`IBMDB2I` tables are created by specifying the `ENGINE=IBMDB2I` option on a `CREATE TABLE` or `ALTER TABLE` statement. These tables are stored as DB2 for i objects in the QSYS.LIB file system. Therefore, in contrast to the behavior of other storage engines, `IBMDB2I` table and index data does not reside beneath the datadir directory with other MySQL table data.

When the first `IBMDB2I` table is created in a MySQL schema, the corresponding DB2 schema will be created (if it does not

already exist).

Note that if the user profile running MySQL has sufficient authority dropping a MySQL schema will drop a DB2 schema of the same name even if the schema never contained any `IBMDB2I` tables and contains objects not related to MySQL. Therefore, it is recommended that extreme caution be used when dropping MySQL schemas when the `IBMDB2I` plugin is installed.

### 13.7.3.1. Identifier names

DB2 for i file objects have both a short (10-character) system name and an SQL name. The DB2 for i SQL name is always the same as the MySQL name. However, because MySQL's sensitivity to the letter case of schema and table names depends on the file system containing the datadir, mapping the MySQL name to the system name of the corresponding DB2 for i object must account for several factors, described below.

When MySQL is operating in a case-sensitive mode (that is, datadir is in a case-sensitive file-system like (/QOpenSys), the case of the system name of the `IBMDB2I` object reflects the case of the name specified to MySQL. If the object has all uppercase characters and is equal to or less than 10 characters in length, the system name will be undelimited and in uppercase. If the object name has mixed or lower-case letters, the IBM i system name will contain up to 8 characters of the name in the specified case and will be delimited by surrounding quotation marks. If the MySQL name has more characters than can fit in the delimited system name, the system name will be generated as a mangled name delimited by surrounding quotation marks.

Examples of this naming behavior are given below:

**Table 13.7. Naming Behavior in DB2 Storage Engine**

| MySQL name     | DB2 for i SQL name | IBM i System name |
|----------------|--------------------|-------------------|
| mytable        | mytable            | "mytable"         |
| mylongertable  | mylongertable      | "mylo0001"        |
| UPPERTABLE     | UPPERTABLE         | UPPERTABLE        |
| UPPERLONGTABLE | UPPERLONGTABLE     | UPPER00001        |
| MixedTab       | MixedTab           | "MixedTab"        |
| MixedlongerTab | MixedlongerTab     | "Mixe0001"        |

If MySQL is operating in a case-insensitive mode, the IBM i system name will contain up to 8 characters of the name in lower case and will be delimited by surrounding quotation marks. If the MySQL name has more characters than can fit in the delimited system name, the system name will be generated as a mangled name delimited by surrounding quotation marks.

Note that IBM i system names are not changed when a RENAME TABLE command is executed. Only the DB2 for i SQL name changes.

### 13.7.3.2. Index names

Unlike MySQL, DB2 for i requires that index names be unique to an entire schema. To support MySQL indexes, `IBMDB2I` creates the DB2 for i indexes with modified file names. The generated name is a concatenation of the index name, three underscores (\_), and the table name. For example, `CREATE INDEX idx1 ON tab1 (a, b)` would create a DB2 index named `idx____tab1`. If the `ibmdb2i_create_index_option` value is set to 1, an additional index may be created which is named with an additional `H_` marker between the index and table names (for example, `idx____H_tab1`). These generated names are then mangled to create the an IBM i system name, as described above.

If a table is renamed, the indexes will also be renamed.

This index name generation scheme also has implications for the length of index and table names; to permit the generated name and allow for delimiting quotation marks, the combined length of the index and table names must be less than or equal to 121 characters.

### 13.7.3.2.1. Data type mapping

When creating a table, `IBMDB2I` may map the MySQL types specified on a `CREATE TABLE` statement into a corresponding or compatible DB2 for i type. Examples include the `BIT` type, which is stored as a `BINARY` field, or the `MEDIUMINT` type, which is stored as an `INTEGER` field. For most data types, this mapping is transparent. Data types which have restrictions unique to `IBMDB2I` are documented in [Section 13.7.7, “Notes and Limitations”](#).

## 13.7.4. Database/metadata management

When an `IBMDB2I` table is created, a File Level ID (FID) file is created in the database directory. This file has an extension .FID and contains the last known FID of the associated DB2 for i physical file. The `IBMDB2I` engine uses this FID value to determine

whether incompatible changes have been made to the table by an external (non-MySQL) interface. If the physical file is altered, DB2 for i automatically generates a new FID. The next time `IBMDB2I` attempts to access the file, it will detect that the new FID does not match the known FID, and it will prevent MySQL from using the table.

In some cases, the changes to the physical file that cause the FID to be updated may not adversely affect access through MySQL and `IBMDB2I`. In this case, a user may wish to override the FID check that `IBMDB2I` performs. A user with appropriate permissions may do so simply by deleting the `.FID` file associated with the table and performing a `FLUSH TABLE` statement against the table. `IBMDB2I` will then regenerate the file with the new FID the next time the table is accessed from MySQL.

If triggers or constraints are applied to the table from a native DB2 interface, they will be respected when accessing the table from MySQL, but MySQL will have no knowledge of the triggers or constraints. Likewise, views and indexes can be created over the tables from a DB2 interface, but the indexes will not be accessible from MySQL.

### 13.7.5. Transaction behavior

The `IBMDB2I` storage engine supports row-level transaction management. All MySQL isolation levels are supported by the engine, and where highest performance is required, transaction support can be disabled globally or per session by modifying the `ibm-db2i_transaction_unsafe` configuration option.

`IBMDB2I` uses the underlying DB2 for i transaction support to implement MySQL isolation levels. DB2 for i uses table and row locks to implement the various isolation levels, as described below:

**Table 13.8. `IBMDB2I` Isolation Levels**

| Isolation level    | Read-only (SELECT)                                                                                                     |                                                               | Read-write (UPDATE, DELETE)                                                                                            |                                                               |
|--------------------|------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------|
|                    | Lock enforcement                                                                                                       | Visibility of uncommitted work on behalf of other connections | Lock enforcement                                                                                                       | Visibility of uncommitted work on behalf of other connections |
| SERIALIZABLE       | Table is locked until end of transaction. Other connections may read rows while locked.                                | N/A                                                           | Table is locked until end of transaction. Other connections may read rows while locked.                                | N/A                                                           |
| REPEATABLE READ    | Rows that have been read are locked until end of transaction. Other connections may read and insert rows while locked. | Rows cannot be read until work is committed.                  | Rows that have been read are locked until end of transaction. Other connections may read and insert rows while locked. | Rows cannot be read until work is committed.                  |
| READ COMMITTED     | Row is locked while cursor is positioned on that row. Other connections may read and insert rows while locked.         | Rows cannot be read until work is committed.                  | Row is locked while cursor is positioned on that row. Other connections may read and insert rows while locked.         | Rows cannot be read until work is committed.                  |
| READ UNCOMMITTED   | Row is locked while cursor is positioned on that row. Other connections may read and insert rows while locked.         | Rows can be read before work is committed.                    | Row is locked while cursor is positioned on that row. Other connections may read and insert rows while locked.         | Rows can be read before work is committed.                    |
| transaction_unsafe | No locks                                                                                                               | Full access                                                   | Table is locked until end of transaction. Other connections may read rows while locked.                                | Unrestricted access                                           |

Attempts to access locked rows time out according to the timeout value associated with the underlying DB2 physical file. This timeout wait is 30 seconds by default. Refer to <http://publib.boulder.ibm.com/infocenter/iseries/v5r4/index.jsp?topic=/db2/rbafoconrec.htm> for more information.

Because `IBMDB2I` does not multi-version rows under commitment control, row lock contention may occur under certain scenarios. In particular, when multiple connections attempt to read overlapping ranges of rows while performing a statement that does updates, the connections may contend for the same row locks. This may lead to delays until the row lock timeout expires. Creating appropriate indexes and increasing query selectivity to reduce range overlap may help to alleviate this contention.

### 13.7.6. Principles and Terminology

`AUTO_INCREMENT`

The MySQL auto\_increment column attribute can be used to generate a unique identity for new rows. The [IBMDB2I](#) storage engine maps the MySQL auto\_increment attribute to the DB2 for i identity attribute.

For most MySQL storage engines, the auto\_increment value is determined by adding one to the maximum value stored in the table for the column. For the [IBMDB2I](#) storage engine, DB2 for i generates the identity value by adding one to the last generated value. Following are some example MySQL statements to illustrate the point.

```
create table t1 (a int auto increment, primary key(a)) engine = ibmdb2i;
insert into t1 values(3);
insert into t1 values(null),(null);
```

For the first INSERT statement, an explicit value of 3 is specified for the auto\_increment column, so the value 3 is stored in the inserted row. For the second INSERT statement null is specified, so generated values 1 and 2 will be stored in the rows.

Duplicate key failures can occur in DB2 for i if a MySQL application mixes explicit auto\_increment values with generated values within a table. For the example above, if one more record is inserted into the table for which an auto\_increment value is generated, a duplicate key error will occur because the value 3 (that is, the last generated value plus one) already exists in the table. To effect the MySQL behavior for auto\_increment columns, the [IBMDB2I](#) storage engine will detect a duplicate key error, alter the restart value for the DB2 identity column to the maximum value plus one, and retry the failed insert, but only if the following conditions are true:

- The duplicate key error occurred on an index for which the auto\_increment column is a key field
- An exclusive (LENR) lock can be acquired on the table
- The error occurred on the first or only row of the [INSERT](#) statement.

The [IBMDB2I](#) storage engine does not support the following usage of auto\_increment columns:

1. Any MySQL global or session variable that affects the start, increment, or offset for generated auto\_increment values.
2. Any MySQL feature that returns the *next value to be used* for an auto\_increment column.
3. An auto\_increment column on a MySQL partitioned table.

### 13.7.7. Notes and Limitations

- When using multiples instances of MySQL on a single i5 host you should be aware that the two independent instances will access the same database within the DB2 environment. This can lead to namespace collisions and issues. To get round this limitation, you should configure different IBM i independent auxilliary storage pools (ISAPs) for each MySQL server, and then use the [ibmdb2i\\_rdb\\_name](#) option to MySQL to configure which IASP should be used for each MySQL instance.
- Indexes over [VARBINARY](#) columns may not provide accurate estimates the optimizer. Queries over such indexes may produce error 2027 in the error log but will succeed. This affects only the performance of these queries, not the correctness of the results.
- Setting [ibmdb2i\\_system\\_trace\\_level = 16 \(STRTRC\)](#) may cause unpredictable failures including error 2088 on some operations. This is unlikely to affect any users, as this value is recommended only for serviceability purposes.
- [IBMDB2I](#) honors the [CASCADE/RESTRICT](#) option on the [DROP TABLE](#) statement.
- The use of [FLUSH TABLES WITH READ LOCK](#) is discouraged when using [IBMDB2I](#) tables. Due to differences in internal locking implementations, [FLUSH TABLES WITH READ LOCK](#) may produce deadlocks on [IBMDB2I](#) tables.
- Row-based replication is supported by [IBMDB2I](#). Statement-based replication is not supported.
- Schema name lengths are limited to 10 characters in IBM i 5.4 and 30 characters in IBM i 6.1. If the schema name is mixed- or lower-case, two characters must be subtracted from the limit to account for surrounding quotation marks.
- The RENAME TABLE command cannot be used to move [IBMDB2I](#) tables from one database to another.
- The maximum length of the internal row format for [IBMDB2I](#) is 32767 bytes. Because the internal row format may differ from the MySQL row format due to data mapping differences (see Creating schemas and tables section), anticipating this limit may be difficult.
- The combined length of the index and table names must be less than or equal to 121 characters.

- Indexes over TEXT or BLOB columns with a maximum length greater than 255 characters are not supported. The ibm-db2i\_map\_blob\_to\_varchar option can be used to work around this limitation for TEXT fields up to 64K characters.
- Specific restrictions apply to certain data types as described in the following chart:

**Table 13.9. Data Type Restrictions in IBMDB2I**

| MySQL data type                | Restriction                                                                                                                                                                                                       |
|--------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LONGBLOB or LONGTEXT           | The maximum length of a DB2 BLOB data type is 2GB.                                                                                                                                                                |
| DATE                           | IBMDB2I does not support the special date value of '0000-00-00'. The restrictions on DATE and DATETIME columns can be removed by setting the value of ibm-db2i_compat_opt_allow_zero_date_vals to 1.              |
| DATETIME                       | IBMDB2I does not support the special datetime value of '0000-00-00 00:00:00'. The restrictions on DATE and DATETIME columns can be removed by setting the value of ibm-db2i_compat_opt_allow_zero_date_vals to 1. |
| DECIMAL(p, s) or NUMERIC(p, s) | If p is greater than 63 and s is greater than (p-63), the field definition is truncated to DECIMAL(63, s-(p-63)). If p is greater than 63 and s is less than or equal to (p-63), the definition is not supported. |
| TIME                           | By default, IBMDB2I only supports times in the range '00:00:00' to '23:59:59.' See the ibm-db2i_create_time_columns_as_tod option for more information.                                                           |

- These MySQL statements are not supported by the IBMDB2I Engine:
  - CACHE INDEX and LOAD INDEX INTO CACHE
  - HANDLER
  - CHECK TABLE
  - REPAIR TABLE
  - BACKUP-RESTORE TABLE
- The ucs2\_spanish2\_ci and utf8\_spanish2\_ci collations are not supported by IBMDB2I. There are no plans to support these collations.
- The ucs2\_swedish\_ci and utf8\_swedish\_ci collations were added in MySQL 5.1.35, supported by IBMDB2I. As with other language-specific unicode collations, the support will be only be available on IBM i 6.1 and later releases.

## 13.7.8. Character sets and collations

DB2 for i only supports a single collation per index or foreign key constraint. A foreign key constraint must have the same collation as a primary key constraint, if one exists..

Character sets and collations supported by IBMDB2I are described in the list below. IBM i 6.1 is required for the most comprehensive collation support. Note that Chinese, Japanese, and Korean character sets are converted to UTF-16 for storage in DB2 for i; utf8\_general\_ci is converted to UCS2 for storage in DB2 for i.

**Table 13.10. Collation Compatibility in IBMDB2I and MySQL**

| MySQL Collation     | Supported in IBM i 5.4 | Supported in IBM i 6.1 |
|---------------------|------------------------|------------------------|
| armscci8_general_ci |                        |                        |
| armscci8_bin        |                        |                        |
| ascii_general_ci    |                        | Yes                    |
| ascii_bin           |                        | Yes                    |
| big5_chinese_ci     | Yes                    | Yes                    |
| big5_bin            | Yes                    | Yes                    |
| cp1250_croatian_ci  |                        | Yes                    |
| cp1250_czech_cs     |                        | Yes                    |
| cp1250_general_ci   |                        | Yes                    |

| <b>MySQL Collation</b> | <b>Supported in IBM i 5.4</b> | <b>Supported in IBM i 6.1</b> |
|------------------------|-------------------------------|-------------------------------|
| cp1250_polish_ci       |                               | Yes                           |
| cp1250_bin             |                               | Yes                           |
| cp1251_bulgarian_ci    |                               | Yes                           |
| cp1251_general_ci      |                               | Yes                           |
| cp1251_general_cs      |                               | Yes                           |
| cp1251_ukrainian_ci    |                               |                               |
| cp1251_bin             |                               | Yes                           |
| cp1256_general_ci      |                               | Yes                           |
| cp1256_bin             |                               | Yes                           |
| cp1257_general_ci      |                               |                               |
| cp1257_lithuanian_ci   |                               |                               |
| cp1257_bin             |                               |                               |
| cp850_general_ci       | Yes                           | Yes                           |
| cp850_bin              | Yes                           | Yes                           |
| cp852_general_ci       |                               | Yes                           |
| cp852_bin              |                               | Yes                           |
| cp866_general_ci       |                               |                               |
| cp866_bin              |                               |                               |
| cp932_japanese_ci      | Yes                           | Yes                           |
| cp932_bin              | Yes                           | Yes                           |

### 13.7.9. Error codes and trouble-shooting information

Errors reported by the `IBMDB2I` engine may originate from two locations. Error values under 2500 originate in DB2 for i. Error values over 2500 originate in the storage engine itself. Occasionally, errors are reported by `IBMDB2I` but, due to the architecture of MySQL, cannot be directly exposed to MySQL client interfaces. In these cases, issuing a `SHOW ERRORS` statement or referring to the MySQL error log may be necessary to determine the cause of a failure. Errors which originate in DB2 for i are usually encountered in the DB2 for i SQL Server Mode job (QSQSRVR) which services the MySQL client connection; additional information about failures can often be found by looking in the job log of the associated QSQSRVR job.

Following is the list of codes and messages for errors that occur in DB2 for i that are reported by the `IBMDB2I` engine. %d and %s represent numbers and strings, respectively, that are replaced when the message is displayed.

**Table 13.11. Error Codes from `IBMDB2I`**

| Error Code Number | Error Message Text                                                |
|-------------------|-------------------------------------------------------------------|
| 0                 | Successful                                                        |
| 2016              | Thread ID is too long                                             |
| 2017              | Error creating a SPACE memory object                              |
| 2018              | Error creating a FILE memory object                               |
| 2019              | Error creating a SPACE synchronization token                      |
| 2020              | Error creating a FILE synchronization token                       |
| 2021              | See message %-.7s in joblog for job %-.6s%-.10s%-.10s.            |
| 2022              | Error unlocking a synchronization token when closing a connection |
| 2023              | Invalid action specified for an 'object lock' request             |
| 2024              | Invalid action specified for a savepoint request                  |
| 2025              | Partial keys are not supported with an ICU sort sequence          |
| 2026              | Error retrieving an ICU sort key                                  |
| 2027              | Error converting single-byte sort sequence to UCS-2               |
| 2028              | An unsupported collation was specified                            |
| 2029              | Validation failed for referenced table of foreign key constraint  |

| Error Code Number | Error Message Text                                                      |
|-------------------|-------------------------------------------------------------------------|
| 2030              | Error extracting table for constraint information                       |
| 2031              | Error extracting referenced table for constraint information            |
| 2032              | Invalid action specified for a 'commitment control' request             |
| 2033              | Invalid commitment control isolation level specified on 'open' request  |
| 2034              | Invalid file handle                                                     |
| 2036              | Invalid option specified for returning data on 'read' request           |
| 2037              | Invalid orientation specified for 'read' request                        |
| 2038              | Invalid option type specified for 'read' request                        |
| 2039              | Invalid isolation level for starting commitment control                 |
| 2040              | Error unlocking a synchronization token in module QMYALC                |
| 2041              | Length of space for returned format is not long enough                  |
| 2042              | SQL XA transactions are currently unsupported by this interface         |
| 2043              | The associated QSQSRVR job was killed or ended unexpectedly.            |
| 2044              | Error unlocking a synchronization token in module QMYSEI                |
| 2045              | Error unlocking a synchronization token in module QMYSPO                |
| 2046              | Error converting input CCSID from short form to long form               |
| 2048              | Error getting associated CCSID for CCSID conversion                     |
| 2049              | Error converting a string from one CCSID to another                     |
| 2050              | Error unlocking a synchronization token                                 |
| 2051              | Error destroying a synchronization token                                |
| 2052              | Error locking a synchronization token                                   |
| 2053              | Error recreating a synchronization token                                |
| 2054              | A space handle was not specified for a constraint request               |
| 2055              | An SQL cursor was specified for a delete request                        |
| 2057              | Error on delete request because current UFCB for connection is not open |
| 2058              | An SQL cursor was specified for an object initialization request        |
| 2059              | An SQL cursor was specified for an object override request              |
| 2060              | A space handle was not specified for an object override request         |
| 2061              | An SQL cursor was specified for an information request                  |
| 2062              | An SQL cursor was specified for an object lock request                  |
| 2063              | An SQL cursor was specified for an optimize request                     |
| 2064              | A data handle was not specified for a read request                      |
| 2065              | A row number handle was not specified for a read request                |
| 2066              | A key handle was not specified for a read request                       |
| 2067              | An SQL cursor was specified for an row estimation request               |
| 2068              | A space handle was not specified for a row estimation request           |
| 2069              | An SQL cursor was specified for a release record request                |
| 2070              | A statement handle was not specified for an 'execute immediate' request |
| 2071              | A statement handle was not specified for a 'prepare open' request       |
| 2072              | An SQL cursor was specified for an update request                       |
| 2073              | The UFCB was not open for read                                          |
| 2074              | Error on update request because current UFCB for connection is not open |
| 2075              | A data handle was not specified for an update request                   |
| 2076              | An SQL cursor was specified for a write request                         |
| 2077              | A data handle was not specified for a write request                     |
| 2078              | An unknown function was specified on a process request                  |
| 2079              | A share definition was not specified for an 'allocate share' request    |

| Error Code Number | Error Message Text                                                                                          |
|-------------------|-------------------------------------------------------------------------------------------------------------|
| 2080              | A share handle was not specified for an 'allocate share' request                                            |
| 2081              | A use count handle was not specified for an 'allocate share' request                                        |
| 2082              | A 'records per key' handle was not specified for an information request                                     |
| 2083              | Error resolving LOB address                                                                                 |
| 2084              | Length of a LOB space is too small                                                                          |
| 2085              | An unknown function was specified for a server request                                                      |
| 2086              | Object authorization failed. See message %-.7s in joblog for job %-.6s/%-.10s/%-.10s. for more information. |
| 2088              | Error locking mutex on server                                                                               |
| 2089              | Error unlocking mutex on server                                                                             |
| 2090              | Error checking for RDB name in RDB Directory                                                                |
| 2091              | Error creating mutex on server                                                                              |
| 2094              | Error unlocking mutex                                                                                       |
| 2095              | Error connecting to server job                                                                              |
| 2096              | Error connecting to server job                                                                              |
| 2098              | Function check occurred while registering parameter spaces. See job log.                                    |
| 2101              | End of block                                                                                                |
| 2102              | The file has changed and might not be compatible with the MySQL table definition                            |
| 2103              | Error giving pipe to server job                                                                             |
| 2104              | There are open object locks when attempting to deallocate                                                   |
| 2105              | There is no open lock                                                                                       |
| 2108              | The maximum value for the auto_increment data type was exceeded                                             |
| 2109              | Error occurred closing the pipe                                                                             |
| 2110              | Error occurred taking a descriptor for the pipe                                                             |
| 2111              | Error writing to pipe                                                                                       |
| 2112              | Server was interrupted                                                                                      |
| 2113              | No pipe descriptor exists for reuse                                                                         |
| 2114              | Error occurred during an SQL prepare statement                                                              |
| 2115              | Error occurred during an SQL open                                                                           |
| 2122              | An unspecified error was returned from the system.                                                          |
|                   |                                                                                                             |
|                   |                                                                                                             |
|                   |                                                                                                             |

Following is the list of error codes and messages that occur within the [IBMDB2I](#) storage engine.

