warning`, `Info`, and `Verbose`. The following code snippet illustrates creating a switch:

```
ts.Switch = new SourceSwitch("MySwitch", "Verbose");
```

This creates a `SourceSwitch`, called `MySwitch`, and sets the trace level to `Verbose`, meaning that all trace messages will be written.

It is convenient to be able to change the trace level without having to recompile the code. This is achieved by specifying the trace level in application configuration file, `app.config`. You then simply need to specify the desired trace level in the configuration file and restart the application. The trace source is configured within the `system.diagnostics` section of the file. The following XML snippet illustrates this:

```
<configuration>
 ...
 <system.diagnostics>
 <sources>
 <source name="mysql" switchName="MySwitch"
 switchType="System.Diagnostics.SourceSwitch" />
 ...
 </system.diagnostics>
</configuration>
```

```

</sources>
<switches>
 <add name="MySwitch" value="Verbose" />
 ...
</switches>
</system.diagnostics>
...
</configuration>

```

By default trace information is written to the Output window of Microsoft Visual Studio. However, there are a wide range of listeners than can be attached to the trace source, so that trace messages can be written out to various destinations. It is also possible to create custom listeners to allow trace messages to be written to other destinations as mobile devices and web services. A commonly used example of a listener is [ConsoleTraceListener](#), which writes trace messages to the console.

To add a listener at run time you can use code such as the following:

```
ts.Listeners.Add(new ConsoleTraceListener());
```

You can then call methods on trace source object to generate trace information. For example, the [TraceInformation\(\)](#), [TraceEvent\(\)](#), or [TraceData\(\)](#) methods can be used.

The [TraceInformation\(\)](#) method simply prints a string passed as a parameter. The [TraceEvent\(\)](#) method, as well as the optional informational string, requires a [TraceEventType](#) value to be passed to indicate the trace message type, and also an application specific ID. The [TraceEventType](#) can have a value of [Verbose](#), [Information](#), [Warning](#), [Error](#), and [Critical](#). Using the [TraceData\(\)](#) method you can pass any object, for example an exception object, instead of a message.

To ensure than these generated trace messages gets flushed from the trace source buffers to listeners, you need to invoke the [Flush\(\)](#) method. When you are finished using a trace source, you should call the [Close\(\)](#) method. The [Close\(\)](#) method first calls [Flush\(\)](#), to ensure any remaining data is written out. It then frees up resources, and closes the listeners associated with the trace source.

```

ts.TraceInformation("Informational message");
ts.TraceEvent(TraceEventType.Error, 3, "Optional error message");
ts.TraceData(TraceEventType.Error, 3, ex); // pass exception object
ts.Flush();
...
ts.Close();

```

### 21.2.5.14.1. Viewing MySQL Trace Information

This section describes how to set up your application to view MySQL trace information.

The first thing you need to do is create a suitable [app.config](#) file for your application. An example is shown in the following code:

```

<?xml version="1.0" encoding="utf-8" ?>
<configuration>
 <system.diagnostics>
 <sources>
 <source name="mysql" switchName="SourceSwitch"
 switchType="System.Diagnostics.SourceSwitch" >
 <listeners>
 <add name="console" />
 <remove name ="Default" />
 </listeners>
 </source>
 </sources>
 <switches>
 <!-- You can set the level at which tracing is to occur -->
 <add name="SourceSwitch" value="Verbose" />
 <!-- You can turn tracing off -->
 <!--add name="SourceSwitch" value="Off" -->
 </switches>
 <sharedListeners>
 <add name="console"
 type="System.Diagnostics.ConsoleTraceListener"
 initializeData="false"/>
 </sharedListeners>
 </system.diagnostics>
</configuration>

```

This ensures a suitable trace source is created, along with a switch. The switch level in this case is set to [Verbose](#) to display the maximum amount of information.

In the application the only other step required is to add [logging=true](#) to the connection string. An example application could be:

```

using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Diagnostics;
using MySql.Data;
using MySql.Data.MySqlClient;
using MySql.Web;

namespace ConsoleApplication1
{
 class Program
 {
 static void Main(string[] args)
 {

 string connStr = "server=localhost;user=root;database=world;port=3306;password=*****;logging=true";
 MySqlConnection conn = new MySqlConnection(connStr);
 try
 {
 Console.WriteLine("Connecting to MySQL...");
 conn.Open();

 string sql = "SELECT Name, HeadOfState FROM Country WHERE Continent='Oceania'";
 MySqlCommand cmd = new MySqlCommand(sql, conn);
 MySqlDataReader rdr = cmd.ExecuteReader();

 while (rdr.Read())
 {
 Console.WriteLine(rdr[0] + " -- " + rdr[1]);
 }

 rdr.Close();
 conn.Close();
 }
 catch (Exception ex)
 {
 Console.WriteLine(ex.ToString());
 }
 Console.WriteLine("Done.");
 }
 }
}

```

This simple application will then generate the following output:

```

Connecting to MySQL...
mysql Information: 1 : 1: Connection Opened: connection string = 'server=localhost;User Id=root;database=world;port=3306;password=*****;logging=True'
mysql Information: 3 : 1: Query Opened: SHOW VARIABLES
mysql Information: 4 : 1: Resultset Opened: field(s) = 2, affected rows = -1, inserted id = -1
mysql Information: 5 : 1: Resultset Closed. Total rows=272, skipped rows=0, size (bytes)=7058
mysql Information: 6 : 1: Query Closed
mysql Information: 3 : 1: Query Opened: SHOW COLLATION
mysql Information: 4 : 1: Resultset Opened: field(s) = 6, affected rows = -1, inserted id = -1
mysql Information: 5 : 1: Resultset Closed. Total rows=127, skipped rows=0, size (bytes)=4102
mysql Information: 6 : 1: Query Closed
mysql Information: 3 : 1: Query Opened: SET character_set_results=NULL
mysql Information: 4 : 1: Resultset Opened: field(s) = 0, affected rows = 0, inserted id = 0
mysql Information: 5 : 1: Resultset Closed. Total rows=0, skipped rows=0, size (bytes)=0
mysql Information: 6 : 1: Query Closed
mysql Information: 10 : 1: Set Database: world
mysql Information: 3 : 1: Query Opened: SELECT Name, HeadOfState FROM Country WHERE Continent='Oceania'
mysql Information: 4 : 1: Resultset Opened: field(s) = 2, affected rows = -1, inserted id = -1
American Samoa -- George W. Bush
Australia -- Elisabeth II
...
Wallis and Futuna -- Jacques Chirac
Vanuatu -- John Bani
United States Minor Outlying Islands -- George W. Bush
mysql Information: 5 : 1: Resultset Closed. Total rows=28, skipped rows=0, size (bytes)=788
mysql Information: 6 : 1: Query Closed
Done.
mysql Information: 2 : 1: Connection Closed

```

The first number displayed in the trace message corresponds to the MySQL event type:

Event	Description
1	ConnectionOpened: connection string
2	ConnectionClosed:
3	QueryOpened: mysql server thread id, query text
4	ResultOpened: field count, affected rows (-1 if select), inserted id (-1 if select)
5	ResultClosed: total rows read, rows skipped, size of resultset in bytes
6	QueryClosed:

7	StatementPrepared: prepared sql, statement id
8	StatementExecuted: statement id, mysql server thread id
9	StatementClosed: statement id
10	NonQuery: [varies]
11	UsageAdvisorWarning: usage advisor flag. NoIndex = 1, BadIndex = 2, SkippedRows = 3, SkippedColumns = 4, FieldConversion = 5.
12	Warning: level, code, message
13	Error: error number, error message

The second number displayed in the trace message is the connection count.

Although this example uses the `ConsoleTraceListener`, any of the other standard listeners could have been used. Another possibility is to create a custom listener that uses the information passed using the `TraceEvent` method. For example, a custom trace listener could be created to perform active monitoring of the MySQL event messages, rather than simply writing these to an output device.

It is also possible to add listeners to the MySQL Trace Source at run time. This can be done with the following code:

```
MySQLTrace.Listeners.Add(new ConsoleTraceListener());
```

MySQL Connector/.NET 6.3.2 introduced the ability to switch tracing on and off at run time. This can be achieved using the calls `MySQLTrace.EnableQueryAnalyzer(string host, int postInterval)` and `MySQLTrace.DisableQueryAnalyzer()`. The parameter `host` is the URL of the MySQL Enterprise Monitor server to monitor. The parameter `postInterval` is how often the data should be periodically posted to MySQL Enterprise Monitor, in seconds.

#### 21.2.5.14.2. Building Custom Listeners

To build custom listeners that work with the MySQL Connector/.NET Trace Source, it is necessary to understand the key methods used, and the event data formats used.

The main method involved in passing trace messages is the `TraceSource.TraceEvent` method. This has the prototype:

```
public void TraceEvent(
 TraceEventType eventType,
 int id,
 string format,
 params Object[] args
)
```

This trace source method will process the list of attached listeners and call the listener's `TraceListener.TraceEvent` method. The prototype for the `TraceListener.TraceEvent` method is as follows:

```
public virtual void TraceEvent(
 TraceEventCache eventCache,
 string source,
 TraceEventType eventType,
 int id,
 string format,
 params Object[] args
)
```

The first three parameters are used in the standard as [defined by Microsoft](#). The last three parameters contain MySQL-specific trace information. Each of these parameters is now discussed in more detail.

##### int id

This is a MySQL-specific identifier. It identifies the MySQL event type that has occurred, resulting in a trace message being generated. This value is defined by the `MySQLTraceEventType` public enum contained in the MySQL Connector/.NET code:

```
public enum MySQLTraceEventType : int
{
 ConnectionOpened = 1,
 ConnectionClosed,
 QueryOpened,
 ResultOpened,
 ResultClosed,
 QueryClosed,
 StatementPrepared,
 StatementExecuted,
 StatementClosed,
 NonQuery,
 UsageAdvisorWarning,
```

```

 Warning,
 Error
}

```

The MySQL event type also determines the contents passed using the parameter `params Object[] args`. The nature of the `args` parameters are described in further detail in the following material.

#### `string format`

This is the format string that contains zero or more format items, which correspond to objects in the args array. This would be used by a listener such as `ConsoleTraceListener` to write a message to the output device.

#### `params Object[] args`

This is a list of objects that depends on the MySQL event type, `id`. However, the first parameter passed using this list is always the driver id. The driver id is a unique number that is incremented each time the connector is opened. This enables groups of queries on the same connection to be identified. The parameters that follow driver id depend of the MySQL event id, and are as follows:

MySQL-specific event type	Arguments (params Object[] args)
ConnectionOpened	Connection string
ConnectionClosed	No additional parameters
QueryOpened	mysql server thread id, query text
ResultOpened	field count, affected rows (-1 if select), inserted id (-1 if select)
ResultClosed	total rows read, rows skipped, size of resultset in bytes
QueryClosed	No additional parameters
StatementPrepared	prepared sql, statement id
StatementExecuted	statement id, mysql server thread id
StatementClosed	statement id
NonQuery	Varies
UsageAdvisorWarning	usage advisor flag. NoIndex = 1, BadIndex = 2, SkippedRows = 3, SkippedColumns = 4, FieldConversion = 5.
Warning	level, code, message
Error	error number, error message

This information will allow you to create custom trace listeners that can actively monitor the MySQL-specific events.

### 21.2.5.15. Using the Bulk Loader

MySQL Connector/.NET features a bulk loader class that wraps the MySQL statement `LOAD DATA INFILE`. This gives MySQL Connector/.NET the ability to load a data file from a local or remote host to the server. The class concerned is `MySqlBulkLoader`. This class has various methods, the main one being `load` to cause the specified file to be loaded to the server. Various parameters can be set to control how the data file is processed. This is achieved through setting various properties of the class. For example, the field separator used, such as comma or tab, can be specified, along with the record terminator, such as newline.

The following code shows a simple example of using the `MySqlBulkLoader` class. First an empty table needs to be created, in this case in the `test` database:

```

CREATE TABLE Career (
 Name VARCHAR(100) NOT NULL,
 Age INTEGER,
 Profession VARCHAR(200)
);

```

A simple tab-delimited data file is also created (it could use any other field delimiter such as comma):

```

Table Career in Test Database
Name Age Profession
Tony 47 Technical Writer
Ana 43 Nurse
Fred 21 IT Specialist
Simon 45 Hairy Biker

```

Note that with this test file the first three lines will need to be ignored, as they do not contain table data. This can be achieved using the `NumberOfLinesToSkip` property. This file can then be loaded and used to populate the `Career` table in the `test` data-

base:

```

using System;
using System.Text;
using MySql.Data;
using MySql.Data.MySqlClient;

namespace ConsoleApplication1
{
 class Program
 {
 static void Main(string[] args)
 {

 string connStr = "server=localhost;user=root;database=test;port=3306;password=*****;";
 MySqlConnection conn = new MySqlConnection(connStr);

 MySqlBulkLoader bl = new MySqlBulkLoader(conn);
 bl.TableName = "Career";
 bl.FieldTerminator = "\t";
 bl.LineTerminator = "\n";
 bl.FileName = "c:/career_data.txt";
 bl.NumberOfLinesToSkip = 3;

 try
 {
 Console.WriteLine("Connecting to MySQL...");
 conn.Open();

 // Upload data from file
 int count = bl.Load();
 Console.WriteLine(count + " lines uploaded.");

 string sql = "SELECT Name, Age, Profession FROM Career";
 MySqlCommand cmd = new MySqlCommand(sql, conn);
 MySqlDataReader rdr = cmd.ExecuteReader();

 while (rdr.Read())
 {
 Console.WriteLine(rdr[0] + " -- " + rdr[1] + " -- " + rdr[2]);
 }

 rdr.Close();
 conn.Close();
 }
 catch (Exception ex)
 {
 Console.WriteLine(ex.ToString());
 }
 Console.WriteLine("Done.");
 }
 }
}

```

Further information on `LOAD DATA INFILE` can be found in [Section 12.2.6, “`LOAD DATA INFILE` Syntax”](#). Further information on `MySqlBulkLoader` can be found in the reference documentation that was included with your connector.

## 21.2.6. Connector/NET Connection String Options Reference

Name	Default	Description
<code>Allow Batch</code>	true	When true, multiple SQL statements can be sent with one command execution. -Note- Starting with MySQL 4.1.1, batch statements should be separated by the server-defined separator character. Commands sent to earlier versions of MySQL should be separated with ;.
<code>Allow User Variables</code>	false	Setting this to <code>true</code> indicates that the provider expects user variables in the SQL. This option was added in Connector/NET version 5.2.2.
<code>Allow ZeroDatetime</code>	false	If set to <code>True</code> , <code>MySqlDataReader.GetValue()</code> will return a <code>MySqlDateTime</code> object for date or datetime columns that have illegal values, such as zero datetime values, and a <code>System.DateTime</code> object for legal values. If set to <code>False</code> (the default setting) it will cause a <code>System.DateTime</code> object to be returned for all legal values and an exception to be thrown for illegal values, such as zero datetime values.
<code>AutoEnlist</code>	true	If <code>AutoEnlist</code> is set to <code>true</code> , which is the default, a connection opened using <code>TransactionScope</code> participates in this scope, it commits when the scope commits and rolls back if <code>TransactionScope</code> does not commit. However, this feature is considered security sensitive and therefore cannot be used in a medium trust environment.
<code>BlobAsUTF8ExcludePattern</code>	null	
<code>BlobAsUTF8IncludePattern</code>	null	

<code>CertificateFile</code>	null	This option specifies the path to a certificate file in PFX format. For an example of usage see <a href="#">Section 21.2.4.7, “Tutorial: Using SSL with MySQL Connector/.NET”</a> . Was introduced with 6.2.1.
<code>CertificatePassword</code>	null	This option enables you to specify a password which is used in conjunction with a certificate specified using the option <code>CertificateFile</code> . For an example of usage see <a href="#">Section 21.2.4.7, “Tutorial: Using SSL with MySQL Connector/.NET”</a> . Was introduced with 6.2.1.
<code>Certificate Store Location</code>	null	This option enables you to access a certificate held in a personal store, rather than use a certificate file and password combination. For an example of usage see <a href="#">Section 21.2.4.7, “Tutorial: Using SSL with MySQL Connector/.NET”</a> . Was introduced with 6.2.1.
<code>Certificate Thumbprint</code>	null	This option enables you to specify a certificate thumbprint to ensure correct identification of a certificate contained within a personal store. For an example of usage see <a href="#">Section 21.2.4.7, “Tutorial: Using SSL with MySQL Connector/.NET”</a> . Was introduced with 6.2.1.
<code>CharSet, Character Set</code>		Specifies the character set that should be used to encode all queries sent to the server. Resultsets are still returned in the character set of the data returned.
<code>Connect Timeout, Connection Timeout</code>	15	The length of time (in seconds) to wait for a connection to the server before terminating the attempt and generating an error.
<code>Connection Reset</code>	false	If true, the connection state will be reset when it is retrieved from the pool. If set to false this avoids making an additional server round trip when obtaining a connection, but the connection state is not reset.
<code>Convert Zero Datetime</code>	false	True to have <code>MySqlDataReader.GetValue()</code> and <code>MySqlDataReader.GetDateTime()</code> return <code>DateTime.MinValue</code> for date or datetime columns that have illegal values.
<code>Default Command Timeout</code>	30	Sets the default value of the command timeout to be used. This does not supercede the individual command timeout property on an individual command object. If you set the command timeout property, that will be used. This option was added in Connector/.NET 5.1.4
<code>Encrypt, UseSSL</code>	false	For Connector/.NET 5.0.3 and later, when <code>true</code> , SSL encryption is used for all data sent between the client and server if the server has a certificate installed. Recognized values are <code>true</code> , <code>false</code> , <code>yes</code> , and <code>no</code> . In versions before 5.0.3, this option had no effect. From version 6.2.1 this option is deprecated and is replaced by <code>SSL Mode</code> . However, the option is still supported if used. If this option is set to <code>true</code> it is equivalent to <code>SSL Mode = Preferred</code> .
<code>FunctionsReturnString</code>	false	This will cause the connector to return binary/varbinary values as strings, if they do not have a tablename in the metadata.
<code>Host, Server, Data Source, Data-Source, Address, Addr, Network Address</code>	localhost	The name or network address of the instance of MySQL to which to connect. Multiple hosts can be specified separated by &. This can be useful where multiple MySQL servers are configured for replication and you are not concerned about the precise server you are connecting to. No attempt is made by the provider to synchronize writes to the database so care should be taken when using this option. In Unix environment with Mono, this can be a fully qualified path to MySQL socket file name. With this configuration, the Unix socket will be used instead of TCP/IP socket. Currently only a single socket name can be given so accessing MySQL in a replicated environment using Unix sockets is not currently supported.
<code>Ignore Prepare</code>	true	When true, instructs the provider to ignore any calls to <code>MySqlCommand.Prepare()</code> . This option is provided to prevent issues with corruption of the statements when use with server side prepared statements. If you want to use server-side prepare statements, set this option to false. This option was added in Connector/.NET 5.0.3 and Connector/.NET 1.0.9.
<code>Initial Catalog, Database</code>	mysql	The name of the database to use intially
<code>Interactive, InteractiveSession</code>	false	If set to true the client is interactive. An interactive client is one where the server variable <code>CLIENT_INTERACTIVE</code> is set. If an interactive client is set, the <code>wait_timeout</code> variable is set to the value of <code>interactive_timeout</code> . The client will then timeout after this period of inactivity. More details can be found in the server manual <a href="#">Section 5.1.4, “Server System Variables”</a> .

<code>Logging</code>	false	When true, various pieces of information is output to any configured TraceListeners. See <a href="#">Section 21.2.5.14, “Using the MySQL Connector/NET Trace Source Object”</a> for further details.
<code>Old_Guids</code>	false	This option was introduced in Connector/NET 6.1.1. The backend representation of a GUID type was changed from <code>BINARY(16)</code> to <code>CHAR(36)</code> . This was done to allow developers to use the server function <code>UUID()</code> to populate a GUID table - <code>UUID()</code> generates a 36-character string. Developers of older applications can add 'Old_Guids=true' to the connection string to use a GUID of data type <code>BINARY(16)</code> .
<code>Old_Syntax, OldSyntax</code>	false	This option was deprecated in Connector/NET 5.2.2. All code should now be written using the '@' symbol as the parameter marker.
<code>Password, pwd</code>		The password for the MySQL account being used.
<code>Persist_Security_Info</code>	false	When set to <code>false</code> or <code>no</code> (strongly recommended), security-sensitive information, such as the password, is not returned as part of the connection if the connection is open or has ever been in an open state. Resetting the connection string resets all connection string values including the password. Recognized values are <code>true</code> , <code>false</code> , <code>yes</code> , and <code>no</code> .
<code>Pipe_Name, Pipe</code>	mysql	When set to the name of a named pipe, the <code>MySqlConnection</code> will attempt to connect to MySQL on that named pipe. This setting only applies to the Windows platform.
<code>Port</code>	3306	The port MySQL is using to listen for connections. This value is ignored if Unix socket is used.
<code>Procedure_Cache_Size</code>	25	Sets the size of the stored procedure cache. By default, Connector/NET will store the metadata (input/output data types) about the last 25 stored procedures used. To disable the stored procedure cache, set the value to zero (0). This option was added in Connector/NET 5.0.2 and Connector/NET 1.0.9.
<code>Protocol</code>	socket	Specifies the type of connection to make to the server. Values can be: <code>socket</code> or <code>tcp</code> for a socket connection, <code>pipe</code> for a named pipe connection, <code>unix</code> for a Unix socket connection, <code>memory</code> to use MySQL shared memory.
<code>Respect_Binary_Flags</code>	true	Setting this option to <code>false</code> means that Connector/NET will ignore a column's binary flags as set by the server. This option was added in Connector/NET version 5.1.3.
<code>Shared_Memory_Name</code>	MYSQL	The name of the shared memory object to use for communication if the connection protocol is set to <code>memory</code> .
<code>Sql_Server_Mode</code>	false	Allow SQL Server syntax. When set to <code>true</code> enables Connector/NET to support square brackets around symbols instead of backticks. This enables Visual Studio wizards that bracket symbols with [] to work with Connector/NET. This option incurs a performance hit, so should only be used if necessary. This option was added in version 6.3.1.
<code>SSL_Mode</code>	None	<p>This option has the following values:</p> <ul style="list-style-type: none"> <li>• <b>None</b> - do not use SSL.</li> <li>• <b>Preferred</b> - use SSL if the server supports it, but allow connection in all cases.</li> <li>• <b>Required</b> - Always use SSL. Deny connection if server does not support SSL.</li> <li>• <b>VerifyCA</b> - Always use SSL. Validate the CA but tolerate name mismatch.</li> <li>• <b>VerifyFull</b> - Always use SSL. Fail if the host name is not correct.</li> </ul> <p>This option was introduced in MySQL Connector/NET 6.2.1.</p>
<code>TreatBlobsAsUTF8</code>	false	
<code>Treat_Tiny_As_Boolean</code>	true	Setting this value to <code>false</code> indicates that <code>TINYINT(1)</code> will be treated as an <code>INT</code> . See also <a href="#">Section 10.1.1, “Overview of Numeric Types”</a> for a further explanation of the <code>TINYINT</code> and <code>BOOL</code> data

		types.
<code>Use Affected Rows</code>	false	When <code>true</code> the connection will report changed rows instead of found rows. This option was added in Connector/NET version 5.2.6.
<code>Use Procedure Bodies</code>	true	When set to <code>true</code> , the default value, MySQL Connector/NET expects the body of the procedure to be viewable. This enables it to determine the parameter types and order. The option should be set to <code>false</code> when the user connecting to the database does not have the <code>SELECT</code> privileges for the <code>mysql.proc</code> (stored procedures) table, or cannot view <code>I_S.ROUTINES</code> . In this case, MySQL Connector/NET will not be able to determine the types and order of the parameters, and must be alerted to this fact by setting this option to <code>false</code> . When set to <code>false</code> , MySQL Connector/NET will not rely on this information being available when the procedure is called. Because MySQL Connector/NET will not be able to determine this information, you should explicitly set the types of all the parameters before the call and the parameters should be added to the command in the same order as they appear in the procedure definition. This option was added in MySQL Connector/NET 5.0.4 and MySQL Connector/NET 1.0.10.
<code>User Id, Username, Uid, User name</code>		The MySQL login account being used.
<code>Use Compression</code>	false	<p>Setting this option to <code>true</code> enables compression of packets exchanged between the client and the server. This exchange is defined by the MySQL client-server protocol.</p> <p>Compression is used if both client and server support ZLIB compression, and the client has requested compression using this option.</p> <p>A compressed packet header is: packet length (3 bytes), packet number (1 byte), and Uncompressed Packet Length (3 bytes). The Uncompressed Packet Length is the number of bytes in the original, uncompressed packet. If this is zero then the data in this packet has not been compressed. When the compression protocol is in use, either the client or the server may compress packets. However, compression will not occur if the compressed length is greater than the original length. Thus, some packets will contain compressed data while other packets will not.</p>
<code>Use Usage Advisor</code>	false	
<code>Use Performance Monitor</code>	false	

The following table lists the valid names for connection pooling values within the `ConnectionString`. For more information about connection pooling, see Connection Pooling for the MySQL Data Provider.

Name	Default	Description
<code>Cache Server Configuration</code> , <code>CacheServerConfiguration</code> , <code>CacheServerConfig</code>	false	Specifies whether server variables should be updated when a pooled connection is returned. Turning this on will yield faster opens but will also not catch any server changes made by other connections.
<code>Connection Lifetime</code>	0	When a connection is returned to the pool, its creation time is compared with the current time, and the connection is destroyed if that time span (in seconds) exceeds the value specified by <code>Connection Lifetime</code> . This is useful in clustered configurations to force load balancing between a running server and a server just brought online. A value of zero (0) causes pooled connections to have the maximum connection timeout.
<code>Max Pool Size</code>	100	The maximum number of connections allowed in the pool.
<code>Min Pool Size</code>	0	The minimum number of connections allowed in the pool.
<code>Pooling</code>	true	When <code>true</code> , the <code>MySqlConnection</code> object is drawn from the appropriate pool, or if necessary, is created and added to the appropriate pool. Recognized values are <code>true</code> , <code>false</code> , <code>yes</code> , and <code>no</code> .

## 21.2.7. Connector/NET API Reference

This section of the manual contains a complete reference to the Connector/.NET ADO.NET component, automatically generated from the embedded documentation.

### 21.2.7.1. MySql.Data.MySqlClient

[Namespace hierarchy](#)

#### Classes

Class	Description
<a href="#">MySqlCommand</a>	
<a href="#">MySqlCommandBuilder</a>	
<a href="#">MySqlConnection</a>	
<a href="#">MySqlDataAdapter</a>	
<a href="#">MySqlDataReader</a>	Provides a means of reading a forward-only stream of rows from a MySQL database. This class cannot be inherited.
<a href="#">MySqlError</a>	Collection of error codes that can be returned by the server
<a href="#">MySQLException</a>	The exception that is thrown when MySQL returns an error. This class cannot be inherited.
<a href="#"> MySqlHelper</a>	Helper class that makes it easier to work with the provider.
<a href="#"> MySqlInfoMessageEventArgs</a>	Provides data for the InfoMessage event. This class cannot be inherited.
<a href="#"> MySqlParameter</a>	Represents a parameter to a <a href="#">MySqlCommand</a> , and optionally, its mapping to DataSetcolumns. This class cannot be inherited.
<a href="#"> MySqlParameterCollection</a>	Represents a collection of parameters relevant to a <a href="#">MySqlCommand</a> as well as their respective mappings to columns in a DataSet. This class cannot be inherited.
<a href="#"> MySqlRowUpdatedEventArgs</a>	Provides data for the RowUpdated event. This class cannot be inherited.
<a href="#"> MySqlRowUpdatingEventArgs</a>	Provides data for the RowUpdating event. This class cannot be inherited.
<a href="#"> MySqlTransaction</a>	

#### Delegates

Delegate	Description
<a href="#"> MySqlInfoMessageEventHandler</a>	Represents the method that will handle the <a href="#">InfoMessage</a> event of a <a href="#">MySqlConnection</a> .
<a href="#"> MySqlRowUpdatedEventHandler</a>	Represents the method that will handle the RowUpdatedevent of a <a href="#">MySqlDataAdapter</a> .
<a href="#"> MySqlRowUpdatingEventHandler</a>	Represents the method that will handle the RowUpdatingevent of a <a href="#">MySqlDataAdapter</a> .