**Table 13.12. Error Codes and Messages in [IBMDB2I](#)**

| Error Code Number | Error Message Text                                                                                                                                                                                                                                                                               |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2501              | Error opening codeset conversion from %.64s to %.64s (errno = %d). <b>Resolution:</b> Alter the table definition to specify a character set that is supported by the <a href="#">IBMDB2I</a> engine.                                                                                             |
| 2502              | Invalid %-.10s name '%-.128s'. <b>Resolution:</b> If a field name, ensure that it is less than the maximum length of 126 characters. If an index name, ensure that the length of the index name plus the length of the table name is less than 121 characters.                                   |
| 2503              | Unsupported move from '%-.128s' to '%-.128s' on RENAME TABLE statement. <b>Resolution:</b> Moving a table from one schema to another is not supported by the <a href="#">IBMDB2I</a> engine. Create a new table in the 'to' schema, copy the data to the new table, and then drop the old table. |
| 2504              | The %-.64s character set is not supported. <b>Resolution:</b> Try using another character set.                                                                                                                                                                                                   |
| 2505              | Auto_increment is not allowed for a partitioned table. <b>Resolution:</b> Remove the auto_increment attribute from the table or do not partition the table.                                                                                                                                      |

| Error Code Number | Error Message Text                                                                                                                                                                                                                                                                                                                |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2506              | Character set conversion error due to unknown encoding scheme %d. <b>Resolution:</b> Alter the table definition to ensure that character sets assigned to columns are supported by the <a href="#">IBMDB2I</a> engine.                                                                                                            |
| 2508              | Table '%.128s' was not found by the storage engine. <b>Resolution:</b> A table definition exists in MySQL, but the corresponding table in DB2 for i is not found. Delete the MySQL table or restore the DB2 table.                                                                                                                |
| 2509              | Could not resolve to %.128s in library %.10s type %.10s (errno = %d). <b>Resolution:</b> Restore the missing IBM i object to the system.                                                                                                                                                                                          |
| 2510              | Error on _PGMCALL for program %.10s in library %.10s (error = %d). <b>Resolution:</b> This is an internal error.                                                                                                                                                                                                                  |

| 2515              | Data out of range for column '%.192s'. <b>Resolution:</b> DB2 for i does not support a zero value for DATE and DATETIME data types. Specify a new value for the column.                                                                                                                                                           |
| 2516              | Schema name '%.128s' exceeds maximum length of %d characters. <b>Resolution:</b> Change the schema name so that its length does not exceed the maximum. For mixed case or lower case names, permit 2 characters for outer quotation marks.                                                                                        |
| 2517              | Multiple collations not supported in a single index. <b>Resolution:</b> DB2 for i only supports sort sequences at the table or index level, so all character-based columns in the primary key or index must be using the same collation. Alter the table definition so that all columns use the same collation.                   |
| 2518              | Sort sequence was not found. <b>Resolution:</b> Alter the table to use a collation that is supported by the <a href="#">IBMDB2I</a> engine.                                                                                                                                                                                       |
| 2519              | One or more characters in column %.128s were substituted during conversion. <b>Resolution:</b> This is a warning that during the conversion of data from MySQL to DB2 some characters were replaced with substitute characters.                                                                                                   |
| 2520              | A decimal column exceeded the maximum precision. Data may be truncated. <b>Resolution:</b> A decimal column specified on a CREATE TABLE or ALTER TABLE command has greater precision than DB2 permits. Data stored in this column may be truncated. Change the column specification to have a precision less than or equal to 63. |
| 2521              | Some data returned by DB2 for table %s could not be converted for MySQL. <b>Resolution:</b> This is a warning that some data could not be converted from DB2 to MySQL. Data was likely inserted into the table using DB2 interfaces that is valid data for DB2 but is invalid for MySQL.                                          |
| 2523              | Column %.128s contains characters that cannot be converted. <b>Resolution:</b> An error occurred converting data from the MySQL character set to the associated DB2 coded character set identifier (CCSID). Omit the incompatible characters or alter the table to specify a different character set for the column.              |
| 2524              | An invalid name was specified for ibmdb2i_rdb_name. <b>Resolution:</b> Specify a valid relational database (RDB) name.                                                                                                                                                                                                            |
| 2525              | A duplicate key was encountered for index '%.128s'. <b>Resolution:</b> : Specify a unique key value for the row. Generally, this error occurs if a unique constraint or index has been applied to the table from a non-MySQL interface.                                                                                           |
| 2528              | Some attribute(s) defined for column '%.128s' may not be honored by accesses from DB2.                                                                                                                                                                                                                                            |

## 13.8. The [MERGE](#) Storage Engine

The [MERGE](#) storage engine, also known as the [MRG\\_MyISAM](#) engine, is a collection of identical [MyISAM](#) tables that can be used as one. “Identical” means that all tables have identical column and index information. You cannot merge [MyISAM](#) tables in which the columns are listed in a different order, do not have exactly the same columns, or have the indexes in different order. However, any or all of the [MyISAM](#) tables can be compressed with [myisampack](#). See [Section 4.6.5, “myisampack — Generate Compressed, Read-Only MyISAM Tables”](#). Differences in table options such as [AVG\\_ROW\\_LENGTH](#), [MAX\\_ROWS](#), or [PACK\\_KEYS](#) do not matter.

An alternative to a [MERGE](#) table is a partitioned table, which stores partitions of a single table in separate files. Partitioning enables some operations to be performed more efficiently and is not limited to the [MyISAM](#) storage engine. For more information, see [Chapter 18, Partitioning](#).

When you create a [MERGE](#) table, MySQL creates two files on disk. The files have names that begin with the table name and have an extension to indicate the file type. An [.frm](#) file stores the table format, and an [.MRG](#) file contains the names of the underlying [MyISAM](#) tables that should be used as one. The tables do not have to be in the same database as the [MERGE](#) table.

You can use [SELECT](#), [DELETE](#), [UPDATE](#), and [INSERT](#) on [MERGE](#) tables. You must have [SELECT](#), [DELETE](#), and [UPDATE](#) priv-

ileges on the `MyISAM` tables that you map to a `MERGE` table.

### Note

The use of `MERGE` tables entails the following security issue: If a user has access to `MyISAM` table `t`, that user can create a `MERGE` table `m` that accesses `t`. However, if the user's privileges on `t` are subsequently revoked, the user can continue to access `t` by doing so through `m`.

Use of `DROP TABLE` with a `MERGE` table drops only the `MERGE` specification. The underlying tables are not affected.

To create a `MERGE` table, you must specify a `UNION=(list-of-tables)` option that indicates which `MyISAM` tables to use. You can optionally specify an `INSERT_METHOD` option to control how inserts into the `MERGE` table take place. Use a value of `FIRST` or `LAST` to cause inserts to be made in the first or last underlying table, respectively. If you specify no `INSERT_METHOD` option or if you specify it with a value of `NO`, inserts into the `MERGE` table are not permitted and attempts to do so result in an error.

The following example shows how to create a `MERGE` table:

```
mysql> CREATE TABLE t1 (
-> a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
-> message CHAR(20)) ENGINE=MyISAM;
mysql> CREATE TABLE t2 (
-> a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
-> message CHAR(20)) ENGINE=MyISAM;
mysql> INSERT INTO t1 (message) VALUES ('Testing'),('table'),('t1');
mysql> INSERT INTO t2 (message) VALUES ('Testing'),('table'),('t2');
mysql> CREATE TABLE total (
-> a INT NOT NULL AUTO_INCREMENT,
-> message CHAR(20), INDEX(a))
-> ENGINE=MERGE UNION=(t1,t2) INSERT_METHOD=LAST;
```

Note that column `a` is indexed as a `PRIMARY KEY` in the underlying `MyISAM` tables, but not in the `MERGE` table. There it is indexed but not as a `PRIMARY KEY` because a `MERGE` table cannot enforce uniqueness over the set of underlying tables. (Similarly, a column with a `UNIQUE` index in the underlying tables should be indexed in the `MERGE` table but not as a `UNIQUE` index.)

After creating the `MERGE` table, you can use it to issue queries that operate on the group of tables as a whole:

```
mysql> SELECT * FROM total;
+---+-----+
| a | message |
+---+-----+
1	Testing
2	table
3	t1
1	Testing
2	table
3	t2
+---+-----+
```

To remap a `MERGE` table to a different collection of `MyISAM` tables, you can use one of the following methods:

- `DROP` the `MERGE` table and re-create it.
- Use `ALTER TABLE tbl_name UNION=(...)` to change the list of underlying tables.

Beginning with MySQL 5.1.24, it is also possible to use `ALTER TABLE ... UNION=( )` (that is, with an empty `UNION` clause) to remove all of the underlying tables.

As of MySQL 5.1.15, the underlying table definitions and indexes must conform more closely than previously to the definition of the `MERGE` table. Conformance is checked when a table that is part of a `MERGE` table is opened, not when the `MERGE` table is created. If any table fails the conformance checks, the operation that triggered the opening of the table fails. This means that changes to the definitions of tables within a `MERGE` may cause a failure when the `MERGE` table is accessed. The conformance checks applied to each table are:

- The underlying table and the `MERGE` table must have the same number of columns.
- The column order in the underlying table and the `MERGE` table must match.
- Additionally, the specification for each corresponding column in the parent `MERGE` table and the underlying tables are compared and must satisfy these checks:
  - The column type in the underlying table and the `MERGE` table must be equal.
  - The column length in the underlying table and the `MERGE` table must be equal.

- The column of the underlying table and the `MERGE` table can be `NULL`.
- The underlying table must have at least as many indexes as the `MERGE` table. The underlying table may have more indexes than the `MERGE` table, but cannot have fewer.

**Note**

A known issue exists where indexes on the same columns must be in identical order, in both the `MERGE` table and the underlying `MyISAM` table. See [Bug#33653](#).

Each index must satisfy these checks:

- The index type of the underlying table and the `MERGE` table must be the same.
- The number of index parts (that is, multiple columns within a compound index) in the index definition for the underlying table and the `MERGE` table must be the same.
- For each index part:
  - Index part lengths must be equal.
  - Index part types must be equal.
  - Index part languages must be equal.
  - Check whether index parts can be `NULL`.

For information about the table checks applied prior to MySQL 5.1.15, see [Section 13.8.2, “`MERGE` Table Problems”](#).

As of MySQL 5.1.20, if a `MERGE` table cannot be opened or used because of a problem with an underlying table, `CHECK TABLE` displays information about which table caused the problem.

**Additional Resources**

- A forum dedicated to the `MERGE` storage engine is available at <http://forums.mysql.com/list.php?93>.

### 13.8.1. `MERGE` Table Advantages and Disadvantages

`MERGE` tables can help you solve the following problems:

- Easily manage a set of log tables. For example, you can put data from different months into separate tables, compress some of them with `myisampack`, and then create a `MERGE` table to use them as one.
- Obtain more speed. You can split a large read-only table based on some criteria, and then put individual tables on different disks. A `MERGE` table structured this way could be much faster than using a single large table.
- Perform more efficient searches. If you know exactly what you are looking for, you can search in just one of the underlying tables for some queries and use a `MERGE` table for others. You can even have many different `MERGE` tables that use overlapping sets of tables.
- Perform more efficient repairs. It is easier to repair individual smaller tables that are mapped to a `MERGE` table than to repair a single large table.
- Instantly map many tables as one. A `MERGE` table need not maintain an index of its own because it uses the indexes of the individual tables. As a result, `MERGE` table collections are *very* fast to create or remap. (You must still specify the index definitions when you create a `MERGE` table, even though no indexes are created.)
- If you have a set of tables from which you create a large table on demand, you can instead create a `MERGE` table from them on demand. This is much faster and saves a lot of disk space.
- Exceed the file size limit for the operating system. Each `MyISAM` table is bound by this limit, but a collection of `MyISAM` tables is not.
- You can create an alias or synonym for a `MyISAM` table by defining a `MERGE` table that maps to that single table. There should be no really notable performance impact from doing this (only a couple of indirect calls and `memcpy()` calls for each read).

The disadvantages of `MERGE` tables are:

- You can use only identical `MyISAM` tables for a `MERGE` table.
- Some `MyISAM` features are unavailable in `MERGE` tables. For example, you cannot create `FULLTEXT` indexes on `MERGE` tables. (You can create `FULLTEXT` indexes on the underlying `MyISAM` tables, but you cannot search the `MERGE` table with a full-text search.)
- If the `MERGE` table is nontemporary, all underlying `MyISAM` tables must be nontemporary. If the `MERGE` table is temporary, the `MyISAM` tables can be any mix of temporary and nontemporary.
- `MERGE` tables use more file descriptors than `MyISAM` tables. If 10 clients are using a `MERGE` table that maps to 10 tables, the server uses  $(10 \times 10) + 10$  file descriptors. (10 data file descriptors for each of the 10 clients, and 10 index file descriptors shared among the clients.)
- Index reads are slower. When you read an index, the `MERGE` storage engine needs to issue a read on all underlying tables to check which one most closely matches a given index value. To read the next index value, the `MERGE` storage engine needs to search the read buffers to find the next value. Only when one index buffer is used up does the storage engine need to read the next index block. This makes `MERGE` indexes much slower on `eq_ref` searches, but not much slower on `ref` searches. For more information about `eq_ref` and `ref`, see [Section 12.8.2, “EXPLAIN Syntax”](#).

### 13.8.2. `MERGE` Table Problems

The following are known problems with `MERGE` tables:

- In versions of MySQL Server prior to 5.1.23 and 6.0.4, it was possible to create temporary merge tables with non-temporary child `MyISAM` tables.

From versions 5.1.23 and 6.0.4, `MERGE` children were locked through the parent table. If the parent was temporary, it was not locked and so the children were not locked either. Parallel use of the `MyISAM` tables corrupted them.

From 6.0.6 onwards, the children are locked independently from the parent. It is possible to have non-temporary children with a temporary parent. Even though the temporary `MERGE` table itself is not locked, each non-temporary child `MyISAM` table is locked anyway.

The reintroduction of support for non-temporary children with a temporary `MERGE` table was completed in 6.0.14. Note that 5.1.23 onwards does not currently have the child locking scheme required to support this.

- If you use `ALTER TABLE` to change a `MERGE` table to another storage engine, the mapping to the underlying tables is lost. Instead, the rows from the underlying `MyISAM` tables are copied into the altered table, which then uses the specified storage engine.
- The `INSERT_METHOD` table option for a `MERGE` table indicates which underlying `MyISAM` table to use for inserts into the `MERGE` table. However, use of the `AUTO_INCREMENT` table option for that `MyISAM` table has no effect for inserts into the `MERGE` table until at least one row has been inserted directly into the `MyISAM` table.
- A `MERGE` table cannot maintain uniqueness constraints over the entire table. When you perform an `INSERT`, the data goes into the first or last `MyISAM` table (as determined by the `INSERT_METHOD` option). MySQL ensures that unique key values remain unique within that `MyISAM` table, but not over all the underlying tables in the collection.
- Because the `MERGE` engine cannot enforce uniqueness over the set of underlying tables, `REPLACE` does not work as expected. The two key facts are:
  - `REPLACE` can detect unique key violations only in the underlying table to which it is going to write (which is determined by the `INSERT_METHOD` option). This differs from violations in the `MERGE` table itself.
  - If `REPLACE` detects a unique key violation, it will change only the corresponding row in the underlying table it is writing to; that is, the first or last table, as determined by the `INSERT_METHOD` option.

Similar considerations apply for `INSERT ... ON DUPLICATE KEY UPDATE`.

- `MERGE` tables do not support partitioning. That is, you cannot partition a `MERGE` table, nor can any of a `MERGE` table's underlying `MyISAM` tables be partitioned.
- You should not use `ANALYZE TABLE`, `REPAIR TABLE`, `OPTIMIZE TABLE`, `ALTER TABLE`, `DROP TABLE`, `DELETE` without a `WHERE` clause, or `TRUNCATE TABLE` on any of the tables that are mapped into an open `MERGE` table. If you do so, the `MERGE` table may still refer to the original table and yield unexpected results. To work around this problem, ensure that no

`MERGE` tables remain open by issuing a `FLUSH TABLES` statement prior to performing any of the named operations.

The unexpected results include the possibility that the operation on the `MERGE` table will report table corruption. If this occurs after one of the named operations on the underlying `MyISAM` tables, the corruption message is spurious. To deal with this, issue a `FLUSH TABLES` statement after modifying the `MyISAM` tables.

- `DROP TABLE` on a table that is in use by a `MERGE` table does not work on Windows because the `MERGE` storage engine's table mapping is hidden from the upper layer of MySQL. Windows does not permit open files to be deleted, so you first must flush all `MERGE` tables (with `FLUSH TABLES`) or drop the `MERGE` table before dropping the table.
- As of MySQL 5.1.15, the definition of the `MyISAM` tables and the `MERGE` table are checked when the tables are accessed (for example, as part of a `SELECT` or `INSERT` statement). The checks ensure that the definitions of the tables and the parent `MERGE` table definition match by comparing column order, types, sizes and associated indexes. If there is a difference between the tables, an error is returned and the statement fails. Because these checks take place when the tables are opened, any changes to the definition of a single table, including column changes, column ordering, and engine alterations will cause the statement to fail.

Prior to MySQL 5.1.15, table checks are applied as follows:

- When you create or alter `MERGE` table, there is no check to ensure that the underlying tables are existing `MyISAM` tables and have identical structures. When the `MERGE` table is used, MySQL checks that the row length for all mapped tables is equal, but this is not foolproof. If you create a `MERGE` table from dissimilar `MyISAM` tables, you are very likely to run into strange problems.
- Similarly, if you create a `MERGE` table from non-`MyISAM` tables, or if you drop an underlying table or alter it to be a non-`MyISAM` table, no error for the `MERGE` table occurs until later when you attempt to use it.
- Because the underlying `MyISAM` tables need not exist when the `MERGE` table is created, you can create the tables in any order, as long as you do not use the `MERGE` table until all of its underlying tables are in place. Also, if you can ensure that a `MERGE` table will not be used during a given period, you can perform maintenance operations on the underlying tables, such as backing up or restoring them, altering them, or dropping and recreating them. It is not necessary to redefine the `MERGE` table temporarily to exclude the underlying tables while you are operating on them.
- The order of indexes in the `MERGE` table and its underlying tables should be the same. If you use `ALTER TABLE` to add a `UNIQUE` index to a table used in a `MERGE` table, and then use `ALTER TABLE` to add a nonunique index on the `MERGE` table, the index ordering is different for the tables if there was already a nonunique index in the underlying table. (This happens because `ALTER TABLE` puts `UNIQUE` indexes before nonunique indexes to facilitate rapid detection of duplicate keys.) Consequently, queries on tables with such indexes may return unexpected results.
- If you encounter an error message similar to `ERROR 1017 (HY000): CAN'T FIND FILE: 'TBL_NAME.MRG' (errno: 2)`, it generally indicates that some of the underlying tables do not use the `MyISAM` storage engine. Confirm that all of these tables are `MyISAM`.
- The maximum number of rows in a `MERGE` table is  $2^{64}$  ( $\sim 1.844E+19$ ; the same as for a `MyISAM` table), provided that the server was built using the `--with-big-tables` option. (All standard MySQL 5.1 standard binaries are built with this option; for more information, see [Section 2.3.3, “Typical configure Options”](#).) It is not possible to merge multiple `MyISAM` tables into a single `MERGE` table that would have more than this number of rows.
- The `MERGE` storage engine does not support `INSERT DELAYED` statements.
- Use of underlying `MyISAM` tables of differing row formats with a parent `MERGE` table is currently known to fail. See [Bug#32364](#).
- As of MySQL 5.1.23, you cannot change the union list of a nontemporary `MERGE` table when `LOCK TABLES` is in effect. The following does *not* work:

```
CREATE TABLE m1 ... ENGINE=MRG_MYISAM ...;
LOCK TABLES t1 WRITE, t2 WRITE, m1 WRITE;
ALTER TABLE m1 ... UNION=(t1,t2) ...;
```

However, you can do this with a temporary `MERGE` table.

- As of MySQL 5.1.23, you cannot create a `MERGE` table with `CREATE ... SELECT`, neither as a temporary `MERGE` table, nor as a nontemporary `MERGE` table. For example:

```
CREATE TABLE m1 ... ENGINE=MRG_MYISAM ... SELECT ...;
```

Attempts to do this result in an error: `tbl_name` is not `BASE_TABLE`.

- In some cases, differing `PACK_KEYS` table option values among the `MERGE` and underlying tables cause unexpected results if

the underlying tables contain `CHAR` or `BINARY` columns. As a workaround, use `ALTER TABLE` to ensure that all involved tables have the same `PACK_KEYS` value. (Bug#50646)

## 13.9. The `MEMORY` Storage Engine

The `MEMORY` storage engine creates tables with contents that are stored in memory. Formerly, these were known as `HEAP` tables. `MEMORY` is the preferred term, although `HEAP` remains supported for backward compatibility.

**Table 13.13. `MEMORY` Storage Engine Features**

| Storage limits                         | RAM | Transactions                                 | No  | Locking granularity                                | Table |
|----------------------------------------|-----|----------------------------------------------|-----|----------------------------------------------------|-------|
| <b>MVCC</b>                            | No  | <b>Geospatial data type support</b>          | No  | <b>Geospatial indexing support</b>                 | No    |
| <b>B-tree indexes</b>                  | Yes | <b>Hash indexes</b>                          | Yes | <b>Full-text search indexes</b>                    | No    |
| <b>Clustered indexes</b>               | No  | <b>Data caches</b>                           | N/A | <b>Index caches</b>                                | N/A   |
| <b>Compressed data</b>                 | No  | <b>Encrypted data<sup>a</sup></b>            | Yes | <b>Cluster database support</b>                    | No    |
| <b>Replication support<sup>b</sup></b> | Yes | <b>Foreign key support</b>                   | No  | <b>Backup / point-in-time recovery<sup>c</sup></b> | Yes   |
| <b>Query cache support</b>             | Yes | <b>Update statistics for data dictionary</b> | Yes |                                                    |       |

<sup>a</sup>Implemented in the server (via encryption functions), rather than in the storage engine.

<sup>b</sup>Implemented in the server, rather than in the storage product

<sup>c</sup>Implemented in the server, rather than in the storage product

### Important

Developers looking to deploy applications that use the `MEMORY` storage engine should consider whether MySQL Cluster is a better choice. A typical use case for the `MEMORY` engine involves these characteristics:

- Operations such as session management or caching
- In-memory storage for fast access and low latency
- A read-only or read-mostly data access pattern (limited updates)

However, `MEMORY` performance is constrained by contention resulting from single-thread execution and table lock overhead when processing updates. This limits scalability when load increases, particularly for statement mixes that include writes. Also, `MEMORY` does not preserve table contents across server restarts.

MySQL Cluster offers the same features as the `MEMORY` engine with higher performance levels, and provides additional features not available with `MEMORY`:

- Row-level locking and multiple-thread operation for low contention between clients
- Scalability even with statement mixes that include writes
- Optional disk-backed operation for data durability
- Shared-nothing architecture and multiple-host operation with no single point of failure, enabling 99.999% availability
- Automatic data distribution across nodes; application developers need not craft custom sharding or partitioning solutions
- Support for variable-length data types (including `BLOB` and `TEXT`) not supported by `MEMORY`

For a white paper with more detailed comparison of the `MEMORY` storage engine and MySQL Cluster, see [Scaling Web Services with MySQL Cluster: An Alternative to the MySQL Memory Storage Engine](#). This white paper includes a performance study of the two technologies and a step-by-step guide describing how existing `MEMORY` users can migrate to MySQL Cluster.

The `MEMORY` storage engine associates each table with one disk file. The file name begins with the table name and has an extension of `.frm` to indicate that it stores the table definition.

To specify that you want to create a `MEMORY` table, indicate that with an `ENGINE` table option:

```
CREATE TABLE t (i INT) ENGINE = MEMORY;
```

As indicated by the engine name, `MEMORY` tables are stored in memory. They use hash indexes by default, which makes them very fast, and very useful for creating temporary tables. However, when the server shuts down, all rows stored in `MEMORY` tables are lost. The tables themselves continue to exist because their definitions are stored in `.frm` files on disk, but they are empty when the server restarts.