#### Enumerations

Enumeration	Description
<a href="#"> MySqlDbType</a>	Specifies MySQL specific data type of a field, property, for use in a <a href="#"> MySqlParameter</a> .
<a href="#"> MySqlErrorCode</a>	

### 21.2.7.1.1. MySql.Data.MySqlClientHierarchy

#### See Also

[MySql.Data.MySqlClient Namespace](#)

### 21.2.7.1.2. MySqlCommand Class

For a list of all members of this type, see [MySqlCommand Members](#).

#### Syntax: Visual Basic

```
NotInheritable Public Class MySqlCommand_
 Inherits Component_
 Implements IDbCommand, ICloneable
```

#### Syntax: C#

```
public sealed class MySqlCommand : Component, IDbCommand, ICloneable
```

#### Thread Safety

Public static (Shared in Visual Basic) members of this type are safe for multithreaded operations. Instance members are not guaranteed to be thread-safe.

#### Requirements

Namespace:  [MySql.Data.MySqlClient](#)

Assembly: MySql.Data (in MySql.Data.dll)

#### See Also

### 21.2.7.1.2.1. MySqlCommand Members

[MySqlCommand overview](#)

#### Public Instance Constructors

<a href="#"> MySqlCommand</a>	Overloaded. Initializes a new instance of the MySqlCommand class.
-------------------------------	-------------------------------------------------------------------

#### Public Instance Properties

<a href="#"> CommandText</a>	
<a href="#"> CommandTimeout</a>	
<a href="#"> CommandType</a>	
<a href="#"> Connection</a>	
<a href="#"> Container</a> (inherited from Component)	Gets the IContainer that contains the Component.
<a href="#"> IsPrepared</a>	
<a href="#"> Parameters</a>	
<a href="#"> Site</a> (inherited from Component)	Gets or sets the ISite of the Component.
<a href="#"> Transaction</a>	
<a href="#"> UpdatedRowSource</a>	

#### Public Instance Methods

<a href="#"> Cancel</a>	Attempts to cancel the execution of a MySqlCommand. This operation is not supported.
<a href="#"> CreateObjRef</a> (inherited from MarshalByRefObject)	Creates an object that contains all the relevant information required to generate a proxy used to communicate with a remote object.
<a href="#"> CreateParameter</a>	Creates a new instance of a <a href="#"> MySqlParameter</a> object.
<a href="#"> Dispose</a> (inherited from Component)	Releases all resources used by the Component.
<a href="#"> Equals</a> (inherited from Object)	Determines whether the specified Object is equal to the current Object.
<a href="#"> ExecuteNonQuery</a>	

<a href="#">ExecuteReader</a>	Overloaded.
<a href="#">ExecuteScalar</a>	
<a href="#">GetHashCode</a> (inherited from Object)	Serves as a hash function for a particular type. GetHashCode is suitable for use in hashing algorithms and data structures like a hash table.
<a href="#">GetLifetimeService</a> (inherited from MarshalByRefObject)	Retrieves the current lifetime service object that controls the lifetime policy for this instance.
<a href="#">GetType</a> (inherited from Object)	Gets the Type of the current instance.
<a href="#">InitializeLifetimeService</a> (inherited from MarshalByRefObject)	Obtains a lifetime service object to control the lifetime policy for this instance.
<a href="#">Prepare</a>	
<a href="#">ToString</a> (inherited from Component)	Returns a String containing the name of the Component, if any. This method should not be overridden.

**Public Instance Events**

<a href="#">Disposed</a> (inherited from Component)	Adds an event handler to listen to the Disposed event on the component.
-----------------------------------------------------	-------------------------------------------------------------------------

**See Also**[MySqlCommand Class](#) , [MySql.Data.MySqlClient Namespace](#)**21.2.7.1.2.1.1. [MySqlCommand](#) Constructor**Initializes a new instance of the [MySqlCommand](#) class.**Overload List**Initializes a new instance of the [MySqlCommand](#) class.

[MySqlConnection overview](#)

**Public Instance Constructors**

<a href="#">MySqlConnection</a>	Overloaded. Initializes a new instance of the MySqlConnection class.
---------------------------------	----------------------------------------------------------------------

**Public Instance Properties**

<a href="#">ConnectionString</a>	
<a href="#">ConnectionTimeout</a>	
<a href="#">Container</a> (inherited from Component)	Gets the IContainer that contains the Component.
<a href="#">Database</a>	
<a href="#">DataSource</a>	Gets the name of the MySQL server to which to connect.
<a href="#">ServerThread</a>	Returns the id of the server thread this connection is executing on
<a href="#">ServerVersion</a>	
<a href="#">Site</a> (inherited from Component)	Gets or sets the ISite of the Component.
<a href="#">State</a>	
<a href="#">UseCompression</a>	Indicates if this connection should use compression when communicating with the server.

**Public Instance Methods**

<a href="#">BeginTransaction</a>	Overloaded.
<a href="#">ChangeDatabase</a>	
<a href="#">Close</a>	
<a href="#">CreateCommand</a>	
<a href="#">CreateObjRef</a> (inherited from MarshalByRefObject)	Creates an object that contains all the relevant information required to generate a proxy used to communicate with a remote object.
<a href="#">Dispose</a> (inherited from Component)	Releases all resources used by the Component.
<a href="#">Equals</a> (inherited from Object)	Determines whether the specified Object is equal to the current Object.
<a href="#">GetHashCode</a> (inherited from Object)	Serves as a hash function for a particular type. GetHashCode is suitable for use in hashing algorithms and data structures like a hash table.
<a href="#">GetLifetimeService</a> (inherited from MarshalByRefObject)	Retrieves the current lifetime service object that controls the lifetime policy for this instance.
<a href="#">GetType</a> (inherited from Object)	Gets the Type of the current instance.
<a href="#">InitializeLifetimeService</a> (inherited from MarshalByRefObject)	Obtains a lifetime service object to control the lifetime policy for this instance.
<a href="#">Open</a>	
<a href="#">Ping</a>	Ping
<a href="#">ToString</a> (inherited from Component)	Returns a String containing the name of the Component, if any. This method should not be overridden.

**Public Instance Events**

<a href="#">Disposed</a> (inherited from Component)	Adds an event handler to listen to the Disposed event on the component.
<a href="#">InfoMessage</a>	
<a href="#">StateChange</a>

**21.2.7.1.2.1.1.3.1.1.1. [MySqlConnection](#) Constructor**

Initializes a new instance of the [MySqlConnection](#) class.

## Overload List

Initializes a new instance of the [MySqlConnection](#) class.

- [public MySqlConnection\(\);](#)
- [public MySqlConnection\(string\);](#)

### See Also

[MySqlConnection Class](#) , [MySQL.Data.MySqlClient Namespace](#)

### 21.2.7.1.2.1.1.3.1.1.1.1. [MySqlConnection](#) Constructor

Initializes a new instance of the [MySqlConnection](#) class.

#### Syntax: Visual Basic

```
Overloads Public Sub New()
```

#### Syntax: C#

```
public MySqlConnection();
```

### See Also

[MySqlConnection Class](#) , [MySQL.Data.MySqlClient Namespace](#) , [MySqlConnection Constructor Overload List](#)

### 21.2.7.1.2.1.1.3.1.1.1.2. [MySqlConnection](#) Constructor

#### Syntax: Visual Basic

```
Overloads Public Sub New(
 ByVal connectionString As String
)
```

#### Syntax: C#

```
public MySqlConnection(
 string connectionString
)
```

### See Also

[MySqlConnection Class](#) , [MySQL.Data.MySqlClient Namespace](#) , [MySqlConnection Constructor Overload List](#)

### 21.2.7.1.2.1.1.3.1.1.2. ConnectionString Property

#### Syntax: Visual Basic

```
NotOverridable Public Property ConnectionString As String
 Implements IDbConnection.ConnectionString
```

#### Syntax: C#

```
public string ConnectionString {get; set;}
```

#### Implements

[IDbConnection.ConnectionString](#)

### See Also

[MySqlConnection Class](#) , [MySQL.Data.MySqlClient Namespace](#)

### 21.2.7.1.2.1.1.3.1.1.3. ConnectionTimeout Property

**Syntax: Visual Basic**

```
NotOverridable Public ReadOnly Property ConnectionTimeout As Integer
 Implements IDbConnection.ConnectionTimeout
```

**Syntax: C#**

```
public int ConnectionTimeout {get;}
```

**Implements**

IDbConnection.ConnectionTimeout

**See Also**

[MySqlConnection Class](#) , [MySQL.Data.MySqlClient Namespace](#)

## 21.2.7.1.2.1.1.3.1.1.4. Database Property

**Syntax: Visual Basic**

```
NotOverridable Public ReadOnly Property Database As String
 Implements IDbConnection.Database
```

**Syntax: C#**

```
public string Database {get;}
```

**Implements**

IDbConnection.Database

**See Also**

[MySqlConnection Class](#) , [MySQL.Data.MySqlClient Namespace](#)

## 21.2.7.1.2.1.1.3.1.1.5. DataSource Property

Gets the name of the MySQL server to which to connect.

**Syntax: Visual Basic**

```
Public ReadOnly Property DataSource As String
```

**Syntax: C#**

```
public string DataSource {get;}
```

**See Also**

[MySqlConnection Class](#) , [MySQL.Data.MySqlClient Namespace](#)

## 21.2.7.1.2.1.1.3.1.1.6. ServerThread Property

Returns the id of the server thread this connection is executing on

**Syntax: Visual Basic**

```
Public ReadOnly Property ServerThread As Integer
```

**Syntax: C#**

```
public int ServerThread {get;}
```

**See Also**

[MySqlConnection Class](#) , [MySQL.Data.MySqlClient Namespace](#)

### 21.2.7.1.2.1.1.3.1.1.7. ServerVersion Property

#### Syntax: Visual Basic

```
Public ReadOnly Property ServerVersion As String
```

#### Syntax: C#

```
public string ServerVersion {get;}
```

#### See Also

[MySqlConnection Class](#) ,  [MySql.Data.MySqlClient Namespace](#)

### 21.2.7.1.2.1.1.3.1.1.8. State Property

#### Syntax: Visual Basic

```
NotOverridable Public ReadOnly Property State As ConnectionState _
 Implements IDbConnection.State
```

#### Syntax: C#

```
public System.Data.ConnectionState State {get;}
```

#### Implements

IDbConnection.State

#### See Also

[MySqlConnection Class](#) ,  [MySql.Data.MySqlClient Namespace](#)

### 21.2.7.1.2.1.1.3.1.1.9. UseCompression Property

Indicates if this connection should use compression when communicating with the server.

#### Syntax: Visual Basic

```
Public ReadOnly Property UseCompression As Boolean
```

#### Syntax: C#

```
public bool UseCompression {get;}
```

#### See Also

[MySqlConnection Class](#) ,  [MySql.Data.MySqlClient Namespace](#)

### 21.2.7.1.2.1.1.3.1.1.10. BeginTransaction Method

#### Overload List

- [public MySqlTransaction BeginTransaction\(\);](#)
- [public MySqlTransaction BeginTransaction\(IsolationLevel\);](#)

#### See Also

[MySqlConnection Class](#) ,  [MySql.Data.MySqlClient Namespace](#)

### 21.2.7.1.2.1.1.3.1.1.10.1. [MySqlConnection.BeginTransaction](#) Method

#### Syntax: Visual Basic

```
Overloads Public Function BeginTransaction() As MySqlTransaction
```

**Syntax: C#**

```
public MySqlTransaction BeginTransaction();
```

**See Also**

[MySqlConnection Class](#) ,  [MySql.Data.MySqlClient Namespace](#) , [MySqlConnection.BeginTransaction Overload List](#)

**21.2.7.1.2.1.1.3.1.1.10.1.1.1. MySqlTransaction Class**

For a list of all members of this type, see  [MySqlTransaction Members](#) .

**Syntax: Visual Basic**

```
NotInheritable Public Class MySqlTransaction_
 Implements IDbTransaction, IDisposable
```

**Syntax: C#**

```
public sealed class MySqlTransaction : IDbTransaction, IDisposable
```

**Thread Safety**

Public static (Shared in Visual Basic) members of this type are safe for multithreaded operations. Instance members are not guaranteed to be thread-safe.

**Requirements**

Namespace:  [MySql.Data.MySqlClient](#)

Assembly: MySql.Data (in MySql.Data.dll)

**See Also**

[MySqlTransaction Members](#) ,  [MySql.Data.MySqlClient Namespace](#)

**21.2.7.1.2.1.1.3.1.1.10.1.1.1. MySqlTransaction Members**

[MySqlTransaction overview](#)

**Public Instance Properties**

<a href="#">Connection</a>	Gets the <a href="#"> MySqlConnection</a> object associated with the transaction, or a null reference (Nothing in Visual Basic) if the transaction is no longer valid.
<a href="#">IsolationLevel</a>	Specifies the IsolationLevel for this transaction.

**Public Instance Methods**

<a href="#">Commit</a>	
<a href="#">Equals(inherited from Object)</a>	Determines whether the specified Object is equal to the current Object.
<a href="#">GetHashCode(inherited from Object)</a>	Serves as a hash function for a particular type. GetHashCode is suitable for use in hashing algorithms and data structures like a hash table.
<a href="#">GetType(inherited from Object)</a>	Gets the Type of the current instance.
<a href="#">Rollback</a>	
<a href="#">ToString(inherited from Object)</a>	Returns a String that represents the current Object.

**See Also**

[MySqlTransaction Class](#) ,  [MySql.Data.MySqlClient Namespace](#)

**21.2.7.1.2.1.1.3.1.1.10.1.1.1.1. Connection Property**

Gets the [MySqlConnection](#) object associated with the transaction, or a null reference (Nothing in Visual Basic) if the transaction is no longer valid.

#### Syntax: Visual Basic

```
Public ReadOnly Property Connection As MySqlConnection
```

#### Syntax: C#

```
public MySqlConnection Connection {get;}
```

#### Property Value

The [MySqlConnection](#) object associated with this transaction.

#### Remarks

A single application may have multiple database connections, each with zero or more transactions. This property enables you to determine the connection object associated with a particular transaction created by [BeginTransaction](#).

#### See Also

[MySqlTransaction Class](#) ,  [MySql.Data.MySqlClient Namespace](#)

### 21.2.7.1.2.1.1.3.1.1.10.1.1.1.2. IsolationLevel Property

Specifies the IsolationLevel for this transaction.

#### Syntax: Visual Basic

```
NotOverridable Public ReadOnly Property IsolationLevel As IsolationLevel _
 Implements IDbTransaction.IsolationLevel
```

#### Syntax: C#

```
public System.Data.IsolationLevel IsolationLevel {get;}
```

#### Property Value

The IsolationLevel for this transaction. The default is ReadCommitted.

#### Implements

[IDbTransaction.IsolationLevel](#)

#### Remarks

Parallel transactions are not supported. Therefore, the IsolationLevel applies to the entire transaction.

#### See Also

[MySqlTransaction Class](#) ,  [MySql.Data.MySqlClient Namespace](#)

### 21.2.7.1.2.1.1.3.1.1.10.1.1.1.3. [MySqlTransaction.Commit](#) Method

#### Syntax: Visual Basic

```
NotOverridable Public Sub Commit() _
 Implements IDbTransaction.Commit
```

#### Syntax: C#

```
public void Commit();
```

#### Implements

[IDbTransaction.Commit](#)

**See Also**

[MySqlTransaction Class](#) ,  [MySql.Data.MySqlClient Namespace](#)

**21.2.7.1.2.1.1.3.1.1.10.1.1.1.4. MySqlTransaction.Rollback Method****Syntax: Visual Basic**

```
NotOverridable Public Sub Rollback() _
 Implements IDbTransaction.Rollback
```

**Syntax: C#**

```
public void Rollback();
```

**Implements**

IDbTransaction.Rollback

**See Also**

[MySqlTransaction Class](#) ,  [MySql.Data.MySqlClient Namespace](#)

**21.2.7.1.2.1.1.3.1.1.10.2. MySqlConnection.BeginTransaction Method****Syntax: Visual Basic**

```
Overloads Public Function BeginTransaction(_
 ByVal iso As IsolationLevel _
) As MySqlTransaction
```

**Syntax: C#**

```
public MySqlTransaction BeginTransaction(
 IsolationLevel iso
);
```

**See Also**

[MySqlConnection Class](#) ,  [MySql.Data.MySqlClient Namespace](#) , [MySqlConnection.BeginTransaction Overload List](#)

**21.2.7.1.2.1.1.3.1.1.11. MySqlConnection.ChangeDatabase Method****Syntax: Visual Basic**

```
NotOverridable Public Sub ChangeDatabase(_
 ByVal databaseName As String _
) _
 Implements IDbConnection.ChangeDatabase
```

**Syntax: C#**

```
public void ChangeDatabase(
 string databaseName
);
```

**Implements**

IDbConnection.ChangeDatabase

**See Also**

[MySqlConnection Class](#) ,  [MySql.Data.MySqlClient Namespace](#)

**21.2.7.1.2.1.1.3.1.1.12. MySqlConnection.Close Method****Syntax: Visual Basic**

```
NotOverridable Public Sub Close() _
 Implements IDbConnection.Close
```

**Syntax: C#**

```
public void Close();
```

**Implements**

IDbConnection.Close

**See Also**[MySqlConnection Class](#) , [MySQL.Data.MySqlClient Namespace](#)**21.2.7.1.2.1.1.3.1.1.13. `MySqlConnection.CreateCommand` Method****Syntax: Visual Basic**

```
Public Function CreateCommand() As MySqlCommand
```

**Syntax: C#**

```
public MySqlCommand CreateCommand();
```

**See Also**[MySqlConnection Class](#) , [MySQL.Data.MySqlClient Namespace](#)**21.2.7.1.2.1.1.3.1.1.14. `MySqlConnection.Open` Method****Syntax: Visual Basic**

```
NotOverridable Public Sub Open() _
 Implements IDbConnection.Open
```

**Syntax: C#**

```
public void Open();
```

**Implements**

IDbConnection.Open

**See Also**[MySqlConnection Class](#) , [MySQL.Data.MySqlClient Namespace](#)**21.2.7.1.2.1.1.3.1.1.15. `MySqlConnection.Ping` Method**

Ping

**Syntax: Visual Basic**

```
Public Function Ping() As Boolean
```

**Syntax: C#**

```
public bool Ping();
```

**Return Value****See Also**[MySqlConnection Class](#) , [MySQL.Data.MySqlClient Namespace](#)**21.2.7.1.2.1.1.3.1.1.16. `MySqlConnection.InfoMessage` Event****Syntax: Visual Basic**

```
Public Event InfoMessage As MySqlInfoMessageEventHandler
```

**Syntax: C#**

```
public event MySqlInfoMessageEventHandler InfoMessage;
```

**See Also**

[MySqlConnection Class](#) , [MySql.Data.MySqlClient Namespace](#)

**21.2.7.1.2.1.1.3.1.1.16.1. MySqlInfoMessageEventHandler Delegate**

Represents the method that will handle the [InfoMessage](#) event of a [MySqlConnection](#) .

**Syntax: Visual Basic**

```
Public Delegate Sub MySqlInfoMessageEventHandler(_
 ByVal sender As Object, _
 ByVal args As MySqlInfoMessageEventArgs _
)
```

**Syntax: C#**

```
public delegate void MySqlInfoMessageEventHandler(
 object sender,
 MySqlInfoMessageEventArgs args
);
```

**Requirements**

Namespace: [MySql.Data.MySqlClient](#)

Assembly: MySql.Data (in MySql.Data.dll)

**See Also**

[MySql.Data.MySqlClient Namespace](#)

**21.2.7.1.2.1.1.3.1.1.16.1.1. MySqlInfoMessageEventArgs Class**

Provides data for the InfoMessage event. This class cannot be inherited.

For a list of all members of this type, see [MySqlInfoMessageEventArgs Members](#) .

**Syntax: Visual Basic**

```
Public Class MySqlInfoMessageEventArgs_
 Inherits EventArgs
```

**Syntax: C#**

```
public class MySqlInfoMessageEventArgs : EventArgs
```

**Thread Safety**

Public static (Shared in Visual Basic) members of this type are safe for multithreaded operations. Instance members are not guaranteed to be thread-safe.

**Requirements**

Namespace: [MySql.Data.MySqlClient](#)

Assembly: MySql.Data (in MySql.Data.dll)

**See Also**

**Public Instance Constructors**

<b>MySqlInfoMessageEventArgs</b> Constructor	Initializes a new instance of the <b>MySqlInfoMessageEventArgs</b> class.
----------------------------------------------	---------------------------------------------------------------------------

## Public Instance Fields

[errors](#)

## Public Instance Methods

Equals(inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode(inherited from Object)	Serves as a hash function for a particular type. GetHashCode is suitable for use in hashing algorithms and data structures like a hash table.
GetType(inherited from Object)	Gets the Type of the current instance.
ToString(inherited from Object)	Returns a String that represents the current Object.

## Protected Instance Methods

Finalize(inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone(inherited from Object)	Creates a shallow copy of the current Object.

### 21.2.7.1.2.1.1.4. `MySqlCommand` Constructor

**Syntax: Visual Basic**

```
Overloads Public Sub New(_
 ByVal cmdText As String, _
 ByVal connection As MySqlConnection, _
 ByVal transaction As MySqlTransaction _
)
```

**Syntax: C#**

```
public MySqlCommand(
 string cmdText,
 MySqlConnection connection,
 MySqlTransaction transaction
)
```

**See Also**

[MySqlCommand Class](#) ,  [MySql.Data.MySqlClient Namespace](#) , [MySqlCommand Constructor Overload List](#)

### 21.2.7.1.2.1.2. CommandText Property

**Syntax: Visual Basic**

```
NotOverridable Public Property CommandText As String _
 Implements IDbCommand.CommandText
```

**Syntax: C#**

```
public string CommandText {get; set;}
```

**Implements**

`IDbCommand.CommandText`

**See Also**

[MySqlCommand Class](#) ,  [MySql.Data.MySqlClient Namespace](#)

### 21.2.7.1.2.1.3. CommandTimeout Property

**Syntax: Visual Basic**

```
NotOverridable Public Property CommandTimeout As Integer _
 Implements IDbCommand.CommandTimeout
```

**Syntax: C#**

```
public int CommandTimeout {get; set;}
```

**Implements**

IDbCommand.CommandTimeout

**See Also**[MySqlCommand Class](#) ,  [MySql.Data.MySqlClient Namespace](#)

#### 21.2.7.1.2.1.4. CommandType Property

**Syntax: Visual Basic**

```
NotOverridable Public Property CommandType As CommandType __
 Implements IDbCommand.CommandType
```

**Syntax: C#**

```
public System.Data.CommandType CommandType {get; set;}
```

**Implements**

IDbCommand.CommandType

**See Also**[MySqlCommand Class](#) ,  [MySql.Data.MySqlClient Namespace](#)

#### 21.2.7.1.2.1.5. Connection Property

**Syntax: Visual Basic**

```
Public Property Connection As MySqlConnection
```

**Syntax: C#**

```
public MySqlConnection Connection {get; set;}
```

**See Also**[MySqlCommand Class](#) ,  [MySql.Data.MySqlClient Namespace](#)

#### 21.2.7.1.2.1.6. IsPrepared Property

**Syntax: Visual Basic**

```
Public ReadOnly Property IsPrepared As Boolean
```

**Syntax: C#**

```
public bool IsPrepared {get;}
```

**See Also**[MySqlCommand Class](#) ,  [MySql.Data.MySqlClient Namespace](#)

#### 21.2.7.1.2.1.7. Parameters Property

**Syntax: Visual Basic**

```
Public ReadOnly Property Parameters As MySqlParameterCollection
```

**Syntax: C#**

```
public MySqlParameterCollection Parameters {get;}
```

**See Also**

[MySqlCommand Class](#) ,  [MySql.Data.MySqlClient Namespace](#)

**21.2.7.1.2.1.7.1.1. MySqlParameterCollection Class**

Represents a collection of parameters relevant to a [MySqlCommand](#) as well as their respective mappings to columns in a [DataSet](#). This class cannot be inherited.

For a list of all members of this type, see  [MySqlParameterCollection Members](#) .

**Syntax: Visual Basic**

```
NotInheritable Public Class MySqlParameterCollection
 Inherits MarshalByRefObject
 Implements IDataParameterCollection, IList, ICollection, IEnumerable
```

**Syntax: C#**

```
public sealed class MySqlParameterCollection : MarshalByRefObject, IDataParameterCollection, IList, ICollection, IEnumerable
```

**Thread Safety**

Public static (Shared in Visual Basic) members of this type are safe for multithreaded operations. Instance members are not guaranteed to be thread-safe.

**Requirements**

Namespace:  [MySql.Data.MySqlClient](#)

Assembly: MySql.Data (in MySql.Data.dll)

**See Also**

[MySqlParameterCollection Members](#) ,  [MySql.Data.MySqlClient Namespace](#)

**21.2.7.1.2.1.7.1.1. MySqlParameterCollection Members**

[MySqlParameterCollection overview](#)

**Public Instance Constructors**

<a href="#"> MySqlParameterCollection Constructor</a>	Initializes a new instance of the <a href="#"> MySqlParameterCollection</a> class.
-------------------------------------------------------	------------------------------------------------------------------------------------

**Public Instance Properties**

<a href="#">Count</a>	Gets the number of <a href="#"> MySqlParameter</a> objects in the collection.
<a href="#">Item</a>	Overloaded. Gets the <a href="#"> MySqlParameter</a> with a specified attribute. In C#, this property is the indexer for the <a href="#"> MySqlParameterCollection</a> class.

**Public Instance Methods**

<a href="#">Add</a>	Overloaded. Adds the specified <a href="#"> MySqlParameter</a> object to the <a href="#"> MySqlParameterCollection</a> .
<a href="#">Clear</a>	Removes all items from the collection.
<a href="#">Contains</a>	Overloaded. Gets a value indicating whether a <a href="#"> MySqlParameter</a> exists in the collection.
<a href="#">CopyTo</a>	Copies <a href="#"> MySqlParameter</a> objects from the <a href="#"> MySqlParameterCollection</a> to the specified array.
<a href="#">CreateObjRef</a> (inherited from <a href="#"> MarshalByRefObject</a> )	Creates an object that contains all the relevant information required to generate a proxy used to communicate with a remote object.
<a href="#">Equals</a> (inherited from <a href="#"> Object</a> )	Determines whether the specified <a href="#"> Object</a> is equal to the current <a href="#"> Object</a> .

	Object.
GetHashCode(inherited from Object)	Serves as a hash function for a particular type. GetHashCode is suitable for use in hashing algorithms and data structures like a hash table.
GetLifetimeService(inherited from MarshalByRefObject)	Retrieves the current lifetime service object that controls the lifetime policy for this instance.
GetType(inherited from Object)	Gets the Type of the current instance.
IndexOf	Overloaded. Gets the location of a <a href="#">MySqlParameter</a> in the collection.
InitializeLifetimeService(inherited from MarshalByRefObject)	Obtains a lifetime service object to control the lifetime policy for this instance.
Insert	Inserts a MySqlParameter into the collection at the specified index.
Remove	Removes the specified MySqlParameter from the collection.
RemoveAt	Overloaded. Removes the specified <a href="#">MySqlParameter</a> from the collection.
ToString(inherited from Object)	Returns a String that represents the current Object.

```
Public Sub New()
```

**Syntax: C#**

```
public MySqlParameterCollection();
```

**See Also**[MySqlParameterCollection Class](#) , [MySql.Data.MySqlClient Namespace](#)**21.2.7.1.2.1.7.1.1.2. Count Property**

Gets the number of MySqlParameter objects in the collection.

**Syntax: Visual Basic**

```
NotOverridable Public ReadOnly Property Count As Integer _
 Implements ICollection.Count
```

**Syntax: C#**

```
public int Count {get;}
```

**Implements**

ICollection.Count

**See Also**[MySqlParameterCollection Class](#) , [MySql.Data.MySqlClient Namespace](#)**21.2.7.1.2.1.7.1.1.3. Item Property**Gets the [MySqlParameter](#) with a specified attribute. In C#, this property is the indexer for the [MySqlParameterCollection](#) class.

**Overload List**

Gets the [MySqlParameter](#) at the specified index.

- `public MySqlParameter this[int] {get; set;}`

Gets the [MySqlParameter](#) with the specified name.

- `public MySqlParameter this[string] {get; set;}`

**See Also**

**21.2.7.1.2.1.7.1.1.3.1. [MySqlParameter](#) Class**

Represents a parameter to a [MySqlCommand](#) , and optionally, its mapping to DataSetcolumns. This class cannot be inherited.

For a list of all members of this type, see [MySqlParameter Members](#) .

**Syntax: Visual Basic**

```
NotInheritable Public Class MySqlParameter_
 Inherits MarshalByRefObject_
 Implements IDataParameter, IDbDataParameter, ICloneable
```

**Syntax: C#**

```
public sealed class MySqlParameter : MarshalByRefObject, IDataParameter, IDbDataParameter, ICloneable
```

**Thread Safety**

Public static (Shared in Visual Basic) members of this type are safe for multithreaded operations. Instance members are not guaranteed to be thread-safe.

[MySqlParameter overview](#)

**Public Instance Constructors**

<a href="#">MySqlParameter</a>	Overloaded. Initializes a new instance of the <a href="#">MySqlParameter</a> class.
--------------------------------	-------------------------------------------------------------------------------------

**Public Instance Properties**

<a href="#">DbType</a>	Gets or sets the DbType of the parameter.
<a href="#">Direction</a>	Gets or sets a value indicating whether the parameter is input-only, output-only, bidirectional, or a stored procedure return value parameter. As of MySQL version 4.1 and earlier, input-only is the only valid choice.
<a href="#">IsNullable</a>	Gets or sets a value indicating whether the parameter accepts null values.
<a href="#">IsUnsigned</a>	

<a href="#">MySqlDbType</a>	Gets or sets the MySqlDbType of the parameter.
<a href="#">ParameterName</a>	Gets or sets the name of the MySqlParameter.
<a href="#">Precision</a>	Gets or sets the maximum number of digits used to represent the <a href="#">Value</a> property.
<a href="#">Scale</a>	Gets or sets the number of decimal places to which <a href="#">Value</a> is resolved.
<a href="#">Size</a>	Gets or sets the maximum size, in bytes, of the data within the column.
<a href="#">SourceColumn</a>	Gets or sets the name of the source column that is mapped to the DataSet used for loading or returning the <a href="#">Value</a> .
<a href="#">SourceVersion</a>	Gets or sets the DataRow Version to use when loading <a href="#">Value</a> .
<a href="#">Value</a>	Gets or sets the value of the parameter.

### Public Instance Methods

<a href="#">CreateObjRef</a> (inherited from MarshalByRefObject)	Creates an object that contains all the relevant information required to generate a proxy used to communicate with a remote object.
<a href="#">Equals</a> (inherited from Object)	Determines whether the specified Object is equal to the current Object.
<a href="#">GetHashCode</a> (inherited from Object)	Serves as a hash function for a particular type. GetHashCode is suitable for use in hashing algorithms and data structures like a hash table.
<a href="#">GetLifetimeService</a> (inherited from MarshalByRefObject)	Retrieves the current lifetime service object that controls the lifetime policy for this instance.
<a href="#">GetType</a> (inherited from Object)	Gets the Type of the current instance.
<a href="#">InitializeLifetimeService</a> (inherited from MarshalByRefObject)	Obtains a lifetime service object to control the lifetime policy for this instance.
<a href="#">ToString</a>	Overridden. Gets a string containing the <a href="#">ParameterName</a> .

Initializes a new instance of the MySqlParameter class.

##### Overload List

Initializes a new instance of the MySqlParameter class.

- [public MySqlParameter\(\);](#)

Initializes a new instance of the [MySqlParameter](#) class with the parameter name and the data type.

- [public MySqlParameter\(string,MySqlDbType\);](#)

Initializes a new instance of the [MySqlParameter](#) class with the parameter name, the [MySqlDbType](#), and the size.

- [public MySqlParameter\(string,MySqlDbType,int\);](#)

Initializes a new instance of the [MySqlParameter](#) class with the parameter name, the type of the parameter, the size of the parameter, a ParameterDirection, the precision of the parameter, the scale of the parameter, the source column, a DataRowVersion to use, and the value of the parameter.

- `public MySqlParameter(string,MySqlDbType,int, ParameterDirection, bool, byte, byte, string, DataRowVersion, object);`

Initializes a new instance of the [MySqlParameter](#) class with the parameter name, the [MySqlDbType](#), the size, and the source column name.

- `public MySqlParameter(string,MySqlDbType,int,string);`

Initializes a new instance of the [MySqlParameter](#) class with the parameter name and a value of the new [MySqlParameter](#).

- `public MySqlParameter(string,object);`

Specifies MySQL specific data type of a field, property, for use in a [MySqlParameter](#).

## Syntax: Visual Basic

```
Public Enum MySqlDbType
```

### Syntax: C#

```
public enum MySqlDbType
```

### Members

Member Name	Description
Newdate	Obsolete. Use Datetime or Date type.
Timestamp	A timestamp. The range is '1970-01-01 00:00:01' to sometime in the year 2038.
Time	The range is '-838:59:59' to '838:59:59'
Date	Date The supported range is '1000-01-01' to '9999-12-31'
Datetime	The supported range is '1000-01-01 00:00:00' to '9999-12-31 23:59:59'
Year	A year in 2- or 4-digit format (default is 4-digit). The allowable values are 1901 to 2155, 0000 in the 4-digit year format, and 1970-2069 if you use the 2-digit format (70-69).
TinyBlob	A BLOB column with a maximum length of 255 ( $2^8 - 1$ ) characters
Blob	A BLOB column with a maximum length of 65535 ( $2^{16} - 1$ ) characters
MediumBlob	A BLOB column with a maximum length of 16777215 ( $2^{24} - 1$ ) characters
LongBlob	A BLOB column with a maximum length of 4294967295 or 4G ( $2^{32} - 1$ ) characters
Int16	A 16-bit signed integer. The signed range is -32768 to 32767. The unsigned range is 0 to 65535
Int24	Specifies a 24 (3 byte) signed or unsigned value
Int32	A 32-bit signed integer
Int64	A 64-bit signed integer
Byte	The signed range is -128 to 127. The unsigned range is 0 to 255.
Float	A small (single-precision) floating-point number. Allowable values are -3.402823466E+38 to -1.175494351E-38, 0, and 1.175494351E-38 to 3.402823466E+38.
Double	A normal-size (double-precision) floating-point number. Allowable values are -1.7976931348623157E+308 to -2.2250738585072014E-308, 0, and 2.2250738585072014E-308 to 1.7976931348623157E+308.
UByte	An 8-bit unsigned value
UInt16	A 16-bit unsigned value
UInt24	A 24-bit unsigned value
UInt32	A 32-bit unsigned value
UInt64	A 64-bit unsigned value
Decimal	A fixed precision and scale numeric value between -1038 -1 and 10 38 -1
NewDecimal	New Decimal
Set	A set. A string object that can have zero or more values, each of which must be chosen from the list of values 'value1', 'value2', ...

	A SET can have a maximum of 64 members.
String	Obsolete Use VarChar type
VarChar	A variable-length string containing 0 to 255 characters
VarString	A variable-length string containing 0 to 65535 characters
Enum	An enumeration. A string object that can have only one value, chosen from the list of values 'value1', 'value2', ..., NULL or the special "" error value. An ENUM can have a maximum of 65535 distinct values.
Geometry	
Bit	Bit-field data type
TinyText	A nonbinary string column supporting a maximum length of 255 ( $2^8 - 1$ ) characters
Text	A nonbinary string column supporting a maximum length of 65535 ( $2^{16} - 1$ ) characters
MediumText	A nonbinary string column supporting a maximum length of 16777215 ( $2^{24} - 1$ ) characters
LongText	A nonbinary string column supporting a maximum length of 4294967295 ( $2^{32} - 1$ ) characters

[MySql.Data.MySqlClient Namespace](#)

### 21.2.7.1.2.1.7.1.1.3.1.1.1.3. MySqlParameter Constructor (String, MySqlDbType, Int32)

Initializes a new instance of the  [MySqlParameter](#)  class with the parameter name, the  [MySqlDbType](#)  , and the size.

#### Syntax: Visual Basic

```
Overloads Public Sub New(_
 ByVal parameterName As String, _
 ByVal dbType As MySqlDbType, _
 ByVal size As Integer _
)
```

#### Syntax: C#

```
public MySqlParameter(
 string parameterName,
 MySqlDbType dbType,
 int size
);
```

## Parameters

- [parameterName](#) : The name of the parameter to map.
- [dbType](#) : One of the  [MySqlDbType](#)  values.
- [size](#) : The length of the parameter.

## See Also

[MySqlParameter Class](#)  ,  [MySql.Data.MySqlClient Namespace](#)  ,  [MySqlParameter Constructor Overload List](#)

### 21.2.7.1.2.1.7.1.1.3.1.1.1.4. MySqlParameter Constructor

Initializes a new instance of the  [MySqlParameter](#)  class with the parameter name, the type of the parameter, the size of the paramet-

er, a ParameterDirection, the precision of the parameter, the scale of the parameter, the source column, a DataRowVersion to use, and the value of the parameter.

#### Syntax: Visual Basic

```
Overloads Public Sub New(_
 ByVal parameterName As String, _
 ByVal dbType As MySqlDbType, _
 ByVal size As Integer, _
 ByVal direction As ParameterDirection, _
 ByVal isNullable As Boolean, _
 ByVal precision As Byte, _
 ByVal scale As Byte, _
 ByVal sourceColumn As String, _
 ByVal sourceVersion As DataRowVersion, _
 ByVal value As Object _
)
```

#### Syntax: C#

```
public MySqlParameter(
 string parameterName,
 MySqlDbType dbType,
 int size,
 ParameterDirection direction,
 bool isNullable,
 byte precision,
 byte scale,
 string sourceColumn,
 DataRowVersion sourceVersion,
 object value
);
```

#### Parameters

- **parameterName**: The name of the parameter to map.
- **dbType**: One of the [MySqlDbType](#) values.
- **size**: The length of the parameter.
- **direction**: One of the ParameterDirection values.
- **isNullable**: true if the value of the field can be null, otherwise false.
- **precision**: The total number of digits to the left and right of the decimal point to which **Value** is resolved.
- **scale**: The total number of decimal places to which **Value** is resolved.
- **sourceColumn**: The name of the source column.
- **sourceVersion**: One of the DataRowVersion values.
- **value**: An Object that is the value of the [MySqlParameter](#).

#### Exceptions

Exception Type	Condition
ArgumentException

#### 21.2.7.1.2.1.7.1.1.3.1.1.1.4.1. Value Property

Gets or sets the value of the parameter.

#### Syntax: Visual Basic

```
NotOverridable Public Property Value As Object _
 Implements IDataParameter.Value
```

**Syntax: C#**

```
public object Value {get; set;}
```

**Implements**

IDataParameter.Value

**See Also**[MySqlParameter Class](#) ,  [MySql.Data.MySqlClient Namespace](#)**21.2.7.1.2.1.7.1.1.3.1.1.1.5. MySqlParameter Constructor**

Initializes a new instance of the [MySqlParameter](#) class with the parameter name, the [MySqlDbType](#), the size, and the source column name.

**Syntax: Visual Basic**

```
Overloads Public Sub New(_
 ByVal parameterName As String, _
 ByVal dbType As MySqlDbType, _
 ByVal size As Integer, _
 ByVal sourceColumn As String _
)
```

**Syntax: C#**

```
public MySqlParameter(_
 string parameterName, _
 MySqlDbType dbType, _
 int size, _
 string sourceColumn
);
```

**Parameters**

- `parameterName`: The name of the parameter to map.
- `dbType`: One of the [MySqlDbType](#) values.
- `size`: The length of the parameter.
- `sourceColumn`: The name of the source column.

**See Also**[MySqlParameter Class](#) ,  [MySql.Data.MySqlClient Namespace](#) , [MySqlParameter Constructor Overload List](#)**21.2.7.1.2.1.7.1.1.3.1.1.1.6. MySqlParameter Constructor**

Initializes a new instance of the [MySqlParameter](#) class with the parameter name and a value of the new [MySqlParameter](#).

**Syntax: Visual Basic**

```
Overloads Public Sub New(_
 ByVal parameterName As String, _
 ByVal value As Object _
)
```

**Syntax: C#**

```
public MySqlParameter(_
 string parameterName, _
 object value
);
```

**Parameters**

- `parameterName`: The name of the parameter to map.

- **value**: An Objectthat is the value of the [MySqlParameter](#) .

[MySqlParameter Class](#) ,  [MySql.Data.MySqlClient Namespace](#) , [MySqlParameter Constructor Overload List](#)

### 21.2.7.1.2.1.7.1.1.3.1.1.2. DbType Property

Gets or sets the DbTypeof the parameter.

#### Syntax: Visual Basic

```
NotOverridable Public Property DbType As DbType
 Implements IDataParameter.DbType
```

#### Syntax: C#

```
public System.Data.DbType DbType {get; set;}
```

#### Implements

IDataParameter.DbType

#### See Also

[MySqlParameter Class](#) ,  [MySql.Data.MySqlClient Namespace](#)

### 21.2.7.1.2.1.7.1.1.3.1.1.3. Direction Property

Gets or sets a value indicating whether the parameter is input-only, output-only, bidirectional, or a stored procedure return value parameter. As of MySQL version 4.1 and earlier, input-only is the only valid choice.

#### Syntax: Visual Basic

```
NotOverridable Public Property Direction As ParameterDirection
 Implements IDataParameter.Direction
```

#### Syntax: C#

```
public System.Data.ParameterDirection Direction {get; set;}
```

#### Implements

IDataParameter.Direction

#### See Also

[MySqlParameter Class](#) ,  [MySql.Data.MySqlClient Namespace](#)

### 21.2.7.1.2.1.7.1.1.3.1.1.4. IsNullable Property

Gets or sets a value indicating whether the parameter accepts null values.

#### Syntax: Visual Basic

```
NotOverridable Public Property IsNullable As Boolean
 Implements IDataParameter.IsNullable
```

#### Syntax: C#

```
public bool IsNullable {get; set;}
```

#### Implements

IDataParameter.IsNotNullable

**See Also**

[MySqlParameter Class](#) , [MySql.Data.MySqlClient Namespace](#)

### 21.2.7.1.2.1.7.1.1.3.1.1.5. IsUnsigned Property

**Syntax: Visual Basic**

```
Public Property IsUnsigned As Boolean
```

**Syntax: C#**

```
public bool IsUnsigned {get; set;}
```

**See Also**

[MySqlParameter Class](#) , [MySql.Data.MySqlClient Namespace](#)

### 21.2.7.1.2.1.7.1.1.3.1.1.6. MySqlDbType Property

Gets or sets the MySqlDbType of the parameter.

**Syntax: Visual Basic**

```
Public Property MySqlDbType As MySqlDbType
```

**Syntax: C#**

```
public MySqlDbType MySqlDbType {get; set;}
```

**See Also**

[MySqlParameter Class](#) , [MySql.Data.MySqlClient Namespace](#)

### 21.2.7.1.2.1.7.1.1.3.1.1.7. ParameterName Property

Gets or sets the name of the MySqlParameter.

**Syntax: Visual Basic**

```
NotOverridable Public Property ParameterName As String _
 Implements IDataParameter.ParameterName
```

**Syntax: C#**

```
public string ParameterName {get; set;}
```

**Implements**

IDataParameter.ParameterName

**See Also**

[MySqlParameter Class](#) , [MySql.Data.MySqlClient Namespace](#)

### 21.2.7.1.2.1.7.1.1.3.1.1.8. Precision Property

Gets or sets the maximum number of digits used to represent the [Value](#) property.

**Syntax: Visual Basic**

```
NotOverridable Public Property Precision As Byte _
 Implements IDbDataParameter.Precision
```

**Syntax: C#**

```
public byte Precision {get; set;}
```

**Implements**

IDbDataParameter.Precision

**See Also**[MySqlParameter Class](#) ,  [MySql.Data.MySqlClient Namespace](#)

### 21.2.7.1.2.1.7.1.1.3.1.1.9. Scale Property

Gets or sets the number of decimal places to which [Value](#) is resolved.

**Syntax: Visual Basic**

```
NotOverridable Public Property Scale As Byte
 Implements IDbDataParameter.Scale
```

**Syntax: C#**

```
public byte Scale {get; set;}
```

**Implements**

IDbDataParameter.Scale

**See Also**[MySqlParameter Class](#) ,  [MySql.Data.MySqlClient Namespace](#)

### 21.2.7.1.2.1.7.1.1.3.1.1.10. Size Property

Gets or sets the maximum size, in bytes, of the data within the column.

**Syntax: Visual Basic**

```
NotOverridable Public Property Size As Integer
 Implements IDbDataParameter.Size
```

**Syntax: C#**

```
public int Size {get; set;}
```

**Implements**

IDbDataParameter.Size

**See Also**[MySqlParameter Class](#) ,  [MySql.Data.MySqlClient Namespace](#)

### 21.2.7.1.2.1.7.1.1.3.1.1.11. SourceColumn Property

Gets or sets the name of the source column that is mapped to the DataSet used for loading or returning the [Value](#).

**Syntax: Visual Basic**

```
NotOverridable Public Property SourceColumn As String
 Implements IDataParameter.SourceColumn
```

**Syntax: C#**

```
public string SourceColumn {get; set;}
```

**Implements**

IDataParameter.SourceColumn

**See Also**

[MySqlParameter Class](#) , [MySql.Data.MySqlClient Namespace](#)

**21.2.7.1.2.1.7.1.1.3.1.1.12. SourceVersion Property**

Gets or sets the `DataRowVersion` to use when loading `Value`.

**Syntax: Visual Basic**

```
NotOverridable Public Property SourceVersion As DataRowVersion _
 Implements IDataParameter.SourceVersion
```

**Syntax: C#**

```
public System.Data.DataRowVersion SourceVersion {get; set;}
```

**Implements**

`IDataParameter.SourceVersion`

**See Also**

[MySqlParameter Class](#) , [MySql.Data.MySqlClient Namespace](#)

**21.2.7.1.2.1.7.1.1.3.1.1.13. MySqlParameter.ToString Method**

Overrides. Gets a string containing the `ParameterName`.

**Syntax: Visual Basic**

```
Overrides Public Function ToString() As String
```

**Syntax: C#**

```
public override string ToString();
```

**Return Value****See Also**

[MySqlParameter Class](#) , [MySql.Data.MySqlClient Namespace](#)

**21.2.7.1.2.1.7.1.1.3.2. Item Property (Int32)**

Gets the `MySqlParameter` at the specified index.

**Syntax: Visual Basic**

```
Overloads Public Default Property Item(_
 ByVal index As Integer _
) As MySqlParameter
```

**Syntax: C#**

```
public MySqlParameter this[_
 int index
] {get; set;}
```

**See Also**

[MySqlParameterCollection Class](#) , [MySql.Data.MySqlClient Namespace](#) , [MySqlParameterCollection.Item Overload List](#)

**21.2.7.1.2.1.7.1.1.3.3. Item Property (String)**

Gets the `MySqlParameter` with the specified name.

**Syntax: Visual Basic**

```
Overloads Public Default Property Item(_
```

```
 ByVal name As String _
) As MySqlParameter
```

**Syntax: C#**

```
public MySqlParameter this[
 stringname
] {get; set;}
```

**See Also**

[MySqlParameterCollection Class](#) ,  [MySql.Data.MySqlClient Namespace](#) ,  [MySqlParameterCollection.Item Overload List](#)

**21.2.7.1.2.1.7.1.1.4. Add Method**

Adds the specified [MySqlParameter](#) object to the [MySqlParameterCollection](#) .

**Overload List**

Adds the specified [MySqlParameter](#) object to the [MySqlParameterCollection](#) .

- [public MySqlParameter Add\(MySqlParameter\);](#)

Adds the specified [MySqlParameter](#) object to the [MySqlParameterCollection](#) .

- [public int Add\(object\);](#)

Adds a [MySqlParameter](#) to the [MySqlParameterCollection](#) given the parameter name and the data type.

- [public MySqlParameter Add\(string,MySqlDbType\);](#)

Adds a [MySqlParameter](#) to the [MySqlParameterCollection](#) with the parameter name, the data type, and the column length.

- [public MySqlParameter Add\(string,MySqlDbType,int\);](#)

Adds a [MySqlParameter](#) to the [MySqlParameterCollection](#) with the parameter name, the data type, the column length, and the source column name.

- [public MySqlParameter Add\(string,MySqlDbType,int,string\);](#)

Adds a [MySqlParameter](#) to the [MySqlParameterCollection](#) given the specified parameter name and value.

- [public MySqlParameter Add\(string,object\);](#)

**See Also**

[MySqlParameterCollection Class](#) ,  [MySql.Data.MySqlClient Namespace](#)

**21.2.7.1.2.1.7.1.1.4.1. [MySqlParameterCollection.Add](#) Method**

Adds the specified [MySqlParameter](#) object to the [MySqlParameterCollection](#) .

**Syntax: Visual Basic**

```
Overloads Public Function Add(_
 ByVal value As MySqlParameter _
) As MySqlParameter
```

**Syntax: C#**

```
public MySqlParameter Add(
```

```
MySqlParameter value
);
```

### Parameters

- **value**: The [MySqlParameter](#) to add to the collection.

### Return Value

The newly added [MySqlParameter](#) object.

### See Also

[MySqlParameterCollection Class](#) ,  [MySql.Data.MySqlClient Namespace](#) , [MySqlParameterCollection.Add Overload List](#)

#### 21.2.7.1.2.1.7.1.1.4.2. [MySqlParameterCollection.Add](#) Method

Adds the specified [MySqlParameter](#) object to the [MySqlParameterCollection](#).

### Syntax: Visual Basic

```
NotOverridable Overloads Public Function Add(_
 ByVal value As Object _
) As Integer _
 Implements IList.Add
```

### Syntax: C#

```
public int Add(
 object value
);
```

### Parameters

- **value**: The [MySqlParameter](#) to add to the collection.

### Return Value

The index of the new [MySqlParameter](#) object.

### Implements

IList.Add

### See Also

[MySqlParameterCollection Class](#) ,  [MySql.Data.MySqlClient Namespace](#) , [MySqlParameterCollection.Add Overload List](#)

#### 21.2.7.1.2.1.7.1.1.4.3. [MySqlParameterCollection.Add](#) Method

Adds a [MySqlParameter](#) to the [MySqlParameterCollection](#) given the parameter name and the data type.

### Syntax: Visual Basic

```
Overloads Public Function Add(_
 ByVal parameterName As String, _
 ByVal dbType As MySqlDbType _
) As MySqlParameter
```

### Syntax: C#

```
public MySqlParameter Add(
 string parameterName,
 MySqlDbType dbType
);
```

### Parameters

- `parameterName`: The name of the parameter.
- `dbType`: One of the [MySqlDbType](#) values.

#### Return Value

The newly added [MySqlParameter](#) object.

#### See Also

[MySqlParameterCollection Class](#) ,  [MySql.Data.MySqlClient Namespace](#) , [MySqlParameterCollection.Add Overload List](#)

### 21.2.7.1.2.1.7.1.1.4.4. [MySqlParameterCollection.Add](#) Method

Adds a [MySqlParameter](#) to the [MySqlParameterCollection](#) with the parameter name, the data type, and the column length.

#### Syntax: Visual Basic

```
Overloads Public Function Add(_
 ByVal parameterName As String, _
 ByVal dbType As MySqlDbType, _
 ByVal size As Integer _
) As MySqlParameter
```

#### Syntax: C#

```
public MySqlParameter Add(
 string parameterName,
 MySqlDbType dbType,
 int size
);
```

#### Parameters

- `parameterName`: The name of the parameter.
- `dbType`: One of the [MySqlDbType](#) values.
- `size`: The length of the column.

#### Return Value

The newly added [MySqlParameter](#) object.

#### See Also

[MySqlParameterCollection Class](#) ,  [MySql.Data.MySqlClient Namespace](#) , [MySqlParameterCollection.Add Overload List](#)

### 21.2.7.1.2.1.7.1.1.4.5. [MySqlParameterCollection.Add](#) Method

Adds a [MySqlParameter](#) to the [MySqlParameterCollection](#) with the parameter name, the data type, the column length, and the source column name.

#### Syntax: Visual Basic

```
Overloads Public Function Add(_
 ByVal parameterName As String, _
 ByVal dbType As MySqlDbType, _
 ByVal size As Integer, _
 ByVal sourceColumn As String _
) As MySqlParameter
```

#### Syntax: C#

```
public MySqlParameter Add(
 string parameterName,
 MySqlDbType dbType,
 int size,
 string sourceColumn
);
```

#### Parameters

- `parameterName`: The name of the parameter.
- `dbType`: One of the [MySqlDbType](#) values.
- `size`: The length of the column.
- `sourceColumn`: The name of the source column.

### Return Value

The newly added [MySqlParameter](#) object.

### See Also

[MySqlParameterCollection Class](#) ,  [MySql.Data.MySqlClient Namespace](#) , [MySqlParameterCollection.Add Overload List](#)

## 21.2.7.1.2.1.7.1.1.4.6. [MySqlParameterCollection.Add](#) Method

Adds a [MySqlParameter](#) to the [MySqlParameterCollection](#) given the specified parameter name and value.

### Syntax: Visual Basic

```
Overloads Public Function Add(_
 ByVal parameterName As String, _
 ByVal value As Object _
) As MySqlParameter
```

### Syntax: C#

```
public MySqlParameter Add(
 string parameterName,
 object value
);
```

### Parameters

- `parameterName`: The name of the parameter.
- `value`: The [Value](#) of the [MySqlParameter](#) to add to the collection.

### Return Value

The newly added [MySqlParameter](#) object.

### See Also

[MySqlParameterCollection Class](#) ,  [MySql.Data.MySqlClient Namespace](#) , [MySqlParameterCollection.Add Overload List](#)

## 21.2.7.1.2.1.7.1.1.5. [MySqlParameterCollection.Clear](#) Method

Removes all items from the collection.

### Syntax: Visual Basic

```
NotOverridable Public Sub Clear() _
 Implements IList.Clear
```

### Syntax: C#

```
public void Clear();
```

### Implements

IList.Clear

### See Also

[MySqlParameterCollection Class](#) ,  [MySql.Data.MySqlClient Namespace](#)

## 21.2.7.1.2.1.7.1.1.6. Contains Method

Gets a value indicating whether a [MySqlParameter](#) exists in the collection.

### Overload List

Gets a value indicating whether a MySqlParameter exists in the collection.

- [public bool Contains\(object\);](#)

Gets a value indicating whether a [MySqlParameter](#) with the specified parameter name exists in the collection.

- [public bool Contains\(string\);](#)

### See Also

[MySqlParameterCollection Class](#) , [MySql.Data.MySqlClient Namespace](#)

## 21.2.7.1.2.1.7.1.1.6.1. [MySqlParameterCollection.Contains](#) Method

Gets a value indicating whether a MySqlParameter exists in the collection.

### Syntax: Visual Basic

```
NotOverridable Overloads Public Function Contains(_
 ByVal value As Object _
) As Boolean _
 Implements IList.Contains
```

### Syntax: C#

```
public bool Contains(
 object value
);
```

### Parameters

- [value](#): The value of the [MySqlParameter](#) object to find.

### Return Value

true if the collection contains the [MySqlParameter](#) object; otherwise, false.

### Implements

IList.Contains

### See Also

[MySqlParameterCollection Class](#) , [MySql.Data.MySqlClient Namespace](#) , [MySqlParameterCollection.Contains Overload List](#)

## 21.2.7.1.2.1.7.1.1.6.2. [MySqlParameterCollection.Contains](#) Method

Gets a value indicating whether a [MySqlParameter](#) with the specified parameter name exists in the collection.

### Syntax: Visual Basic

```
NotOverridable Overloads Public Function Contains(_
 ByVal name As String _
) As Boolean _
 Implements IDataParameterCollection.Contains
```

### Syntax: C#

```
public bool Contains(
 string name
);
```

```
) ;
```

### Parameters

- **name**: The name of the [MySqlParameter](#) object to find.

### Return Value

true if the collection contains the parameter; otherwise, false.

### Implements

[IDataParameterCollection](#).Contains

### See Also

[MySqlParameterCollection Class](#) ,  [MySql.Data.MySqlClient Namespace](#) , [MySqlParameterCollection.Contains Overload List](#)

## 21.2.7.1.2.1.7.1.1.7. [MySqlParameterCollection.CopyTo](#) Method

Copies [MySqlParameter](#) objects from the [MySqlParameterCollection](#) to the specified array.