This example shows how you might create, use, and remove a `MEMORY` table:

```
mysql> CREATE TABLE test ENGINE=MEMORY
-> SELECT ip,SUM(downloads) AS down
-> FROM log_table GROUP BY ip;
mysql> SELECT COUNT(ip),AVG(down) FROM test;
mysql> DROP TABLE test;
```

`MEMORY` tables have the following characteristics:

- Space for `MEMORY` tables is allocated in small blocks. Tables use 100% dynamic hashing for inserts. No overflow area or extra key space is needed. No extra space is needed for free lists. Deleted rows are put in a linked list and are reused when you insert new data into the table. `MEMORY` tables also have none of the problems commonly associated with deletes plus inserts in hashed tables.
- `MEMORY` tables can have up to 32 indexes per table, 16 columns per index and a maximum key length of 3072 bytes.
- The `MEMORY` storage engine supports both `HASH` and `BTREE` indexes. You can specify one or the other for a given index by adding a `USING` clause as shown here:

```
CREATE TABLE lookup
 (id INT, INDEX USING HASH (id))
 ENGINE = MEMORY;
CREATE TABLE lookup
 (id INT, INDEX USING BTREE (id))
 ENGINE = MEMORY;
```

For general characteristics of B-tree and hash indexes, see [Section 7.5.3, “How MySQL Uses Indexes”](#).

- If a `MEMORY` table hash index has a high degree of key duplication (many index entries containing the same value), updates to the table that affect key values and all deletes are significantly slower. The degree of this slowdown is proportional to the degree of duplication (or, inversely proportional to the index cardinality). You can use a `BTREE` index to avoid this problem.
- `MEMORY` tables can have nonunique keys. (This is an uncommon feature for implementations of hash indexes.)
- Columns that are indexed can contain `NULL` values.
- `MEMORY` tables use a fixed-length row-storage format. Variable-length types such as `VARCHAR` are stored using a fixed length.
- `MEMORY` tables cannot contain `BLOB` or `TEXT` columns.
- `MEMORY` includes support for `AUTO_INCREMENT` columns.
- `MEMORY` supports `INSERT DELAYED`. See [Section 12.2.5.2, “`INSERT DELAYED` Syntax”](#).
- Non-`TEMPORARY` `MEMORY` tables are shared among all clients, just like any other non-`TEMPORARY` table.
- `MEMORY` table contents are stored in memory, which is a property that `MEMORY` tables share with internal temporary tables that the server creates on the fly while processing queries. However, the two types of tables differ in that `MEMORY` tables are not subject to storage conversion, whereas internal temporary tables are:
  - `MEMORY` tables are never converted to disk tables. If an internal temporary table becomes too large, the server automatically converts it to on-disk storage, as described in [Section 7.8.4, “How MySQL Uses Internal Temporary Tables”](#).
  - The maximum size of `MEMORY` tables is limited by the `max_heap_table_size` system variable, which has a default value of 16MB. To have larger (or smaller) `MEMORY` tables, you must change the value of this variable. The value in effect for `CREATE TABLE` is the value used for the life of the table. (If you use `ALTER TABLE` or `TRUNCATE TABLE`, the value in effect at that time becomes the new maximum size for the table. A server restart also sets the maximum size of existing `MEMORY` tables to the global `max_heap_table_size` value.) You can set the size for individual tables as de-

scribed later in this section.

- The server needs sufficient memory to maintain all `MEMORY` tables that are in use at the same time.
- Memory is not reclaimed if you delete individual rows from a `MEMORY` table. Memory is reclaimed only when the entire table is deleted. Memory that was previously used for rows that have been deleted will be re-used for new rows only within the same table. To free up the memory used by rows that have been deleted, use `ALTER TABLE ENGINE=MEMORY` to force a table rebuild.

To free all the memory used by a `MEMORY` table when you no longer require its contents, you should execute `DELETE` or `TRUNCATE TABLE` to remove all rows, or remove the table altogether using `DROP TABLE`.

- If you want to populate a `MEMORY` table when the MySQL server starts, you can use the `--init-file` option. For example, you can put statements such as `INSERT INTO ... SELECT` or `LOAD DATA INFILE` into this file to load the table from a persistent data source. See [Section 5.1.2, “Server Command Options”](#), and [Section 12.2.6, “LOAD DATA INFILE Syntax”](#).
- A server's `MEMORY` tables become empty when it is shut down and restarted. However, if the server is a replication master, its slave are not aware that these tables have become empty, so they returns out-of-date content if you select data from these tables. To handle this, when a `MEMORY` table is used on a master for the first time since it was started, a `DELETE` statement is written to the master's binary log automatically, thus synchronizing the slave to the master again. Note that even with this strategy, the slave still has outdated data in the table during the interval between the master's restart and its first use of the table. However, if you use the `--init-file` option to populate the `MEMORY` table on the master at startup, it ensures that this time interval is zero.
- The memory needed for one row in a `MEMORY` table is calculated using the following expression:

```
SUM_OVER_ALL_BTREE_KEYS(max_length_of_key + sizeof(char*) * 4)
+ SUM_OVER_ALL_HASH_KEYS(sizeof(char*) * 2)
+ ALIGN(length_of_row+1, sizeof(char*))
```

`ALIGN()` represents a round-up factor to cause the row length to be an exact multiple of the `char` pointer size. `sizeof(char*)` is 4 on 32-bit machines and 8 on 64-bit machines.

As mentioned earlier, the `max_heap_table_size` system variable sets the limit on the maximum size of `MEMORY` tables. To control the maximum size for individual tables, set the session value of this variable before creating each table. (Do not change the global `max_heap_table_size` value unless you intend the value to be used for `MEMORY` tables created by all clients.) The following example creates two `MEMORY` tables, with a maximum size of 1MB and 2MB, respectively:

```
mysql> SET max_heap_table_size = 1024*1024;
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t1 (id INT, UNIQUE(id)) ENGINE = MEMORY;
Query OK, 0 rows affected (0.01 sec)

mysql> SET max_heap_table_size = 1024*1024*2;
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t2 (id INT, UNIQUE(id)) ENGINE = MEMORY;
Query OK, 0 rows affected (0.00 sec)
```

Both tables will revert to the server's global `max_heap_table_size` value if the server restarts.

You can also specify a `MAX_ROWS` table option in `CREATE TABLE` statements for `MEMORY` tables to provide a hint about the number of rows you plan to store in them. This does not enable the table to grow beyond the `max_heap_table_size` value, which still acts as a constraint on maximum table size. For maximum flexibility in being able to use `MAX_ROWS`, set `max_heap_table_size` at least as high as the value to which you want each `MEMORY` table to be able to grow.

#### Additional Resources

- A forum dedicated to the `MEMORY` storage engine is available at <http://forums.mysql.com/list.php?92>.

## 13.10. The `EXAMPLE` Storage Engine

The `EXAMPLE` storage engine is a stub engine that does nothing. Its purpose is to serve as an example in the MySQL source code that illustrates how to begin writing new storage engines. As such, it is primarily of interest to developers.

To enable the `EXAMPLE` storage engine if you build MySQL from source, invoke `configure` with the `-with-example-storage-engine` option.

To examine the source for the `EXAMPLE` engine, look in the `storage/example` directory of a MySQL source distribution.

When you create an `EXAMPLE` table, the server creates a table format file in the database directory. The file begins with the table name and has an `.frm` extension. No other files are created. No data can be stored into the table. Retrievals return an empty result.

```
mysql> CREATE TABLE test (i INT) ENGINE = EXAMPLE;
Query OK, 0 rows affected (0.78 sec)

mysql> INSERT INTO test VALUES(1),(2),(3);
ERROR 1031 (HY000): Table storage engine for 'test' doesn't have this option

mysql> SELECT * FROM test;
Empty set (0.31 sec)
```

The `EXAMPLE` storage engine does not support indexing.

## 13.11. The `FEDERATED` Storage Engine

The `FEDERATED` storage engine enables data to be accessed from a remote MySQL database on a local server without using replication or cluster technology. When using a `FEDERATED` table, queries on the local server are automatically executed on the remote (federated) tables. No data is stored on the local tables.

To include the `FEDERATED` storage engine if you build MySQL from source, invoke `configure` with the `--with-federated-storage-engine` option.

Beginning with MySQL 5.1.26, the `FEDERATED` storage engine is not enabled by default in the running server; to enable `FEDERATED`, you must start the MySQL server binary using the `--federated` option.

To examine the source for the `FEDERATED` engine, look in the `storage/federated` directory of a MySQL source distribution.

### 13.11.1. `FEDERATED` Storage Engine Overview

When you create a table using one of the standard storage engines (such as `MyISAM`, `CSV` or `InnoDB`), the table consists of the table definition and the associated data. When you create a `FEDERATED` table, the table definition is the same, but the physical storage of the data is handled on a remote server.

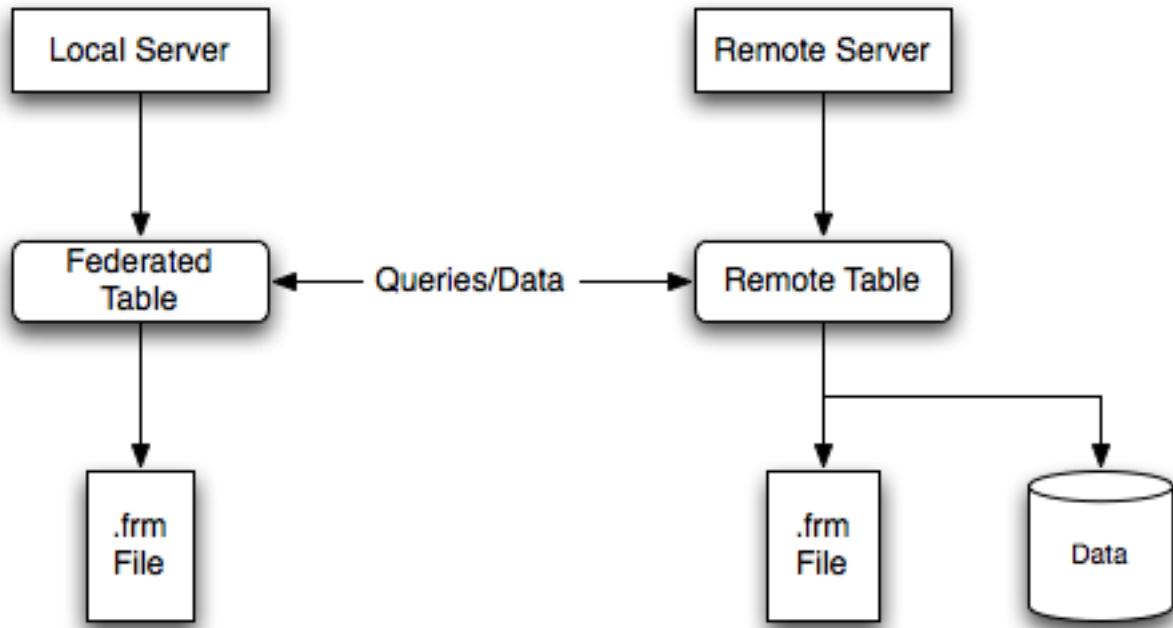

A `FEDERATED` table consists of two elements:

- A *remote server* with a database table, which in turn consists of the table definition (stored in the `.frm` file) and the associated data. The table type of the remote table may be any type supported by the remote `mysqld` server, including `MyISAM` or `InnoDB`.
- A *local server* with a database table, where the table definition matches that of the corresponding table on the remote server. The table definition is stored within the `.frm` file. However, there is no data file on the local server. Instead, the table definition includes a connection string that points to the remote table.

When executing queries and statements on a `FEDERATED` table on the local server, the operations that would normally insert, update or delete information from a local data file are instead sent to the remote server for execution, where they update the data file on the remote server or return matching rows from the remote server.

The basic structure of a `FEDERATED` table setup is shown in [Figure 13.2, “`FEDERATED` Table Structure”](#).

**Figure 13.2. `FEDERATED` Table Structure**

When a client issues an SQL statement that refers to a **FEDERATED** table, the flow of information between the local server (where the SQL statement is executed) and the remote server (where the data is physically stored) is as follows:

1. The storage engine looks through each column that the **FEDERATED** table has and constructs an appropriate SQL statement that refers to the remote table.
2. The statement is sent to the remote server using the MySQL client API.
3. The remote server processes the statement and the local server retrieves any result that the statement produces (an affected-rows count or a result set).
4. If the statement produces a result set, each column is converted to internal storage engine format that the **FEDERATED** engine expects and can use to display the result to the client that issued the original statement.

The local server communicates with the remote server using MySQL client C API functions. It invokes `mysql_real_query()` to send the statement. To read a result set, it uses `mysql_store_result()` and fetches rows one at a time using `mysql_fetch_row()`.

### 13.11.2. How to Create **FEDERATED** Tables

To create a **FEDERATED** table you should follow these steps:

1. Create the table on the remote server. Alternatively, make a note of the table definition of an existing table, perhaps using the `SHOW CREATE TABLE` statement.
2. Create the table on the local server with an identical table definition, but adding the connection information that links the local table to the remote table.

For example, you could create the following table on the remote server:

```

CREATE TABLE test_table (
 id INT(20) NOT NULL AUTO_INCREMENT,
 name VARCHAR(32) NOT NULL DEFAULT '',
 other INT(20) NOT NULL DEFAULT '0',
 PRIMARY KEY (id),
 INDEX name (name),
 INDEX other_key (other)
)
ENGINE=MyISAM
DEFAULT CHARSET=latin1;

```

To create the local table that will be federated to the remote table, there are two options available. You can either create the local table and specify the connection string (containing the server name, login, password) to be used to connect to the remote table using the `CONNECTION`, or you can use an existing connection that you have previously created using the `CREATE SERVER` statement.

### Important

When you create the local table it *must* have an identical field definition to the remote table.

### Note

You can improve the performance of a `FEDERATED` table by adding indexes to the table on the host, even though the tables will not actually be created locally. The optimization will occur because the query sent to the remote server will include the contents of the `WHERE` clause will be sent to the remote server and executed locally. This reduces the network traffic that would otherwise request the entire table from the server for local processing.

#### 13.11.2.1. Creating a `FEDERATED` Table Using `CONNECTION`

To use the first method, you must specify the `CONNECTION` string after the engine type in a `CREATE TABLE` statement. For example:

```
CREATE TABLE federated_table (
 id INT(20) NOT NULL AUTO_INCREMENT,
 name VARCHAR(32) NOT NULL DEFAULT '',
 other INT(20) NOT NULL DEFAULT '0',
 PRIMARY KEY (id),
 INDEX name (name),
 INDEX other_key (other)
)
ENGINE=FEDERATED
DEFAULT CHARSET=latin1
CONNECTION='mysql://fed_user@remote_host:9306/federated/test_table';
```

### Note

`CONNECTION` replaces the `COMMENT` used in some previous versions of MySQL.

The `CONNECTION` string contains the information required to connect to the remote server containing the table that will be used to physically store the data. The connection string specifies the server name, login credentials, port number and database/table information. In the example, the remote table is on the server `remote_host`, using port 9306. The name and port number should match the host name (or IP address) and port number of the remote MySQL server instance you want to use as your remote table.

The format the connection string is as follows:

```
scheme://user_name[:password]@host_name[:port_num]/db_name/tbl_name
```

Where:

- `scheme`: A recognized connection protocol. Only `mysql` is supported as the `scheme` value at this point.
- `user_name`: The user name for the connection. This user must have been created on the remote server, and must have suitable privileges to perform the required actions (`SELECT`, `INSERT`, `UPDATE`, and so forth) on the remote table.
- `password`: (Optional) The corresponding password for `user_name`.
- `host_name`: The host name or IP address of the remote server.
- `port_num`: (Optional) The port number for the remote server. The default is 3306.
- `db_name`: The name of the database holding the remote table.
- `tbl_name`: The name of the remote table. The name of the local and the remote table do not have to match.

Sample connection strings:

```
CONNECTION='mysql://username:password@hostname:port/database tablename'
CONNECTION='mysql://username@hostname/database tablename'
CONNECTION='mysql://username:password@hostname/database tablename'
```

#### 13.11.2.2. Creating a `FEDERATED` Table Using `CREATE SERVER`

If you are creating a number of **FEDERATED** tables on the same server, or if you want to simplify the process of creating **FEDERATED** tables, you can use the **CREATE SERVER** statement to define the server connection parameters, just as you would with the **CONNECTION** string.

The format of the **CREATE SERVER** statement is:

```
CREATE SERVER
 server_name
 FOREIGN DATA WRAPPER wrapper_name
 OPTIONS (option [, option] ...)
```

The *server\_name* is used in the connection string when creating a new **FEDERATED** table.

For example, to create a server connection identical to the **CONNECTION** string:

```
CONNECTION='mysql://fed_user@remote_host:9306/federated/test_table';
```

You would use the following statement:

```
CREATE SERVER fedlink
 FOREIGN DATA WRAPPER mysql
 OPTIONS (USER 'fed_user', HOST 'remote_host', PORT 9306, DATABASE 'federated');
```

To create a **FEDERATED** table that uses this connection, you still use the **CONNECTION** keyword, but specify the name you used in the **CREATE SERVER** statement.

```
CREATE TABLE test_table (
 id INT(20) NOT NULL AUTO_INCREMENT,
 name VARCHAR(32) NOT NULL DEFAULT '',
 other INT(20) NOT NULL DEFAULT '0',
 PRIMARY KEY (id),
 INDEX name (name),
 INDEX other_key (other)
)
ENGINE=FEDERATED
DEFAULT CHARSET=latin1
CONNECTION='fedlink/test_table';
```

The connection name in this example contains the name of the connection (**fedlink**) and the name of the table (**test\_table**) to link to, separated by a slash. If you specify only the connection name without a table name, the table name of the local table is used instead.

For more information on **CREATE SERVER**, see [Section 12.1.16, “CREATE SERVER Syntax”](#).

The **CREATE SERVER** statement accepts the same arguments as the **CONNECTION** string. The **CREATE SERVER** statement updates the rows in the **mysql.servers** table. See the following table for information on the correspondence between parameters in a connection string, options in the **CREATE SERVER** statement, and the columns in the **mysql.servers** table. For reference, the format of the **CONNECTION** string is as follows:

```
scheme://user_name[:password]@host_name[:port_num]/db_name/tbl_name
```

| Description       | <b>CONNECTION</b> string | <b>CREATE SERVER</b> option | <b>mysql.servers</b> column |
|-------------------|--------------------------|-----------------------------|-----------------------------|
| Connection scheme | <i>scheme</i>            | <i>wrapper_name</i>         | Wrapper                     |
| Remote user       | <i>user_name</i>         | USER                        | Username                    |
| Remote password   | <i>password</i>          | PASSWORD                    | Password                    |
| Remote host       | <i>host_name</i>         | HOST                        | Host                        |
| Remote port       | <i>port_num</i>          | PORT                        | Port                        |
| Remote database   | <i>db_name</i>           | DATABASE                    | Db                          |

### 13.11.3. **FEDERATED** Storage Engine Notes and Tips

You should be aware of the following points when using the **FEDERATED** storage engine:

- **FEDERATED** tables may be replicated to other slaves, but you must ensure that the slave servers are able to use the user/password combination that is defined in the **CONNECTION** string (or the row in the **mysql.servers** table) to connect to the remote server.

The following items indicate features that the **FEDERATED** storage engine does and does not support:

- The remote server must be a MySQL server.
- The remote table that a **FEDERATED** table points to *must* exist before you try to access the table through the **FEDERATED** table.
- It is possible for one **FEDERATED** table to point to another, but you must be careful not to create a loop.
- A **FEDERATED** table does not support indexes per se. Because access to the table is handled remotely, it is the remote table that supports the indexes. Care should be taken when creating a **FEDERATED** table since the index definition from an equivalent **MyISAM** or other table may not be supported. For example, creating a **FEDERATED** table with an index prefix on **VARCHAR**, **TEXT** or **BLOB** columns will fail. The following definition in **MyISAM** is valid:

```
CREATE TABLE `T1`(`A` VARCHAR(100),UNIQUE KEY(`A`(30))) ENGINE=MYISAM;
```

The key prefix in this example is incompatible with the **FEDERATED** engine, and the equivalent statement will fail:

```
CREATE TABLE `T1`(`A` VARCHAR(100),UNIQUE KEY(`A`(30))) ENGINE=FEDERATED
CONNECTION='MySQL://127.0.0.1:3306/TEST/T1';
```

If possible, you should try to separate the column and index definition when creating tables on both the remote server and the local server to avoid these index issues.

- Internally, the implementation uses **SELECT**, **INSERT**, **UPDATE**, and **DELETE**, but not **HANDLER**.
- The **FEDERATED** storage engine supports **SELECT**, **INSERT**, **UPDATE**, **DELETE**, **TRUNCATE TABLE**, and indexes. It does not support **ALTER TABLE**, or any Data Definition Language statements that directly affect the structure of the table, other than **DROP TABLE**. The current implementation does not use prepared statements.
- **FEDERATED** accepts **INSERT ... ON DUPLICATE KEY UPDATE** statements, but if a duplicate-key violation occurs, the statement fails with an error.
- Performance on a **FEDERATED** table when performing bulk inserts (for example, on a **INSERT INTO ... SELECT ...** statement) is slower than with other table types because each selected row is treated as an individual **INSERT** statement on the **FEDERATED** table.
- Transactions are not supported.
- Before MySQL 5.1.21, for a multiple-row insert into a **FEDERATED** table that refers to a remote transactional table, if the insert failed for a row due to constraint failure, the remote table would contain a partial commit (the rows preceding the failed one) instead of rolling back the statement completely. This occurred because the rows were treated as individual inserts.

As of MySQL 5.1.21, **FEDERATED** performs bulk-insert handling such that multiple rows are sent to the remote table in a batch. This provides a performance improvement and enables the remote table to perform improvement. Also, if the remote table is transactional, it enables the remote storage engine to perform statement rollback properly should an error occur. This capability has the following limitations:

- The size of the insert cannot exceed the maximum packet size between servers. If the insert exceeds this size, it is broken into multiple packets and the rollback problem can occur.
- Bulk-insert handling does not occur for **INSERT ... ON DUPLICATE KEY UPDATE**.
- There is no way for the **FEDERATED** engine to know if the remote table has changed. The reason for this is that this table must work like a data file that would never be written to by anything other than the database system. The integrity of the data in the local table could be breached if there was any change to the remote database.
- When using a **CONNECTION** string, you cannot use an '@' character in the password. You can get round this limitation by using the **CREATE SERVER** statement to create a server connection.
- The **insert\_id** and **timestamp** options are not propagated to the data provider.
- Any **DROP TABLE** statement issued against a **FEDERATED** table drops only the local table, not the remote table.
- **FEDERATED** tables do not work with the query cache.
- User-defined partitioning is not supported for **FEDERATED** tables. Beginning with MySQL 5.1.15, it is no longer possible to create such tables at all.

### 13.11.4. FEDERATED Storage Engine Resources

The following additional resources are available for the `FEDERATED` storage engine:

- A forum dedicated to the `FEDERATED` storage engine is available at <http://forums.mysql.com/list.php?105>.

## 13.12. The ARCHIVE Storage Engine

The `ARCHIVE` storage engine is used for storing large amounts of data without indexes in a very small footprint.

**Table 13.14. ARCHIVE Storage Engine Features**

| Storage limits                         | None | Transactions                                 | No  | Locking granularity                                | Row |
|----------------------------------------|------|----------------------------------------------|-----|----------------------------------------------------|-----|
| <b>MVCC</b>                            | No   | <b>Geospatial data type support</b>          | Yes | <b>Geospatial indexing support</b>                 | No  |
| <b>B-tree indexes</b>                  | No   | <b>Hash indexes</b>                          | No  | <b>Full-text search indexes</b>                    | No  |

<sup>a</sup>Implemented in the server (via encryption functions), rather than in the storage engine.