### Syntax: Visual Basic

```
NotOverridable Public Sub CopyTo(_
 ByVal array As Array, _
 ByVal index As Integer _
) _
- Implements ICollection.CopyTo
```

### Syntax: C#

```
public void CopyTo(
 Array array,
 int index
);
```

### Parameters

- **array**:
- **index**:

### Implements

[ICollection](#).CopyTo

### See Also

[MySqlParameterCollection Class](#) ,  [MySql.Data.MySqlClient Namespace](#)

## 21.2.7.1.2.1.7.1.1.8. [IndexOf](#) Method

Gets the location of a [MySqlParameter](#) in the collection.

### Overload List

Gets the location of a [MySqlParameter](#) in the collection.

- [public int IndexOf\(object\);](#)

Gets the location of the [MySqlParameter](#) in the collection with a specific parameter name.

- [public int IndexOf\(string\);](#)

**See Also**

[MySqlParameterCollection Class](#) ,  [MySql.Data.MySqlClient Namespace](#)

### 21.2.7.1.2.1.7.1.1.8.1. [MySqlParameterCollection](#).IndexOf Method

Gets the location of a [MySqlParameter](#) in the collection.

**Syntax: Visual Basic**

```
NotOverridable Overloads Public Function IndexOf(_
 ByVal value As Object _
) As Integer _
' Implements IList.IndexOf
```

**Syntax: C#**

```
public int IndexOf(
 object value
);
```

**Parameters**

- **value**: The [MySqlParameter](#) object to locate.

**Return Value**

The zero-based location of the [MySqlParameter](#) in the collection.

**Implements**

IList.IndexOf

**See Also**

[MySqlParameterCollection Class](#) ,  [MySql.Data.MySqlClient Namespace](#) , [MySqlParameterCollection.IndexOf Overload List](#)

### 21.2.7.1.2.1.7.1.1.8.2. [MySqlParameterCollection](#).IndexOf Method

Gets the location of the [MySqlParameter](#) in the collection with a specific parameter name.

**Syntax: Visual Basic**

```
NotOverridable Overloads Public Function IndexOf(_
 ByVal parameterName As String _
) As Integer _
' Implements IDataParameterCollection.IndexOf
```

**Syntax: C#**

```
public int IndexOf(
 string parameterName
);
```

**Parameters**

- **parameterName**: The name of the [MySqlParameter](#) object to retrieve.

**Return Value**

The zero-based location of the [MySqlParameter](#) in the collection.

**Implements**

IDataParameterCollection.IndexOf

**See Also**

[MySqlParameterCollection Class](#) , [MySql.Data.MySqlClient Namespace](#) , [MySqlParameterCollection.IndexOf Overload List](#)

### 21.2.7.1.2.1.7.1.1.9. `MySqlParameterCollection.Insert` Method

Inserts a MySqlParameter into the collection at the specified index.

#### Syntax: Visual Basic

```
NotOverridable Public Sub Insert(_
 ByVal index As Integer, _
 ByVal value As Object _
) _
- Implements IList.Insert
```

#### Syntax: C#

```
public void Insert(
 int index,
 object value
);
```

#### Parameters

- `index`:
- `value`:

#### Implements

IList.Insert

#### See Also

[MySqlParameterCollection Class](#) , [MySql.Data.MySqlClient Namespace](#)

### 21.2.7.1.2.1.7.1.1.10. `MySqlParameterCollection.Remove` Method

Removes the specified MySqlParameter from the collection.

#### Syntax: Visual Basic

```
NotOverridable Public Sub Remove(_
 ByVal value As Object _
) _
- Implements IList.Remove
```

#### Syntax: C#

```
public void Remove(
 object value
);
```

#### Parameters

- `value`:

#### Implements

IList.Remove

#### See Also

[MySqlParameterCollection Class](#) , [MySql.Data.MySqlClient Namespace](#)

### 21.2.7.1.2.1.7.1.1.11. `RemoveAt` Method

Removes the specified `MySqlParameter` from the collection.

## Overload List

Removes the specified [MySqlParameter](#) from the collection using a specific index.

- [public void RemoveAt\(int\);](#)

Removes the specified [MySqlParameter](#) from the collection using the parameter name.

- [public void RemoveAt\(string\);](#)

## See Also

[MySqlParameterCollection Class](#) , [MySql.Data.MySqlClient Namespace](#)

### 21.2.7.1.2.1.7.1.1.11.1. [MySqlParameterCollection.RemoveAt](#) Method

Removes the specified [MySqlParameter](#) from the collection using a specific index.

#### Syntax: Visual Basic

```
NotOverridable Overloads Public Sub RemoveAt(_
 ByVal index As Integer _
) _
- Implements IList.RemoveAt
```

#### Syntax: C#

```
public void RemoveAt(
 int index
);
```

## Parameters

- [index](#): The zero-based index of the parameter.

## Implements

[IList.RemoveAt](#)

## See Also

[MySqlParameterCollection Class](#) , [MySql.Data.MySqlClient Namespace](#) , [MySqlParameterCollection.RemoveAt Overload List](#)

### 21.2.7.1.2.1.7.1.1.11.2. [MySqlParameterCollection.RemoveAt](#) Method

Removes the specified [MySqlParameter](#) from the collection using the parameter name.

#### Syntax: Visual Basic

```
NotOverridable Overloads Public Sub RemoveAt(_
 ByVal name As String _
) _
- Implements IDataParameterCollection.RemoveAt
```

#### Syntax: C#

```
public void RemoveAt(
 string name
);
```

## Parameters

- [name](#): The name of the [MySqlParameter](#) object to retrieve.

**Implements**

IDataParameterCollection.RemoveAt

**See Also**[MySqlParameterCollection Class](#) ,  [MySql.Data.MySqlClient Namespace](#) ,  [MySqlParameterCollection.RemoveAt Overload List](#)**21.2.7.1.2.1.8. Transaction Property****Syntax: Visual Basic**

```
Public Property Transaction As MySqlTransaction
```

**Syntax: C#**

```
public MySqlTransaction Transaction {get; set;}
```

**See Also** [MySqlCommand Class](#) ,  [MySql.Data.MySqlClient Namespace](#)**21.2.7.1.2.1.9. UpdatedRowSource Property****Syntax: Visual Basic**

```
NotOverridable Public Property UpdatedRowSource As UpdateRowSource _
 Implements IDbCommand.UpdatedRowSource
```

**Syntax: C#**

```
public System.Data.UpdateRowSource UpdatedRowSource {get; set;}
```

**Implements**

IDbCommand.UpdatedRowSource

**See Also** [MySqlCommand Class](#) ,  [MySql.Data.MySqlClient Namespace](#)**21.2.7.1.2.1.10. `MySqlCommand.Cancel` Method**

Attempts to cancel the execution of a MySqlCommand. This operation is not supported.

**Syntax: Visual Basic**

```
NotOverridable Public Sub Cancel() _
 Implements IDbCommand.Cancel
```

**Syntax: C#**

```
public void Cancel();
```

**Implements**

IDbCommand.Cancel

**Remarks**

Cancelling an executing command is currently not supported on any version of MySQL.

**Exceptions**

Exception Type	Condition
NotSupportedException	This operation is not supported.

**See Also**

[MySqlCommand Class](#) ,  [MySql.Data.MySqlClient Namespace](#)

#### 21.2.7.1.2.1.11. `MySqlCommand.CreateParameter` Method

Creates a new instance of a [MySqlParameter](#) object.

**Syntax: Visual Basic**

```
Public Function CreateParameter() As MySqlParameter
```

**Syntax: C#**

```
public MySqlParameter CreateParameter();
```

**Return Value**

A [MySqlParameter](#) object.

**Remarks**

This method is a strongly-typed version of CreateParameter.

**See Also**

[MySqlCommand Class](#) ,  [MySql.Data.MySqlClient Namespace](#)

#### 21.2.7.1.2.1.12. `MySqlCommand.ExecuteNonQuery` Method

**Syntax: Visual Basic**

```
NotOverridable Public Function ExecuteNonQuery() As Integer _
 Implements IDbCommand.ExecuteNonQuery
```

**Syntax: C#**

```
public int ExecuteNonQuery();
```

**Implements**

[IDbCommand.ExecuteNonQuery](#)

**See Also**

[MySqlCommand Class](#) ,  [MySql.Data.MySqlClient Namespace](#)

#### 21.2.7.1.2.1.13. `ExecuteReader` Method

**Overload List**

- [public MySqlDataReader ExecuteReader\(\);](#)
- [public MySqlDataReader ExecuteReader\(CommandBehavior\);](#)

**See Also**

[MySqlCommand Class](#) ,  [MySql.Data.MySqlClient Namespace](#)

#### 21.2.7.1.2.1.13.1. `MySqlCommand.ExecuteReader` Method

**Syntax: Visual Basic**

```
Overloads Public Function ExecuteReader() As MySqlDataReader
```

**Syntax: C#**

```
public MySqlDataReader ExecuteReader();
```

#### See Also

[MySqlCommand Class](#) , [MySql.Data.MySqlClient Namespace](#) , [MySqlCommand.ExecuteReader Overload List](#)

#### 21.2.7.1.2.1.13.1.1. MySqlDataReader Class

Provides a means of reading a forward-only stream of rows from a MySQL database. This class cannot be inherited.

For a list of all members of this type, see [MySqlDataReader Members](#) .

#### Syntax: Visual Basic

```
NotInheritable Public Class MySqlDataReader_
 Inherits MarshalByRefObject_
 Implements IEnumerable, IDataReader, IDisposable, IDataRecord
```

#### Syntax: C#

```
public sealed class MySqlDataReader : MarshalByRefObject, IEnumerable, IDataReader, IDisposable, IDataRecord
```

#### Thread Safety

Public static (Shared in Visual Basic) members of this type are safe for multithreaded operations. Instance members are not guaranteed to be thread-safe.

#### Requirements

Namespace: [MySql.Data.MySqlClient](#)

Assembly: MySql.Data (in MySql.Data.dll)

#### See Also

[MySqlDataReader Members](#) , [MySql.Data.MySqlClient Namespace](#)

#### 21.2.7.1.2.1.13.1.1.1. MySqlDataReader Members

##### [MySqlDataReader overview](#)

##### Public Instance Properties

<a href="#">Depth</a>	Gets a value indicating the depth of nesting for the current row. This method is not supported currently and always returns 0.
<a href="#">FieldCount</a>	Gets the number of columns in the current row.
<a href="#">HasRows</a>	Gets a value indicating whether the MySqlDataReader contains one or more rows.
<a href="#">IsClosed</a>	Gets a value indicating whether the data reader is closed.
<a href="#">Item</a>	Overloaded. Overloaded. Gets the value of a column in its native format. In C#, this property is the indexer for the MySqlDataReader class.
<a href="#">RecordsAffected</a>	Gets the number of rows changed, inserted, or deleted by execution of the SQL statement.

##### Public Instance Methods

<a href="#">Close</a>	Closes the MySqlDataReader object.
<a href="#">CreateObjRef(inherited from MarshalByRefObject)</a>	Creates an object that contains all the relevant information required to generate a proxy used to communicate with a remote object.
<a href="#">Equals(inherited from Object)</a>	Determines whether the specified Object is equal to the current Object.
<a href="#">GetBoolean</a>	Gets the value of the specified column as a Boolean.
<a href="#">GetByte</a>	Gets the value of the specified column as a byte.

<a href="#">GetBytes</a>	Reads a stream of bytes from the specified column offset into the buffer an array starting at the given buffer offset.
<a href="#">GetChar</a>	Gets the value of the specified column as a single character.
<a href="#">GetChars</a>	Reads a stream of characters from the specified column offset into the buffer as an array starting at the given buffer offset.
<a href="#">GetDataTypeName</a>	Gets the name of the source data type.
<a href="#">GetDateTime</a>	
<a href="#">GetDecimal</a>	
<a href="#">GetDouble</a>	
<a href="#">GetFieldType</a>	Gets the Type that is the data type of the object.
<a href="#">GetFloat</a>	
<a href="#">GetGuid</a>	
<a href="#">GetHashCode</a> (inherited from Object)	Serves as a hash function for a particular type. GetHashCode is suitable for use in hashing algorithms and data structures like a hash table.
<a href="#">GetInt16</a>	
<a href="#">GetInt32</a>	
<a href="#">GetInt64</a>	
<a href="#">GetLifetimeService</a> (inherited from MarshalByRefObject)	Retrieves the current lifetime service object that controls the lifetime policy for this instance.
<a href="#">GetMySqlDateTime</a>	
<a href="#">GetName</a>	Gets the name of the specified column.
<a href="#">GetOrdinal</a>	Gets the column ordinal, given the name of the column.
<a href="#">GetSchemaTable</a>	Returns a DataTable that describes the column metadata of the MySqlDataReader.
<a href="#">GetString</a>	
<a href="#">GetTimeSpan</a>	
<a href="#">GetType</a> (inherited from Object)	Gets the Typeof the current instance.
<a href="#">GetUInt16</a>	
<a href="#">GetUInt32</a>	
<a href="#">GetUInt64</a>	
<a href="#">GetValue</a>	Gets the value of the specified column in its native format.
<a href="#">GetValues</a>	Gets all attribute columns in the collection for the current row.
<a href="#">InitializeLifetimeService</a> (inherited from MarshalByRefObject)	Obtains a lifetime service object to control the lifetime policy for this instance.
<a href="#">IsDBNull</a>	Gets a value indicating whether the column contains non-existent or missing values.
<a href="#">NextResult</a>	Advances the data reader to the next result, when reading the results of batch SQL statements.
<a href="#">Read</a>	Advances the MySqlDataReader to the next record.
<a href="#">ToString</a> (inherited from Object)	Returns a Stringthat represents the current Object.

### 21.2.7.1.2.1.13.1.1.1.1. Depth Property

Gets a value indicating the depth of nesting for the current row. This method is not supported currently and always returns 0.

#### Syntax: Visual Basic

```
NotOverridable Public ReadOnly Property Depth As Integer _
 Implements IDataReader.Depth
```

**Syntax: C#**

```
public int Depth {get;}
```

**Implements**

IDataReader.Depth

**See Also**[MySqlDataReader Class](#) ,  [MySql.Data.MySqlClient Namespace](#)

### 21.2.7.1.2.1.13.1.1.1.2. FieldCount Property

Gets the number of columns in the current row.

**Syntax: Visual Basic**

```
NotOverridable Public ReadOnly Property FieldCount As Integer
 Implements IDataRecord.FieldCount
```

**Syntax: C#**

```
public int FieldCount {get;}
```

**Implements**

IDataRecord.FieldCount

**See Also**[MySqlDataReader Class](#) ,  [MySql.Data.MySqlClient Namespace](#)

### 21.2.7.1.2.1.13.1.1.1.3. HasRows Property

Gets a value indicating whether the MySqlDataReader contains one or more rows.

**Syntax: Visual Basic**

```
Public ReadOnly Property HasRows As Boolean
```

**Syntax: C#**

```
public bool HasRows {get;}
```

**See Also**[MySqlDataReader Class](#) ,  [MySql.Data.MySqlClient Namespace](#)

### 21.2.7.1.2.1.13.1.1.1.4. IsClosed Property

Gets a value indicating whether the data reader is closed.

**Syntax: Visual Basic**

```
NotOverridable Public ReadOnly Property IsClosed As Boolean
 Implements IDataReader.IsClosed
```

**Syntax: C#**

```
public bool IsClosed {get;}
```

**Implements**

IDataReader.IsClosed

**See Also**

[MySqlDataReader Class](#) ,  [MySql.Data.MySqlClient Namespace](#)**21.2.7.1.2.1.13.1.1.1.5. Item Property**

Overloaded. Gets the value of a column in its native format. In C#, this property is the indexer for the MySqlDataReader class.

**Overload List**

Overloaded. Gets the value of a column in its native format. In C#, this property is the indexer for the MySqlDataReader class.

- [public object this\[int\] {get;}](#)

Gets the value of a column in its native format. In C#, this property is the indexer for the MySqlDataReader class.

- [public object this\[string\] {get;}](#)

**See Also**[MySqlDataReader Class](#) ,  [MySql.Data.MySqlClient Namespace](#)**21.2.7.1.2.1.13.1.1.1.5.1. Item Property (Int32)**

Overloaded. Gets the value of a column in its native format. In C#, this property is the indexer for the MySqlDataReader class.

**Syntax: Visual Basic**

```
NotOverridable Overloads Public Default ReadOnly Property Item(_
 ByVal i As Integer _
) _
Implements IDataRecord.Item As Object _
Implements IDataRecord.Item
```

**Syntax: C#**

```
public object this[_
inti
] {get;}
```

**Implements**

IDataRecord.Item

**See Also**[MySqlDataReader Class](#) ,  [MySql.Data.MySqlClient Namespace](#) ,  [MySqlDataReader.Item Overload List](#)**21.2.7.1.2.1.13.1.1.1.5.2. Item Property (String)**

Gets the value of a column in its native format. In C#, this property is the indexer for the MySqlDataReader class.

**Syntax: Visual Basic**

```
NotOverridable Overloads Public Default ReadOnly Property Item(_
 ByVal name As String _
) _
Implements IDataRecord.Item As Object _
Implements IDataRecord.Item
```

**Syntax: C#**

```
public object this[_
stringname
] {get;}
```

**Implements**

IDataRecord.Item

**See Also**

[MySqlDataReader Class](#) ,  [MySql.Data.MySqlClient Namespace](#) ,  [MySqlDataReader.Item Overload List](#)

#### 21.2.7.1.2.1.13.1.1.1.6. RecordsAffected Property

Gets the number of rows changed, inserted, or deleted by execution of the SQL statement.

**Syntax: Visual Basic**

```
NotOverridable Public ReadOnly Property RecordsAffected As Integer _
 Implements IDataReader.RecordsAffected
```

**Syntax: C#**

```
public int RecordsAffected {get;}
```

**Implements**

IDataReader.RecordsAffected

**See Also**

[MySqlDataReader Class](#) ,  [MySql.Data.MySqlClient Namespace](#)

#### 21.2.7.1.2.1.13.1.1.1.7. [MySqlDataReader.Close](#) Method

Closes the MySqlDataReader object.

**Syntax: Visual Basic**

```
NotOverridable Public Sub Close() _
 Implements IDataReader.Close
```

**Syntax: C#**

```
public void Close();
```

**Implements**

IDataReader.Close

**See Also**

[MySqlDataReader Class](#) ,  [MySql.Data.MySqlClient Namespace](#)

#### 21.2.7.1.2.1.13.1.1.1.8. [MySqlDataReader.GetBoolean](#) Method

Gets the value of the specified column as a Boolean.

**Syntax: Visual Basic**

```
NotOverridable Public Function GetBoolean(_
 ByVal i As Integer _
) As Boolean _
 Implements IDataRecord.GetBoolean
```

**Syntax: C#**

```
public bool GetBoolean(
 int i
>);
```

**Parameters**

- [i:](#)

**Return Value****Implements**

IDataRecord.GetBoolean

**See Also**[MySqlDataReader Class](#) ,  [MySql.Data.MySqlClient Namespace](#)**21.2.7.1.2.1.13.1.1.1.9. MySqlDataReader .GetByte Method**

Gets the value of the specified column as a byte.

**Syntax: Visual Basic**

```
NotOverridable Public Function GetByte(_
 ByVal i As Integer _
) As Byte _
 Implements IDataRecord.GetByte
```

**Syntax: C#**

```
public byte GetByte(
 int i
);
```

**Parameters**

- [i:](#)

**Return Value****Implements**

IDataRecord.GetByte

**See Also**[MySqlDataReader Class](#) ,  [MySql.Data.MySqlClient Namespace](#)**21.2.7.1.2.1.13.1.1.1.10. MySqlDataReader .GetBytes Method**

Reads a stream of bytes from the specified column offset into the buffer an array starting at the given buffer offset.

**Syntax: Visual Basic**

```
NotOverridable Public Function GetBytes(_
 ByVal i As Integer, _
 ByVal dataIndex As Long, _
 ByVal buffer As Byte(), _
 ByVal bufferIndex As Integer, _
 ByVal length As Integer _
) As Long _
 Implements IDataRecord.GetBytes
```

**Syntax: C#**

```
public long GetBytes(
 int i,
 long dataIndex,
 byte[] buffer,
 int bufferIndex,
 int length
);
```

**Parameters**

- **i:** The zero-based column ordinal.
- **dataIndex:** The index within the field from which to begin the read operation.
- **buffer:** The buffer into which to read the stream of bytes.
- **bufferIndex:** The index for buffer to begin the read operation.
- **length:** The maximum length to copy into the buffer.

**Return Value**

The actual number of bytes read.

**Implements**

IDataRecord.GetBytes

**See Also**

[MySqlDataReader Class](#) ,  [MySql.Data.MySqlClient Namespace](#)

**21.2.7.1.2.1.13.1.1.1.11. MySqlDataReader .GetChar Method**

Gets the value of the specified column as a single character.

**Syntax: Visual Basic**

```
NotOverridable Public Function GetChar(_
 ByVal i As Integer _
) As Char _
- Implements IDataRecord.GetChar
```

**Syntax: C#**

```
public char GetChar(
 int i
);
```

**Parameters**

- **i:**

**Return Value****Implements**

IDataRecord.GetChar

**See Also**

[MySqlDataReader Class](#) ,  [MySql.Data.MySqlClient Namespace](#)

**21.2.7.1.2.1.13.1.1.1.12. MySqlDataReader .GetChars Method**

Reads a stream of characters from the specified column offset into the buffer as an array starting at the given buffer offset.

**Syntax: Visual Basic**

```
NotOverridable Public Function GetChars(_
 ByVal i As Integer, _
 ByVal fieldOffset As Long, _
 ByVal buffer As Char(), _
 ByVal bufferoffset As Integer, _
 ByVal length As Integer _
) As Long _
- Implements IDataRecord.GetChars
```

**Syntax: C#**

```
public long GetChars(
 int i,
 long fieldOffset,
 char[] buffer,
 int bufferOffset,
 int length
);
```

**Parameters**

- `i`:
- `fieldOffset`:
- `buffer`:
- `bufferoffset`:
- `length`:

**Return Value****Implements**

IDataRecord.GetChars

**See Also**[MySqlDataReader Class](#) ,  [MySql.Data.MySqlClient Namespace](#)**21.2.7.1.2.1.13.1.1.13. `MySqlDataReader`.`GetDataTypeName` Method**

Gets the name of the source data type.

**Syntax: Visual Basic**

```
NotOverridable Public Function GetDataTypeName(_
 ByVal i As Integer _
) As String _
 Implements IDataRecord.GetDataTypeName
```

**Syntax: C#**

```
public string GetDataTypeName(
 int i
);
```

**Parameters**

- `i`:

**Return Value****Implements**

IDataRecord.GetDataTypeName

**See Also**[MySqlDataReader Class](#) ,  [MySql.Data.MySqlClient Namespace](#)**21.2.7.1.2.1.13.1.1.14. `MySqlDataReader`.`GetDateTime` Method****Syntax: Visual Basic**

```
NotOverridable Public Function GetDateTime(_
 ByVal index As Integer _
) As Date _
 Implements IDataRecord.GetDateTime
```

**Syntax: C#**

```
public DateTime GetDateTime(
 int index
);
```

**Implements**

IDataRecord.GetDateTime

**See Also**[MySqlDataReader Class](#) ,  [MySql.Data.MySqlClient Namespace](#)**21.2.7.1.2.1.13.1.1.1.15. `MySqlDataReader.GetDecimal` Method****Syntax: Visual Basic**

```
NotOverridable Public Function GetDecimal(_
 ByVal index As Integer _
) As Decimal _
 Implements IDataRecord.GetDecimal
```

**Syntax: C#**

```
public decimal GetDecimal(
 int index
);
```

**Implements**

IDataRecord.GetDecimal

**See Also**[MySqlDataReader Class](#) ,  [MySql.Data.MySqlClient Namespace](#)**21.2.7.1.2.1.13.1.1.1.16. `MySqlDataReader.GetDouble` Method****Syntax: Visual Basic**

```
NotOverridable Public Function GetDouble(_
 ByVal index As Integer _
) As Double _
 Implements IDataRecord.GetDouble
```

**Syntax: C#**

```
public double GetDouble(
 int index
);
```

**Implements**

IDataRecord.GetDouble

**See Also**[MySqlDataReader Class](#) ,  [MySql.Data.MySqlClient Namespace](#)**21.2.7.1.2.1.13.1.1.1.17. `MySqlDataReader.GetFieldType` Method**

Gets the Type that is the data type of the object.

**Syntax: Visual Basic**

```
NotOverridable Public Function GetFieldType(_
 ByVal i As Integer _
) As Type _
 Implements IDataRecord.GetFieldType
```

**Syntax: C#**

```
public Type GetFieldType(
 int i
);
```

**Parameters**

- *i*:

**Return Value****Implements**

IDataRecord.GetFieldType

**See Also**[MySqlDataReader Class](#) ,  [MySql.Data.MySqlClient Namespace](#)**21.2.7.1.2.1.13.1.1.1.18. [MySqlDataReader .GetFloat](#) Method****Syntax: Visual Basic**

```
NotOverridable Public Function GetFloat(_
 ByVal index As Integer _
) As Single _
- Implements IDataRecord.GetFloat
```

**Syntax: C#**

```
public float GetFloat(
 int index
);
```

**Implements**

IDataRecord.GetFloat

**See Also**[MySqlDataReader Class](#) ,  [MySql.Data.MySqlClient Namespace](#)**21.2.7.1.2.1.13.1.1.1.19. [MySqlDataReader .GetGuid](#) Method****Syntax: Visual Basic**

```
NotOverridable Public Function GetGuid(_
 ByVal index As Integer _
) As Guid _
- Implements IDataRecord.GetGuid
```

**Syntax: C#**

```
public Guid GetGuid(
 int index
);
```

**Implements**

IDataRecord.GetGuid

**See Also**[MySqlDataReader Class](#) ,  [MySql.Data.MySqlClient Namespace](#)**21.2.7.1.2.1.13.1.1.1.20. [MySqlDataReader .GetInt16](#) Method****Syntax: Visual Basic**

```
NotOverridable Public Function GetInt16(_
 ByVal index As Integer _
) As Short _
 Implements IDataRecord.GetInt16
```

**Syntax: C#**

```
public short GetInt16(
 int index
);
```

**Implements**

IDataRecord.GetInt16

**See Also**[MySqlDataReader Class](#) ,  [MySql.Data.MySqlClient Namespace](#)**21.2.7.1.2.1.13.1.1.1.21. MySqlDataReader.GetInt32 Method****Syntax: Visual Basic**

```
NotOverridable Public Function GetInt32(_
 ByVal index As Integer _
) As Integer _
 Implements IDataRecord.GetInt32
```

**Syntax: C#**

```
public int GetInt32(
 int index
);
```

**Implements**

IDataRecord.GetInt32

**See Also**[MySqlDataReader Class](#) ,  [MySql.Data.MySqlClient Namespace](#)**21.2.7.1.2.1.13.1.1.1.22. MySqlDataReader.GetInt64 Method****Syntax: Visual Basic**

```
NotOverridable Public Function GetInt64(_
 ByVal index As Integer _
) As Long _
 Implements IDataRecord.GetInt64
```

**Syntax: C#**

```
public long GetInt64(
 int index
);
```

**Implements**

IDataRecord.GetInt64

**See Also**[MySqlDataReader Class](#) ,  [MySql.Data.MySqlClient Namespace](#)**21.2.7.1.2.1.13.1.1.1.23. MySqlDataReader.GetMySqlDateTime Method****Syntax: Visual Basic**

```
Public Function GetMySqlDateTime(_
 ByVal index As Integer _
```

```
) As MySqlDateTime
```

**Syntax: C#**

```
public MySqlDateTime GetMySqlDateTime(
 int index
);
```

**See Also**

[MySqlDataReader Class](#) , [MySql.Data.MySqlClient Namespace](#)

**21.2.7.1.2.1.13.1.1.1.24. `MySqlDataReader.GetName` Method**

Gets the name of the specified column.

**Syntax: Visual Basic**

```
NotOverridable Public Function GetName(_
 ByVal i As Integer _
) As String _
- Implements IDataRecord.GetName
```

**Syntax: C#**

```
public string GetName(
 int i
);
```

**Parameters**

- `i`:

**Return Value****Implements**

`IDataRecord.GetName`

**See Also**

[MySqlDataReader Class](#) , [MySql.Data.MySqlClient Namespace](#)

**21.2.7.1.2.1.13.1.1.1.25. `MySqlDataReader.GetOrdinal` Method**

Gets the column ordinal, given the name of the column.

**Syntax: Visual Basic**

```
NotOverridable Public Function GetOrdinal(_
 ByVal name As String _
) As Integer _
- Implements IDataRecord.GetOrdinal
```

**Syntax: C#**

```
public int GetOrdinal(
 string name
);
```

**Parameters**

- `name`:

**Return Value****Implements**

IDataRecord.GetOrdinal

**See Also**

[MySqlDataReader Class](#) ,  [MySql.Data.MySqlClient Namespace](#)

#### 21.2.7.1.2.1.13.1.1.1.26. `MySqlDataReader.GetSchemaTable` Method

Returns a DataTable that describes the column metadata of the MySqlDataReader.

**Syntax: Visual Basic**

```
NotOverridable Public Function GetSchemaTable() As DataTable _
 Implements IDataReader.GetSchemaTable
```

**Syntax: C#**

```
public DataTable GetSchemaTable();
```

**Return Value**

**Implements**

IDataReader.GetSchemaTable

**See Also**

[MySqlDataReader Class](#) ,  [MySql.Data.MySqlClient Namespace](#)

#### 21.2.7.1.2.1.13.1.1.1.27. `MySqlDataReader.GetString` Method

**Syntax: Visual Basic**

```
NotOverridable Public Function GetString(_
 ByVal index As Integer _
) As String _
 Implements IDataReader.GetString
```

**Syntax: C#**

```
public string GetString(
 int index
>);
```

**Implements**

IDataRecord.GetString

**See Also**

[MySqlDataReader Class](#) ,  [MySql.Data.MySqlClient Namespace](#)

#### 21.2.7.1.2.1.13.1.1.1.28. `MySqlDataReader.GetTimeSpan` Method

**Syntax: Visual Basic**

```
Public Function GetTimeSpan(_
 ByVal index As Integer _
) As TimeSpan
```

**Syntax: C#**

```
public TimeSpan GetTimeSpan(
 int index
>);
```

**See Also**

[MySqlDataReader Class](#) ,  [MySql.Data.MySqlClient Namespace](#)

## 21.2.7.1.2.1.13.1.1.1.29. [MySqlDataReader.GetUInt16](#) Method

### Syntax: Visual Basic

```
Public Function GetUInt16(_
 ByVal index As Integer _
) As UInt16
```

### Syntax: C#

```
public ushort GetUInt16(
 int index
);
```

### See Also

[MySqlDataReader Class](#) ,  [MySql.Data.MySqlClient Namespace](#)

## 21.2.7.1.2.1.13.1.1.1.30. [MySqlDataReader.GetUInt32](#) Method

### Syntax: Visual Basic

```
Public Function GetUInt32(_
 ByVal index As Integer _
) As UInt32
```

### Syntax: C#

```
public uint GetUInt32(
 int index
);
```

### See Also

[MySqlDataReader Class](#) ,  [MySql.Data.MySqlClient Namespace](#)

## 21.2.7.1.2.1.13.1.1.1.31. [MySqlDataReader.GetUInt64](#) Method

### Syntax: Visual Basic

```
Public Function GetUInt64(_
 ByVal index As Integer _
) As UInt64
```

### Syntax: C#

```
public ulong GetUInt64(
 int index
);
```

### See Also

[MySqlDataReader Class](#) ,  [MySql.Data.MySqlClient Namespace](#)

## 21.2.7.1.2.1.13.1.1.1.32. [MySqlDataReader.GetValue](#) Method

Gets the value of the specified column in its native format.

### Syntax: Visual Basic

```
NotOverridable Public Function GetValue(_
 ByVal i As Integer _
) As Object _
 Implements IDataRecord.GetValue
```

### Syntax: C#

```
public object GetValue(
 int i
);
```

**Parameters**

- `i`:

**Return Value****Implements**

IDataRecord.GetValue

**See Also**[MySqlDataReader Class](#) ,  [MySql.Data.MySqlClient Namespace](#)**21.2.7.1.2.1.13.1.1.1.33. `MySqlDataReader.GetValues` Method**

Gets all attribute columns in the collection for the current row.

**Syntax: Visual Basic**

```
NotOverridable Public Function GetValues(_
 ByVal values As Object() _
) As Integer
 Implements IDataRecord.GetValues
```

**Syntax: C#**

```
public int GetValues(
 object[] values
);
```

**Parameters**

- `values`:

**Return Value****Implements**

IDataRecord.GetValues

**See Also**[MySqlDataReader Class](#) ,  [MySql.Data.MySqlClient Namespace](#)**21.2.7.1.2.1.13.1.1.1.34. `MySqlDataReader.IsDBNull` Method**

Gets a value indicating whether the column contains non-existent or missing values.

**Syntax: Visual Basic**

```
NotOverridable Public Function IsDBNull(_
 ByVal i As Integer _
) As Boolean
 Implements IDataRecord.IsDBNull
```

**Syntax: C#**

```
public bool IsDBNull(
 int i
);
```

**Parameters**

- `i`:

**Return Value****Implements**

IDataRecord.IsDBNull

**See Also**[MySqlDataReader Class](#) ,  [MySql.Data.MySqlClient Namespace](#)**21.2.7.1.2.1.13.1.1.1.35. `MySqlDataReader.NextResult` Method**

Advances the data reader to the next result, when reading the results of batch SQL statements.

**Syntax: Visual Basic**

```
NotOverridable Public Function NextResult() As Boolean _
 Implements IDataReader.NextResult
```

**Syntax: C#**

```
public bool NextResult();
```

**Return Value****Implements**

IDataReader.NextResult

**See Also**[MySqlDataReader Class](#) ,  [MySql.Data.MySqlClient Namespace](#)**21.2.7.1.2.1.13.1.1.1.36. `MySqlDataReader.Read` Method**

Advances the MySqlDataReader to the next record.

**Syntax: Visual Basic**

```
NotOverridable Public Function Read() As Boolean _
 Implements IDataReader.Read
```

**Syntax: C#**

```
public bool Read();
```

**Return Value****Implements**

IDataReader.Read

**See Also**[MySqlDataReader Class](#) ,  [MySql.Data.MySqlClient Namespace](#)**21.2.7.1.2.1.13.2. `MySqlCommand.ExecuteReader` Method****Syntax: Visual Basic**

```
Overloads Public Function ExecuteReader(_
 ByVal behavior As CommandBehavior _
) As MySqlDataReader
```

**Syntax: C#**

```
public MySqlDataReader ExecuteReader(
 CommandBehaviorbehavior
);
```

**See Also**

[MySqlCommand Class](#) ,  [MySql.Data.MySqlClient Namespace](#) ,  [MySqlCommand.ExecuteReader Overload List](#)

### 21.2.7.1.2.1.14. `MySqlCommand . ExecuteScalar` Method

**Syntax: Visual Basic**

```
NotOverridable Public Function ExecuteScalar() As Object
 Implements IDbCommand.ExecuteScalar
```

**Syntax: C#**

```
public object ExecuteScalar();
```

**Implements**

`IDbCommand.ExecuteScalar`

**See Also**

[MySqlCommand Class](#) ,  [MySql.Data.MySqlClient Namespace](#)

### 21.2.7.1.2.1.15. `MySqlCommand . Prepare` Method

**Syntax: Visual Basic**

```
NotOverridable Public Sub Prepare()
 Implements IDbCommand.Prepare
```

**Syntax: C#**

```
public void Prepare();
```

**Implements**

`IDbCommand.Prepare`

**See Also**

[MySqlCommand Class](#) ,  [MySql.Data.MySqlClient Namespace](#)

### 21.2.7.1.3. `MySqlCommandBuilder` Class

For a list of all members of this type, see [MySqlCommandBuilder Members](#) .

**Syntax: Visual Basic**

```
NotInheritable Public Class MySqlCommandBuilder
 Inherits Component
```

**Syntax: C#**

```
public sealed class MySqlCommandBuilder : Component
```

**Thread Safety**

Public static (Shared in Visual Basic) members of this type are safe for multithreaded operations. Instance members are not guaranteed to be thread-safe.

**Requirements**

Namespace:  `MySql.Data.MySqlClient`

Assembly:  `MySql.Data` (in  `MySql.Data.dll`)

**See Also**

[MySqlCommandBuilder Members](#) , [MySql.Data.MySqlClient Namespace](#)

### 21.2.7.1.3.1. [MySqlCommandBuilder](#) Members

[MySqlCommandBuilder](#) overview

#### Public Static (Shared) Methods

<a href="#">DeriveParameters</a>	Overloaded. Retrieves parameter information from the stored procedure specified in the MySqlCommand and populates the Parameters collection of the specified MySqlCommand object. This method is not currently supported since stored procedures are not available in MySql.
----------------------------------	------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

#### Public Instance Constructors

<a href="#">MySqlCommandBuilder</a>	Overloaded. Initializes a new instance of the MySqlCommandBuilder class.
-------------------------------------	--------------------------------------------------------------------------

#### Public Instance Properties

<a href="#">Container</a> (inherited from Component)	Gets the IContainer that contains the Component.
<a href="#">DataAdapter</a>	
<a href="#">QuotePrefix</a>	
<a href="#">QuoteSuffix</a>	
<a href="#">Site</a> (inherited from Component)	Gets or sets the ISite of the Component.

#### Public Instance Methods

<a href="#">CreateObjRef</a> (inherited from MarshalByRefObject)	Creates an object that contains all the relevant information required to generate a proxy used to communicate with a remote object.
<a href="#">Dispose</a> (inherited from Component)	Releases all resources used by the Component.
<a href="#">Equals</a> (inherited from Object)	Determines whether the specified Object is equal to the current Object.
<a href="#">GetDeleteCommand</a>	
<a href="#">GetHashCode</a> (inherited from Object)	Serves as a hash function for a particular type. GetHashCode is suitable for use in hashing algorithms and data structures like a hash table.
<a href="#">GetInsertCommand</a>	
<a href="#">GetLifetimeService</a> (inherited from MarshalByRefObject)	Retrieves the current lifetime service object that controls the lifetime policy for this instance.
<a href="#">GetType</a> (inherited from Object)	Gets the Type of the current instance.
<a href="#">GetUpdateCommand</a>	
<a href="#">InitializeLifetimeService</a> (inherited from MarshalByRefObject)	Obtains a lifetime service object to control the lifetime policy for this instance.
<a href="#">RefreshSchema</a>	
<a href="#">ToString</a> (inherited from Component)	Returns a String containing the name of the Component, if any. This method should not be overridden.

#### Public Instance Events

<a href="#">Disposed</a> (inherited from Component)	Adds an event handler to listen to the Disposed event on the component.
-----------------------------------------------------	-------------------------------------------------------------------------

#### See Also

[MySQLCommandBuilder Class](#) , [MySQL.Data.MySqlClient Namespace](#)**21.2.7.1.3.1.1. DeriveParameters Method**

Retrieves parameter information from the stored procedure specified in the MySqlCommand and populates the Parameters collection of the specified MySqlCommand object. This method is not currently supported since stored procedures are not available in MySql.

**Overload List**

Retrieves parameter information from the stored procedure specified in the MySqlCommand and populates the Parameters collection of the specified MySqlCommand object. This method is not currently supported since stored procedures are not available in MySql.

- [public static void DeriveParameters\(MySqlCommand\);](#)
- [public static void DeriveParameters\(MySqlCommand,bool\);](#)

**See Also**[MySQLCommandBuilder Class](#) , [MySQL.Data.MySqlClient Namespace](#)**21.2.7.1.3.1.1.1. MySqlCommandBuilder.DeriveParameters Method**

Retrieves parameter information from the stored procedure specified in the MySqlCommand and populates the Parameters collection of the specified MySqlCommand object. This method is not currently supported since stored procedures are not available in MySql.

**Syntax: Visual Basic**

```
Overloads Public Shared Sub DeriveParameters(_
 ByVal command As MySqlCommand _)
)
```

**Syntax: C#**

```
public static void DeriveParameters(
MySqlCommand command
);
```

**Parameters**

- **command**: The MySqlCommand referencing the stored procedure from which the parameter information is to be derived. The derived parameters are added to the Parameters collection of the MySqlCommand.

**Exceptions**

Exception Type	Condition
InvalidOperationException	The command text is not a valid stored procedure name.

**See Also**[MySQLCommandBuilder Class](#) , [MySQL.Data.MySqlClient Namespace](#) , [MySQLCommandBuilder.DeriveParameters Overload List](#)**21.2.7.1.3.1.1.2. MySqlCommandBuilder.DeriveParameters Method****Syntax: Visual Basic**

```
Overloads Public Shared Sub DeriveParameters(_
 ByVal command As MySqlCommand, _
 ByVal useProc As Boolean _)
)
```

**Syntax: C#**

```
public static void DeriveParameters(
MySqlCommand command,
```

```
booluseProc
);
```

**21.2.7.1.3.1.2. MySqlCommandBuilder Constructor**

Initializes a new instance of the [MySqlCommandBuilder](#) class.

**Overload List**

Initializes a new instance of the [MySqlCommandBuilder](#) class.

- [public MySqlCommandBuilder\(\);](#)
- [public MySqlCommandBuilder\(MySqlDataAdapter\);](#)
- [public MySqlCommandBuilder\(MySqlDataAdapter,bool\);](#)
- [public MySqlCommandBuilder\(bool\);](#)

**See Also**

[MySqlCommandBuilder Class](#) ,  [MySql.Data.MySqlClient Namespace](#)

**21.2.7.1.3.1.2.1. MySqlCommandBuilder Constructor**

Initializes a new instance of the [MySqlCommandBuilder](#) class.

**Syntax: Visual Basic**

```
Overloads Public Sub New()
```

**Syntax: C#**

```
public MySqlCommandBuilder();
```

**See Also**

[MySqlCommandBuilder Class](#) ,  [MySql.Data.MySqlClient Namespace](#) ,  [MySqlCommandBuilder Constructor Overload List](#)

**21.2.7.1.3.1.2.2. MySqlCommandBuilder Constructor****Syntax: Visual Basic**

```
Overloads Public Sub New(
 ByVal adapter As MySqlDataAdapter
)
```

**Syntax: C#**

```
public MySqlCommandBuilder(
 MySqlDataAdapter adapter
);
```

**See Also**

[MySqlCommandBuilder Class](#) ,  [MySql.Data.MySqlClient Namespace](#) ,  [MySqlCommandBuilder Constructor Overload List](#)

**21.2.7.1.3.1.2.2.1. MySqlDataAdapter Class**

For a list of all members of this type, see [MySqlDataAdapter Members](#) .

**Syntax: Visual Basic**

```
NotInheritable Public Class MySqlDataAdapter_
 Inherits DbDataAdapter
```

**Syntax: C#**

```
public sealed class MySqlDataAdapter : DbDataAdapter
```

**Thread Safety**

Public static (Shared in Visual Basic) members of this type are safe for multithreaded operations. Instance members are not guaranteed to be thread-safe.

**Requirements**

Namespace: [MySql.Data.MySqlClient](#)

Assembly: MySql.Data (in MySql.Data.dll)

**See Also**

**21.2.7.1.3.1.2.2.1.1. MySqlDataAdapter Members**

[MySqlDataAdapter overview](#)

**Public Instance Constructors**

<a href="#">MySqlDataAdapter</a>	Overloaded. Initializes a new instance of the MySqlDataAdapter class.
----------------------------------	-----------------------------------------------------------------------

**Public Instance Properties**

<a href="#">AcceptChangesDuringFill</a> (inherited from DataAdapter)	Gets or sets a value indicating whether AcceptChanges is called on a DataRow after it is added to the DataTable during any of the Fill operations.
<a href="#">AcceptChangesDuringUpdate</a> (inherited from DataAdapter)	Gets or sets whether AcceptChanges is called during a Update.
<a href="#">Container</a> (inherited from Component)	Gets the IContainer that contains the Component.
<a href="#">ContinueUpdateOnError</a> (inherited from DataAdapter)	Gets or sets a value that specifies whether to generate an exception when an error is encountered during a row update.
<a href="#">DeleteCommand</a>	Overloaded.
<a href="#">FillLoadOption</a> (inherited from DataAdapter)	Gets or sets the LoadOption that determines how the adapter fills the DataTable from the DbDataReader.
<a href="#">InsertCommand</a>	Overloaded.
<a href="#">MissingMappingAction</a> (inherited from DataAdapter)	Determines the action to take when incoming data does not have a matching table or column.
<a href="#">MissingSchemaAction</a> (inherited from DataAdapter)	Determines the action to take when existing DataSet schema does not match incoming data.
<a href="#">ReturnProviderSpecificTypes</a> (inherited from DataAdapter)	Gets or sets whether the Fill method should return provider-specific values or common CLS-compliant values.
<a href="#">SelectCommand</a>	Overloaded.
<a href="#">Site</a> (inherited from Component)	Gets or sets the ISite of the Component.
<a href="#">TableMappings</a> (inherited from DataAdapter)	Gets a collection that provides the master mapping between a source table and a DataTable.
<a href="#">UpdateBatchSize</a> (inherited from DbDataAdapter)	Gets or sets a value that enables or disables batch processing support, and specifies the number of commands that can be executed in a batch.
<a href="#">UpdateCommand</a>	Overloaded.

**Public Instance Methods**

<a href="#">CreateObjRef</a> (inherited from MarshalByRefObject)	Creates an object that contains all the relevant information required to generate a proxy used to communicate with a remote object.
------------------------------------------------------------------	-------------------------------------------------------------------------------------------------------------------------------------

Dispose(inherited from Component)	Releases all resources used by the Component.
Equals(inherited from Object)	Determines whether the specified Object is equal to the current Object.
Fill(inherited from DbDataAdapter)	Overloaded. Adds or refreshes rows in the DataSet to match those in the data source using the DataSetName, and creates a DataTable named "Table."
FillSchema(inherited from DbDataAdapter)	Overloaded. Configures the schema of the specified DataTable-based on the specified SchemaType.
GetFillParameters(inherited from DbDataAdapter)	Gets the parameters set by the user when executing an SQL SELECT statement.
GetHashCode(inherited from Object)	Serves as a hash function for a particular type. GetHashCode is suitable for use in hashing algorithms and data structures like a hash table.
GetLifetimeService(inherited from MarshalByRefObject)	Retrieves the current lifetime service object that controls the lifetime policy for this instance.
GetType(inherited from Object)	Gets the Type of the current instance.
InitializeLifetimeService(inherited from MarshalByRefObject)	Obtains a lifetime service object to control the lifetime policy for this instance.
ResetFillLoadOption(inherited from DataAdapter)	Resets FillLoadOption to its default state and causes Fill to honor AcceptChangesDuringFill.
ShouldSerializeAcceptChangesDuringFill(inherited from DataAdapter)	Determines whether the AcceptChangesDuringFill property should be persisted.
ShouldSerializeFillLoadOption(inherited from DataAdapter)	Determines whether the FillLoadOption property should be persisted.
ToString(inherited from Component)	Returns a String containing the name of the Component, if any. This method should not be overridden.
Update(inherited from DbDataAdapter)	Overloaded. Calls the respective INSERT, UPDATE, or DELETE statements for each inserted, updated, or deleted row in the specified DataSet.

### Public Instance Events

Disposed(inherited from Component)	Adds an event handler to listen to the Disposed event on the component.
FillError(inherited from DataAdapter)	Returned when an error occurs during a fill operation.
RowUpdated	Occurs during Update after a command is executed against the data source. The attempt to update is made, so the event fires.
RowUpdating	Occurs during Update before a command is executed against the data source. The attempt to update is made, so the event fires.

### Protected Internal Instance Properties

FillCommandBehavior(inherited from DbDataAdapter)	Gets or sets the behavior of the command used to fill the data adapter.
---------------------------------------------------	-------------------------------------------------------------------------

### 21.2.7.1.3.1.2.2.1.1.6. `MySqlDataAdapter.RowUpdated` Event

Occurs during Update after a command is executed against the data source. The attempt to update is made, so the event fires.

#### Syntax: Visual Basic

```
Public Event RowUpdated As MySqlRowUpdatedEventHandler
```

#### Syntax: C#

```
public event MySqlRowUpdatedEventHandler RowUpdated;
```

#### Event Data

The event handler receives an argument of type `MySqlRowUpdatedEventArgs` containing data related to this event. The following `MySqlRowUpdatedEventArgs` properties provide information specific to this event.

Property	Description
<code>Command</code>	Gets or sets the MySqlCommand executed when Update is called.
<code>Errors</code>	Gets any errors generated by the .NET Framework data provider when the Command was executed.
<code>RecordsAffected</code>	Gets the number of rows changed, inserted, or deleted by execution of the SQL statement.
<code>Row</code>	Gets the DataRows sent through an Update.
<code>RowCount</code>	Gets the number of rows processed in a batch of updated records.
<code>StatementType</code>	Gets the type of SQL statement executed.
<code>Status</code>	Gets the UpdateStatus of the Command property.
<code>TableMapping</code>	Gets the DataTableMappings sent through an Update.

### 21.2.7.1.3.1.2.2.1.1.6.1. `MySqlRowUpdatedEventHandler` Delegate

Represents the method that will handle the RowUpdated event of a `MySqlDataAdapter`.

#### Syntax: Visual Basic

```
Public Delegate Sub MySqlRowUpdatedEventHandler(_
 ByVal sender As Object, _
 ByVal e As MySqlRowUpdatedEventArgs _)
```

#### Syntax: C#

```
public delegate void MySqlRowUpdatedEventHandler(
 object sender,
 MySqlRowUpdatedEventArgs e);
```

#### Requirements

Namespace: [MySql.Data.MySqlClient](#)

Assembly: MySql.Data (in MySql.Data.dll)

#### See Also

[MySql.Data.MySqlClient Namespace](#)

### 21.2.7.1.3.1.2.2.1.1.6.1.1. `MySqlRowUpdatedEventArgs` Class

Provides data for the RowUpdated event. This class cannot be inherited.

For a list of all members of this type, see [MySqlRowUpdatedEventArgs Members](#).

#### Syntax: Visual Basic

```
NotInheritable Public Class MySqlRowUpdatedEventArgs_
 Inherits RowUpdatedEventArgs
```

#### Syntax: C#

```
public sealed class MySqlRowUpdatedEventArgs : RowUpdatedEventArgs
```

#### Thread Safety

Public static (Shared in Visual Basic) members of this type are safe for multithreaded operations. Instance members are not guaranteed to be thread-safe.

#### Requirements

Namespace:  [MySql.Data.MySqlClient](#)

Assembly: MySql.Data (in MySql.Data.dll)

#### See Also

### 21.2.7.1.3.1.2.2.1.1.6.1.1.1. [MySqlRowUpdatedEventArgs](#) Members

[MySqlRowUpdatedEventArgs](#)  overview

#### Public Instance Constructors

<a href="#"> MySqlRowUpdatedEventArgs Constructor</a>	Initializes a new instance of the MySqlRowUpdatedEventArgs class.
-------------------------------------------------------	-------------------------------------------------------------------

#### Public Instance Properties

<a href="#"> Command</a>	Overloaded. Gets or sets the MySqlCommand executed when Update is called.
<a href="#"> Errors</a> (inherited from RowUpdatedEventArgs)	Gets any errors generated by the .NET Framework data provider when the Command was executed.
<a href="#"> RecordsAffected</a> (inherited from RowUpdatedEventArgs)	Gets the number of rows changed, inserted, or deleted by execution of the SQL statement.
<a href="#"> Row</a> (inherited from RowUpdatedEventArgs)	Gets the DataRows sent through an Update.
<a href="#"> RowCount</a> (inherited from RowUpdatedEventArgs)	Gets the number of rows processed in a batch of updated records.
<a href="#"> StatementType</a> (inherited from RowUpdatedEventArgs)	Gets the type of SQL statement executed.
<a href="#"> Status</a> (inherited from RowUpdatedEventArgs)	Gets the UpdateStatus of the Command property.
<a href="#"> TableMapping</a> (inherited from RowUpdatedEventArgs)	Gets the DataTableMappings sent through an Update.

#### Public Instance Methods

<a href="#"> CopyToRows</a> (inherited from RowUpdatedEventArgs)	Overloaded. Copies references to the modified rows into the provided array.
<a href="#"> Equals</a> (inherited from Object)	Determines whether the specified Object is equal to the current Object.
<a href="#"> GetHashCode</a> (inherited from Object)	Serves as a hash function for a particular type. GetHashCode is suitable for use in hashing algorithms and data structures like a hash table.
<a href="#"> GetType</a> (inherited from Object)	Gets the Type of the current instance.
<a href="#"> ToString</a> (inherited from Object)	Returns a String that represents the current Object.

[MySqlRowUpdatedEventArgs Class](#) ,  [MySql.Data.MySqlClient Namespace](#)

### 21.2.7.1.3.1.2.2.1.1.6.1.1.1.1. `MySqlRowUpdatedEventArgs` Constructor

Initializes a new instance of the `MySqlRowUpdatedEventArgs` class.

**Syntax: Visual Basic**

```
Public Sub New(_
 ByVal row As DataRow, _
 ByVal command As IDbCommand, _
 ByVal statementType As StatementType, _
 ByVal tableMapping As DataTableMapping _
)
```

**Syntax: C#**

```
public MySqlRowUpdatedEventArgs(
 DataRow row,
 IDbCommand command,
 StatementType statementType,
 DataTableMapping tableMapping
) ;
```

**Parameters**

- `row`: The `DataRow` sent through an `Update`.
- `command`: The `IDbCommand` executed when `Update` is called.
- `statementType`: One of the `StatementType` values that specifies the type of query executed.
- `tableMapping`: The `DataTableMapping` sent through an `Update`.

[MySqlRowUpdatedEventArgs Class](#) ,  [MySql.Data.MySqlClient Namespace](#)

### 21.2.7.1.3.1.2.2.1.1.6.1.1.1.2. `Command` Property

Gets or sets the  `MySqlCommand` executed when `Update` is called.

**Syntax: Visual Basic**

```
Overloads Public ReadOnly Property Command As MySqlCommand
```

**Syntax: C#**

```
new public MySqlCommand Command {get;}
```

**See Also**

[MySqlRowUpdatedEventArgs Class](#) ,  [MySql.Data.MySqlClient Namespace](#)

### 21.2.7.1.3.1.2.2.1.1.7. `MySqlDataAdapter.RowUpdating` Event

Occurs during `Update` before a command is executed against the data source. The attempt to update is made, so the event fires.

**Syntax: Visual Basic**

```
Public Event RowUpdating As MySqlRowUpdatingEventHandler
```

**Syntax: C#**

```
public event MySqlRowUpdatingEventHandler RowUpdating;
```

**Event Data**

The event handler receives an argument of type [MySqlRowUpdatingEventArgs](#) containing data related to this event. The following [MySqlRowUpdatingEventArgs](#) properties provide information specific to this event.

Property	Description
<a href="#">Command</a>	Gets or sets the MySqlCommand to execute when performing the Update.
<a href="#">Errors</a>	Gets any errors generated by the .NET Framework data provider when the Command executes.
<a href="#">Row</a>	Gets the DataRow that will be sent to the server as part of an insert, update, or delete operation.
<a href="#">StatementType</a>	Gets the type of SQL statement to execute.
<a href="#">Status</a>	Gets or sets the UpdateStatus of the Command property.
<a href="#">TableMapping</a>	Gets the DataTableMapping to send through the Update.

### 21.2.7.1.3.1.2.2.1.1.7.1. [MySqlRowUpdatingEventHandler](#) Delegate

Represents the method that will handle the RowUpdating event of a [MySqlDataAdapter](#).