<sup>b</sup>Implemented in the server, rather than in the storage product

<sup>c</sup>Implemented in the server, rather than in the storage product

The `ARCHIVE` storage engine is included in MySQL binary distributions. To enable this storage engine if you build MySQL from source, invoke `configure` with the `--with-archive-storage-engine` option.

To examine the source for the `ARCHIVE` engine, look in the `storage/archive` directory of a MySQL source distribution.

You can check whether the `ARCHIVE` storage engine is available with the `SHOW ENGINES` statement.

When you create an `ARCHIVE` table, the server creates a table format file in the database directory. The file begins with the table name and has an `.frm` extension. The storage engine creates other files, all having names beginning with the table name. The data file has an extension of `.ARZ`. (Prior to MySQL 5.1.15, a metadata file with an extension of `.ARM` is created as well.) An `.ARN` file may appear during optimization operations.

The `ARCHIVE` engine supports `INSERT` and `SELECT`, but not `DELETE`, `REPLACE`, or `UPDATE`. It does support `ORDER BY` operations, `BLOB` columns, and basically all but spatial data types (see Section 11.17.4.1, “MySQL Spatial Data Types”). The `ARCHIVE` engine uses row-level locking.

As of MySQL 5.1.6, the `ARCHIVE` engine supports the `AUTO_INCREMENT` column attribute. The `AUTO_INCREMENT` column can have either a unique or nonunique index. Attempting to create an index on any other column results in an error. The `ARCHIVE` engine also supports the `AUTO_INCREMENT` table option in `CREATE TABLE` and `ALTER TABLE` statements to specify the initial sequence value for a new table or reset the sequence value for an existing table, respectively.

As of MySQL 5.1.6, the `ARCHIVE` engine ignores `BLOB` columns if they are not requested and scans past them while reading. Formerly, the following two statements had the same cost, but as of 5.1.6, the second is much more efficient than the first:

```
SELECT a, b, blob_col FROM archive_table;
SELECT a, b FROM archive_table;
```

**Storage:** Rows are compressed as they are inserted. The `ARCHIVE` engine uses `zlib` lossless data compression (see <http://www.zlib.net/>). You can use `OPTIMIZE TABLE` to analyze the table and pack it into a smaller format (for a reason to use `OPTIMIZE TABLE`, see later in this section). The engine also supports `CHECK TABLE`. There are several types of insertions that are used:

- An `INSERT` statement just pushes rows into a compression buffer, and that buffer flushes as necessary. The insertion into the buffer is protected by a lock. A `SELECT` forces a flush to occur, unless the only insertions that have come in were `INSERT DELAYED` (those flush as necessary). See Section 12.2.5.2, “`INSERT DELAYED` Syntax”.
- A bulk insert is visible only after it completes, unless other inserts occur at the same time, in which case it can be seen partially.

A `SELECT` never causes a flush of a bulk insert unless a normal insert occurs while it is loading.

**Retrieval:** On retrieval, rows are uncompressed on demand; there is no row cache. A `SELECT` operation performs a complete table scan: When a `SELECT` occurs, it finds out how many rows are currently available and reads that number of rows. `SELECT` is performed as a consistent read. Note that lots of `SELECT` statements during insertion can deteriorate the compression, unless only bulk or delayed inserts are used. To achieve better compression, you can use `OPTIMIZE TABLE` or `REPAIR TABLE`. The number of rows in `ARCHIVE` tables reported by `SHOW TABLE STATUS` is always accurate. See [Section 12.4.2.5, “`OPTIMIZE TABLE` Syntax”](#), [Section 12.4.2.6, “`REPAIR TABLE` Syntax”](#), and [Section 12.4.5.38, “`SHOW TABLE STATUS` Syntax”](#).

#### Additional Resources

- A forum dedicated to the `ARCHIVE` storage engine is available at <http://forums.mysql.com/list.php?112>.

## 13.13. The `CSV` Storage Engine

The `CSV` storage engine stores data in text files using comma-separated values format.

To enable the `CSV` storage engine if you build MySQL from source, invoke `configure` with the `--with-csv-storage-engine` option.

To examine the source for the `CSV` engine, look in the `storage/csv` directory of a MySQL source distribution.

When you create a `CSV` table, the server creates a table format file in the database directory. The file begins with the table name and has an `.frm` extension. The storage engine also creates a data file. Its name begins with the table name and has a `.CSV` extension. The data file is a plain text file. When you store data into the table, the storage engine saves it into the data file in comma-separated values format.

```
mysql> CREATE TABLE test (i INT NOT NULL, c CHAR(10) NOT NULL)
-> ENGINE = CSV;
Query OK, 0 rows affected (0.12 sec)

mysql> INSERT INTO test VALUES(1,'record one'),(2,'record two');
Query OK, 2 rows affected (0.00 sec)
Records: 2 Duplicates: 0 Warnings: 0

mysql> SELECT * FROM test;
+---+---+
| i | c |
+---+---+
| 1 | record one |
| 2 | record two |
+---+---+
2 rows in set (0.00 sec)
```

Starting with MySQL 5.1.9, creating a CSV table also creates a corresponding Metafile that stores the state of the table and the number of rows that exist in the table. The name of this file is the same as the name of the table with the extension `CSM`.

If you examine the `test.CSV` file in the database directory created by executing the preceding statements, its contents should look like this:

```
"1","record one"
"2","record two"
```

This format can be read, and even written, by spreadsheet applications such as Microsoft Excel or StarOffice Calc.

### 13.13.1. Repairing and Checking CSV Tables

#### Functionality introduced in version 5.1.9

The CSV storage engines supports the `CHECK` and `REPAIR` statements to verify and if possible repair a damaged CSV table.

When running the `CHECK` statement, the CSV file will be checked for validity by looking for the correct field separators, escaped fields (matching or missing quotation marks), the correct number of fields compared to the table definition and the existence of a corresponding CSV metafile. The first invalid row discovered will report an error. Checking a valid table produces output like that shown below:

```
mysql> check table csvtest;
+-----+-----+-----+-----+
| Table | Op | Msg_type | Msg_text |
+-----+-----+-----+-----+
| test.csvtest | check | status | OK |
+-----+-----+-----+-----+
```

```
1 row in set (0.00 sec)
```

A check on a corrupted table returns a fault:

```
mysql> check table csvtest;
+-----+-----+-----+-----+
| Table | Op | Msg_type | Msg_text |
+-----+-----+-----+-----+
| test.csvtest | check | error | Corrupt |
+-----+-----+-----+-----+
1 row in set (0.01 sec)
```

If the check fails, the table is marked as crashed (corrupt). Once a table has been marked as corrupt, it is automatically repaired when you next run `CHECK` or execute a `SELECT` statement. The corresponding corrupt status and new status will be displayed when running `CHECK`:

```
mysql> check table csvtest;
+-----+-----+-----+-----+
| Table | Op | Msg_type | Msg_text |
+-----+-----+-----+-----+
| test.csvtest | check | warning | Table is marked as crashed |
| test.csvtest | check | status | OK |
+-----+-----+-----+-----+
2 rows in set (0.08 sec)
```

To repair a table you can use `REPAIR`, this copies as many valid rows from the existing CSV data as possible, and then replaces the existing CSV file with the recovered rows. Any rows beyond the corrupted data are lost.

```
mysql> repair table csvtest;
+-----+-----+-----+-----+
| Table | Op | Msg_type | Msg_text |
+-----+-----+-----+-----+
| test.csvtest | repair | status | OK |
+-----+-----+-----+-----+
1 row in set (0.02 sec)
```

### Warning

Note that during repair, only the rows from the CSV file up to the first damaged row are copied to the new table. All other rows from the first damaged row to the end of the table are removed, even valid rows.

## 13.13.2. CSV Limitations

### Important

The `CSV` storage engine does not support indexing.

Partitioning is not supported for tables using the `CSV` storage engine. Beginning with MySQL 5.1.12, it is no longer possible to create partitioned `CSV` tables. (See [Bug#19307](#))

Beginning with MySQL 5.1.23, tables using the `CSV` storage engine can no longer be created with `NULL` columns. However, for backward compatibility, you can continue to use such tables that were created in previous MySQL releases. ([Bug#32050](#))

## 13.14. The `BLACKHOLE` Storage Engine

The `BLACKHOLE` storage engine acts as a “black hole” that accepts data but throws it away and does not store it. Retrievals always return an empty result:

```
mysql> CREATE TABLE test(i INT, c CHAR(10)) ENGINE = BLACKHOLE;
Query OK, 0 rows affected (0.03 sec)

mysql> INSERT INTO test VALUES(1,'record one'),(2,'record two');
Query OK, 2 rows affected (0.00 sec)
Records: 2 Duplicates: 0 Warnings: 0

mysql> SELECT * FROM test;
Empty set (0.00 sec)
```

To enable the `BLACKHOLE` storage engine if you build MySQL from source, invoke `configure` with the `-with-blackhole-storage-engine` option.

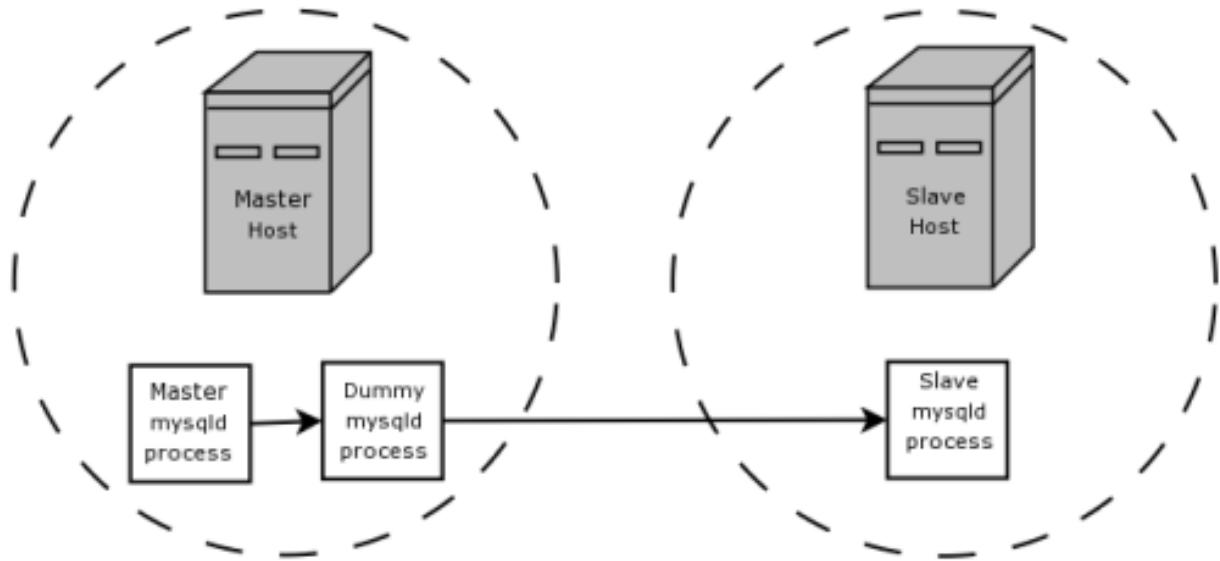

To examine the source for the `BLACKHOLE` engine, look in the `sql` directory of a MySQL source distribution.

When you create a `BLACKHOLE` table, the server creates a table format file in the database directory. The file begins with the table name and has an `.frm` extension. There are no other files associated with the table.

The `BLACKHOLE` storage engine supports all kinds of indexes. That is, you can include index declarations in the table definition.

You can check whether the `BLACKHOLE` storage engine is available with the `SHOW ENGINES` statement.

Inserts into a `BLACKHOLE` table do not store any data, but if the binary log is enabled, the SQL statements are logged (and replicated to slave servers). This can be useful as a repeater or filter mechanism. Suppose that your application requires slave-side filtering rules, but transferring all binary log data to the slave first results in too much traffic. In such a case, it is possible to set up on the master host a “dummy” slave process whose default storage engine is `BLACKHOLE`, depicted as follows:

The master writes to its binary log. The “dummy” `mysqld` process acts as a slave, applying the desired combination of `replicate-do-*` and `replicate-ignore-*` rules, and writes a new, filtered binary log of its own. (See [Section 16.1.3, “Replication and Binary Logging Options and Variables”](#).) This filtered log is provided to the slave.

The dummy process does not actually store any data, so there is little processing overhead incurred by running the additional `mysqld` process on the replication master host. This type of setup can be repeated with additional replication slaves.

`INSERT` triggers for `BLACKHOLE` tables work as expected. However, because the `BLACKHOLE` table does not actually store any data, `UPDATE` and `DELETE` triggers are not activated: The `FOR EACH ROW` clause in the trigger definition does not apply because there are no rows.

Other possible uses for the `BLACKHOLE` storage engine include:

- Verification of dump file syntax.
- Measurement of the overhead from binary logging, by comparing performance using `BLACKHOLE` with and without binary logging enabled.
- `BLACKHOLE` is essentially a “no-op” storage engine, so it could be used for finding performance bottlenecks not related to the storage engine itself.

The `BLACKHOLE` storage engine does not support `INSERT DELAYED`, `LOCK TABLES`, or `UNLOCK TABLES` statements prior to MySQL 5.1.19.

As of MySQL 5.1.4, the `BLACKHOLE` engine is transaction-aware, in the sense that committed transactions are written to the binary log and rolled-back transactions are not.

### Blackhole Engine and Auto Increment Columns

The Blackhole engine is a no-op engine. Any operations performed on a table using Blackhole will have no effect. This should be born in mind when considering the behavior of primary key columns that auto increment. The engine will not automatically increment field values, and does not retain auto increment field state. This has important implications in replication.

Consider the following replication scenario where all three of the following conditions apply:

1. On a master server there is a blackhole table with an auto increment field that is a primary key.

2. On a slave the same table exists but using the MyISAM engine.
3. Inserts are performed into the master's table without explicitly setting the auto increment value in the `INSERT` statement itself or through using a `SET INSERT_ID` statement.

In this scenario replication will fail with a duplicate entry error on the primary key column.

In statement based replication, the value of `INSERT_ID` in the context event will always be the same. Replication will therefore fail due to trying insert a row with a duplicate value for a primary key column.

In row based replication, the value that the engine returns for the row always be the same for each insert. This will result in the slave attempting to replay two insert log entries using the same value for the primary key column, and so replication will fail.

### Column Filtering

When using row-based replication, (`binlog_format=ROW`), a slave where the last columns are missing from a table is supported, as described in the section [Section 16.4.1.7, “Replication with Differing Table Definitions on Master and Slave”](#).

This filtering works on the slave side, that is, the columns are copied to the slave before they are filtered out. There are at least two cases where it is not desirable to copy the columns to the slave:

1. If the data is confidential, so the slave server should not have access to it.
2. If the master has many slaves, filtering before sending to the slaves may reduce network traffic.

Master column filtering can be achieved using the `BLACKHOLE` engine. This is carried out in a way similar to how master table filtering is achieved - by using the `BLACKHOLE` engine and the option `--replicate-[do|ignore]-table`.

The setup for the master is:

```
CREATE TABLE t1 (public_col_1, ..., public_col_N,
 secret_col_1, ..., secret_col_M) ENGINE=MyISAM;
```

The setup for the trusted slave is:

```
CREATE TABLE t1 (public_col_1, ..., public_col_N) ENGINE=BLACKHOLE;
```

The setup for the untrusted slave is:

```
CREATE TABLE t1 (public_col_1, ..., public_col_N) ENGINE=MyISAM;
```

---

# Chapter 14. High Availability and Scalability

When using MySQL you may need to ensure the availability or scalability of your MySQL installation. Availability refers to the ability to cope with, and if necessary recover from, failures on the host, including failures of MySQL, the operating system, or the hardware. Scalability refers to the ability to spread the load of your application queries across multiple MySQL servers. As your application and usage increases, you may need to spread the queries for the application across multiple servers to improve response times.

There are a number of solutions available for solving issues of availability and scalability. The two primary solutions supported by MySQL are MySQL Replication and MySQL Cluster. Further options are available using third-party solutions such as DRBD (Distributed Replicated Block Device) and Heartbeat, and more complex scenarios can be solved through a combination of these technologies. These tools work in different ways:

- *MySQL Replication* enables statements and data from one MySQL server instance to be replicated to another MySQL server instance. Without using more complex setups, data can only be replicated from a single master server to any number of slaves. The replication is asynchronous, so the synchronization does not take place in real time, and there is no guarantee that data from the master has been replicated to the slaves.

- **Advantages**

- MySQL Replication is available on all platforms supported by MySQL, and since it isn't operating system-specific it can operate across different platforms.
- Replication is asynchronous and can be stopped and restarted at any time, making it suitable for replicating over slower links, partial links and even across geographical boundaries.
- Data can be replicated from one master to any number of slaves, making replication suitable in environments with heavy reads, but light writes (for example, many web applications), by spreading the load across multiple slaves.

- **Disadvantages**

- Data can only be written to the master. In advanced configurations, though, you can set up a multiple-master configuration where the data is replicated around a ring configuration.
- There is no guarantee that data on master and slaves is consistent at a given point in time. Because replication is asynchronous, there may be a small delay between data being written to the master and it being available on the slaves. This can cause problems in applications where a write to the master must be available for a read on the slaves (for example a web application).

- **Recommended uses**

- Scale-out solutions that require a large number of reads but fewer writes (for example, web serving).
- Logging/data analysis of live data. By replicating live data to a slave you can perform queries on the slave without affecting the operation of the master.
- Online backup (availability), where you need an active copy of the data available. You need to combine this with other tools, such as custom scripts or Heartbeat. However, because of the asynchronous architecture, the data may be incomplete.
- Offline backup. You can use replication to keep a copy of the data. By replicating the data to a slave, you take the slave down and get a reliable snapshot of the data (without MySQL running), then restart MySQL and replication to catch up. The master (and any other slaves) can be kept running during this period.

For information on setting up and configuring replication, see [Chapter 16, Replication](#).

- *MySQL Cluster* is a synchronous solution that enables multiple MySQL instances to share database information. Unlike replication, data in a cluster can be read from or written to any node within the cluster, and information is distributed to the other nodes.

- **Advantages**

- Offers multiple read and write nodes for data storage.
- Provides automatic failover between nodes. Only transaction information for the active node being used is lost in the event of a failure.
- Data on nodes is instantaneously distributed to the other data nodes.

- **Disadvantages**

- Available on a limited range of platforms.
- Nodes within a cluster should be connected through a LAN; geographically separate nodes are not supported. However, you can replicate from one cluster to another using MySQL Replication, although the replication in this case is still asynchronous.

- **Recommended uses**

- Applications that need very high availability, such as telecoms and banking.
- Applications that require an equal or higher number of writes compared to reads.

For information on MySQL Cluster, see [Chapter 17, MySQL Cluster NDB 6.X/7.X](#).

- *DRBD (Distributed Replicated Block Device)* is a solution from Linbit supported only on Linux. DRBD creates a virtual block device (which is associated with an underlying physical block device) that can be replicated from the primary server to a secondary server. You create a file system on the virtual block device, and this information is then replicated, at the block level, to the secondary server.

Because the block device, not the data you are storing on it, is being replicated the validity of the information is more reliable than with data-only replication solutions. DRBD can also ensure data integrity by only returning from a write operation on the primary server when the data has been written to the underlying physical block device on both the primary and secondary servers.

- **Advantages**

- Provides high availability and data integrity across two servers in the event of hardware or system failure.
- Can ensure data integrity by enforcing write consistency on the primary and secondary nodes.

- **Disadvantages**

- Only provides a method for duplicating data across the nodes. Secondary nodes cannot use the DRBD device while data is being replicated, and so the MySQL on the secondary node cannot be simultaneously active.
- Can not be used to scale performance, since you can not redirect reads to the secondary node.

- **Recommended uses**

- High availability situations where concurrent access to the data is not required, but instant access to the active data in the event of a system or hardware failure is required.

For information on configuring DRBD and configuring MySQL for use with a DRBD device, see [Section 14.1, “Using MySQL with DRBD”](#).

- *memcached* is a simple, yet highly scalable key-based cache that stores data and objects wherever dedicated or spare RAM is available for very quick access by applications. You use *memcached* in combination with your application and MySQL to reduce the number of reads from the database.

When writing your application, you first try to load the data from the *memcached* cache, if the data you are looking for cannot be found, you then load the data from the MySQL database as normal, and populate the cache with the information that you loaded. Because *memcached* can be used to store entire objects that might normally consist of multiple table lookups and aggregations, you can significantly increase the speed of your application because the requirement to load data directly from the database is reduced or even eliminated. Because the cache is entirely in RAM, the response time is very fast, and the information can be distributed among many servers to make the best use of any spare RAM capacity.

- **Advantages**

- Very fast, RAM based, cache.
- Reduces load on the MySQL server, allowing MySQL to concentrate on persistent storage and data writes.
- Highly distributable and scalable, allowing multiple servers to be part of the cache group.
- Highly portable - the *memcached* interface is supported by many languages and systems, including Perl, Python, PHP, Ruby, Java and the MySQL server.

- **Disadvantages**

- Data is not persistent - only use the cache to store information that can be reloaded from a MySQL database.
- Fault tolerance is implied, rather than explicit. If a `memcached` node fails, then your application must be capable of loading the data from MySQL and updating the cache.

#### • Recommended uses

- High scalability situations where you have a very high number of reads, particularly of complex data objects that can easily be cached in the final, usable, form directly within the cache.

For information on installing, configuring and using `memcached`, including using the many APIs available for communicating with `memcached`, see [Section 14.5, “Using MySQL with memcached”](#).

- *Heartbeat* is a software solution for Linux. It is not a data replication or synchronization solution, but a solution for monitoring servers and switching active MySQL servers automatically in the event of failure. Heartbeat needs to be combined with MySQL Replication or DRBD to provide automatic failover.

For more information on configuring Heartbeat for use with MySQL and DRBD, see [Section 14.2, “Using Linux HA Heartbeat”](#).