#### Syntax: Visual Basic

```
Public Delegate Sub MySqlRowUpdatingEventHandler(_
 ByVal sender As Object, _
 ByVal e As MySqlRowUpdatingEventArgs _
)
```

#### Syntax: C#

```
public delegate void MySqlRowUpdatingEventHandler(
 object sender,
 MySqlRowUpdatingEventArgs e
);
```

## Requirements

Namespace: [MySql.Data.MySqlClient](#)

Assembly: MySql.Data (in MySql.Data.dll)

## See Also

[MySqlRowUpdatingEventArgs](#) overview

#### Public Instance Constructors

<a href="#">MySqlRowUpdatingEventArgs Constructor</a>	Initializes a new instance of the MySqlRowUpdatingEventArgs class.
-------------------------------------------------------	--------------------------------------------------------------------

#### Public Instance Properties

<a href="#">Command</a>	Overloaded. Gets or sets the MySqlCommand to execute when performing the Update.
<a href="#">Errors</a> (inherited from RowUpdatingEventArgs)	Gets any errors generated by the .NET Framework data provider when the Commandexecutes.
<a href="#">Row</a> (inherited from RowUpdatingEventArgs)	Gets the DataRowthat will be sent to the server as part of an insert, update, or delete operation.
<a href="#">StatementType</a> (inherited from RowUpdatingEventArgs)	Gets the type of SQL statement to execute.
<a href="#">Status</a> (inherited from RowUpdatingEventArgs)	Gets or sets the UpdateStatusof the Commandproperty.
<a href="#">TableMapping</a> (inherited from RowUpdatingEventArgs)	Gets the DataTableMappingto send through the Update.

#### Public Instance Methods

<a href="#">Equals</a> (inherited from Object)	Determines whether the specified Objectis equal to the current Object.
<a href="#">GetHashCode</a> (inherited from Object)	Serves as a hash function for a particular type. GetHashCodeis suitable for use in hashing algorithms and data structures like a hash table.
<a href="#">GetType</a> (inherited from Object)	Gets the Typeof the current instance.
<a href="#">ToString</a> (inherited from Object)	Returns a Stringthat represents the current Object.

### 21.2.7.1.3.1.2.2.1.1.7.1.1.1.1.1. [MySqlRowUpdatingEventArgs](#) Constructor

Initializes a new instance of the MySqlRowUpdatingEventArgs class.

#### Syntax: Visual Basic

```
Public Sub New(_
 ByVal row As DataRow, _
 ByVal command As IDbCommand, _
 ByVal statementType As StatementType, _
 ByVal tableMapping As DataTableMapping _
)
```

#### Syntax: C#

```
public MySqlRowUpdatingEventArgs(_
 DataRow row, _
 IDbCommand command, _
 StatementType statementType, _
 DataTableMapping tableMapping
);
```

## Parameters

- **row**: The DataRow to Update.
- **command**: The IDbCommand to execute during Update.
- **statementType**: One of the StatementType values that specifies the type of query executed.
- **tableMapping**: The DataTableMappings sent through an Update.

### 21.2.7.1.3.1.2.2.1.1.7.1.1.1.2. Command Property

Gets or sets the MySqlCommand to execute when performing the Update.

#### Syntax: Visual Basic

```
Overloads Public Property Command As MySqlCommand
```

#### Syntax: C#

```
new public MySqlCommand Command {get; set;}
```

## See Also

[MySqlRowUpdatingEventArgs Class](#) ,  [MySql.Data.MySqlClient Namespace](#)

### 21.2.7.1.3.1.2.3. [MySqlCommandBuilder](#) Constructor

#### Syntax: Visual Basic

```
Overloads Public Sub New(_
 ByVal adapter As MySqlDataAdapter, _
 ByVal lastOneWins As Boolean _
)
```

#### Syntax: C#

```
public MySqlCommandBuilder(_
 MySqlDataAdapter adapter, _
 bool lastOneWins
);
```

## See Also

[MySqlCommandBuilder Class](#) ,  [MySql.Data.MySqlClient Namespace](#) , [MySqlCommandBuilder Constructor Overload List](#)

### 21.2.7.1.3.1.2.4. [MySqlCommandBuilder](#) Constructor

#### Syntax: Visual Basic

```
Overloads Public Sub New(_
 ByVal lastOneWins As Boolean _
)
```

#### Syntax: C#

```
public MySqlCommandBuilder(_
 bool lastOneWins
);
```

## See Also

### 21.2.7.1.3.1.3. DataAdapter Property

**Syntax: Visual Basic**

```
Public Property DataAdapter As MySqlDataAdapter
```

**Syntax: C#**

```
public MySqlDataAdapter DataAdapter {get; set;}
```

**See Also**

[MySqlCommandBuilder Class](#) , [MySql.Data.MySqlClient Namespace](#)

#### 21.2.7.1.3.1.4. QuotePrefix Property

**Syntax: Visual Basic**

```
Public Property QuotePrefix As String
```

**Syntax: C#**

```
public string QuotePrefix {get; set;}
```

**See Also**

[MySqlCommandBuilder Class](#) , [MySql.Data.MySqlClient Namespace](#)

#### 21.2.7.1.3.1.5. QuoteSuffix Property

**Syntax: Visual Basic**

```
Public Property QuoteSuffix As String
```

**Syntax: C#**

```
public string QuoteSuffix {get; set;}
```

**See Also**

[MySqlCommandBuilder Class](#) , [MySql.Data.MySqlClient Namespace](#)

#### 21.2.7.1.3.1.6. `MySqlCommandBuilder.GetDeleteCommand` Method

**Syntax: Visual Basic**

```
Public Function GetDeleteCommand() As MySqlCommand
```

**Syntax: C#**

```
public MySqlCommand GetDeleteCommand();
```

**See Also**

[MySqlCommandBuilder Class](#) , [MySql.Data.MySqlClient Namespace](#)

#### 21.2.7.1.3.1.7. `MySqlCommandBuilder.GetInsertCommand` Method

**Syntax: Visual Basic**

```
Public Function GetInsertCommand() As MySqlCommand
```

**Syntax: C#**

```
public MySqlCommand GetInsertCommand();
```

**See Also**

[MySqlCommandBuilder Class](#) , [MySql.Data.MySqlClient Namespace](#)

### 21.2.7.1.3.1.8. `MySqlCommandBuilder.GetUpdateCommand` Method

#### Syntax: Visual Basic

```
Public Function GetUpdateCommand() As MySqlCommand
```

#### Syntax: C#

```
public MySqlCommand GetUpdateCommand();
```

#### See Also

[MySqlCommandBuilder Class](#) , [MySql.Data.MySqlClient Namespace](#)

### 21.2.7.1.3.1.9. `MySqlCommandBuilder.RefreshSchema` Method

#### Syntax: Visual Basic

```
Public Sub RefreshSchema()
```

#### Syntax: C#

```
public void RefreshSchema();
```

#### See Also

[MySqlCommandBuilder Class](#) , [MySql.Data.MySqlClient Namespace](#)

### 21.2.7.1.4. `MySQLException` Class

The exception that is thrown when MySQL returns an error. This class cannot be inherited.

For a list of all members of this type, see [MySQLException Members](#).

#### Syntax: Visual Basic

```
NotInheritable Public Class MySqlException_
 Inherits SystemException
```

#### Syntax: C#

```
public sealed class MySqlException : SystemException
```

#### Thread Safety

Public static (Shared in Visual Basic) members of this type are safe for multithreaded operations. Instance members are not guaranteed to be thread-safe.

#### Requirements

Namespace: [MySql.Data.MySqlClient](#)

Assembly: MySql.Data (in MySql.Data.dll)

#### See Also

[MySQLException Members](#) , [MySql.Data.MySqlClient Namespace](#)

### 21.2.7.1.4.1. `MySQLException` Members

#### [MySQLException](#) overview

#### Public Instance Properties

Data(inherited from Exception)	Gets a collection of key/value pairs that provide additional, user-defined information about the exception.
HelpLink(inherited from Exception)	Gets or sets a link to the help file associated with this exception.
InnerException(inherited from Exception)	Gets the Exception instance that caused the current exception.

Message(inherited from Exception)	Gets a message that describes the current exception.
Number	Gets a number that identifies the type of error. This number corresponds to the error numbers given in <a href="#">Section B.3, “Server Error Codes and Messages”</a> .
Source(inherited from Exception)	Gets or sets the name of the application or the object that causes the error.
StackTrace(inherited from Exception)	Gets a string representation of the frames on the call stack at the time the current exception was thrown.
TargetSite(inherited from Exception)	Gets the method that throws the current exception.

### Public Instance Methods

Equals(inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetBaseException(inherited from Exception)	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions.
GetHashCode(inherited from Object)	Serves as a hash function for a particular type. GetHashCode is suitable for use in hashing algorithms and data structures like a hash table.
GetObjectData(inherited from Exception)	When overridden in a derived class, sets the SerializationInfo with information about the exception.
GetType(inherited from Exception)	Gets the runtime type of the current instance.
ToString(inherited from Exception)	Creates and returns a string representation of the current exception.

### See Also

[MySqlException Class](#) ,  [MySql.Data.MySqlClient Namespace](#)

#### 21.2.7.1.4.1.1. Number Property

Gets a number that identifies the type of error.

##### Syntax: Visual Basic

```
Public ReadOnly Property Number As Integer
```

##### Syntax: C#

```
public int Number {get;}
```

### See Also

[MySqlException Class](#) ,  [MySql.Data.MySqlClient Namespace](#)

#### 21.2.7.1.5. MySqlHelper Class

Helper class that makes it easier to work with the provider.

For a list of all members of this type, see [MySqlHelper Members](#) .

##### Syntax: Visual Basic

```
NotInheritable Public Class MySqlHelper
```

##### Syntax: C#

```
public sealed class MySqlHelper
```

### Thread Safety

Public static (Shared in Visual Basic) members of this type are safe for multithreaded operations. Instance members are not guaranteed to be thread safe.

teed to be thread-safe.

## Requirements

Namespace:  [MySql.Data.MySqlClient](#)

Assembly: MySql.Data (in MySql.Data.dll)

## See Also

[MySqlHelper Members](#) ,  [MySql.Data.MySqlClient Namespace](#)

### 21.2.7.1.5.1. [MySqlHelper Members](#)

[MySqlHelper overview](#)

#### Public Static (Shared) Methods

<a href="#"> ExecuteDataRow</a>	Executes a single SQL statement and returns the first row of the resultset. A new MySqlConnection object is created, opened, and closed during this method.
<a href="#"> ExecuteDataset</a>	Overloaded. Executes a single SQL statement and returns the resultset in a DataSet. A new MySqlConnection object is created, opened, and closed during this method.
<a href="#"> ExecuteNonQuery</a>	Overloaded. Executes a single command against a MySQL database. The <a href="#"> MySqlConnection</a> is assumed to be open when the method is called and remains open after the method completes.
<a href="#"> ExecuteReader</a>	Overloaded. Executes a single command against a MySQL database.
<a href="#"> ExecuteScalar</a>	Overloaded. Execute a single command against a MySQL database.
<a href="#"> UpdateDataSet</a>	Updates the given table with data from the given DataSet

#### Public Instance Methods

<a href="#"> Equals(inherited from Object)</a>	Determines whether the specified Object is equal to the current Object.
<a href="#"> GetHashCode(inherited from Object)</a>	Serves as a hash function for a particular type. GetHashCode is suitable for use in hashing algorithms and data structures like a hash table.
<a href="#"> GetType(inherited from Object)</a>	Gets the Type of the current instance.
<a href="#"> ToString(inherited from Object)</a>	Returns a String that represents the current Object.

## See Also

[MySqlHelper Class](#) ,  [MySql.Data.MySqlClient Namespace](#)

### 21.2.7.1.5.1.1. [MySqlHelper.ExecuteDataRow](#) Method

Executes a single SQL statement and returns the first row of the resultset. A new MySqlConnection object is created, opened, and closed during this method.

#### Syntax: Visual Basic

```
Public Shared Function ExecuteDataRow(_
 ByVal connectionString As String, _
 ByVal commandText As String, _
 ParamArray parms As MySqlParameter() _
) As DataRow
```

#### Syntax: C#

```
public static DataRow ExecuteDataRow(_
 string connectionString, _
 string commandText, _
 params MySqlParameter[] parms
```

```
) ;
```

### Parameters

- `connectionString`: Settings to be used for the connection
- `commandText`: Command to execute
- `parms`: Parameters to use for the command

### Return Value

DataRow containing the first row of the resultset

#### See Also

[MySqlHelper Class](#) ,  [MySql.Data.MySqlClient Namespace](#)

### 21.2.7.1.5.1.2. ExecuteDataset Method

Executes a single SQL statement and returns the resultset in a DataSet. The state of the `MySqlConnection` object remains unchanged after execution of this method.

#### Overload List

Executes a single SQL statement and returns the resultset in a DataSet. The state of the `MySqlConnection` object remains unchanged after execution of this method.

- `public static DataSet ExecuteDataset(MySqlConnection,string);`

Executes a single SQL statement and returns the resultset in a DataSet. The state of the `MySqlConnection` object remains unchanged after execution of this method.

- `public static DataSet ExecuteDataset(MySqlConnection,string,params MySqlParameter[]);`

Executes a single SQL statement and returns the resultset in a DataSet. A new `MySqlConnection` object is created, opened, and closed during this method.

- `public static DataSet ExecuteDataset(string,string);`

Executes a single SQL statement and returns the resultset in a DataSet. A new `MySqlConnection` object is created, opened, and closed during this method.

- `public static DataSet ExecuteDataset(string,string,params MySqlParameter[]);`

#### See Also

[MySqlHelper Class](#) ,  [MySql.Data.MySqlClient Namespace](#)

### 21.2.7.1.5.1.2.1. `MySqlHelper.ExecuteDataset` Method

Executes a single SQL statement and returns the resultset in a DataSet. The state of the `MySqlConnection` object remains unchanged after execution of this method.

#### Syntax: Visual Basic

```
Overloads Public Shared Function ExecuteDataset(_
 ByVal connection As MySqlConnection, _
 ByVal commandText As String _
) As DataSet
```

#### Syntax: C#

```
public static DataSet ExecuteDataset(
 MySqlConnection connection,
 string commandText
);
```

**Parameters**

- **connection:** [MySqlConnection](#) object to use
- **commandText:** Command to execute

**Return Value**

DataSetcontaining the resultset

**See Also**

[MySqlHelper Class](#) , [MySql.Data.MySqlClient Namespace](#) , [MySqlHelper.ExecuteDataset Overload List](#)

**21.2.7.1.5.1.2.2. [MySqlHelper.ExecuteDataset](#) Method**

Executes a single SQL statement and returns the resultset in a DataSet. The state of the [MySqlConnection](#) object remains unchanged after execution of this method.

**Syntax: Visual Basic**

```
Overloads Public Shared Function ExecuteDataset(_
 ByVal connection As MySqlConnection, _
 ByVal commandText As String, _
 ParamArray commandParameters As MySqlParameter() _
) As DataSet
```

**Syntax: C#**

```
public static DataSet ExecuteDataset(
 MySqlConnection connection,
 string commandText,
 params MySqlParameter[] commandParameters
);
```

**Parameters**

- **connection:** [MySqlConnection](#) object to use
- **commandText:** Command to execute
- **commandParameters:** Parameters to use for the command

**Return Value**

DataSetcontaining the resultset

**See Also**

[MySqlHelper Class](#) , [MySql.Data.MySqlClient Namespace](#) , [MySqlHelper.ExecuteDataset Overload List](#)

**21.2.7.1.5.1.2.3. [MySqlHelper.ExecuteDataset](#) Method**

Executes a single SQL statement and returns the resultset in a DataSet. A new [MySqlConnection](#) object is created, opened, and closed during this method.

**Syntax: Visual Basic**

```
Overloads Public Shared Function ExecuteDataset(_
 ByVal connectionString As String, _
 ByVal commandText As String _
) As DataSet
```

**Syntax: C#**

```
public static DataSet ExecuteDataset(
 string connectionString,
 string commandText
);
```

**Parameters**

- **connectionString**: Settings to be used for the connection
- **commandText**: Command to execute

**Return Value**

DataSetcontaining the resultset

**See Also**

[MySqlHelper Class](#) ,  [MySql.Data.MySqlClient Namespace](#) ,  [MySqlHelper.ExecuteDataset Overload List](#)

**21.2.7.1.5.1.2.4. `MySqlHelper.ExecuteDataset` Method**

Executes a single SQL statement and returns the resultset in a DataSet. A new MySqlConnection object is created, opened, and closed during this method.

**Syntax: Visual Basic**

```
Overloads Public Shared Function ExecuteDataset(_
 ByVal connectionString As String, _
 ByVal commandText As String, _
 ParamArray commandParameters As MySqlParameter() _
) As DataSet
```

**Syntax: C#**

```
public static DataSet ExecuteDataset(
 string connectionString,
 string commandText,
 params MySqlParameter[] commandParameters
);
```

**Parameters**

- **connectionString**: Settings to be used for the connection
- **commandText**: Command to execute
- **commandParameters**: Parameters to use for the command

**Return Value**

DataSetcontaining the resultset

**See Also**

[MySqlHelper Class](#) ,  [MySql.Data.MySqlClient Namespace](#) ,  [MySqlHelper.ExecuteDataset Overload List](#)

**21.2.7.1.5.1.3. `ExecuteNonQuery` Method**

Executes a single command against a MySQL database. The `MySqlConnection` is assumed to be open when the method is called and remains open after the method completes.

**Overload List**

Executes a single command against a MySQL database. The `MySqlConnection` is assumed to be open when the method is called and remains open after the method completes.

- `public static int ExecuteNonQuery(MySqlConnection, string, params MySqlParameter[]);`

Executes a single command against a MySQL database. A new [MySqlConnection](#) is created using the [ConnectionString](#) given.

- `public static int ExecuteNonQuery(string, string, params MySqlParameter[]);`

#### See Also

[MySqlHelper Class](#) , [MySql.Data.MySqlClient Namespace](#)

##### 21.2.7.1.5.1.3.1. [MySqlHelper.ExecuteNonQuery](#) Method

Executes a single command against a MySQL database. The [MySqlConnection](#) is assumed to be open when the method is called and remains open after the method completes.

#### Syntax: Visual Basic

```
Overloads Public Shared Function ExecuteNonQuery(_
 ByVal connection As MySqlConnection, _
 ByVal commandText As String, _
 ParamArray commandParameters As MySqlParameter() _
) As Integer
```

#### Syntax: C#

```
public static int ExecuteNonQuery(
 MySqlConnection connection,
 string commandText,
 params MySqlParameter[] commandParameters
);
```

#### Parameters

- `connection`: [MySqlConnection](#) object to use
- `commandText`: SQL statement to be executed
- `commandParameters`: Array of [MySqlParameter](#) objects to use with the command.

#### Return Value

#### See Also

[MySqlHelper Class](#) , [MySql.Data.MySqlClient Namespace](#) , [MySqlHelper.ExecuteNonQuery Overload List](#)

##### 21.2.7.1.5.1.3.2. [MySqlHelper.ExecuteNonQuery](#) Method

Executes a single command against a MySQL database. A new [MySqlConnection](#) is created using the [ConnectionString](#) given.

#### Syntax: Visual Basic

```
Overloads Public Shared Function ExecuteNonQuery(_
 ByVal connectionString As String, _
 ByVal commandText As String, _
 ParamArray parms As MySqlParameter() _
) As Integer
```

#### Syntax: C#

```
public static int ExecuteNonQuery(
 string connectionString,
 string commandText,
 params MySqlParameter[] parms
);
```

#### Parameters

- `connectionString`: [ConnectionString](#) to use
- `commandText`: SQL statement to be executed

- **parms:** Array of [MySqlParameter](#) objects to use with the command.

**Return Value****See Also**

[MySqlHelper Class](#) , [MySql.Data.MySqlClient Namespace](#) , [MySqlHelper.ExecuteNonQuery Overload List](#)

**21.2.7.1.5.1.4. ExecuteReader Method**

Executes a single command against a MySQL database.

**Overload List**

Executes a single command against a MySQL database.

- [public static MySqlDataReader ExecuteReader\(string,string\);](#)

Executes a single command against a MySQL database.

- [public static MySqlDataReader ExecuteReader\(string,string,params MySqlParameter\[\]\);](#)

**See Also**

[MySqlHelper Class](#) , [MySql.Data.MySqlClient Namespace](#)

**21.2.7.1.5.1.4.1. [MySqlHelper.ExecuteReader](#) Method**

Executes a single command against a MySQL database.

**Syntax: Visual Basic**

```
Overloads Public Shared Function ExecuteReader(_
 ByVal connectionString As String, _
 ByVal commandText As String _
) As MySqlDataReader
```

**Syntax: C#**

```
public static MySqlDataReader ExecuteReader(
 string connectionString,
 string commandText
);
```

**Parameters**

- **connectionString:** Settings to use for this command
- **commandText:** Command text to use

**Return Value**

[MySqlDataReader](#) object ready to read the results of the command

**See Also**

[MySqlHelper Class](#) , [MySql.Data.MySqlClient Namespace](#) , [MySqlHelper.ExecuteReader Overload List](#)

**21.2.7.1.5.1.4.2. [MySqlHelper.ExecuteReader](#) Method**

Executes a single command against a MySQL database.

**Syntax: Visual Basic**

```
Overloads Public Shared Function ExecuteReader(_
 ByVal connectionString As String, _
 ByVal commandText As String, _
```

```
ParamArray commandParameters As MySqlParameter() _
) As MySqlDataReader
```

**Syntax: C#**

```
public static MySqlDataReader ExecuteReader(
 string connectionString,
 string commandText,
 params MySqlParameter[] commandParameters
>;
```

**Parameters**

- **connectionString**: Settings to use for this command
- **commandText**: Command text to use
- **commandParameters**: Array of **MySqlParameter** objects to use with the command

**Return Value**

**MySqlDataReader** object ready to read the results of the command

**See Also**

[MySqlHelper Class](#) , [MySql.Data.MySqlClient Namespace](#) , [MySqlHelper.ExecuteReader Overload List](#)

**21.2.7.1.5.1.5. ExecuteScalar Method**

Execute a single command against a MySQL database.

**Overload List**

Execute a single command against a MySQL database.

- [public static object ExecuteScalar\(MySqlConnection,string\);](#)

Execute a single command against a MySQL database.

- [public static object ExecuteScalar\(MySqlConnection,string,params MySqlParameter\[\]\);](#)

Execute a single command against a MySQL database.

- [public static object ExecuteScalar\(string,string\);](#)

Execute a single command against a MySQL database.

- [public static object ExecuteScalar\(string,string,params MySqlParameter\[\]\);](#)

**See Also**

[MySqlHelper Class](#) , [MySql.Data.MySqlClient Namespace](#)

**21.2.7.1.5.1.5.1. [MySqlHelper.ExecuteScalar](#) Method**

Execute a single command against a MySQL database.

**Syntax: Visual Basic**

```
Overloads Public Shared Function ExecuteScalar(_
 ByVal connection As MySqlConnection, _
 ByVal commandText As String _
) As Object
```

**Syntax: C#**

```
public static object ExecuteScalar(
MySqlConnection connection,
string commandText
);
```

**Parameters**

- **connection:** [MySqlConnection](#) object to use
- **commandText:** Command text to use for the command

**Return Value**

The first column of the first row in the result set, or a null reference if the result set is empty.

**See Also**

[MySqlHelper Class](#) ,  [MySql.Data.MySqlClient Namespace](#) ,  [MySqlHelper.ExecuteScalar Overload List](#)

**21.2.7.1.5.1.5.2.  [MySqlHelper .ExecuteScalar](#) Method**

Execute a single command against a MySQL database.

**Syntax: Visual Basic**

```
Overloads Public Shared Function ExecuteScalar(_
 ByVal connection As MySqlConnection, _
 ByVal commandText As String, _
 ParamArray commandParameters As MySqlParameter() _
) As Object
```

**Syntax: C#**

```
public static object ExecuteScalar(
MySqlConnection connection,
string commandText,
params MySqlParameter[] commandParameters
);
```

**Parameters**

- **connection:** [MySqlConnection](#) object to use
- **commandText:** Command text to use for the command
- **commandParameters:** Parameters to use for the command

**Return Value**

The first column of the first row in the result set, or a null reference if the result set is empty.

**See Also**

[MySqlHelper Class](#) ,  [MySql.Data.MySqlClient Namespace](#) ,  [MySqlHelper.ExecuteScalar Overload List](#)

**21.2.7.1.5.1.5.3.  [MySqlHelper .ExecuteScalar](#) Method**

Execute a single command against a MySQL database.

**Syntax: Visual Basic**

```
Overloads Public Shared Function ExecuteScalar(_
 ByVal connectionString As String, _
 ByVal commandText As String _
) As Object
```

**Syntax: C#**

```
public static object ExecuteScalar(
 string connectionString,
 string commandText
);
```

**Parameters**

- **connectionString**: Settings to use for the update
- **commandText**: Command text to use for the update

**Return Value**

The first column of the first row in the result set, or a null reference if the result set is empty.

**See Also**

[MySqlHelper Class](#) ,  [MySql.Data.MySqlClient Namespace](#) ,  [MySqlHelper.ExecuteScalar Overload List](#)

**21.2.7.1.5.1.5.4. `MySqlHelper.ExecuteScalar` Method**

Execute a single command against a MySQL database.

**Syntax: Visual Basic**

```
Overloads Public Shared Function ExecuteScalar(_
 ByVal connectionString As String, _
 ByVal commandText As String, _
 ParamArray commandParameters As MySqlParameter() _
) As Object
```

**Syntax: C#**

```
public static object ExecuteScalar(
 string connectionString,
 string commandText,
 params MySqlParameter[] commandParameters
);
```

**Parameters**

- **connectionString**: Settings to use for the command
- **commandText**: Command text to use for the command
- **commandParameters**: Parameters to use for the command

**Return Value**

The first column of the first row in the result set, or a null reference if the result set is empty.

**See Also**

[MySqlHelper Class](#) ,  [MySql.Data.MySqlClient Namespace](#) ,  [MySqlHelper.ExecuteScalar Overload List](#)

**21.2.7.1.5.1.6. `MySqlHelper.UpdateDataSet` Method**

Updates the given table with data from the given DataSet

**Syntax: Visual Basic**

```
Public Shared Sub UpdateDataSet(_
 ByVal connectionString As String, _
 ByVal commandText As String, _
 ByVal ds As DataSet, _
 ByVal tablename As String _
)
```

**Syntax: C#**

```
public static void UpdateDataSet(
```

```
string connectionString,
string commandText,
DataSets ds,
string tablename
);
```

**Parameters**

- **connectionString**: Settings to use for the update
- **commandText**: Command text to use for the update
- **ds**: DataSet containing the new data to use in the update
- **tablename**: Tablename in the data set to update

**See Also**

[MySqlHelper Class](#) ,  [MySql.Data.MySqlClient Namespace](#)

**21.2.7.1.6. MySqlErrorCode Enumeration****Syntax: Visual Basic**

```
Public Enum MySqlErrorCode
```

**Syntax: C#**

```
public enum MySqlErrorCode
```

### 21.2.7.2.2.1. MySqlConversionException Members

[MySqlConversionException overview](#)

#### Public Instance Constructors

<a href="#"> MySqlConversionException Constructor</a>	Ctor
-------------------------------------------------------	------

#### Public Instance Properties

Data(inherited from Exception)	Gets a collection of key/value pairs that provide additional, user-defined information about the exception.
HelpLink(inherited from Exception)	Gets or sets a link to the help file associated with this exception.
InnerException(inherited from Exception)	Gets the Exception instance that caused the current exception.
Message(inherited from Exception)	Gets a message that describes the current exception.
Source(inherited from Exception)	Gets or sets the name of the application or the object that causes the error.
StackTrace(inherited from Exception)	Gets a string representation of the frames on the call stack at the time the current exception was thrown.
TargetSite(inherited from Exception)	Gets the method that throws the current exception.

#### Public Instance Methods

<a href="#"> Equals(inherited from Object)</a>	Determines whether the specified Object is equal to the current Object.
------------------------------------------------	-------------------------------------------------------------------------

GetBaseException(inherited from Exception)	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions.
GetHashCode(inherited from Object)	Serves as a hash function for a particular type. GetHashCode is suitable for use in hashing algorithms and data structures like a hash table.
GetObjectData(inherited from Exception)	When overridden in a derived class, sets the SerializationInfo with information about the exception.
GetType(inherited from Exception)	Gets the runtime type of the current instance.
ToString(inherited from Exception)	Creates and returns a string representation of the current exception.

### Protected Instance Properties

HResult(inherited from Exception)	Gets or sets HRESULT, a coded numeric value that is assigned to a specific exception.
-----------------------------------	---------------------------------------------------------------------------------------

### Protected Instance Methods

Finalize(inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone(inherited from Object)	Creates a shallow copy of the current Object.