The information and suitability of the various technologies and different scenarios is summarized in the following table.

| Requirements                          | MySQL Replica-tion          | MySQL Replica-tion + Heartbeat | MySQL Heart-beat + DRBD                            | MySQL Cluster                             | MySQL + mem-cached |
|---------------------------------------|-----------------------------|--------------------------------|----------------------------------------------------|-------------------------------------------|--------------------|
| <b>Availability</b>                   |                             |                                |                                                    |                                           |                    |
| Automated IP failover                 | No                          | Yes                            | Yes                                                | No                                        | No                 |
| Automated database fail-over          | No                          | No                             | Yes                                                | Yes                                       | No                 |
| Typical failover time                 | User/ script-dependent      | Varies                         | < 30 seconds                                       | < 3 seconds                               | App dependent      |
| Automatic resynchronization of data   | No                          | No                             | Yes                                                | Yes                                       | No                 |
| Geographic redundancy support         | Yes                         | Yes                            | Yes, when combined with MySQL Replication          | Yes, when combined with MySQL Replication | No                 |
| <b>Scalability</b>                    |                             |                                |                                                    |                                           |                    |
| Built-in load balancing               | No                          | No                             | No                                                 | Yes                                       | Yes                |
| Supports Read-intensive applications  | Yes                         | Yes                            | Yes, when combined with MySQL Replication          | Yes                                       | Yes                |
| Supports Write-intensive applications | No                          | No                             | Yes                                                | Yes                                       | No                 |

## 14.1. Using MySQL with DRBD

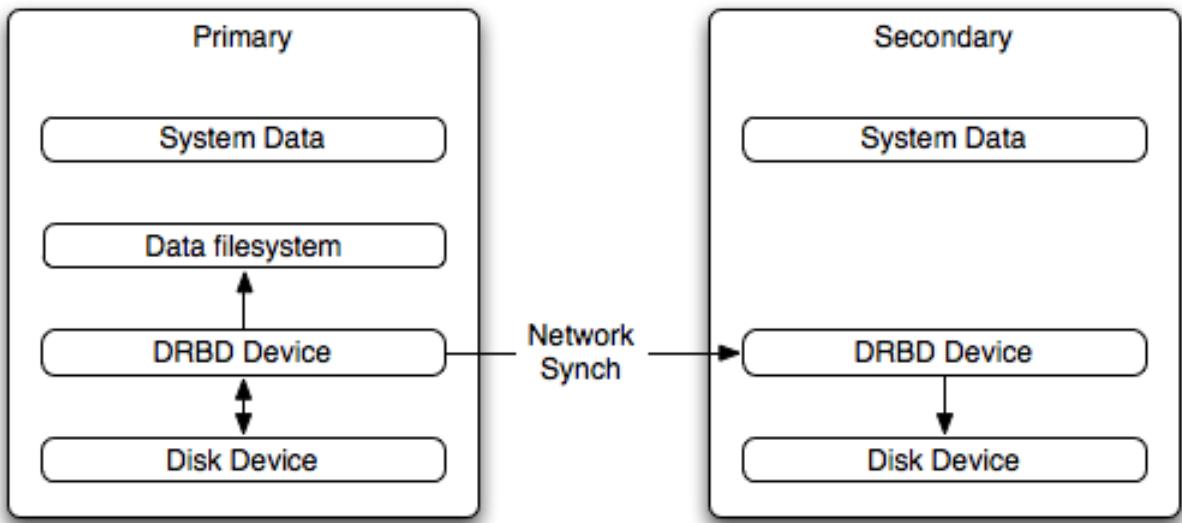

The Distributed Replicated Block Device (DRBD) is a Linux Kernel module that constitutes a distributed storage system. You can use DRBD to share block devices between Linux servers and, in turn, share file systems and data.

DRBD implements a block device which can be used for storage and which is replicated from a primary server to one or more secondary servers. The distributed block device is handled by the DRBD service. Writes to the DRBD block device are distributed among the servers. Each DRBD service writes the information from the DRBD block device to a local physical block device (hard disk).

On the primary data writes are written both to the underlying physical block device and distributed to the secondary DRBD ser-

vices. On the secondary, the writes received through DRBD and written to the local physical block device. On both the primary and the secondary, reads from the DRBD block device are handled by the underlying physical block device. The information is shared between the primary DRBD server and the secondary DRBD server synchronously and at a block level, and this means that DRBD can be used in high-availability solutions where you need failover support.

**Figure 14.1. DRBD Architecture Overview**

When used with MySQL, DRBD can be used to ensure availability in the event of a failure. MySQL is configured to store information on the DRBD block device, with one server acting as the primary and a second machine available to operate as an immediate replacement in the event of a failure.

For automatic failover support you can combine DRBD with the Linux Heartbeat project, which manages the interfaces on the two servers and automatically configures the secondary (passive) server to replace the primary (active) server in the event of a failure. You can also combine DRBD with MySQL Replication to provide both failover and scalability within your MySQL environment.

For information on how to configure DRBD and MySQL, including Heartbeat support, see [Section 14.1.1, “Configuring the DRBD Environment”](#).

An FAQ for using DRBD and MySQL is available. See [Section A.14, “MySQL 5.1 FAQ: MySQL, DRBD, and Heartbeat”](#).

#### Note

Because DRBD is a Linux Kernel module it is currently not supported on platforms other than Linux.

### 14.1.1. Configuring the DRBD Environment

To set up DRBD, MySQL and Heartbeat you need to follow a number of steps that affect the operating system, DRBD and your MySQL installation.

Before starting the installation process, be aware of the following information, terms and requirements on using DRBD:

- DRBD is a solution for enabling high-availability, and therefore you need to ensure that the two machines within your DRBD setup are as identically configured as possible so that the secondary machine can act as a direct replacement for the primary machine in the event of system failure.
- DRBD works through two (or more) servers, each called a *node*
- The node that contains the primary data, has read/write access to the data, and in an HA environment is the currently active node is called the *primary*.
- The server to which the data is replicated is referred as *secondary*.
- A collection of nodes that are sharing information are referred to as a *DRBD cluster*.

- For DRBD to operate you must have a block device on which the information can be stored on *each* DRBD node. The *lower level* block device can be a physical disk partition, a partition from a volume group or RAID device or any other block device.

Typically you use a spare partition on which the physical data is stored. On the primary node, this disk holds the raw data that you want replicated. On the secondary nodes, the disk holds the data replicated to the secondary server by the DRBD service. Ideally, the size of the partition on the two DRBD servers should be identical, but this is not necessary as long as there is enough space to hold the data that you want distributed between the servers.

- For the distribution of data to work, DRBD is used to create a logical block device that uses the lower level block device for the actual storage of information. To store information on the distributed device, a file system is created on the DRBD logical block device.
- When used with MySQL, once the file system has been created, you move the MySQL data directory (including InnoDB data files and binary logs) to the new file system.
- When you set up the secondary DRBD server, you set up the physical block device and the DRBD logical block device that stores the data. The block device data is then copied from the primary to the secondary server.

The overview for the installation and configuration sequence is as follows:

1. First you need to set up your operating system and environment. This includes setting the correct host name, updating the system and preparing the available packages and software required by DRBD, and configuring a physical block device to be used with the DRBD block device. See [Section 14.1.1.1, “Setting Up Your Operating System for DRBD”](#).
2. Installing DRBD requires installing or compiling the DRBD source code and then configuring the DRBD service to set up the block devices to be shared. See [Section 14.1.1.2, “Installing and Configuring DRBD”](#).
3. Once DRBD has been configured, you must alter the configuration and storage location of the MySQL data. See [Section 14.1.2, “Configuring MySQL for DRBD”](#).

You may optionally want to configure high availability using the Linux Heartbeat service. See [Section 14.2, “Using Linux HA Heartbeat”](#), for more information.

### 14.1.1.1. Setting Up Your Operating System for DRBD

To set your Linux environment for using DRBD there are a number of system configuration steps that you must follow.

- Make sure that the primary and secondary DRBD servers have the correct host name, and that the host names are unique. You can verify this by using the `uname` command:

```
shell> uname -n
drbd-one
```

If the host name is not set correctly, edit the appropriate file (usually `/etc/sysconfig/network`, `/etc/hostname`, or `/etc/conf.d/hostname`) and set the name correctly.

- Each DRBD node must have a unique IP address. Make sure that the IP address information is set correctly within the network configuration and that the host name and IP address has been set correctly within the `/etc/hosts` file.
- Although you can rely on the DNS or NIS system for host resolving, in the event of a major network failure these services may not be available. If possible, add the IP address and host name of each DRBD node into the `/etc/hosts` file for each machine. This ensures that the node information can always be determined even if the DNS/NIS servers are unavailable.
- As a general rule, the faster your network connection the better. Because the block device data is exchanged over the network, everything that is written to the local disk on the DRBD primary is also written to the network for distribution to the DRBD secondary.

For tips on configuring a faster network connection see [Section 14.1.3, “Optimizing Performance and Reliability”](#).

- You must have a spare disk or disk partition that you can use as the physical storage location for the DRBD data that is replicated. You do not have to have a complete disk available, a partition on an existing disk is acceptable.

If the disk is unpartitioned, partition the disk using `fdisk`, `cfdisk` or other partitioning solution. Do not create a file system on the new partition.

Remember that you must have a physical disk available for the storage of the replicated information on each DRBD node. Ensure that the physical partition on the DRBD secondary is at least as big as the partitions on the DRBD primary node. Ideally

the partitions that are used on each node should have identical sizes, although this is not strictly necessary.

- If possible, upgrade your system to the latest available Linux kernel for your distribution. Once the kernel has been installed, you must reboot to make the kernel active. To use DRBD, you must also install the relevant kernel development and header files that are required for building kernel modules. Platform specification information for this is available later in this section.

Before you compile or install DRBD, you must make sure the following tools and files are in place:

- Kernel header files
- Kernel source files
- GCC Compiler
- `glib 2`
- `flex`

Here are some operating system specific tips for setting up your installation:

- **Tips for Red Hat (including CentOS and Fedora):**

Use `up2date` or `yum` to update and install the latest kernel and kernel header files:

```
root-shell> up2date kernel-smp-devel kernel-smp
```

Reboot. If you are going to build DRBD from source, then update your system with the required development packages:

```
root-shell> up2date glib-devel openssl-devel libgcrypt-devel glib2-devel \
pkgconfig ncurses-devel rpm-build rpm-devel redhat-rpm-config gcc \
gcc-c++ bison flex gnutls-devel lm_sensors-devel net-snmp-devel \
python-devel bzip2-devel libselinux-devel perl-DBI
```

If you are going to use the pre-built DRBD RPMs:

```
root-shell> up2date gnutls lm_sensors net-snmp ncurses libgcrypt glib2 openssl glib
```

- **Tips for Debian, Ubuntu, Kubuntu:**

Use `apt-get` to install the kernel packages

```
root-shell> apt-get install linux-headers linux-image-server
```

If you are going to use the pre-built Debian packages for DRBD, you do not need any additional packages.

If you want to build DRBD from source, use the following command to install the required components:

```
root-shell> apt-get install devscripts flex bison build-essential \
dpkg-dev kernel-package debconf-utils dpatch debhelper \
libnet1-dev e2fslibs-dev libglib2.0-dev automake1.9 \
libgnutls-dev libtool libltdl3 libltdl3-dev
```

- **Tips for Gentoo:**

Gentoo is a source based Linux distribution and therefore many of the source files and components that you need are either already installed or are installed automatically by `emerge`.

To install DRBD 0.8.x, you must unmask the `sys-cluster/drbd` build by adding the following line to `/etc/portage/package.keywords`:

```
sys-cluster/drbd ~x86
sys-cluster/drbd-kernel ~x86
```

To enable the DRBD kernel module, you must rebuild your kernel, although the method depends on the kernel version you are using. Determine your current kernel version using `uname -a`.

- For Linux kernels lower than 2.6.33, enable the userspace kernelspace linker to build and load the DRBD kernel driver. To enable the kernelspace linker, rebuild the kernel with this option. The best way to do this is to use `genkernel` with the `--menuconfig` option to select the option and then rebuild the kernel. For example, at the command line as `root`:

```
root-shell> genkernel --menuconfig all
```

Then through the menu options, select DEVICE DRIVERS, CONNECTOR - UNIFIED USERSPACE <-> KERNELSPACE LINKER and finally press 'y' or 'space' to select the CONNECTOR - UNIFIED USERSPACE <-> KERNELSPACE LINKER option. After you exit the menu configuration, the kernel is rebuilt and installed. If this is a new kernel, update your bootloader to point to the kernel if the kernel version is different than your current kernel version. Now reboot to enable the new kernel.

- For Linux Kernel 2.6.33 and later, DRBD is included within the kernel sources. To enable the DRBD module you must rebuild your kernel. The best way to do this is to use `genkernel` with the `--menuconfig` option to select the option and then rebuild the kernel. For example, at the command line as `root`:

```
root-shell> genkernel --menuconfig all
```

Then through the menu options, select DEVICE DRIVERS, BLOCK DEVICES, and then DRBD DISTRIBUTED REPLICATED BLOCK DEVICE SUPPORT. After you exit the menu configuration, the kernel is rebuilt and installed. If this is a new kernel, update your bootloader to point to the kernel if the kernel version is different than your current kernel version. Now reboot to enable the new kernel.

#### 14.1.1.2. Installing and Configuring DRBD

To install DRBD you can choose either the pre-built binary installation packages or you can use the source packages and build from source. If you want to build from source you must have installed the source and development packages.

If you are installing using a binary distribution then you must ensure that the kernel version number of the binary package matches your currently active kernel. You can use `uname` to find out this information:

```
shell> uname -r
2.6.20-gentoo-r6
```

Once DRBD has been built and installed, you need to edit the `/etc/drbd.conf` file and then run a number of commands to build the block device and set up the replication.

Although the steps below are split into those for the primary node and the secondary node, it should be noted that the configuration files for all nodes should be identical, and many of the same steps have to be repeated on each node to enable the DRBD block device.

Building from source:

To download and install from the source code:

1. Download the source code.
2. Unpack the package:

```
shell> tar zxf drbd-8.3.0.tar.gz
```

3. Change to the extracted directory, and then run `make` to build the DRBD driver:

```
shell> cd drbd-8.3.0
shell> make
```

4. Install the kernel driver and commands:

```
shell> make install
```

Binary Installation:

- **SUSE Linux Enterprise Server (SLES)**

For SUSE, use `yast`:

```
shell> yast -i drbd
```

Alternatively:

```
shell> rug install drbd
```

- **Debian**

Use `apt-get` to install the modules. You do not need to install any other components.

```
shell> apt-get install drbd8-utils drbd8-module
```

- **Debian 3.1 and 4.0**

You must install the `module-assistant` to build the DRBD kernel module, in addition to the DRBD components.

```
shell> apt-get install drbd0.7-utils drbd0.7-module-source \
 build-essential module-assistant
shell> module-assistant auto-install drbd0.7
```

- **CentOS**

DRBD can be installed using yum:

```
shell> yum install drbd kmod-drbd
```

- **Ubuntu**

You must enable the universe component for your preferred Ubuntu mirror in `/etc/apt/sources.list`, and then issue these commands:

```
shell> apt-get update
shell> apt-get install drbd8-utils drbd8-module-source \
 build-essential module-assistant
shell> module-assistant auto-install drbd8
```

- **Gentoo**

You can now `emerge` DRBD 0.8.x into your Gentoo installation:

```
root-shell> emerge drbd
```

Once `drbd` has been downloaded and installed, you need to decompress and copy the default configuration file from `/usr/share/doc/drbd-8.0.7/drbd.conf.bz2` into `/etc/drbd.conf`.

### 14.1.1.3. Setting Up a DRBD Primary Node

To set up a DRBD primary node you need to configure the DRBD service, create the first DRBD block device and then create a file system on the device so that you can store files and data.

The DRBD configuration file `/etc/drbd.conf` defines a number of parameters for your DRBD configuration, including the frequency of updates and block sizes, security information and the definition of the DRBD devices that you want to create.

The key elements to configure are the `on` sections which specify the configuration of each node.

To follow the configuration, the sequence below shows only the changes from the default `drbd.conf` file. Configurations within the file can be both global or tied to specific resource.

1. Set the synchronization rate between the two nodes. This is the rate at which devices are synchronized in the background after a disk failure, device replacement or during the initial setup. Keep this in check compared to the speed of your network connection. Gigabit Ethernet can support up to 125 MB/second, 100Mbps Ethernet slightly less than a tenth of that (12MBps). If you are using a shared network connection, rather than a dedicated, then gauge accordingly.

To set the synchronization rate, edit the `rate` setting within the `syncer` block:

```
syncer {
 rate 10M;
```

```
}
```

You may additionally want to set the `al-extents` parameter. The default for this parameter is 257.

For more detailed information on synchronization, the effects of the synchronization rate and the effects on network performance, see [Section 14.1.3.2, “Optimizing the Synchronization Rate”](#).

2. Set up some basic authentication. DRBD supports a simple password hash exchange mechanism. This helps to ensure that only those hosts with the same shared secret are able to join the DRBD node group.

```
cram-hmac-alg "sha1";
shared-secret "shared-string";
```

3. Now you must configure the host information. Remember that you must have the node information for the primary and secondary nodes in the `drbd.conf` file on each host. You need to configure the following information for each node:

- `device`: The path of the logical block device that is created by DRBD.
- `disk`: The block device that stores the data.
- `address`: The IP address and port number of the host that holds this DRBD device.
- `meta-disk`: The location where the metadata about the DRBD device is stored. If you set this to `internal`, DRBD uses the physical block device to store the information, by recording the metadata within the last sections of the disk. The exact size depends on the size of the logical block device you have created, but it may involve up to 128MB.

A sample configuration for our primary server might look like this:

```
on drbd-one {
device /dev/drbd0;
disk /dev/hdd1;
address 192.168.0.240:8888;
meta-disk internal;
}
```

The `on` configuration block should be repeated for the secondary node (and any further) nodes:

```
on drbd-two {
device /dev/drbd0;
disk /dev/hdd1;
address 192.168.0.241:8888;
meta-disk internal;
}
```

The IP address of each `on` block must match the IP address of the corresponding host. Do not set this value to the IP address of the corresponding primary or secondary in each case.

4. Before starting the primary node, create the metadata for the devices:

```
root-shell> drbdadm create-md all
```

5. You are now ready to start DRBD:

```
root-shell> /etc/init.d/drbd start
```

DRBD should now start and initialize, creating the DRBD devices that you have configured.

6. DRBD creates a standard block device - to make it usable, you must create a file system on the block device just as you would with any standard disk partition. Before you can create the file system, you must mark the new device as the primary device (that is, where the data is written and stored), and initialize the device. Because this is a destructive operation, you must specify the command line option to overwrite the raw data:

```
root-shell> drbdadm -- --overwrite-data-of-peer primary all
```

If you are using a version of DRBD 0.7.x or earlier, then you need to use a different command-line option:

```
root-shell> drbdadm -- --do-what-I-say primary all
```

Now create a file system using your chosen file system type:

```
root-shell> mkfs.ext3 /dev/drbd0
```

7. You can now mount the file system and if necessary copy files to the mount point:

```
root-shell> mkdir /mnt/drbd
root-shell> mount /dev/drbd0 /mnt/drbd
root-shell> echo "DRBD Device" >/mnt/drbd/samplefile
```

Your primary node is now ready to use. Next, configure your secondary node or nodes.

#### 14.1.1.4. Setting Up a DRBD Secondary Node

The configuration process for setting up a secondary node is the same as for the primary node, except that you do not have to create the file system on the secondary node device, as this information is automatically transferred from the primary node.

To set up a secondary node:

1. Copy the [/etc/drbd.conf](#) file from your primary node to your secondary node. It should already contain all the information and configuration that you need, since you had to specify the secondary node IP address and other information for the primary node configuration.
2. Create the DRBD metadata on the underlying disk device:

```
root-shell> drbdadm create-md all
```

3. Start DRBD:

```
root-shell> /etc/init.d/drbd start
```

Once DRBD has started, it starts to copy the data from the primary node to the secondary node. Even with an empty file system this takes some time, since DRBD is copying the block information from a block device, not simply copying the file system data.

You can monitor the progress of the copy between the primary and secondary nodes by viewing the output of [/proc/drbd](#):

```
root-shell> cat /proc/drbd
version: 8.0.4 (api:86/proto:86)
SVN Revision: 2947 build by root@drbd-one, 2007-07-30 16:43:05
 0: cs:SyncSource st:Primary/Secondary ds:UpToDate/Inconsistent C r---
 ns:252284 nr:0 dw:0 dr:257280 al:0 bm:15 lo:0 pe:7 ua:157 ap:0
 [=>.....] sync'ed: 12.3% (1845088/2097152)K
 finish: 0:06:06 speed: 4,972 (4,580) K/sec
 resync: used:1/31 hits:15901 misses:16 starving:0 dirty:0 changed:16
 act_log: used:0/257 hits:0 misses:0 starving:0 dirty:0 changed:0
```

You can monitor the synchronization process by using the [watch](#) command to run the command at specific intervals:

```
root-shell> watch -n 10 'cat /proc/drbd'
```

#### 14.1.1.5. Monitoring DRBD Device

Once the primary and secondary machines are configured and synchronized, you can get the status information about your DRBD device by viewing the output from [/proc/drbd](#):

```
root-shell> cat /proc/drbd
version: 8.0.4 (api:86/proto:86)
SVN Revision: 2947 build by root@drbd-one, 2007-07-30 16:43:05
 0: cs:Connected st:Primary/Secondary ds:UpToDate/UpToDate C r---
 ns:2175704 nr:0 dw:99192 dr:2076641 al:33 bm:128 lo:0 pe:0 ua:0 ap:0
 resync: used:0/31 hits:134841 misses:135 starving:0 dirty:0 changed:135
 act_log: used:0/257 hits:24765 misses:33 starving:0 dirty:0 changed:33
```

The first line provides the version/revision and build information.

The second line starts the detailed status information for an individual resource. The individual field headings are as follows:

- cs: connection state

- st: node state (local/remote)
- ld: local data consistency
- ds: data consistency
- ns: network send
- nr: network receive
- dw: disk write
- dr: disk read
- pe: pending (waiting for ack)
- ua: unack'd (still need to send ack)
- al: access log write count

In the previous example, the information shown indicates that the nodes are connected, the local node is the primary (because it is listed first), and the local and remote data is up to date with each other. The remainder of the information is statistical data about the device, and the data exchanged that kept the information up to date.

You can also get the status information for DRBD by using the startup script with the `status` option:

```
root-shell> /etc/init.d/drbd status
 * status: started
 * drbd driver loaded OK; device status: ...
version: 8.3.0 (api:88/proto:86-89)
GIT-hash: 9ba8b93e24d842f0dd3fb1f9b90e8348ddb95829 build by root@gentool.vmbear, 2009-03-14 23:00:06
0: cs:Connected ro:Secondary/Secondary ds:UpToDate/UpToDate C r---
 ns:0 nr:0 dw:0 dr:8385604 al:0 bm:0 lo:0 pe:0 ua:0 ap:0 ep:1 wo:b oos:0
```

The information and statistics are the same.

#### 14.1.1.6. Managing your DRBD Installation

For administration, the main command is `drbdadm`. There are a number of commands supported by this tool to control the connectivity and status of the DRBD devices.

##### Note

For convenience, a bash completion script is available that provides tab completion for options to `drbdadm`. The file `drbdadm.bash_completion` can be found within the standard DRBD source package within the `scripts` directory. To enable, copy the file to `/etc/bash_completion.d/drbdadm`. You can load it manually by using:

```
shell> source /etc/bash_completion.d/drbdadm
```

The most common commands are those to set the primary/secondary status of the local device. You can manually set this information for a number of reasons, including when you want to check the physical status of the secondary device (since you cannot mount a DRBD device in primary mode), or when you are temporarily moving the responsibility of keeping the data in check to a different machine (for example, during an upgrade or physical move of the normal primary node). You can set state of all local device to be the primary using this command:

```
root-shell> drbdadm primary all
```

Or switch the local device to be the secondary using:

```
root-shell> drbdadm secondary all
```

To change only a single DRBD resource, specify the resource name instead of `all`.

You can temporarily disconnect the DRBD nodes:

```
root-shell> drbdadm disconnect all
```

Reconnect them using `connect`:

```
root-shell> drbdadm connect all
```

For other commands and help with `drbdadm` see the DRBD documentation.

### 14.1.1.7. Additional DRBD Configuration Options

Additional options you may want to configure:

- `protocol`: Specifies the level of consistency to be used when information is written to the block device. The option is similar in principle to the `innodb_flush_log_at_trx_commit` option within MySQL. Three levels are supported:
  - `A`: Data is considered written when the information reaches the TCP send buffer and the local physical disk. There is no guarantee that the data has been written to the remote server or the remote physical disk.
  - `B`: Data is considered written when the data has reached the local disk and the remote node's network buffer. The data has reached the remote server, but there is no guarantee it has reached the remote server's physical disk.
  - `C`: Data is considered written when the data has reached the local disk and the remote node's physical disk.

The preferred and recommended protocol is C, as it is the only protocol which ensures the consistency of the local and remote physical storage.