### See Also

#### 21.2.7.2.3.1.4.1.1.4. `MySqlValue.ToString` Method

Returns a string representation of this value

##### Syntax: Visual Basic

```
Overrides Public Function ToString() As String
```

##### Syntax: C#

```
public override string ToString();
```

#### See Also

[MySqlValue Class](#) , [MySql.Data.Types Namespace](#)

#### 21.2.7.2.3.1.4.1.1.5. `MySqlValue.classType` Field

The system type represented by this value

##### Syntax: Visual Basic

```
Protected classType As Type
```

##### Syntax: C#

```
protected Type classType;
```

#### See Also

[MySqlValue Class](#) , [MySql.Data.Types Namespace](#)

#### 21.2.7.2.3.1.4.1.1.6. `MySqlValue.dbType` Field

The generic dbtype of this value

##### Syntax: Visual Basic

```
Protected dbType As DbType
```

##### Syntax: C#

```
protected DbType dbType;
```

#### See Also

[MySqlValue Class](#) , [MySql.Data.Types Namespace](#)

#### 21.2.7.2.3.1.4.1.1.7. `MySqlValue.mySqlDbType` Field

The specific MySQL db type

##### Syntax: Visual Basic

```
Protected mySqlDbType As MySqlDbType
```

##### Syntax: C#

```
protected MySqlDbType mySqlDbType;
```

#### See Also

[MySqlValue Class](#) , [MySql.Data.Types Namespace](#)

#### 21.2.7.2.3.1.4.1.1.8. `MySqlValue.mySqlTypeName` Field

The MySQL specific typename of this value

**Syntax: Visual Basic**

```
Protected mySqlTypeName As String
```

**Syntax: C#**

```
protected string mySqlTypeName;
```

**See Also**

[MySqlValue Class](#) ,  [MySql.Data.Types Namespace](#)

### 21.2.7.2.3.1.4.1.1.9. `MySqlValue.objectValue` Field

**Syntax: Visual Basic**

```
Protected objectValue As Object
```

**Syntax: C#**

```
protected object objectValue;
```

**See Also**

[MySqlValue Class](#) ,  [MySql.Data.Types Namespace](#)

### 21.2.7.2.3.1.5. `IsValidDateTime` Property

Indicates if this object contains a value that can be represented as a DateTime

**Syntax: Visual Basic**

```
Public ReadOnly Property IsValidDateTime As Boolean
```

**Syntax: C#**

```
public bool IsValidDateTime {get;}
```

**See Also**

[MySqlDateTime Class](#) ,  [MySql.Data.Types Namespace](#)

### 21.2.7.2.3.1.6. `Minute` Property

Returns the minute portion of this datetime

**Syntax: Visual Basic**

```
Public Property Minute As Integer
```

**Syntax: C#**

```
public int Minute {get; set;}
```

**See Also**

[MySqlDateTime Class](#) ,  [MySql.Data.Types Namespace](#)

### 21.2.7.2.3.1.7. `Month` Property

Returns the month portion of this datetime

**Syntax: Visual Basic**

```
Public Property Month As Integer
```

**Syntax: C#**

```
public int Month {get; set;}
```

**See Also**

[MySqlDateTime Class](#) ,  [MySql.Data.Types Namespace](#)

### 21.2.7.2.3.1.8. Second Property

Returns the second portion of this datetime

**Syntax: Visual Basic**

```
Public Property Second As Integer
```

**Syntax: C#**

```
public int Second {get; set;}
```

**See Also**

[MySqlDateTime Class](#) ,  [MySql.Data.Types Namespace](#)

### 21.2.7.2.3.1.9. Year Property

Returns the year portion of this datetime

**Syntax: Visual Basic**

```
Public Property Year As Integer
```

**Syntax: C#**

```
public int Year {get; set;}
```

**See Also**

[MySqlDateTime Class](#) ,  [MySql.Data.Types Namespace](#)

### 21.2.7.2.3.1.10. [MySqlDateTime.GetDateTime](#) Method

Returns this value as a DateTime

**Syntax: Visual Basic**

```
Public Function GetDateTime() As Date
```

**Syntax: C#**

```
public DateTime GetDateTime();
```

**See Also**

[MySqlDateTime Class](#) ,  [MySql.Data.Types Namespace](#)

### 21.2.7.2.3.1.11. [MySqlDateTime.ToString](#) Method

Returns a MySQL specific string representation of this value

**Syntax: Visual Basic**

```
Overrides Public Function ToString() As String
```

**Syntax: C#**

```
public override string ToString();
```

#### See Also

## 21.2.8. Connector/NET Support

The developers of Connector/NET greatly value the input of our users in the software development process. If you find Connector/NET lacking some feature important to you, or if you discover a bug and need to file a bug report, please use the instructions in [Section 1.7, “How to Report Bugs or Problems”](#).

### 21.2.8.1. Connector/NET Community Support

- Community support for Connector/NET can be found through the forums at <http://forums.mysql.com>.
- Community support for Connector/NET can also be found through the mailing lists at <http://lists.mysql.com>.
- Paid support is available from Oracle. Additional information is available at <http://dev.mysql.com/support/>.

### 21.2.8.2. How to report Connector/NET Problems or Bugs

If you encounter difficulties or problems with Connector/NET, contact the Connector/NET community [Section 21.2.8.1, “Connector/NET Community Support”](#).

You should first try to execute the same SQL statements and commands from the `mysql` client program or from `admndemo`. This helps you determine whether the error is in Connector/NET or MySQL.

If reporting a problem, you should ideally include the following information with the email:

- Operating system and version
- Connector/NET version
- MySQL server version
- Copies of error messages or other unexpected output
- Simple reproducible sample

Remember that the more information you can supply to us, the more likely it is that we can fix the problem.

If you believe the problem to be a bug, then you must report the bug through <http://bugs.mysql.com/>.

### 21.2.8.3. Connector/NET Change History

The Connector/NET Change History (Changelog) is located with the main Changelog for MySQL. See [Section C.4, “MySQL Connector/NET Change History”](#).

## 21.2.9. Connector/NET FAQ

#### Questions

- [22.2.9.1: How do I obtain the value of an auto-incremented column?](#)

#### Questions and Answers

##### 22.2.9.1: How do I obtain the value of an auto-incremented column?

When using `CommandBuilder`, setting `ReturnGeneratedIdentifiers` property to `true` no longer works, as `CommandBuilder` does not add `last_insert_id()` by default.

`CommandBuilder` hooks up to the `DataAdapter.RowUpdating` event handler, which means it will get called for every row. It examines the command object and, if it is the same referenced object, it essentially rebuilds the object, thereby destroying your command text changes.

One approach to solving this problem is to clone the command object so you have a different actual reference:

```
dataAdapter.InsertCommand = cb.GetInsertCommand().Clone()
```

This will work, but since the CommandBuilder is still connected to the DataAdapter, the RowUpdating event will still fire and performance will be hit. To stop that, once all your commands have been added you need to disconnect the CommandBuilder from the DataAdapter:

```
cb.DataAdapter = null;
```

The last requirement is to make sure the `id` that is returned by `last_insert_id()` has the correct name. For example:

```
SELECT last_insert_id() AS id
```

A complete working example is shown here:

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;

using System.Data;
using MySql.Data;
using MySql.Data.MySqlClient;

namespace GetAutoIncId
{
 class Program
 {
 static void Main(string[] args)
 {
 string connStr = "server=localhost;user=root;database=TestDB;port=3306;password=*****;";
 MySqlConnection conn = new MySqlConnection(connStr);

 try
 {
 Console.WriteLine("Connecting to MySQL...");
 conn.Open();

 string sql = "SELECT * FROM TestTable";

 MySqlDataAdapter da = new MySqlDataAdapter(sql, conn);
 MySqlCommandBuilder cb = new MySqlCommandBuilder(da);

 MySqlCommand cmd = new MySqlCommand();
 cmd.Connection = conn;
 cmd.CommandText = sql;
 // use Cloned object to avoid .NET rebuilding the object, and
 // thereby throwing away our command text additions.
 MySqlCommand insertCmd = cb.GetInsertCommand().Clone();
 insertCmd.CommandText = insertCmd.CommandText + ";SELECT last_insert_id() AS id";
 insertCmd.UpdatedRowSource = UpdateRowSource.FirstReturnedRecord;
 da.InsertCommand = insertCmd;
 cbDataAdapter = null; // Unhook RowUpdating event handler

 DataTable dt = new DataTable();
 da.Fill(dt);

 DataRow row = dt.NewRow();
 row["name"] = "Joe Smith";

 dt.Rows.Add(row);
 da.Update(dt);

 System.Console.WriteLine("ID after update: " + row["id"]);
 }
 catch (Exception ex)
 {
 Console.WriteLine(ex.ToString());
 }

 conn.Close();
 Console.WriteLine("Done.");
 }
 }
}
```

## 21.3. MySQL Connector/J

MySQL provides connectivity for client applications developed in the Java programming language through a JDBC driver, which is called MySQL Connector/J.

MySQL Connector/J is a JDBC Type 4 driver. Different versions are available that are compatible with the JDBC 3.0 and JDBC 4.0 specifications. The Type 4 designation means that the driver is pure-Java implementation of the MySQL protocol and does not

rely on the MySQL client libraries.

Although JDBC is useful by itself, we would hope that if you are not familiar with JDBC that after reading the first few sections of this manual, that you would avoid using naked JDBC for all but the most trivial problems and consider using one of the popular persistence frameworks such as [Hibernate](#), [Spring's JDBC templates](#) or [Ibatis SQL Maps](#) to do the majority of repetitive work and heavier lifting that is sometimes required with JDBC.

This section is not designed to be a complete JDBC tutorial. If you need more information about using JDBC you might be interested in the following online tutorials that are more in-depth than the information presented here:

- [JDBC Basics](#): A tutorial from Sun covering beginner topics in JDBC
- [JDBC Short Course](#): A more in-depth tutorial from Sun and JGuru

#### Key topics:

- For help with connection strings, connection options setting up your connection through JDBC, see [Section 21.3.4.1, “Driver/Datasource Class Names, URL Syntax and Configuration Properties for Connector/J”](#).
- For tips on using Connector/J and JDBC with generic J2EE toolkits, see [Section 21.3.5.2, “Using Connector/J with J2EE and Other Java Frameworks”](#).
- Developers using the Tomcat server platform, see [Section 21.3.5.2.2, “Using Connector/J with Tomcat”](#).
- Developers using JBoss, see [Section 21.3.5.2.3, “Using Connector/J with JBoss”](#).
- Developers using Spring, see [Section 21.3.5.2.4, “Using Connector/J with Spring”](#).
- Developers using GlassFish (Sun Application Server), see [Section 21.3.5.2.5, “Using Connector/J with GlassFish”](#).

### 21.3.1. Connector/J Versions

There are currently four versions of MySQL Connector/J available:

- Connector/J 5.1 is the Type 4 pure Java JDBC driver, which conforms to the JDBC 3.0 and JDBC 4.0 specifications. It provides compatibility with all the functionality of MySQL, including 4.1, 5.0, 5.1, 5.4 and 5.5. Connector/J 5.1 provides ease of development features, including auto-registration with the Driver Manager, standardized validity checks, categorized SQLExceptions, support for the JDBC-4.0 XML processing, per connection client information, `NCHAR`, `NVARCHAR` and `NCLOB` types. This release also includes all bug fixes up to and including Connector/J 5.0.6.
- Connector/J 5.0 provides support for all the functionality offered by Connector/J 3.1 and includes distributed transaction (XA) support.
- Connector/J 3.1 was designed for connectivity to MySQL 4.1 and MySQL 5.0 servers and provides support for all the functionality in MySQL 5.0 except distributed transaction (XA) support.
- Connector/J 3.0 provides core functionality and was designed with connectivity to MySQL 3.x or MySQL 4.1 servers, although it will provide basic compatibility with later versions of MySQL. Connector/J 3.0 does not support server-side prepared statements, and does not support any of the features in versions of MySQL later than 4.1.

The following table summarizes the Connector/J versions available:

Connector/J version	Driver Type	JDBC version	MySQL Server version	Status
5.1	4	3.0, 4.0	4.1, 5.0, 5.1, 5.4, 5.5	Recommended version
5.0	4	3.0	4.1, 5.0	Released version
3.1	4	3.0	4.1, 5.0	Obsolete
3.0	4	3.0	3.x, 4.1	Obsolete

The current recommended version for Connector/J is 5.1. This guide covers all four connector versions, with specific notes given where a setting applies to a specific option.

### 21.3.1.1. Java Versions Supported

The following table summarizes Connector/J Java dependencies:

Connector/J version	Java RTE required	JDK required (to build source code)
5.1	1.5.x, 1.6.x	1.6.x and 1.5.x
5.0	1.3.x, 1.4.x, 1.5.x, 1.6.x	1.4.2, 1.5.x, 1.6.x
3.1	1.2.x, 1.3.x, 1.4.x, 1.5.x, 1.6.x	1.4.2, 1.5.x, 1.6.x
3.0	1.2.x, 1.3.x, 1.4.x, 1.5.x, 1.6.x	1.4.2, 1.5.x, 1.6.x

MySQL Connector/J does not support JDK-1.1.x or JDK-1.0.x.

Because of the implementation of `java.sql.Savepoint`, Connector/J 3.1.0 and newer will not run on a Java runtime older than 1.4 unless the class verifier is turned off (by setting the `-Xverify:none` option to the Java runtime). This is because the class verifier will try to load the class definition for `java.sql.Savepoint` even though it is not accessed by the driver unless you actually use savepoint functionality.

Caching functionality provided by Connector/J 3.1.0 or newer is also not available on JVMs older than 1.4.x, as it relies on `java.util.LinkedHashMap` which was first available in JDK-1.4.0.

If you are building Connector/J from source code using the source distribution (see [Section 21.3.2.4, “Installing from the Development Source Tree”](#)) then you must use JDK 1.4.2 or newer to compile the Connector package. For Connector/J 5.1 you must have both JDK-1.6.x. and JDK-1.5.x installed to be able to build the source code.

### 21.3.2. Connector/J Installation

You can install the Connector/J package using either the binary or source distribution. The binary distribution provides the easiest method for installation; the source distribution enables you to customize your installation further. With either solution, you must manually add the Connector/J location to your Java `CLASSPATH`.

If you are upgrading from a previous version, read the upgrade information before continuing. See [Section 21.3.2.3, “Upgrading from an Older Version”](#).

Connector/J is also available as part of the Maven project. More information, and the Connector/J JAR files can be found at the [Maven repository](#).

#### 21.3.2.1. Installing Connector/J from a Binary Distribution

The easiest method of installation is to use the binary distribution of the Connector/J package. The binary distribution is available either as a Tar/Gzip or Zip file which you must extract to a suitable location and then optionally make the information about the package available by changing your `CLASSPATH` (see [Section 21.3.2.2, “Installing the Driver and Configuring the CLASSPATH”](#)).

MySQL Connector/J is distributed as a .zip or .tar.gz archive containing the sources, the class files, and the JAR archive named `mysql-connector-java-[version]-bin.jar`, and starting with Connector/J 3.1.8 a debug build of the driver in a file named `mysql-connector-java-[version]-bin-g.jar`.

Starting with Connector/J 3.1.9, the `.class` files that constitute the JAR files are only included as part of the driver JAR file.

You should not use the debug build of the driver unless instructed to do so when reporting a problem or a bug, as it is not designed to be run in production environments, and will have adverse performance impact when used. The debug binary also depends on the Aspect/J runtime library, which is located in the `src/lib/aspectjrt.jar` file that comes with the Connector/J distribution.

You will need to use the appropriate graphical or command-line utility to extract the distribution (for example, WinZip for the .zip archive, and `tar` for the .tar.gz archive). Because there are potentially long file names in the distribution, we use the GNU tar archive format. You will need to use GNU tar (or an application that understands the GNU tar archive format) to unpack the .tar.gz variant of the distribution.

#### 21.3.2.2. Installing the Driver and Configuring the `CLASSPATH`

Once you have extracted the distribution archive, you can install the driver by placing `mysql-connect-or-java-[version]-bin.jar` in your classpath, either by adding the full path to it to your `CLASSPATH` environment variable, or by directly specifying it with the command line switch `-cp` when starting your JVM.

If you are going to use the driver with the JDBC DriverManager, you would use `com.mysql.jdbc.Driver` as the class that implements `java.sql.Driver`.

You can set the `CLASSPATH` environment variable under UNIX, Linux or Mac OS X either locally for a user within their `.profile`, `.login` or other login file. You can also set it globally by editing the global `/etc/profile` file.

For example, under a C shell (csh, tcsh) you would add the Connector/J driver to your `CLASSPATH` using the following:

```
shell> setenv CLASSPATH /path/mysql-connector-java-[ver]-bin.jar:$CLASSPATH
```

Or with a Bourne-compatible shell (sh, ksh, bash):

```
shell> export set CLASSPATH=/path/mysql-connector-java-[ver]-bin.jar:$CLASSPATH
```

Within Windows 2000, Windows XP, Windows Server 2003 and Windows Vista, you must set the environment variable through the System Control Panel.

If you want to use MySQL Connector/J with an application server such as GlassFish, Tomcat or JBoss, you will have to read your vendor's documentation for more information on how to configure third-party class libraries, as most application servers ignore the `CLASSPATH` environment variable. For configuration examples for some J2EE application servers, see [Section 21.3.5.2, “Using Connector/J with J2EE and Other Java Frameworks”](#). However, the authoritative source for JDBC connection pool configuration information for your particular application server is the documentation for that application server.

If you are developing servlets or JSPs, and your application server is J2EE-compliant, you can put the driver's .jar file in the WEB-INF/lib subdirectory of your webapp, as this is a standard location for third party class libraries in J2EE web applications.

You can also use the `MysqlDataSource` or `MysqlConnectionPoolDataSource` classes in the `com.mysql.jdbc.jdbc2.optional` package, if your J2EE application server supports or requires them. Starting with Connector/J 5.0.0, the `javax.sql.XADataSource` interface is implemented using the `com.mysql.jdbc.jdbc2.optional.MysqlXADataSource` class, which supports XA distributed transactions when used in combination with MySQL server version 5.0.

The various `MysqlDataSource` classes support the following parameters (through standard set mutators):

- `user`
- `password`
- `serverName` (see the previous section about fail-over hosts)
- `databaseName`
- `port`

### 21.3.2.3. Upgrading from an Older Version

We try to keep the upgrade process as easy as possible, however as is the case with any software, sometimes changes need to be made in new versions to support new features, improve existing functionality, or comply with new standards.

This section has information about what users who are upgrading from one version of Connector/J to another (or to a new version of the MySQL server, with respect to JDBC functionality) should be aware of.

#### 21.3.2.3.1. Upgrading from MySQL Connector/J 3.0 to 3.1

Connector/J 3.1 is designed to be backward-compatible with Connector/J 3.0 as much as possible. Major changes are isolated to new functionality exposed in MySQL-4.1 and newer, which includes Unicode character sets, server-side prepared statements, SQL-State codes returned in error messages by the server and various performance enhancements that can be enabled or disabled using configuration properties.

- **Unicode Character Sets:** See the next section, as well as [Section 9.1, “Character Set Support”](#), for information on this new feature of MySQL. If you have something misconfigured, it will usually show up as an error with a message similar to `Illegal mix of collations`.
- **Server-side Prepared Statements:** Connector/J 3.1 will automatically detect and use server-side prepared statements when they are available (MySQL server version 4.1.0 and newer).

Starting with version 3.1.7, the driver scans SQL you are preparing using all variants of `Connection.prepareStatement()` to determine if it is a supported type of statement to prepare on the server side, and if it is not supported by the server, it instead prepares it as a client-side emulated prepared statement. You can disable this feature by passing `emulateUnsupportedPstmts=false` in your JDBC URL.

If your application encounters issues with server-side prepared statements, you can revert to the older client-side emulated prepared statement code that is still presently used for MySQL servers older than 4.1.0 with the connection property `useServerPrepStmts=false`

- **Datetimes** with all-zero components (`0000-00-00 . . .`): These values can not be represented reliably in Java. Connector/J 3.0.x always converted them to `NULL` when being read from a `ResultSet`.

Connector/J 3.1 throws an exception by default when these values are encountered as this is the most correct behavior according to the JDBC and SQL standards. This behavior can be modified using the `zeroDateTimeBehavior` configuration property. The permissible values are:

- `exception` (the default), which throws an `SQLException` with an `SQLState` of `S1009`.
- `convertToNull`, which returns `NULL` instead of the date.
- `round`, which rounds the date to the nearest closest value which is `0001-01-01`.

Starting with Connector/J 3.1.7, `ResultSet.getString()` can be decoupled from this behavior using `noDatetimeStringSync=true` (the default value is `false`) so that you can retrieve the unaltered all-zero value as a String. It should be noted that this also precludes using any time zone conversions, therefore the driver will not allow you to enable `noDatetimeStringSync` and `useTimezone` at the same time.

- **New SQLState Codes:** Connector/J 3.1 uses SQL:1999 `SQLState` codes returned by the MySQL server (if supported), which are different from the legacy X/Open state codes that Connector/J 3.0 uses. If connected to a MySQL server older than MySQL-4.1.0 (the oldest version to return `SQLStates` as part of the error code), the driver will use a built-in mapping. You can revert to the old mapping by using the configuration property `useSqlStateCodes=false`.
- **ResultSet.getString():** Calling `ResultSet.getString()` on a `BLOB` column will now return the address of the `byte[]` array that represents it, instead of a `String` representation of the `BLOB`. `BLOB` values have no character set, so they cannot be converted to `java.lang.String`s without data loss or corruption.

To store strings in MySQL with LOB behavior, use one of the `TEXT` types, which the driver will treat as a `java.sql.Clob`.

- **Debug builds:** Starting with Connector/J 3.1.8 a debug build of the driver in a file named `mysql-connector-java-[version]-bin-g.jar` is shipped alongside the normal binary jar file that is named `mysql-connector-java-[version]-bin.jar`.

Starting with Connector/J 3.1.9, we do not ship the .class files unbundled, they are only available in the JAR archives that ship with the driver.

You should not use the debug build of the driver unless instructed to do so when reporting a problem or bug, as it is not designed to be run in production environments, and will have adverse performance impact when used. The debug binary also depends on the Aspect/J runtime library, which is located in the `src/lib/aspectjrt.jar` file that comes with the Connector/J distribution.

### 21.3.2.3.2. Upgrading to MySQL Connector/J 5.1.x

- In Connector/J 5.0.x and earlier, the alias for a table in a `SELECT` statement is returned when accessing the result set metadata using `ResultSetMetaData.getColumnName()`. This behavior however is not JDBC compliant, and in Connector/J 5.1 this behavior was changed so that the original table name, rather than the alias, is returned.

The JDBC-compliant behavior is designed to let API users reconstruct the DML statement based on the metadata within `ResultSet` and `ResultSetMetaData`.

You can get the alias for a column in a result set by calling `ResultSetMetaData.getColumnLabel()`. If you want to use the old noncompliant behavior with `ResultSetMetaData.getColumnName()`, use the `useOldAliasAsMetadataBehavior` option and set the value to `true`.

In Connector/J 5.0.x the default value of `useOldAliasMetadataBehavior` was true, but in Connector/J 5.1 this was changed to a default value of false.

### 21.3.2.3.3. JDBC-Specific Issues When Upgrading to MySQL Server 4.1 or Newer

- *Using the UTF-8 Character Encoding* - Prior to MySQL server version 4.1, the UTF-8 character encoding was not supported by the server, however the JDBC driver could use it, allowing storage of multiple character sets in latin1 tables on the server.

Starting with MySQL-4.1, this functionality is deprecated. If you have applications that rely on this functionality, and can not upgrade them to use the official Unicode character support in MySQL server version 4.1 or newer, you should add the following property to your connection URL:

```
useOldUTF8Behavior=true
```

- *Server-side Prepared Statements* - Connector/J 3.1 will automatically detect and use server-side prepared statements when they are available (MySQL server version 4.1.0 and newer). If your application encounters issues with server-side prepared statements, you can revert to the older client-side emulated prepared statement code that is still presently used for MySQL servers older than 4.1.0 with the following connection property:

```
useServerPrepStmts=false
```

#### 21.3.2.4. Installing from the Development Source Tree

##### **Caution**

You should read this section only if you are interested in helping us test our new code. If you just want to get MySQL Connector/J up and running on your system, you should use a standard binary release distribution.

To install MySQL Connector/J from the development source tree, make sure that you have the following prerequisites:

- A Bazaar client, to check out the sources from our Launchpad repository (available from <http://bazaar-vcs.org/>).
- Apache Ant version 1.7 or newer (available from <http://ant.apache.org/>).
- JDK 1.4.2 or later. Although MySQL Connector/J can be used with older JDKs, to compile it from source you must have at least JDK 1.4.2. If you are building Connector/J 5.1 you will need JDK 1.6.x and an older JDK such as JDK 1.5.x. You will then need to point your JAVA\_HOME environment variable at the older installation.

The source code repository for MySQL Connector/J is located on Launchpad at <https://code.launchpad.net/connectorj>.

To check out and compile a specific branch of MySQL Connector/J, follow these steps:

1. Check out the latest code from the branch that you want with one of the following commands.

To check out the latest development branch use:

```
shell> bzr branch lp:connectorj
```

This creates a `connectorj` subdirectory in the current directory that contains the latest sources for the requested branch.

To check out the latest 5.1 code use:

```
shell> bzr branch lp:connectorj/5.1
```

This will create a `5.1` subdirectory in the current directory containing the latest 5.1 code.

2. If you are building Connector/J 5.1 make sure that you have both JDK 1.6.x installed and an older JDK such as JDK 1.5.x. This is because Connector/J supports both JDBC 3.0 (which was prior to JDK 1.6.x) and JDBC 4.0. Set your JAVA\_HOME environment variable to the path of the older JDK installation.
3. Change location to either the `connectorj` or `5.1` directory, depending on which branch you want to build, to make it your current working directory. For example:

```
shell> cd connectorj
```

4. If you are building Connector/J 5.1 you need to edit the `build.xml` to reflect the location of your JDK 1.6.x installation. The lines that you need to change are:

```
<property name="com.mysql.jdbc.java6.javac" value="C:\jvms\jdk1.6.0\bin\javac.exe" />
<property name="com.mysql.jdbc.java6.rtjar" value="C:\jvms\jdk1.6.0\jre\lib\rt.jar" />
```

Alternatively, you can set the value of these property names through the Ant `-D` option.

5. Issue the following command to compile the driver and create a `.jar` file suitable for installation:

```
shell> ant dist
```

This creates a `build` directory in the current directory, where all build output will go. A directory is created in the `build` directory that includes the version number of the sources you are building from. This directory contains the sources, compiled `.class` files, and a `.jar` file suitable for deployment. For other possible targets, including ones that will create a fully packaged distribution, issue the following command:

```
shell> ant -projecthelp
```

6. A newly created `.jar` file containing the JDBC driver will be placed in the directory `build/mysql-connector-java-[version]`.

Install the newly created JDBC driver as you would a binary `.jar` file that you download from MySQL by following the instructions in [Section 21.3.2.2, “Installing the Driver and Configuring the CLASSPATH”](#).

A package containing both the binary and source code for Connector/J 5.1 can also be found at the following location: [Connector/J 5.1 Download](#)

### 21.3.3. Connector/J Examples

Examples of using Connector/J are located throughout this document, this section provides a summary and links to these examples.

- [Example 21.1, “Connector/J: Obtaining a connection from the `DriverManager`”](#)
- [Example 21.2, “Connector/J: Using `java.sql.Statement` to execute a `SELECT` query”](#)
- [Example 21.3, “Connector/J: Calling Stored Procedures”](#)
- [Example 21.4, “Connector/J: Using `Connection.prepareStatement\(\)`”](#)
- [Example 21.5, “Connector/J: Registering output parameters”](#)
- [Example 21.6, “Connector/J: Setting `CallableStatement` input parameters”](#)
- [Example 21.7, “Connector/J: Retrieving results and output parameter values”](#)
- [Example 21.8, “Connector/J: Retrieving `AUTO\_INCREMENT` column values using `Statement.getGeneratedKeys\(\)`”](#)
- [Example 21.9, “Connector/J: Retrieving `AUTO\_INCREMENT` column values using `SELECT LAST\_INSERT\_ID\(\)`”](#)
- [Example 21.10, “Connector/J: Retrieving `AUTO\_INCREMENT` column values in Updatable ResultSets”](#)
- [Example 21.11, “Connector/J: Using a connection pool with a J2EE application server”](#)
- [Example 21.12, “Connector/J: Example of transaction with retry logic”](#)

### 21.3.4. Connector/J (JDBC) Reference

This section of the manual contains reference material for MySQL Connector/J, some of which is automatically generated during the Connector/J build process.

#### 21.3.4.1. Driver/Datasource Class Names, URL Syntax and Configuration Properties for Connector/J

The name of the class that implements `java.sql.Driver` in MySQL Connector/J is `com.mysql.jdbc.Driver`. The `org.gjt.mm.mysql.Driver` class name is also usable to remain backward-compatible with MM.MySQL. You should use this class name when registering the driver, or when otherwise configuring software to use MySQL Connector/J.

The JDBC URL format for MySQL Connector/J is as follows, with items in square brackets ([, ]) being optional:

```
jdbc:mysql://[host][,failoverhost...][:port]/[database] «
[?propertyName1 [=propertyValue1][&propertyName2 [=propertyValue2]]...]
```

If the host name is not specified, it defaults to 127.0.0.1. If the port is not specified, it defaults to 3306, the default port number for

MySQL servers.