- `size`: If you do not want to use the entire partition space with your DRBD block device then you can specify the size of the DRBD device to be created. The size specification can include a quantifier. For example, to set the maximum size of the DRBD partition to 1GB you would use:

```
size 1G;
```

With the configuration file suitably configured and ready to use, you now need to populate the lower-level device with the metadata information, and then start the DRBD service.

### 14.1.2. Configuring MySQL for DRBD

Once you have configured DRBD and have an active DRBD device and file system, you can configure MySQL to use the chosen device to store the MySQL data.

When performing a new installation of MySQL, you can either select to install MySQL entirely onto the DRBD device, or just configure the data directory to be located on the new file system.

In either case, the files and installation must take place on the primary node, because that is the only DRBD node on which you can mount the DRBD device file system as read/write.

Store the following files and information on your DRBD device:

- MySQL data files, including the binary log, and InnoDB data files.
- MySQL configuration file (`my.cnf`).

To set up MySQL to use your new DRBD device and file system:

1. If you are migrating an existing MySQL installation, stop MySQL:

```
shell> mysqladmin shutdown
```

2. Copy the `my.cnf` onto the DRBD device. If you are not already using a configuration file, copy one of the sample configuration files from the MySQL distribution.

```
root-shell> mkdir /mnt/drbd/mysql
root-shell> cp /etc/my.cnf /mnt/drbd/mysql
```

3. Copy your MySQL data directory to the DRBD device and mounted file system.

```
root-shell> cp -R /var/lib/mysql /drbd/mysql/data
```

4. Edit the configuration file to reflect the change of directory by setting the value of the `datadir` option. If you have not already enabled the binary log, also set the value of the `log-bin` option.

```
datadir = /drbd/mysql/data
log-bin = mysql-bin
```

5. Create a symbolic link from `/etc/my.cnf` to the new configuration file on the DRBD device file system.

```
root-shell> ln -s /drbd/mysql/my.cnf /etc/my.cnf
```

6. Now start MySQL and check that the data that you copied to the DRBD device file system is present.

```
root-shell> /etc/init.d/mysql start
```

Your MySQL data should now be located on the file system running on your DRBD device. The data is physically stored on the underlying device that you configured for the DRBD device. Meanwhile, the content of your MySQL databases is copied to the secondary DRBD node.

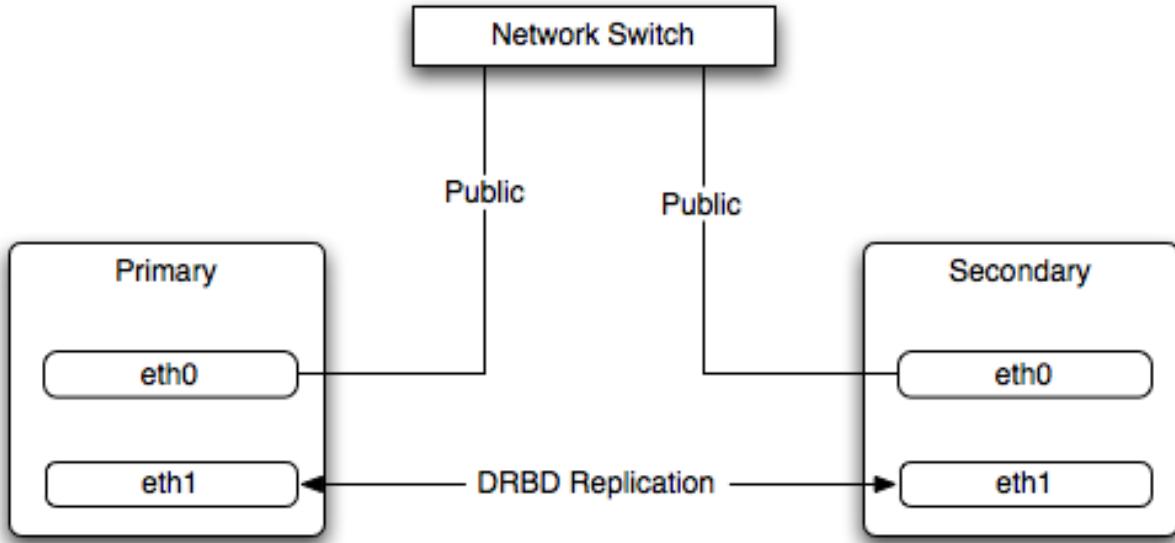

Note that you cannot access the information on your secondary node, as a DRBD device working in secondary mode is not available for use.

### 14.1.3. Optimizing Performance and Reliability

Because of the nature of the DRBD system, the critical requirements are for a very fast exchange of the information between the two hosts. To ensure that your DRBD setup is available to switch over in the event of a failure as quickly as possible, you must transfer the information between the two hosts using the fastest method available.

Typically, a dedicated network circuit should be used for exchanging DRBD data between the two hosts. Use a separate, additional, network interface for your standard network connection. For an example of this layout, see [Figure 14.2, “DRBD Architecture Using Separate Network Interfaces”](#).

**Figure 14.2. DRBD Architecture Using Separate Network Interfaces**

The dedicated DRBD network interfaces should be configured to use a nonrouted TCP/IP network configuration. For example, you might want to set the primary to use 192.168.0.1 and the secondary 192.168.0.2. These networks and IP addresses should not be part of normal network subnet.

**Note**

The preferred setup, whenever possible, is to use a direct cable connection (using a crossover cable with Ethernet, for example) between the two machines. This eliminates the risk of loss of connectivity due to switch failures.

#### 14.1.3.1. Using Bonded Ethernet Network Interfaces

For a set-up where there is a high-throughput of information being written, you may want to use bonded network interfaces. This is where you combine the connectivity of more than one network port, increasing the throughput linearly according to the number of bonded connections.

Bonding also provides an additional benefit in that with multiple network interfaces effectively supporting the same communications channel, a fault within a single network interface in a bonded group does not stop communication. For example, imagine you have a bonded setup with four network interfaces providing a single interface channel between two DRBD servers. If one network interface fails, communication can continue on the other three without interruption, although at a lower speed.

To enable bonded connections you must enable bonding within the kernel. You then need to configure the module to specify the bonded devices and then configure each new bonded device just as you would a standard network device:

- To configure the bonded devices, edit the `/etc/modprobe.conf` file (RedHat) or add a file to the `/etc/modprobe.d` directory. In each case, you define the parameters for the kernel module. First, specify each bonding device:

```
alias bond0 bonding
```

You can then configure additional parameters for the kernel module. Typical parameters are the `mode` option and the `miimon` option.

The `mode` option specifies how the network interfaces are used. The default setting is 0, which means that each network interface is used in a round-robin fashion (this supports aggregation and fault tolerance). Using setting 1 sets the bonding mode to active-backup. This means that only one network interface is used as a time, but that the link automatically fails over to a new interface if the primary interface fails. This settings only supports fault-tolerance.

The `miimon` option enables the MII link monitoring. A positive value greater than zero indicates the monitoring frequency in milliseconds for checking each slave network interface that is configured as part of the bonded interface. A typical value is 100.

You set these options within the module parameter file, and you must set the options for each bonded device individually:

```
options bond0 miimon=100 mode=1
```

- Reboot your server to enable the bonded devices.
- Configure the network device parameters. There are two parts to this, you need to setup the bonded device configuration, and then configure the original network interfaces as 'slaves' of the new bonded interface.
  - For RedHat Linux:

Edit the configuration file for the bonded device. For device `bond0` this would be `/etc/sysconfig/network-scripts/ifcfg-bond0`:

```
DEVICE=bond0
BOOTPROTO=none
ONBOOT=yes
GATEWAY=192.168.0.254
NETWORK=192.168.0.0
NETMASK=255.255.255.0
IPADDR=192.168.0.1
USERCTL=no
```

Then for each network interface that you want to be part of the bonded device, configure the interface as a slave to the 'master' bond. For example, the configuration of `eth0` in `/etc/sysconfig/network-scripts/ifcfg-eth0` might look like this::

```
DEVICE=eth0
BOOTPROTO=none
HWADDR=00:11:22:33:44:55
ONBOOT=yes
TYPE=Ethernet
MASTER=bond0
SLAVE=yes
```

- For Debian Linux:

Edit the `/etc/iftab` file and configure the logical name and MAC address for each devices. For example:

```
eth0 mac 00:11:22:33:44:55
```

Now you need to set the configuration of the devices in `/etc/network/interfaces`:

```
auto bond0
```

```
iface bond0 inet static
 address 192.168.0.1
 netmask 255.255.255.0
 network 192.168.0.0
 gateway 192.168.0.254
 up /sbin/ifenslave bond0 eth0
 up /sbin/ifenslave bond0 eth1
```

- For Gentoo:

Use `emerge` to add the `net-misc/ifenslave` package to your system.

Edit the `/etc/conf.d/net` file and specify the network interface slaves in a bond, the dependencies and then the configuration for the bond itself. A sample configuration might look like this:

```
slaves_bond0="eth0 eth1 eth2"
config_bond0=("192.168.0.1 netmask 255.255.255.0")
depend_bond0() {
 need net.eth0 net.eth1 net.eth2
}
```

Then make sure that you add the new network interface to list of interfaces configured during boot:

```
root-shell> rc-update add default net.bond0
```

Once the bonded devices are configured, reboot your systems.

You can monitor the status of a bonded connection using the `/proc` file system:

```
root-shell> cat /proc/net/bonding/bond0
Bonding Mode: fault-tolerance (active-backup)
Primary Slave: None
Currently Active Slave: eth1
MII Status: up
MII Polling Interval (ms): 100
Up Delay (ms): 200
Down Delay (ms): 200
Slave Interface: eth1
MII Status: up
Link Failure Count: 0
Permanent HW addr: 00:11:22:33:44:55
Slave Interface: eth2
MII Status: up
Link Failure Count: 0
Permanent HW addr: 00:11:22:33:44:56
```

### 14.1.3.2. Optimizing the Synchronization Rate

The `syncer rate` configuration parameter should be configured with care as the synchronization rate can have a significant effect on the performance of the DRBD setup in the event of a node or disk failure where the information is being synchronized from the Primary to the Secondary node.

In DRBD, there are two distinct ways of data being transferred between peer nodes:

- *Replication* refers to the transfer of modified blocks being transferred from the primary to the secondary node. This happens automatically when the block is modified on the primary node, and the replication process uses whatever bandwidth is available over the replication link. The replication process cannot be throttled, because you want to transfer of the block information to happen as quickly as possible during normal operation.
- *Synchronization* refers to the process of bringing peers back in sync after some sort of outage, due to manual intervention, node failure, disk swap, or the initial setup. Synchronization is limited to the `syncer rate` configured for the DRBD device.

Both replication and synchronization can take place at the same time. For example, the block devices can be synchronized while they are actively being used by the primary node. Any I/O that updates on the primary node automatically triggers replication of the modified block. In the event of a failure within an HA environment, it is highly likely that synchronization and replication will take place at the same time.

Unfortunately, if the synchronization rate is set too high, then the synchronization process uses up all the available network bandwidth between the primary and secondary nodes. In turn, the bandwidth available for replication of changed blocks is zero, which

stalls replication and blocks I/O, and ultimately the application fails or degrades.

To avoid enabling the `syncer rate` to consume the available network bandwidth and prevent the replication of changed blocks, set the `syncer rate` to less than the maximum network bandwidth.

Avoid setting the sync rate to more than 30% of the maximum bandwidth available to your device and network bandwidth. For example, if your network bandwidth is based on Gigabit ethernet, you should achieve 110MB/s. Assuming your disk interface is capable of handling data at 110MB/s or more, then the sync rate should be configured as `33M` (33MB/s). If your disk system works at a rate lower than your network interface, use 30% of your disk interface speed.

Depending on the application, you may wish to limit the synchronization rate. For example, on a busy server you may wish to configure a significantly slower synchronization rate to ensure the replication rate is not affected.

The `al-extents` parameter controls the number of 4MB blocks of the underlying disk that can be written to at the same time. Increasing this parameter lowers the frequency of the metadata transactions required to log the changes to the DRBD device, which in turn lowers the number of interruptions in your I/O stream when synchronizing changes. This can lower the latency of changes to the DRBD device. However, if a crash occurs on your primary, then all of the blocks in the activity log (that is, the number of `al-extents` blocks) must be completely resynchronized before replication can continue.

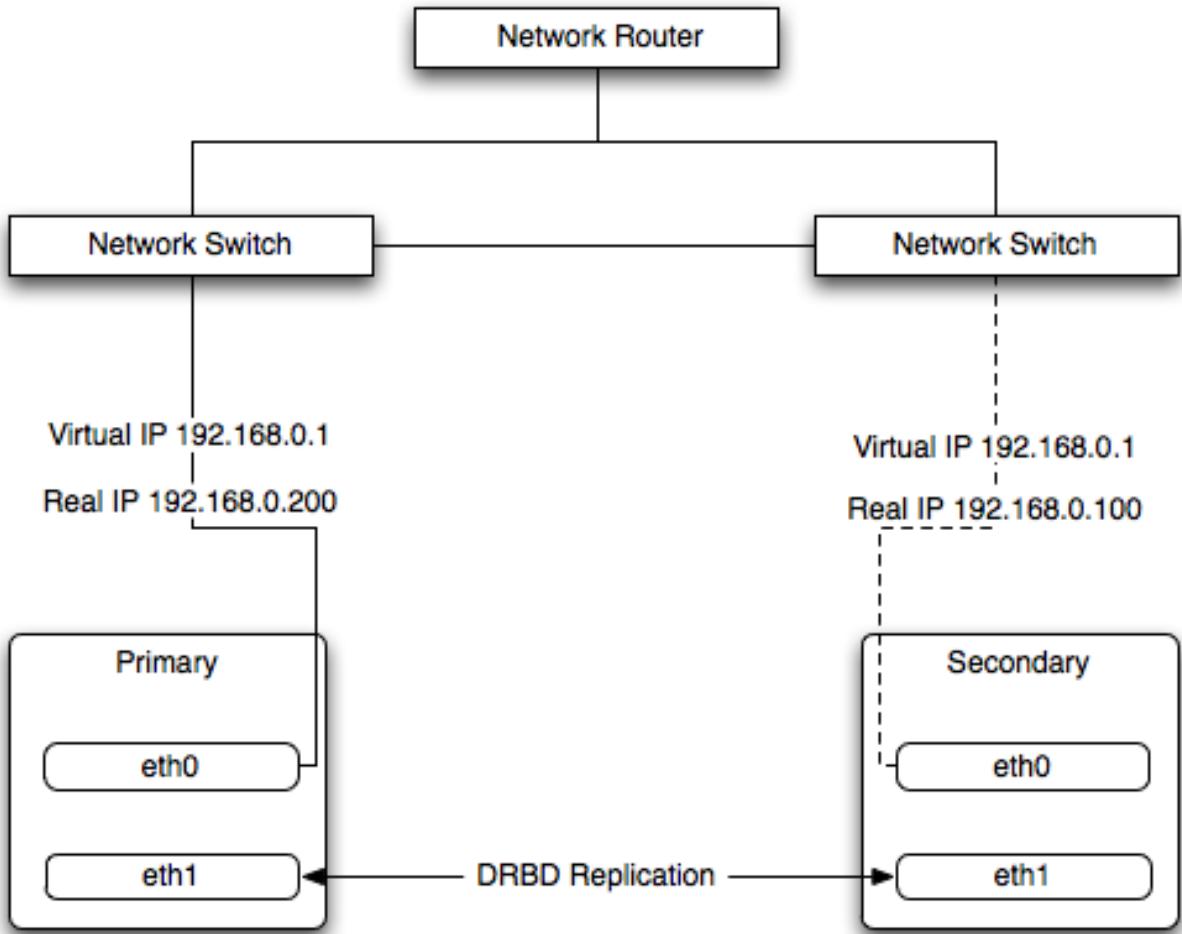

## 14.2. Using Linux HA Heartbeat

The Heartbeat program provides a basis for verifying the availability of resources on one or more systems within a cluster. In this context a resource includes MySQL, the file systems on which the MySQL data is being stored and, if you are using DRBD, the DRBD device being used for the file system. Heartbeat also manages a virtual IP address, and the virtual IP address should be used for all communication to the MySQL instance.

A cluster within the context of Heartbeat is defined as two computers notionally providing the same service. By definition, each computer in the cluster is physically capable of providing the same services as all the others in the cluster. However, because the cluster is designed for high-availability, only one of the servers is actively providing the service at any one time. Each additional server within the cluster is a “hot-spare” that can be brought into service in the event of a failure of the master, its next connectivity or the connectivity of the network in general.

The basics of Heartbeat are very simple. Within the Heartbeat cluster (see [Figure 14.3, “Heartbeat Architecture”](#), each machine sends a ‘heartbeat’ signal to the other hosts in the cluster. The other cluster nodes monitor this heartbeat. The heartbeat can be transmitted over many different systems, including shared network devices, dedicated network interfaces and serial connections. Failure to get a heartbeat from a node is treated as failure of the node. Although we do not know the reason for the failure (it could be an OS failure, a hardware failure in the server, or a failure in the network switch), it is safe to assume that if no heartbeat is produced there is a fault.

**Figure 14.3. Heartbeat Architecture**

In addition to checking the heartbeat from the server, the system can also check the connectivity (using `ping`) to another host on the network, such as the network router. This enables Heartbeat to detect a failure of communication between a server and the router (and therefore failure of the server, since it is no longer capable of providing the necessary service), even if the heartbeat between the servers in the clusters is working fine.

In the event of a failure, the resources on the failed host are disabled, and the resources on one of the replacement hosts is enabled instead. In addition, the Virtual IP address for the cluster is redirected to the new host in place of the failed device.

When used with MySQL and DRBD, the MySQL data is replicated from the master to the slave using the DRBD device, but MySQL is only running on the master. When the master fails, the slave switches the DRBD devices to be primary, the file systems on those devices are mounted, and MySQL is started. The original master (if still available) has its resources disabled, which means shutting down MySQL and unmounting the file systems and switching the DRBD device to secondary.

### 14.2.1. Heartbeat Configuration

Heartbeat configuration requires three files located in `/etc/ha.d`. The `ha.cf` contains the main heartbeat configuration, including the list of the nodes and times for identifying failures. `haresources` contains the list of resources to be managed within the cluster. The `authkeys` file contains the security information for the cluster.

The contents of these files should be identical on each host within the Heartbeat cluster. It is important that you keep these files in sync across all the hosts. Any changes in the information on one host should be copied to the all the others.

For these examples n example of the `ha.cf` file is shown below:

```
logfacility local0
keepalive 500ms
deadtime 10
warnetime 5
initdead 30
mcast bond0 225.0.0.1 694 2 0
mcast bond1 225.0.0.2 694 1 0
auto_fallback off
```

```
node drbd1
node drbd2
```

The individual lines in the file can be identified as follows:

- **logfacility**: Sets the logging, in this case setting the logging to use `syslog`.
- **keepalive**: Defines how frequently the heartbeat signal is sent to the other hosts.
- **deadtime**— the delay in seconds before other hosts in the cluster are considered 'dead' (failed).
- **warn time**: The delay in seconds before a warning is written to the log that a node cannot be contacted.
- **initdead**: The period in seconds to wait during system startup before the other host is considered to be down.
- **mcast**: Defines a method for sending a heartbeat signal. In the above example, a multicast network address is being used over a bonded network device. If you have multiple clusters then the multicast address for each cluster should be unique on your network. Other choices for the heartbeat exchange exist, including a serial connection.

If you are using multiple network interfaces (for example, one interface for your server connectivity and a secondary or bonded interface for your DRBD data exchange), use both interfaces for your heartbeat connection. This decreases the chance of a transient failure causing a invalid failure event.

- **auto\_fallback**: Sets whether the original (preferred) server should be enabled again if it becomes available. Switching this to `on` may cause problems if the preferred went offline and then comes back on line again. If the DRBD device has not been synced properly, or if the problem with the original server happens again you may end up with two different datasets on the two servers, or with a continually changing environment where the two servers flip-flop as the preferred server reboots and then starts again.
- **node**: Sets the nodes within the Heartbeat cluster group. There should be one `node` for each server.

An optional additional set of information provides the configuration for a ping test that checks the connectivity to another host. Use this to ensure that you have connectivity on the public interface for your servers, so the ping test should be to a reliable host such as a router or switch. The additional lines specify the destination machine for the `ping`, which should be specified as an IP address, rather than a host name; the command to run when a failure occurs, the authority for the failure and the timeout before an non-response triggers a failure. A sample configure is shown below:

```
ping 10.0.0.1
respawn hacluster /usr/lib64/heartbeat/ipfail
apiauth ipfail gid=haclient uid=hacluster
deadping 5
```

In the above example, the `ipfail` command, which is part of the Heartbeat solution, is called on a failure and 'fakes' a fault on the currently active server. You need to configure the user and group ID under which the command is executed (using the `apiauth`). The failure is triggered after 5 seconds.

### Note

The `deadping` value must be less than the `deadtime` value.

The `authkeys` file holds the authorization information for the Heartbeat cluster. The authorization relies on a single unique 'key' that is used to verify the two machines in the Heartbeat cluster. The file is used only to confirm that the two machines are in the same cluster and is used to ensure that the multiple clusters can co-exist within the same network.

## 14.2.2. Using Heartbeat with MySQL and DRBD

To use Heartbeat in combination with MySQL, use DRBD (see [Section 14.1, “Using MySQL with DRBD”](#)) or another solution that enables sharing the MySQL database files in event of a system failure. In these examples, DRBD is used as the data sharing solution.

Heartbeat manages the configuration of different resources to manage the switching between two servers in the event of a failure. The resource configuration defines the individual services that should be brought up (or taken down) in the event of a failure.

The `resources` file within `/etc/ha.d` defines the resources that should be managed, and the individual resource mentioned in this file in turn relates to scripts located within `/etc/ha.d/resource.d`. The resource definition is defined all on one line:

```
drbd1 drbddisk Filesystem:::/dev/drbd0:::drbd::ext3 mysql 10.0.0.100
```

The line is notionally split by whitespace. The first entry (`drbd1`) is the name of the preferred host; that is the server that is normally responsible for handling the service. The last field is virtual IP address or name that should be used to share the service. This is the IP address that should be used to connect to the MySQL server. It is automatically allocated to the server that is active when Heartbeat starts.

The remaining fields between these two fields define the resources that should be managed. Each Field should contain the name of the resource (and each name should refer to a script within `/etc/ha.d/resource.d`). In the event of a failure, these resources are started on the backup server by calling the corresponding script (with a single argument, `start`), in order from left to right. If there are additional arguments to the script, you can use a double colon to separate each additional argument.

In the above example, we manage the following resources:

- `drbddisk`: The DRBD resource script, this switches the DRBD disk on the secondary host into primary mode, making the device read/write.
- `Filesystem`: Manages the Filesystem resource. In this case we have supplied additional arguments to specify the DRBD device, mount point and file system type. When executed this should mount the specified file system.
- `mysql`: Manages the MySQL instances and starts the MySQL server. Copy the `mysql.resource` file from the `support-files` directory from any MySQL release into the `/etc/ha.d/resources.d` directory.

If this file is not available in your distribution, you can use the following as the contents of the `/etc/ha.d/resource.d/mysql.resource` file:

```
#!/bin/bash
#
This script is intended to be used as resource script by heartbeat
#
Mar 2006 by Monty Taylor
#
####

. /etc/ha.d/shellfuncs

case "$1" in
 start)
 res=`/etc/init.d/mysql start`
 ret=$?
 ha_log $res
 exit $ret
 ;;
 stop)
 res=`/etc/init.d/mysql stop`
 ret=$?
 ha_log $res
 exit $ret
 ;;
 status)
 if [[`ps -ef | grep '[m]ysqld'` > 1]]; then
 echo "running"
 else
 echo "stopped"
 fi
 ;;
 *)
 echo "Usage: mysql {start|stop|status}"
 exit 1
 ;;
esac

exit 0
```

If you want to be notified of the failure by email, you can add another line to the `haresources` file with the address for warnings and the warning text:

```
MailTo::youremail@address.com::DRBDFailure
```

With the Heartbeat configuration in place, copy the `haresources`, `authkeys` and `ha.cf` files from your primary and secondary servers to make sure that the configuration is identical. Then start the Heartbeat service, either by calling `/etc/init.d/heartbeat start` or by rebooting both primary and secondary servers.

You can test the configuration by running a manual failover, connect to the primary node and run:

```
root-shell> /usr/lib64/heartbeat/hb_standby
```

This causes the current node to relinquish its resources cleanly to the other node.

### 14.2.3. Using Heartbeat with DRBD and `dopd`

As a further extension to using DRBD and Heartbeat together, you can enable `dopd`. The `dopd` daemon handles the situation where a DRBD node is out of date compared to the master and prevents the slave from being promoted to master in the event of a failure. This stops a situation where you have two machines that have been masters ending up different data on the underlying device.

For example, imagine that you have a two server DRBD setup, master and slave. If the DRBD connectivity between master and slave fails, then the slave is out of sync with the master. If Heartbeat identifies a connectivity issue for master and then switches over to the slave, the slave DRBD device is promoted to the primary device, even though the data on the slave and the master is not in synchronization.

In this situation, with `dopd` enabled, the connectivity failure between the master and slave would be identified and the metadata on the slave would be set to `Outdated`. Heartbeat refuses to switch over to the slave even if the master failed. In a dual-host solution this would effectively render the cluster out of action, as there is no additional fail over server. In an HA cluster with three or more servers, control would be passed to the slave that has an up to date version of the DRBD device data.

To enable `dopd`, you need to modify the Heartbeat configuration and specify `dopd` as part of the commands executed during the monitoring process. Add the following lines to your `ha.cf` file:

```
respawn hacluster /usr/lib/heartbeat/dopd
apiauth dopd gid=haclient uid=hacluster
```

Make sure you make the same modification on both your primary and secondary nodes.

Reload the Heartbeat configuration:

```
root-shell> /etc/init.d/heartbeat reload
```

Modify your DRBD configuration by configuration the `outdate-peer` option. Add the configuration line into the `common` section of `/etc/drbd.conf` on both hosts. An example of the full block is shown below:

```
common {
 handlers {
 outdate-peer "/usr/lib/heartbeat/drbd-peer-outdater";
 }
}
```

Finally, set the `fencing` option on your DRBD configured resources:

```
resource my-resource {
 disk {
 fencing resource-only;
 }
}
```

Now reload your DRBD configuration:

```
root-shell> drbdadmin adjust all
```

You can test the system by unplugging your DRBD link and monitoring the output from `/proc/drbd`.

### 14.2.4. Dealing with System Level Errors

Because a kernel panic or oops may indicate potential problem with your server, configure your server to remove itself from the cluster in the event of a problem. Typically on a kernel panic, your system automatically triggers a hard reboot. For a kernel oops, a reboot may not happen automatically, but the issue that caused that oops may still lead to potential problems.

You can force a reboot by setting the `kernel.panic` and `kernel.panic_on_oops` parameters of the kernel control file `/etc/sysctl.conf`. For example:

```
kernel.panic_on_oops = 1
kernel.panic = 1
```

You can also set these parameters during runtime by using the `sysctl` command. You can either specify the parameters on the command line:

```
shell> sysctl -w kernel.panic=1
```

Or you can edit your `sysctl.conf` file and then reload the configuration information:

```
shell> sysctl -p
```

Setting both these parameters to a positive value (representing the number of seconds to wait before rebooting), causes the system to reboot. Your second heartbeat node should then detect that the server is down and then switch over to the failover host.

## 14.3. MySQL and Virtualization

Using virtualization can be an effective way of better utilizing the hardware of your machine when using MySQL, or to provide improved security or isolation of different instances of MySQL on the same machine. In some circumstances, virtualization may be a suitable solution for scaling out your database environment by enabling you to easily deploy additional instances of a pre-configured MySQL server and application environment to new virtualization hosts.

With any virtualization solution there is often a tradeoff between the flexibility and ease of deployment and performance, or between the potential performance advantage and complexities of effectively configuring multiple instances of MySQL to reside within a single physical host.

Different issues are experienced according to the virtualization environment you are using. Virtualization generally falls into one of the following categories:

- **Native virtualization**, including products like VMware Workstation, Parallels Desktop/Parallels Workstation, Microsoft Virtual PC and VirtualBox, all work by acting as an application that runs within an existing operating system environment. Recent versions can take advantage of the virtualization extensions in the Intel and AMD CPUs to help improve performance.

The application-based solutions have a number of advantages, including the ability to prioritize CPU usage (including multiple CPUs) and easily run multiple virtualized environments simultaneously.

With these solutions, you also have the ability to easily create a virtualized environment that can be packaged and shared among different virtualization hosts. For example, you can create a MySQL environment and configuration that can be deployed multiple times to help extend an existing scalability or HA environment.

The major disadvantage of this type of virtualization environment is the effect of the host on the performance of the virtualization instances. Disk storage is typically provided by using one or more files on the host OS which are then emulated to provide physical disks within the virtual instance. Other resources on the host are similarly shared, including CPU, network interfaces and additional devices (USB). It is also difficult to directly share lower-level components, such as PCI devices and that the ability to take advantage of RAID storage solutions.

- **Paravirtualization (Hypervisor)**, including Xen, Solaris xVM (based on Xen), VMware ESX Server, Windows Server 2008 Hyper-V, and Solaris Logical Domains (LDOM), work by running a specialized version of the host operating system. The host OS then enables slightly modified versions of different operating systems to run within the virtualized environment.

With paravirtualization, the level of performance and the control over the underlying hardware used to support the virtualized environments is higher than native virtualization solutions. For example, using paravirtualization you can dedicate individual CPU cores, RAM, disk drives and even PCI devices to be accessible to individual and specific virtual instances.

For example, within a paravirtualized environment you could dedicate a physical disk drive or subsystem to a particular virtual environment and gain a performance benefit over a typical file-based solution virtual disk.

- **Operating system-level virtualization**, including BSD jails, and Solaris Containers/Zones, offer methods for isolating different instances of an operating system environment while sharing the same hardware environment. Unlike the other virtualization solutions, operating system level virtualization is not normally used to run other operating systems, but instead to provide a level of security isolation and resource control within the core operating environment.

The isolation of these different instances is the key advantage of this type of virtualization. Each virtualized instance sees its environment as if it were completely different system. The solution can be an effective method to provide isolated computing resources for different departments or users, or to provide unique instances for testing and development.

The main reasons for using virtualization, particularly with a database or an application stack that includes a database component, include:

- **Security**: Separate instances of different operating systems running within a single host but with effective isolation from each other. When used with MySQL, you can provide an increased level of security between different instances of each server.
- **Consolidation**: Merging a number of individual systems with a relatively small load onto a single, larger, server. This can help reduce footprint and energy costs, or make more efficient use of a larger machine. Performance is the main issue with this solu-

tion as the load of many MySQL databases running in individual virtual instances on a single machine can be considerable.

- **Development/QA/Testing:** By creating different instances of different environments and operating systems you can test your MySQL-based application in different environments.
- **Scalability:** Although using virtualization imposes a performance hit, many virtualization solutions enable you to create a packaged version of an environment, including MySQL and the other application components. By distributing the virtualization environment package to new hosts you can often very quickly scale out by adding new hosts and deploying the virtualized environment.

The remainder of this chapter looks at common issues with using MySQL in a virtualized environment and tips for using MySQL within different virtualization tools.

For advice on common issues and problems, including performance and configuration issues, when using virtualized instances, see [Section 14.3.1, “Common Issues with Virtualization”](#).

### 14.3.1. Common Issues with Virtualization

There are many issues related to using MySQL within a virtualized environment that are common across the different virtualization types. Most are directly related to the performance or security of the environment in which you are deploying the MySQL server compared to the host on which you are running the virtualization solution.

Before deciding to use virtualization as a solution for your database, ensure that the expected load for the server and the expected performance when run in a virtualized environment meet your needs and requirements.

To help you determine the issues and some of the potential solutions, use the following sections:

- For general performance issues, problems and the probable causes, see [Section 14.3.1.1, “Virtualization Performance Issues”](#).
- Disk and storage concerns directly affect database storage because most database access is limited by the I/O bandwidth. For some examples and issues, see [Section 14.3.1.2, “Virtualization Storage Issues”](#).
- Issues related to network configuration and performance may need more careful planning, especially if you are using network-specific technologies such as MySQL replication. For further examples and details, see [Section 14.3.1.3, “Virtualization Networking Issues”](#).

#### 14.3.1.1. Virtualization Performance Issues

Often the biggest consideration is the performance of a virtualized environment once hosted. In most cases, the virtualized environment involves some level of emulation of one or more of the hardware interfaces (CPU, network or disk) of the host environment. The effect is to reduce the effective performance of the virtualized environment compared to running an application natively on the host.

Some core resourcing issues to be aware of include:

- Using virtualization does not reduce the amount of CPU required to support a particular application or environment. If your application stack requires 2GB of RAM on an individual machine, the same RAM requirement applies within your virtualized environment. The additional overhead of the virtualization layer and host operating system or environment often mean that you need 2.5GB or 3GB of RAM to run the same application within the virtualized environment.

Configure your virtualization environment with the correct RAM allocation according to your applications needs, and not to maximize the number of virtualized environments that you can execute within the virtualization host.

- Virtualization of the CPU resources is more complex. If your MySQL database and application stack do not have a high CPU load, then consolidating multiple environments onto a single host is often more efficient. Keep in mind that at peak times your application and database CPU requirement may need to grow beyond your default allocation.

With some virtualization environments (Xen, Solaris Containers, Solaris LDOMs) you can dedicate CPU or core to a virtual instance. Use this functionality to improve performance for database or application loads that have a high constant CPU requirement, as the performance benefit outweighs the flexibility of dynamic allocation of the CPU resources.

- Contention of resources within the host should be taken into account. In a system with high CPU loads, even when dedicating RAM and CPU resources, the I/O channels and interfaces to storage and networking resources may exceed the capacity of the host. Solutions such as Xen and Solaris LDOMs dedicate specific resources to individual virtual instances, but this does not eliminate the effects of the overall load on the host.

- If your database application is time sensitive, including logging and real-time database applications, or you are using MySQL Cluster, then the effects of virtualization may severely reduce the performance of your application. Because of the way the virtualized instances are executed and shared between CPUs and the effects of load on other resources, the response times for your database or application may be much higher than normal. This is especially true if you are running a large number of virtualized instances on a single host.
- Be aware of the limitation of using a single host to run multiple virtualized instances. In the event of a machine or component failure, the problem affects more than just one database instance. For example, a failure in a storage device could bring down all your virtualized instances. Using a RAID solution that supports fault tolerance (RAID levels 1,3,4,5 or 6) helps protect you from the effects of this.

### 14.3.1.2. Virtualization Storage Issues

Due to the random I/O nature of any database solution, running MySQL within a virtualized environment places a heavy load on the storage solution you are using. To help keep the performance of your virtualized solution at the highest level, use the following notes to help configure your systems.

- Some virtualization solutions permit you to use a physical disk directly within your virtual host as if it were a local disk. Use this whenever possible to ensure that disk contention issues do not affect the performance of your virtual environment.

When running multiple virtual machines, use an individual disk for each virtual instance. Using a single disk and multiple partitions, with each partition dedicated to a virtual host, leads to the same contention issues.
- If you are using standard file-based storage for your virtualized disks:
  - File-based storage is subject to fragmentation on the host disk. To prevent fragmentation, create a fixed-size disk (that is, one where the entire space for the disk file is preallocated) instead of a dynamic disk that grows with usage. Be prepared to defragment the disk hosting the files at regular intervals, to reduce the fragmentation.
  - Use separate disk files for the operating system and database disks, and try to avoid partitioning a disk file as this increases the contention within the file.
  - Use a high-performance disk solution, such as RAID or SAN, to store the disk files for your virtualized environments. This improves the performance of what is essentially a large single file on a physical device.
  - When running a number of different virtualized environments within a single host, do not use the same physical host drive for multiple virtual disks. Instead, spread the virtual disks among multiple physical disks. Even when using a RAID device, be aware that each virtual host is equivalent to increasing the load linearly on the host RAID device.

### 14.3.1.3. Virtualization Networking Issues

When running multiple virtual machines on a host, be aware of the networking implications of each virtualized instance. If your host machine has only one network card, then you share the networking throughput for all of your machines through only one card, and this can severely limit the performance of your virtual environments.

If possible, use multiple network cards to support your virtualized instances. Depending on the expected load of each instance, dedicate or spread the allocation of the virtual network devices across these physical devices to ensure that you do not reach saturation.

If you are using packaged virtual machines as the basis for deployment of your MySQL database solution, make sure that the network interfaces are correctly reconfigured. Some solutions duplicate the hardware MAC address, which causes problems when you start up additional instances of the same virtualized environment.

### 14.3.2. Using MySQL within an Amazon EC2 Instance

The Amazon Elastic Compute Cloud (EC2) service provides virtual servers that you can build and deploy to run a variety of different applications and services, including MySQL. The EC2 service is based around the Xen framework, supporting x86, Linux based, platforms with individual instances of a virtual machine referred to as an Amazon Machine Image (AMI). You have complete (root) access to the AMI instance that you create, enabling you to configure and install your AMI in any way you choose.

To use EC2, you create an AMI based on the configuration and applications that you want to use and upload the AMI to the Amazon Simple Storage Service (S3). From the S3 resource, you can deploy one or more copies of the AMI to run as an instance within the EC2 environment. The EC2 environment provides management and control of the instance and contextual information about the instance while it is running.

Because you can create and control the AMI, the configuration, and the applications, you can deploy and create any environment you choose. This includes a basic MySQL server in addition to more extensive replication, HA and scalability scenarios that enable you to take advantage of the EC2 environment, and the ability to deploy additional instances as the demand for your MySQL ser-

vices and applications grow.

To aid the deployment and distribution of work, three different Amazon EC2 instances are available, small (identified as `m1.small`), large (`m1.large`) and extra large (`m1.xlarge`). The different types provide different levels of computing power measured in EC2 computer units (ECU). A summary of the different instance configurations is shown here.

|                 | <b>Small</b> | <b>Large</b> | <b>Extra Large</b> |
|-----------------|--------------|--------------|--------------------|
| Platform        | 32-bit       | 64-bit       | 64-bit             |
| CPU cores       | 1            | 2            | 4                  |
| ECUs            | 1            | 4            | 8                  |
| RAM             | 1.7GB        | 7.5GB        | 15GB               |
| Storage         | 150GB        | 840GB        | 1680GB             |
| I/O Performance | Medium       | High         | High               |

The typical model for deploying and using MySQL within the EC2 environment is to create a basic AMI that you can use to hold your database data and application. Once the basic environment for your database and application has been created you can then choose to deploy the AMI to a suitable instance. Here the flexibility of having an AMI that can be re-deployed from the small to the large or extra large EC2 instance makes it easy to upgrade the hardware environment without rebuilding your application or database stack.

To get started with MySQL on EC2, including information on how to set up and install MySQL within an EC2 installation and how to port and migrate your data to the running instance, see [Section 14.3.2.1, “Setting Up MySQL on an EC2 AMI”](#).

For tips and advice on how to create a scalable EC2 environment using MySQL, including guides on setting up replication, see [Section 14.3.2.3, “Deploying a MySQL Database Using EC2”](#).

### 14.3.2.1. Setting Up MySQL on an EC2 AMI

There are many different ways of setting up an EC2 AMI with MySQL, including using any of the pre-configured AMIs supplied by Amazon.

The default *Getting Started* AMI provided by Amazon uses Fedora Core 4, and you can install MySQL by using `yum`:

```
shell> yum install mysql
```

This installs both the MySQL server and the Perl DBD::mysql driver for the Perl DBI API.

Alternatively, you can use one of the AMIs that include MySQL within the standard installation.

Finally, you can also install a standard version of MySQL downloaded from the MySQL Web site. The installation process and instructions are identical to any other installation of MySQL on Linux. See [Chapter 2, “Installing and Upgrading MySQL”](#).

The standard configuration for MySQL places the data files in the default location, `/var/lib/mysql`. The default data directory on an EC2 instance is `/mnt` (although on the large and extra large instance you can alter this configuration). You must edit `/etc/my.cnf` to set the `datadir` option to point to the larger storage area.

#### Important

The first time you use the main storage location within an EC2 instance it needs to be initialized. The initialization process starts automatically the first time you write to the device. You can start using the device right away, but the write performance of the new device is significantly lower on the initial writes until the initialization process has finished.

To avoid this problem when setting up a new instance, you should start the initialization process before populating your MySQL database. One way to do this is to use `dd` to write to the file system:

```
root-shell> dd if=/dev/zero of=initialize bs=1024M count=50
```

The preceding creates a 50GB on the file system and starts the initialization process. Delete the file once the process has finished.

The initialization process can be time-consuming. On the small instance, initialization takes between two and three hours. For the large and extra large drives, the initialization can be 10 or 20 hours, respectively.

In addition to configuring the correct storage location for your MySQL data files, also consider setting the following other settings

in your instance before you save the instance configuration for deployment:

- Set the MySQL server ID, so that when you use it for replication, the ID information is set correctly.
- Enabling binary logging, so that replication can be initialized without starting and stopping the server.
- Set the caching and memory parameters for your storage engines. There are no limitations or restrictions on what storage engines you use in your EC2 environment. Choose a configuration, possibly using one of the standard configurations provided with MySQL appropriate for the instance on which you expect to deploy. The large and extra large instances have RAM that can be dedicated to caching. Be aware that if you choose to install [memcached](#) on the servers as part of your application stack you must ensure there is enough memory for both MySQL and [memcached](#).

Once you have configured your AMI with MySQL and the rest of your application stack, save the AMI so that you can deploy and reuse the instance.

Once you have your application stack configured in an AMI, populating your MySQL database with data should be performed by creating a dump of your database using [mysqldump](#), transferring the dump to the EC2 instance, and then reloading the information into the EC2 instance database.

Before using your instance with your application in a production situation, be aware of the limitations of the EC2 instance environment. See [Section 14.3.2.2, “EC2 Instance Limitations”](#). To begin using your MySQL AMI, consult the notes on deployment. See [Section 14.3.2.3, “Deploying a MySQL Database Using EC2”](#).

### 14.3.2.2. EC2 Instance Limitations

Be aware of the following limitations of the EC2 instances before deploying your applications. Although these shouldn't affect your ability to deploy within the Amazon EC2 environment, they may alter the way you setup and configure your environment to support your application.

- Data stored within instances is not persistent. If you create an instance and populate the instance with data, then the data only remains in place while the machine is running, and does not survive a reboot. If you shut down the instance, any data it contained is lost.

To ensure that you do not lose information, take regular backups using [mysqldump](#). If the data being stored is critical, consider using replication to keep a “live” backup of your data in the event of a failure. When creating a backup, write the data to the Amazon S3 service to avoid the transfer charges applied when copying data offsite.

- EC2 instances are not persistent. If the hardware on which an instance is running fails, the instance is shut down. This can lead to loss of data or service.
- If you want to use replication with your EC2 instances to a non-EC2 environment, be aware of the transfer costs to and from the EC2 service. Data transfer between different EC2 instances is free, so using replication within the EC2 environment does not incur additional charges.
- Certain HA features are either not directly supported, or have limiting factors or problems that may reduce their utility. For example, using DRBD or MySQL Cluster may not work. The default storage configuration is also not redundant. You can use software-based RAID to improve redundancy, but this implies a further performance hit.

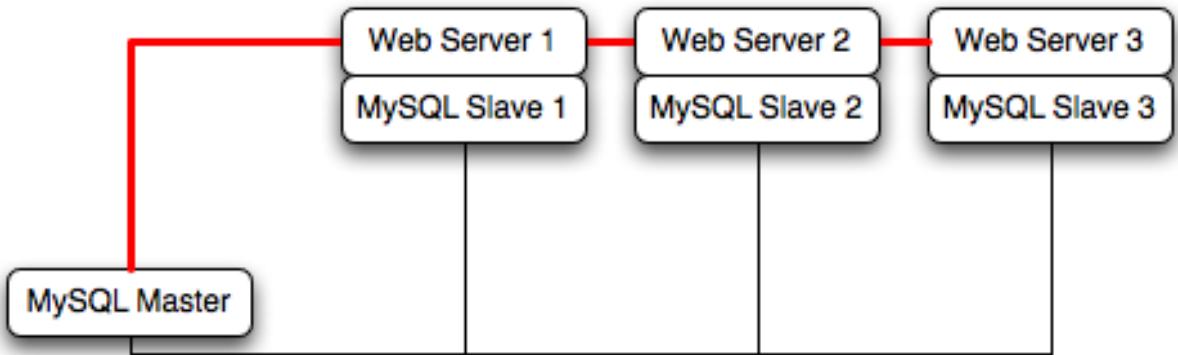

### 14.3.2.3. Deploying a MySQL Database Using EC2

Because you cannot guarantee the uptime and availability of your EC2 instances, when deploying MySQL within the EC2 environment, use an approach that enables you to easily distribute work among your EC2 instances. There are a number of ways of doing this. Using sharding techniques, where you split the application across multiple servers dedicating specific blocks of your dataset and users to different servers is an effective way of doing this. As a general rule, it is easier to create more EC2 instances to support more users than to upgrade the instance to a larger machine.

The EC2 architecture works best when you treat the EC2 instances as temporary, cache-based solutions, rather than as a long-term, high availability solution. In addition to using multiple machines, take advantage of other services, such as [memcached](#) to provide additional caching for your application to help reduce the load on the MySQL server so that it can concentrate on writes. On the large and extra large instances within EC2, the RAM available can provide a large memory cache for data.

Most types of scale-out topology that you would use with your own hardware can be used and applied within the EC2 environment. However, use the limitations and advice already given to ensure that any potential failures do not lose you any data. Also, because the relative power of each EC2 instance is so low, be prepared to alter your application to use sharding and add further EC2 instances to improve the performance of your application.

For example, take the typical scale-out environment shown following, where a single master replicates to one or more slaves (three in this example), with a web server running on each replication slave.