```
jdbc:mysql://[host:port],[host:port].../[database] »
[?propertyName1][=propertyValue1][&propertyName2][=propertyValue2]...
```

If the database is not specified, the connection will be made with no default database. In this case, you will need to either call the `setCatalog()` method on the Connection instance or fully specify table names using the database name (that is, `SELECT dbname.tablename.colname FROM dbname.tablename...`) in your SQL. Not specifying the database to use upon connection is generally only useful when building tools that work with multiple databases, such as GUI database managers.

MySQL Connector/J has fail-over support. This enables the driver to fail-over to any number of slave hosts and still perform read-only queries. Fail-over only happens when the connection is in an `autoCommit(true)` state, because fail-over can not happen reliably when a transaction is in progress. Most application servers and connection pools set `autoCommit` to `true` at the end of every transaction/connection use.

The fail-over functionality has the following behavior:

- If the URL property `autoReconnect` is false: Failover only happens at connection initialization, and fallback occurs when the driver determines that the first host has become available again.
- If the URL property `autoReconnect` is true: Failover happens when the driver determines that the connection has failed (before *every query*), and falls back to the first host when it determines that the host has become available again (after `queriesBeforeRetryMaster` queries have been issued).

In either case, whenever you are connected to a "failed-over" server, the connection will be set to read-only state, so queries that would modify data will have exceptions thrown (the query will **never** be processed by the MySQL server).

Configuration properties define how Connector/J will make a connection to a MySQL server. Unless otherwise noted, properties can be set for a DataSource object or for a Connection object.

Configuration Properties can be set in one of the following ways:

- Using the `set*`() methods on MySQL implementations of `java.sql.DataSource` (which is the preferred method when using implementations of `java.sql.DataSource`):
  - `com.mysql.jdbc.jdbc2.optional.MysqlDataSource`
  - `com.mysql.jdbc.jdbc2.optional.MysqlConnectionPoolDataSource`
- As a key/value pair in the `java.util.Properties` instance passed to `DriverManager.getConnection()` or `Driver.connect()`
- As a JDBC URL parameter in the URL given to `java.sql.DriverManager.getConnection()`, `java.sql.Driver.connect()` or the MySQL implementations of the `javax.sql.DataSource setURL()` method.

### Note

If the mechanism you use to configure a JDBC URL is XML-based, you will need to use the XML character literal `&` to separate configuration parameters, as the ampersand is a reserved character for XML.

The properties are listed in the following tables.

#### Connection/Authentication.

Property Name	Definition	Default Value	Since Version
user	The user to connect as		all versions
password	The password to use when connecting		all versions
socketFactory	The name of the class that the driver should use for creating socket connections to the server. This class must implement the interface 'com.mysql.jdbc.SocketFactory' and have public no-args constructor.	com.mysql.jdbc.StandardSocketFactory	3.0.3
connectTimeout	Timeout for socket connect (in milliseconds), with 0 being no	0	3.0.1

	timeout. Only works on JDK-1.4 or newer. Defaults to '0'.		
socketTimeout	Timeout on network socket operations (0, the default means no timeout).	0	3.0.1
connectionLifecycleInterceptors	A comma-delimited list of classes that implement "com.mysql.jdbc.ConnectionLifecycleInterceptor" that should be notified of connection lifecycle events (creation, destruction, commit, rollback, setCatalog and setAutoCommit) and potentially alter the execution of these commands. ConnectionLifecycleInterceptors are "stackable", more than one interceptor may be specified via the configuration property as a comma-delimited list, with the interceptors executed in order from left to right.		5.1.4
useConfigs	Load the comma-delimited list of configuration properties before parsing the URL or applying user-specified properties. These configurations are explained in the 'Configurations' of the documentation.		3.1.5
interactiveClient	Set the CLIENT_INTERACTIVE flag, which tells MySQL to timeout connections based on INTERACTIVE_TIMEOUT instead of WAIT_TIMEOUT	false	3.1.0
localSocketAddress	Hostname or IP address given to explicitly configure the interface that the driver will bind the client side of the TCP/IP connection to when connecting.		5.0.5
propertiesTransform	An implementation of com.mysql.jdbc.ConnectionPropertiesTransform that the driver will use to modify URL properties passed to the driver before attempting a connection		3.1.4
useCompression	Use zlib compression when communicating with the server (true/false)? Defaults to 'false'.	false	3.0.17

**Networking.**

Property Name	Definition	Default Value	Since Version
maxAllowedPacket	Maximum allowed packet size to send to server. If not set, the value of system variable 'max_allowed_packet' will be used to initialize this upon connecting. This value will not take effect if set larger than the value of 'max_allowed_packet'.	-1	5.1.8
tcpKeepAlive	If connecting using TCP/IP, should the driver set SO_KEEPALIVE?	true	5.0.7
tcpNoDelay	If connecting using TCP/IP, should the driver set SO_TCP_NODELAY (disabling the Nagle Algorithm)?	true	5.0.7
tcpRcvBuf	If connecting using TCP/IP, should the driver set SO_RCV_BUF to the given value? The default value of '0', means use the platform default value for this property)	0	5.0.7
tcpSndBuf	If connecting using TCP/IP, shuold the driver set SO SND BUF to the given value? The default value of '0', means use the platform default value for this property)	0	5.0.7
tcpTrafficClass	If connecting using TCP/IP, should the driver set traffic class or type-of-service fields ?See the documentation for java.net.Socket.setTrafficClass() for more information.	0	5.0.7

**High Availability and Clustering.**

Property Name	Definition	Default Value	Since Version
autoReconnect	Should the driver try to re-establish stale and/or dead connections? If enabled the driver will throw an exception for a queries issued on a stale or dead connection, which belong to the current transaction, but will attempt reconnect before the next query issued on the connection in a new transaction. The use of this feature is not recommended, because it has side effects related to	false	1.1

	session state and data consistency when applications don't handle SQLExceptions properly, and is only designed to be used when you are unable to configure your application to handle SQLExceptions resulting from dead and stale connections properly. Alternatively, investigate setting the MySQL server variable "wait_timeout" to some high value rather than the default of 8 hours.		
autoReconnectForPools	Use a reconnection strategy appropriate for connection pools (defaults to 'false')	false	3.1.3
failOverReadOnly	When failing over in autoReconnect mode, should the connection be set to 'read-only'?	true	3.0.12
maxReconnects	Maximum number of reconnects to attempt if autoReconnect is true, default is '3'.	3	1.1
reconnectAtTxEnd	If autoReconnect is set to true, should the driver attempt reconnections at the end of every transaction?	false	3.0.10
retriesAllDown	When using loadbalancing, the number of times the driver should cycle through available hosts, attempting to connect. Between cycles, the driver will pause for 250ms if no servers are available.	120	5.1.6
initialTimeout	If autoReconnect is enabled, the initial time to wait between re-connect attempts (in seconds, defaults to '2').	2	1.1
roundRobinLoadBalance	When autoReconnect is enabled, and failoverReadonly is false, should we pick hosts to connect to on a round-robin basis?	false	3.1.2
queriesBeforeRetryMaster	Number of queries to issue before falling back to master when failed over (when using multi-host failover). Whichever condition is met first, 'queriesBeforeRetryMaster' or 'secondsBeforeRetryMaster' will cause an attempt to be made to reconnect to the master. Defaults to 50.	50	3.0.2
secondsBeforeRetryMaster	How long should the driver wait, when failed over, before attempting	30	3.0.2
selfDestructOnPingMaxOperations	=If set to a non-zero value, the driver will report close the connection and report failure when Connection.ping() or Connection.isValid(int) is called if the connection's count of commands sent to the server exceeds this value.	0	5.1.6
selfDestructOnPingSecondsLifetime	If set to a non-zero value, the driver will report close the connection and report failure when Connection.ping() or Connection.isValid(int) is called if the connection's lifetime exceeds this value.	0	5.1.6
resourceId	A globally unique name that identifies the resource that this datasource or connection is connected to, used for XAResource.isSameRM() when the driver can't determine this value based on hostnames used in the URL		5.0.1

## Security.

Property Name	Definition	Default Value	Since Version
allowMultiQueries	Allow the use of ';' to delimit multiple queries during one statement (true/false), defaults to 'false'	false	3.1.1
useSSL	Use SSL when communicating with the server (true/false), defaults to 'false'	false	3.0.2
requireSSL	Require SSL connection if useSSL=true? (defaults to 'false').	false	3.1.0
verifyServerCertificate	If "useSSL" is set to "true", should the driver verify the server's certificate? When using this feature, the keystore parameters should be specified by the "clientCertificateKeyStore*" properties, rather than system properties.	true	5.1.6
clientCertificateKeyStoreUrl	URL to the client certificate KeyStore (if not specified, use defaults)		5.1.0
clientCertificateKeyStoreType	KeyStore type for client certificates (NULL or empty means use default, standard keystore types supported by the JVM are		5.1.0

	"JKS" and "PKCS12", your environment may have more available depending on what security products are installed and available to the JVM.		
clientCertificateKeyStorePassword	Password for the client certificates KeyStore		5.1.0
trustCertificateKeyStoreUrl	URL to the trusted root certificate KeyStore (if not specified, use defaults)		5.1.0
trustCertificateKeyStoreType	KeyStore type for trusted root certificates (NULL or empty means use default, standard keystore types supported by the JVM are "JKS" and "PKCS12", your environment may have more available depending on what security products are installed and available to the JVM.		5.1.0
trustCertificateKeyStorePassword	Password for the trusted root certificates KeyStore		5.1.0
allowLoadLocalInfile	Should the driver allow use of 'LOAD DATA LOCAL INFILE...' (defaults to 'true').	true	3.0.3
allowUrlInLocalInfile	Should the driver allow URLs in 'LOAD DATA LOCAL INFILE' statements?	false	3.1.4
paranoid	Take measures to prevent exposure sensitive information in error messages and clear data structures holding sensitive data when possible? (defaults to 'false')	false	3.0.1
passwordCharacterEncoding	What character encoding is used for passwords? Leaving this set to the default value (null), uses the platform character set, which works for ISO8859_1 (i.e. "latin1") passwords. For passwords in other character encodings, the encoding will have to be specified with this property, as it's not possible for the driver to auto-detect this.		5.1.7

**Performance Extensions.**

Property Name	Definition	Default Value	Since Version
callableStmtCacheSize	If 'cacheCallableStmts' is enabled, how many callable statements should be cached?	100	3.1.2
metadataCacheSize	The number of queries to cache ResultSetMetadata for if cacheResultSetMetaData is set to 'true' (default 50)	50	3.1.1
useLocalSessionState	Should the driver refer to the internal values of autocommit and transaction isolation that are set by Connection.setAutoCommit() and Connection.setTransactionIsolation() and transaction state as maintained by the protocol, rather than querying the database or blindly sending commands to the database for commit() or rollback() method calls?	false	3.1.7
useLocalTransactionState	Should the driver use the in-transaction state provided by the MySQL protocol to determine if a commit() or rollback() should actually be sent to the database?	false	5.1.7
prepStmtCacheSize	If prepared statement caching is enabled, how many prepared statements should be cached?	25	3.0.10
prepStmtCacheSqlLimit	If prepared statement caching is enabled, what's the largest SQL the driver will cache the parsing for?	256	3.0.10
alwaysSendSetIsolation	Should the driver always communicate with the database when Connection.setTransactionIsolation() is called? If set to false, the driver will only communicate with the database when the requested transaction isolation is different than the whichever is newer, the last value that was set via Connection.setTransactionIsolation(), or the value that was read from the server when the connection was established.	true	3.1.7
maintainTimeStats	Should the driver maintain various internal timers to enable idle time calculations as well as more verbose error messages when the connection to the server fails? Setting this property to false removes at least two calls to System.currentTimeMillis() per query.	true	3.1.9
useCursorFetch	If connected to MySQL > 5.0.2, and setFetchSize() > 0 on a	false	5.0.0

	statement, should that statement use cursor-based fetching to retrieve rows?		
blobSendChunkSize	Chunk to use when sending BLOB/CLOBs via ServerPreparedStatements	1048576	3.1.9
cacheCallableStmts	Should the driver cache the parsing stage of CallableStatements	false	3.1.2
cachePrepStmts	Should the driver cache the parsing stage of PreparedStatements of client-side prepared statements, the "check" for suitability of server-side prepared and server-side prepared statements themselves?	false	3.0.10
cacheResultSetMetadata	Should the driver cache ResultSetMetaData for Statements and PreparedStatements? (Req. JDK-1.4+, true/false, default 'false')	false	3.1.1
cacheServerConfiguration	Should the driver cache the results of 'SHOW VARIABLES' and 'SHOW COLLATION' on a per-URL basis?	false	3.1.5
defaultFetchSize	The driver will call setFetchSize(n) with this value on all newly-created Statements	0	3.1.9
dontTrackOpenResources	The JDBC specification requires the driver to automatically track and close resources, however if your application doesn't do a good job of explicitly calling close() on statements or result sets, this can cause memory leakage. Setting this property to true relaxes this constraint, and can be more memory efficient for some applications.	false	3.1.7
dynamicCalendars	Should the driver retrieve the default calendar when required, or cache it per connection/session?	false	3.1.5
elideSetAutoCommits	If using MySQL-4.1 or newer, should the driver only issue 'set autocommit=n' queries when the server's state doesn't match the requested state by Connection.setAutoCommit(boolean)?	false	3.1.3
enableQueryTimeouts	When enabled, query timeouts set via Statement.setQueryTimeout() use a shared java.util.Timer instance for scheduling. Even if the timeout doesn't expire before the query is processed, there will be memory used by the TimerTask for the given timeout which won't be reclaimed until the time the timeout would have expired if it hadn't been cancelled by the driver. High-load environments might want to consider disabling this functionality.	true	5.0.6
holdResultsOpenOverStatementClose	Should the driver leave the result sets open on Statement.close() (enabling violates JDBC specification)	false	3.1.7
largeRowSizeThreshold	What size result set row should the JDBC driver consider "large", and thus use a more memory-efficient way of representing the row internally?	2048	5.1.1
loadBalanceStrategy	If using a load-balanced connection to connect to SQL nodes in a MySQL Cluster/NDB configuration (by using the URL prefix "jdbc:mysql:loadbalance://"), which load balancing algorithm should the driver use: (1) "random" - the driver will pick a random host for each request. This tends to work better than round-robin, as the randomness will somewhat account for spreading loads where requests vary in response time, while round-robin can sometimes lead to overloaded nodes if there are variations in response times across the workload. (2) "bestResponseTime" - the driver will route the request to the host that had the best response time for the previous transaction.	random	5.0.6
locatorFetchBufferSize	If 'emulateLocators' is configured to 'true', what size buffer should be used when fetching BLOB data for getBinaryInputStream?	1048576	3.2.1
rewriteBatchedStatements	Should the driver use multiqueries (irregardless of the setting of "allowMultiQueries") as well as rewriting of prepared statements for INSERT into multi-value inserts when executeBatch() is called? Notice that this has the potential for SQL injection if using plain java.sql.Statements and your code doesn't sanitize input correctly. Notice that for prepared statements, server-side prepared statements can not currently take advantage of this rewrite option, and that if you don't specify stream lengths when using PreparedStatement.set*Stream(), the driver won't be able to determine the optimum number of parameters per batch and	false	3.1.13

	you might receive an error from the driver that the resultant packet is too large. Statement.getGeneratedKeys() for these re-written statements only works when the entire batch includes INSERT statements.		
useDirectRowUnpack	Use newer result set row unpacking code that skips a copy from network buffers to a MySQL packet instance and instead reads directly into the result set row data buffers.	true	5.1.1
useDynamicCharsetInfo	Should the driver use a per-connection cache of character set information queried from the server when necessary, or use a built-in static mapping that is more efficient, but isn't aware of custom character sets or character sets implemented after the release of the JDBC driver?	true	5.0.6
useFastDateParsing	Use internal String->Date/Time/Timestamp conversion routines to avoid excessive object creation?	true	5.0.5
useFastIntParsing	Use internal String->Integer conversion routines to avoid excessive object creation?	true	3.1.4
useJvmCharsetConverters	Always use the character encoding routines built into the JVM, rather than using lookup tables for single-byte character sets?	false	5.0.1
useReadAheadInput	Use newer, optimized non-blocking, buffered input stream when reading from the server?	true	3.1.5

**Debugging/Profiling.**

Property Name	Definition	Default Value	Since Version
logger	The name of a class that implements "com.mysql.jdbc.log.Log" that will be used to log messages to. (default is "com.mysql.jdbc.log.StandardLogger", which logs to STDERR)	com.mysql.jdbc.log.StandardLogger	3.1.1
gatherPerfMetrics	Should the driver gather performance metrics, and report them via the configured logger every 'reportMetricsIntervalMillis' milliseconds?	false	3.1.2
profileSQL	Trace queries and their execution/fetch times to the configured logger (true/false) defaults to 'false'	false	3.1.0
profileSql	Deprecated, use 'profileSQL' instead. Trace queries and their execution/fetch times on STDERR (true/false) defaults to 'false'		2.0.14
reportMetricsIntervalMillis	If 'gatherPerfMetrics' is enabled, how often should they be logged (in ms)?	30000	3.1.2
maxQuerySizeToLog	Controls the maximum length/size of a query that will get logged when profiling or tracing	2048	3.1.3
packetDebugEnabled	The maximum number of packets to retain when 'enablePacketDebug' is true	20	3.1.3
slowQueryThresholdMillis	If 'logSlowQueries' is enabled, how long should a query (in ms) before it is logged as 'slow'?	2000	3.1.2
slowQueryThresholdNanos	If 'useNanosForElapsedTime' is set to true, and this property is set to a non-zero value, the driver will use this threshold (in nanosecond units) to determine if a query was slow.	0	5.0.7
useUsageAdvisor	Should the driver issue 'usage' warnings advising proper and efficient usage of JDBC and MySQL Connector/J to the log (true/false, defaults to 'false')?	false	3.1.1
autoGenerateTestcaseScript	Should the driver dump the SQL it is executing, including server-side prepared statements to STDERR?	false	3.1.9
autoSlowLog	Instead of using slowQueryThreshold* to determine if a query is slow enough to be logged, maintain statistics that allow the driver to determine queries that are outside the 99th percentile?	true	5.1.4
clientInfoProvider	The name of a class that implements the com.mysql.jdbc.JDBC4ClientInfoProvider interface in order to support JDBC-4.0's Connection.getClientInfo() methods	com.mysql.jdbc.JDBC4ClientInfoProvider	5.1.0

		entInfoProvider	
dumpMetadataOnColumnNotFound	Should the driver dump the field-level metadata of a result set into the exception message when ResultSet.findColumn() fails?	false	3.1.13
dumpQueriesOnException	Should the driver dump the contents of the query sent to the server in the message for SQLExceptions?	false	3.1.3
enablePacketDebug	When enabled, a ring-buffer of 'packetDebugBufferSize' packets will be kept, and dumped when exceptions are thrown in key areas in the driver's code	false	3.1.3
explainSlowQueries	If 'logSlowQueries' is enabled, should the driver automatically issue an 'EXPLAIN' on the server and send the results to the configured log at a WARN level?	false	3.1.2
includeInnodbStatusInDeadlockExceptions	Include the output of "SHOW ENGINE INNODB STATUS" in exception messages when deadlock exceptions are detected?	false	5.0.7
logSlowQueries	Should queries that take longer than 'slowQueryThresholdMillis' be logged?	false	3.1.2
logXaCommands	Should the driver log XA commands sent by MysqlXaConnection to the server, at the DEBUG level of logging?	false	5.0.5
profilerEventHandler	Name of a class that implements the interface com.mysql.jdbc.profiler.ProfilerEventHandler that will be used to handle profiling/tracing events.	com.mysql.jdbc.profiler.Logging-ProfilerEventHandler	5.1.6
resultSetSizeThreshold	If the usage advisor is enabled, how many rows should a result set contain before the driver warns that it is suspiciously large?	100	5.0.5
traceProtocol	Should trace-level network protocol be logged?	false	3.1.2
useNanosForElapsedTime	For profiling/debugging functionality that measures elapsed time, should the driver try to use nanoseconds resolution if available (JDK >= 1.5)?	false	5.0.7

**Miscellaneous.**

Property Name	Definition	Default Value	Since Version
useUnicode	Forces the driver to use Unicode character encodings. Should only be set to false either when the driver can't determine the character set mapping (in which case, specify the Java character encoding in the characterEncoding property), or you are trying to force the driver to use a character set that MySQL doesn't natively support. Should be 'true' for all versions of MySQL 4.1 or higher unless you are trying to emulate the character set handling support provided in MySQL 4.0. Value is true/false, defaults to 'true'	true	1.1g
characterEncoding	If 'useUnicode' is set to true, what Java character encoding should the driver use when dealing with strings? (defaults is to 'autodetect'). If the encoding cannot be determined, then an exception will be raised.		1.1g
characterSetResults	Character set to tell the server to return results as.		3.0.13
connectionCollation	If set, tells the server to use this collation via 'set collation_connection'		3.0.13
useBlobToStoreUTF8OutsideBMP	Tells the driver to treat [MEDIUM/LONG]BLOB columns as [LONG]VARCHAR columns holding text encoded in UTF-8 that has characters outside the BMP (4-byte encodings), which MySQL server can't handle natively.	false	5.1.3
utf8OutsideBmpExcludedColumnNamePattern	When "useBlobToStoreUTF8OutsideBMP" is set to "true", column names matching the given regex will still be treated as BLOBS unless they match the regex specified for "utf8OutsideBmpIncludedColumnNamePattern". The regex		5.1.3

	must follow the patterns used for the java.util.regex package.		
utf8OutsideBmpIncludedColumnNamePattern	Used to specify exclusion rules to "utf8OutsideBmpExcludedColumnNamePattern". The regex must follow the patterns used for the java.util.regex package.		5.1.3
loadBalanceEnableJMX	Enables JMX-based management of load-balanced connection groups, including live addition/removal of hosts from load-balancing pool.	false	5.1.13
sessionVariables	A comma-separated list of name/value pairs to be sent as SET SESSION ... to the server when the driver connects.		3.1.8
useColumnNamesInFindColumn	Prior to JDBC-4.0, the JDBC specification had a bug related to what could be given as a "column name" to ResultSet methods like findColumn(), or getters that took a String property. JDBC-4.0 clarified "column name" to mean the label, as given in an "AS" clause and returned by ResultSetMetaData.getColumnLabel(), and if no AS clause, the column name. Setting this property to "true" will give behavior that is congruent to JDBC-3.0 and earlier versions of the JDBC specification, but which because of the specification bug could give unexpected results. This property is preferred over "useOldAliasesAsMetadataBehavior" unless you need the specific behavior that it provides with respect to ResultSetMetadata.	false	5.1.7
allowNanAndInf	Should the driver allow NaN or +/- INF values in PreparedStatement.setDouble()?	false	3.1.5
autoClosePstmtStreams	Should the driver automatically call .close() on streams/readers passed as arguments via set*() methods?	false	3.1.12
autoDeserialize	Should the driver automatically detect and de-serialize objects stored in BLOB fields?	false	3.1.5
blobsAreStrings	Should the driver always treat BLOBS as Strings - specifically to work around dubious metadata returned by the server for GROUP BY clauses?	false	5.0.8
capitalizeTypeNames	Capitalize type names in DatabaseMetaData? (usually only useful when using WebObjects, true/false, defaults to 'false')	true	2.0.7
clobCharacterEncoding	The character encoding to use for sending and retrieving TEXT, MEDIUMTEXT and LONGTEXT values instead of the configured connection characterEncoding		5.0.0
clobberStreamingResults	This will cause a 'streaming' ResultSet to be automatically closed, and any outstanding data still streaming from the server to be discarded if another query is executed before all the data has been read from the server.	false	3.0.9
compensateOnDuplicateKeyUpdateCounts	Should the driver compensate for the update counts of "ON DUPLICATE KEY" INSERT statements (2 = 1, 0 = 1) when using prepared statements?	false	5.1.7
continueBatchOnError	Should the driver continue processing batch commands if one statement fails. The JDBC spec allows either way (defaults to 'true').	true	3.0.3
createDatabaseIfNotExist	Creates the database given in the URL if it doesn't yet exist. Assumes the configured user has permissions to create databases.	false	3.1.9
emptyStringsConvertToZero	Should the driver allow conversions from empty string fields to numeric values of '0'?	true	3.1.8
emulateLocators	Should the driver emulate java.sql.Blobs with locators? With this feature enabled, the driver will delay loading the actual Blob data until the one of the retrieval methods (getInputStream(), getBytes(), and so forth) on the blob data stream has been accessed. For this to work, you must use a column alias with the value of the column to the actual name of the Blob. The feature also has the following restrictions: The SELECT that created the result set must reference only one table, the table must have a primary key; the SELECT must alias the original blob column name, specified as a string, to an alternate name; the SELECT must cover all columns that make up the primary key.	false	3.1.0
emulateUnsupportedPstmts	Should the driver detect prepared statements that are not supported?	true	3.1.7

	ted by the server, and replace them with client-side emulated versions?		
exceptionInterceptors	Comma-delimited list of classes that implement com.mysql.jdbc.ExceptionInterceptor. These classes will be instantiated one per Connection instance, and all SQLExceptions thrown by the driver will be allowed to be intercepted by these interceptors, in a chained fashion, with the first class listed as the head of the chain.		5.1.8
functionsNeverReturnBlobs	Should the driver always treat data from functions returning BLOBS as Strings - specifically to work around dubious metadata returned by the server for GROUP BY clauses?	false	5.0.8
generateSimpleParameterMetadata	Should the driver generate simplified parameter metadata for PreparedStatements when no metadata is available either because the server couldn't support preparing the statement, or server-side prepared statements are disabled?	false	5.0.5
ignoreNonTxTables	Ignore non-transactional table warning for rollback? (defaults to 'false').	false	3.0.9
jdbcCompliantTruncation	This sets whether Connector/J should throw java.sql.DataTruncation exceptions when data is truncated. This is required by the JDBC specification when connected to a server that supports warnings (MySQL 4.1.0 and newer). This property has no effect if the server sql-mode includes STRICT_TRANS_TABLES. Note that if STRICT_TRANS_TABLES is not set, it will be set as a result of using this connection string option.	true	3.1.2
loadBalanceBlacklistTimeout	Time in milliseconds between checks of servers which are unavailable.	0	5.1.0
loadBalanceConnectionGroup	Logical group of load-balanced connections within a classloader, used to manage different groups independently. If not specified, live management of load-balanced connections is disabled.		5.1.13
loadBalanceExceptionChecker	Fully-qualified class name of custom exception checker. The class must implement com.mysql.jdbc.LoadBalanceExceptionChecker interface, and is used to inspect SQLExceptions and determine whether they should trigger fail-over to another host in a load-balanced deployment.	com.mysql.jdbc.StandardLoadBalanceExceptionChecker	5.1.13
loadBalancePingTimeout	Time in milliseconds to wait for ping response from each of load-balanced physical connections when using load-balanced Connection.	0	5.1.13
loadBalanceSQLExceptionSub-classFailover	Comma-delimited list of classes/interfaces used by default load-balanced exception checker to determine whether a given SQLException should trigger failover. The comparison is done using Class.isInstance(SQLException) using the thrown SQLException.		5.1.13