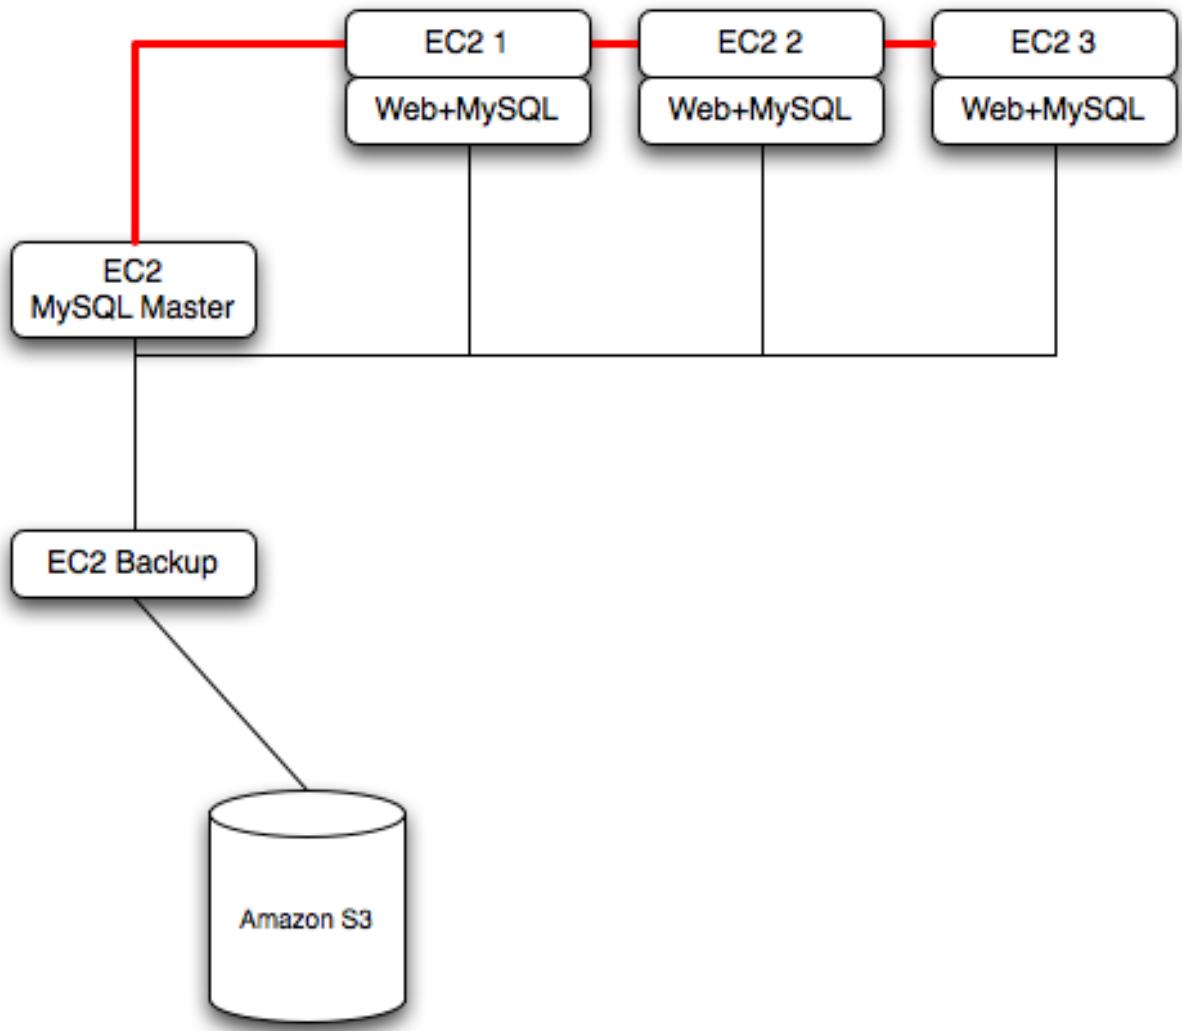

You can reproduce this structure completely within the EC2 environment, using an EC2 instance for the master, and one instance for each of the web and MySQL slave servers.

**Note**

Within the EC2 environment, internal (private) IP addresses used by the EC2 instances are constant. Always use these internal addresses and names when communicating between instances. Only use public IP addresses when communicating with the outside world - for example, when publicizing your application.

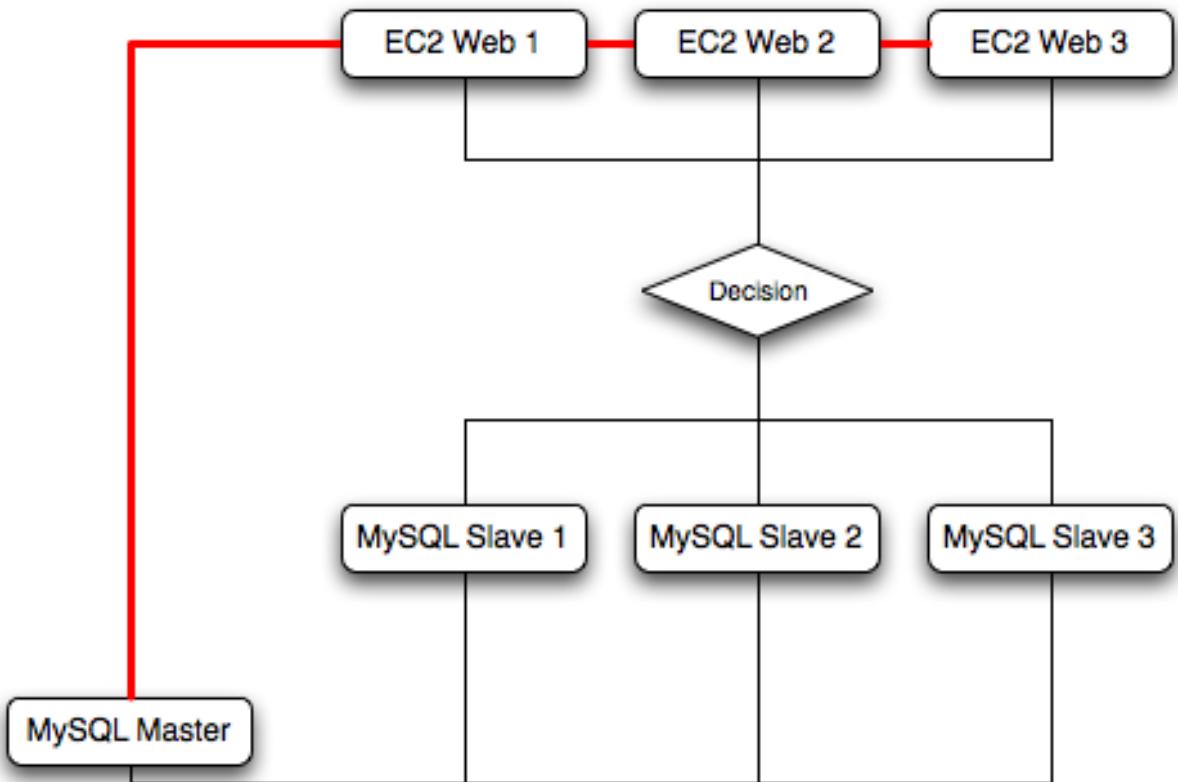

To ensure reliability of your database, add at least one replication slave dedicated to providing an active backup and storage to the Amazon S3 facility. You can see an example of this in the following topology.

Using [memcached](#) within your EC2 instances should provide better performance. The large and extra large instances have a significant amount of RAM. To use [memcached](#) in your application, when loading information from the database, first check whether the item exists in the cache. If the data you are looking for exists in the cache, use it. If not, reload the data from the database and populate the cache.

**Sharding** divides up data in your entire database by allocating individual machines or machine groups to provide a unique set of data according to an appropriate group. For example, you might put all users with a surname ending in the letters A-D onto a single server. When a user connects to the application and their surname is known, queries can be redirected to the appropriate MySQL server.

When using sharding with EC2, separate the web server and MySQL server into separate EC2 instances, and then apply the sharding decision logic into your application. Once you know which MySQL server you should be using for accessing the data you then distribute queries to the appropriate server. You can see a sample of this in the following illustration.

### Warning

With sharding and EC2, be careful that the potential for failure of an instance does not affect your application. If the EC2 instance that provides the MySQL server for a particular shard fails, then all of the data on that shard becomes unavailable.

#### 14.3.3. Virtualization Resources

For more information on virtualization, see the following links:

- [MySQL Virtualization Forum](#)
- [Amazon Elastic Compute Cloud \(Amazon EC2\)](#)
- <http://www.mysql.com/products/enterprise/cloud.html>
- <http://www.mysql.com/products/enterprise/ec2.html>

### 14.4. Using ZFS Replication

To support high availability environments, providing an instant copy of the information on both the currently active machine and the hot backup is a critical part of the HA solution. There are many solutions to this problem, including [Chapter 16, Replication](#) and [Section 14.1, “Using MySQL with DRBD”](#).

The ZFS filesystem provides functionality that enables you to create a snapshot of the filesystem contents and to then transfer the snapshot to another machine and extract the snapshot to recreate the filesystem. You can create a snapshot at any time, and you can create as many snapshots as you like. By continually creating, transferring and restoring snapshots you can provide synchronization between one or more machines in a fashion similar to DRBD.

To understand the replication solution within ZFS, you must first understand the ZFS environment. Below is a simple Solaris system running with a single ZFS pool, mounted at [/scratchpool](#):

| Filesystem      | size | used | avail | capacity | Mounted on |
|-----------------|------|------|-------|----------|------------|
| /dev/dsk/c0d0s0 | 4.6G | 3.7G | 886M  | 82%      | /          |
| /devices        | 0K   | 0K   | 0K    | 0%       | /devices   |

|                                |      |      |      |     |                   |
|--------------------------------|------|------|------|-----|-------------------|
| ctfs                           | 0K   | 0K   | 0K   | 0%  | /system/contract  |
| proc                           | 0K   | 0K   | 0K   | 0%  | /proc             |
| mnttab                         | 0K   | 0K   | 0K   | 0%  | /etc/mnttab       |
| swap                           | 1.4G | 892K | 1.4G | 1%  | /etc/svc/volatile |
| objfs                          | 0K   | 0K   | 0K   | 0%  | /system/object    |
| /usr/lib/libc/libc_hwcap1.so.1 | 4.6G | 3.7G | 886M | 82% | /lib/libc.so.1    |
| fd                             | 0K   | 0K   | 0K   | 0%  | /dev/fd           |
| swap                           | 1.4G | 40K  | 1.4G | 1%  | /tmp              |
| swap                           | 1.4G | 28K  | 1.4G | 1%  | /var/run          |
| /dev/dsk/c0d0s7                | 26G  | 913M | 25G  | 4%  | /export/home      |
| scratchpool                    | 16G  | 24K  | 16G  | 1%  | /scratchpool      |

The MySQL data is stored in a directory on `/scratchpool`. To help demonstrate some of the basic replication functionality, there are also other items stored in `/scratchpool` as well:

|            |    |      |      |    |                         |
|------------|----|------|------|----|-------------------------|
| total 17   |    |      |      |    |                         |
| drwxr-xr-x | 31 | root | bin  | 50 | Jul 21 07:32 DTT/       |
| drwxr-xr-x | 4  | root | bin  | 5  | Jul 21 07:32 SUNWmlib/  |
| drwxr-xr-x | 14 | root | sys  | 16 | Nov 5 09:56 SUNWspro/   |
| drwxrwxrwx | 19 | 1000 | 1000 | 40 | Nov 6 19:16 emacs-22.1/ |

To create a snapshot of the filesystem, you use `zfs snapshot`, and then specify the pool and the snapshot name:

```
root-shell> zfs snapshot scratchpool@snap1
```

To get a list of snapshots already taken:

```
root-shell> zfs list -t snapshot
NAME USED AVAIL REFER MOUNTPOINT
scratchpool@snap1 0 - 24.5K -
scratchpool@snap2 0 - 24.5K -
```

The snapshots themselves are stored within the filesystem metadata, and the space required to keep them varies as time goes on because of the way the snapshots are created. The initial creation of a snapshot is really quick, because instead of taking an entire copy of the data and metadata required to hold the entire snapshot, ZFS merely records the point in time and metadata of when the snapshot was created.

As more changes to the original filesystem are made, the size of the snapshot increases because more space is required to keep the record of the old blocks. Furthermore, if you create lots of snapshots, say one per day, and then delete the snapshots from earlier in the week, the size of the newer snapshots may also increase, as the changes that make up the newer state have to be included in the more recent snapshots, rather than being spread over the seven snapshots that make up the week.

The only issue, from a backup perspective, is that snapshots exist within the confines of the original filesystem. To get the snapshot out into a format that you can copy to another filesystem, tape, etc. you use the `zfs send` command to create a stream version of the snapshot.

For example, to write out the snapshot to a file:

```
root-shell> zfs send scratchpool@snap1 >/backup/scratchpool-snap1
```

Or tape:

```
root-shell> zfs send scratchpool@snap1 >/dev/rmt/0
```

You can also write out the incremental changes between two snapshots using `zfs send`:

```
root-shell> zfs send scratchpool@snap1 scratchpool@snap2 >/backup/scratchpool-changes
```

To recover a snapshot, you use `zfs recv` which applies the snapshot information either to a new filesystem, or to an existing one.

#### 14.4.1. Using ZFS for Filesystem Replication

Because `zfs send` and `zfs recv` use streams to exchange data, you can use them to replicate information from one system to another by combining `zfs send`, `ssh`, and `zfs recv`.

For example, if a snapshot of the `scratchpool` filesystem has been created and this needs to be copied to a new system or filesystem called `slavepool`. You would use the following command, combining the snapshot of `scratchpool`, the transmission to the slave machine (using `ssh`), and the recovery of the snapshot on the slave using `zfs recv`:

```
root-shell> zfs send scratchpool@snap1 | ssh mc@slave pfexec zfs recv -F slavepool
```

The first part, `zfs send scratchpool@snap1`, streams the snapshot, the second, `ssh mc@slave`, and the third, `pfexec zfs recv -F slavepool`, receives the streamed snapshot data and writes it to slavepool. In this instance, I've specified the `-F` option which forces the snapshot data to be applied, and is therefore destructive. This is fine, as I'm creating the first version of my replicated filesystem.

On the slave machine, the replicated filesystem contains the exact same content:

```
root-shell> ls -al /slavepool/
total 23
drwxr-xr-x 6 root root 7 Nov 8 09:13 .
drwxr-xr-x 29 root root 34 Nov 9 07:06 ..
drwxr-xr-x 31 root bin 50 Jul 21 07:32 DTT/
drwxr-xr-x 4 root bin 5 Jul 21 07:32 SUNWmlib/
drwxr-xr-x 14 root sys 16 Nov 5 09:56 SUNWspro/
drwxrwxrwx 19 1000 1000 40 Nov 6 19:16 emacs-22.1/
```

Once a snapshot has been created, to synchronize the filesystem again, you need to create a new snapshot, and then use the incremental snapshot feature of `zfs send` to send the changes between the two snapshots to the slave machine again:

```
root-shell> zfs send -i scratchpool@snapshot1 scratchpool@snapshot2 | ssh mc@192.168.0.93 pfexec zfs recv slavepool
```

Without further modification, this operation fails, because the filesystem on the slave machine can currently be modified, and you can't apply the incremental changes to a destination filesystem that has changed. It is the metadata that has changed. The metadata about the filesystem, like the last time it was accessed - in this case, it is our `ls` that caused the problem.

To prevent changes on the slave filesystem, you must set the filesystem on the slave to be read-only:

```
root-shell> zfs set readonly=on slavepool
```

Setting `readonly` means that you cannot change the filesystem on the slave by normal means, including the filesystem metadata. Operations that would normally update metadata (like our `ls`) silently perform their function without attempting to update the filesystem state.

In essence, the slave filesystem is nothing but a static copy of the original filesystem. However, even when configured to be read-only, a filesystem can have snapshots applied to it. Now the filesystem is read only, re-run the initial copy:

```
root-shell> zfs send scratchpool@snap1 | ssh mc@slave pfexec zfs recv -F slavepool
```

Now you can make changes to the original filesystem and replicate them to the slave.

## 14.4.2. Configuring MySQL for ZFS Replication

Configuring MySQL on the source filesystem is a case of creating the data on the filesystem that you intend to replicate. The configuration file in the example below has been updated to use `/scratchpool/mysql-data` as the data directory, and now you can initialize the tables:

```
root-shell> mysql_install_db --defaults-file=/etc/mysql/5.0/my.cnf --user=mysql
```

To synchronize the initial information, perform a new snapshot and then send an incremental snapshot to the slave using `zfs send`:

```
root-shell> zfs snapshot scratchpool@snap2
root-shell> zfs send -i scratchpool@snap1 scratchpool@snap2 | ssh mc@192.168.0.93 pfexec zfs recv slavepool
```

Doublecheck that the slave has the data by looking at the MySQL data directory on the `slavepool`:

```
root-shell> ls -al /slavepool/mysql-data/
```

Now you can start up MySQL, create some data, and then replicate the changes using `zfs send/ zfs recv` to the slave to synchronize the changes.

The rate at which you perform the synchronization depends on your application and environment. The limitation is the speed required to perform the snapshot and then to send the changes over the network.

To automate the process, create a script that performs the snapshot, send, and receive operation, and then use `cron` to synchronize the changes at set times or intervals. For automated operations, see [Tim Foster's zfs replication tool](#).

## 14.4.3. Handling MySQL Recovery with ZFS

---

When using ZFS replication to provide a constant copy of your data, ensure that you can recover your tables, either manually or automatically, in the event of a failure of the original system.

In the event of a failure, follow this sequence:

1. Stop the script on the master, if it is still up and running.
2. Set the slave filesystem to be read/write:

```
root-shell> zfs set readonly=off slavepool
```

3. Start up `mysqld` on the slave. If you are using `InnoDB`, `Falcon` or `Maria` you get auto-recovery, if it is needed, to make sure the table data is correct, as shown here when I started up from our mid-INSERT snapshot:

```
InnoDB: The log sequence number in ibdata files does not match
InnoDB: the log sequence number in the ib_logfiles!
081109 15:59:59 InnoDB: Database was not shut down normally!
InnoDB: Starting crash recovery.
InnoDB: Reading tablespace information from the .ibd files...
InnoDB: Restoring possible half-written data pages from the doublewrite
InnoDB: buffer...
081109 16:00:03 InnoDB: Started; log sequence number 0 1142807951
081109 16:00:03 [Note] /slavepool/mysql-5.0.67-solaris10-1386/bin/mysqld: ready for connections.
Version: '5.0.67' socket: '/tmp/mysql.sock' port: 3306 MySQL Community Server (GPL)
```

On MyISAM, or other tables, you might need to run `REPAIR TABLE`, and you might even have lost some information. Use a recovery-capable storage engine and a regular synchronization schedule to reduce the risk for significant data loss.

## 14.5. Using MySQL with memcached

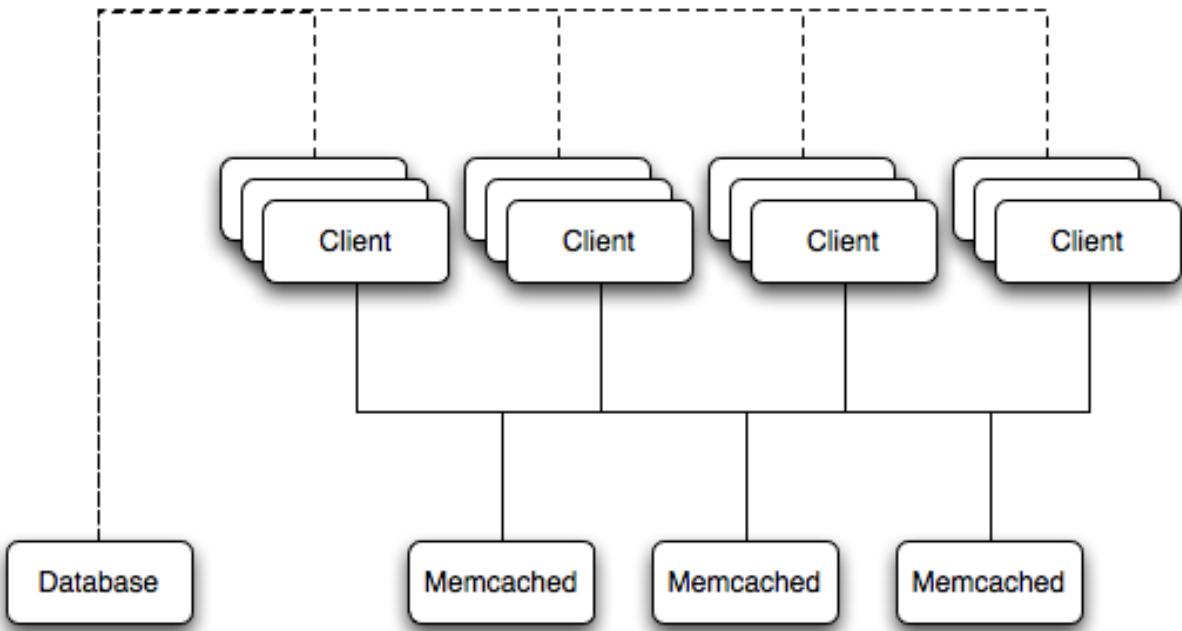

The largest problem with scalability within a typical environment is the speed with which you can access information. For frequently accessed information, using MySQL can be slow because each access of information requires execution of the SQL query and recovery of the information from the database. This also means that queries on tables that are locked or blocking may delay your query and reduce the speed of recovery of information.

`memcached` is a simple, yet highly scalable key-based cache that stores data and objects wherever dedicated or spare RAM is available for very quick access by applications. To use, you run `memcached` on one or more hosts and then use the shared cache to store objects. Because each host's RAM is storing information, the access speed is much faster than loading the information from disk. This can provide a significant performance boost in retrieving data versus loading the data natively from a database. Also, because the cache is just a repository for information, you can use the cache to store any data, including complex structures that would normally require a significant amount of effort to create, but in a ready-to-use format, helping to reduce the load on your MySQL servers.

The typical usage environment is to modify your application so that information is read from the cache provided by `memcached`. If the information isn't in `memcached`, then the data is loaded from the MySQL database and written into the cache so that future requests for the same object benefit from the cached data.

For a typical deployment layout, see [Figure 14.4, “memcached Architecture Overview”](#).

**Figure 14.4. memcached Architecture Overview**

In the example structure, any of the clients can contact one of the `memcached` servers to request a given key. Each client is configured to talk to all of the servers shown in the illustration. Within the client, when the request is made to store the information, the key used to reference the data is hashed and this hash is then used to select one of the `memcached` servers. The selection of the `memcached` server takes place on the client before the server is contacted, keeping the process lightweight.

The same algorithm is used again when a client requests the same key. The same key generates the same hash, and the same `memcached` server is selected as the source for the data. Using this method, the cached data is spread among all of the `memcached` servers, and the cached information is accessible from any client. The result is a distributed, memory-based, cache that can return information, particularly complex data and structures, much faster than natively reading the information from the database.

The data held within a `memcached` server is never stored on disk (only in RAM, which means there is no persistence of data), and the RAM cache is always populated from the backing store (a MySQL database). If a `memcached` server fails, the data can always be recovered from the MySQL database, albeit at a slower speed than loading the information from the cache.

### 14.5.1. Installing `memcached`

You can build and install `memcached` from the source code directly, or you can use an existing operating system package or installation.

#### Installing `memcached` from a Binary Distribution

To install `memcached` on a RedHat, or Fedora host, use `yum`:

```
root-shell> yum install memcached
```

#### Note

On CentOS, you may be able to obtain a suitable RPM from another source, or use the source tarball.

To install `memcached` on a Debian or Ubuntu host, use `apt-get`:

```
root-shell> apt-get install memcached
```

To install `memcached` on a Gentoo host, use `emerge`:

```
root-shell> emerge install memcached
```

#### Building `memcached` from Source

On other Unix-based platforms, including Solaris, AIX, HP-UX and Mac OS X, and Linux distributions not mentioned already, you must install from source. For Linux, make sure you have a 2.6-based kernel, which includes the improved `epoll` interface.

For all platforms, ensure that you have `libevent` 1.1 or higher installed. You can obtain `libevent` from [libevent web page](#).

You can obtain the source for `memcached` from [memcached Web site](#).

To build `memcached`, follow these steps:

1. Extract the `memcached` source package:

```
shell> gunzip -c memcached-1.2.5.tar.gz | tar xf -
```

2. Change to the `memcached-1.2.5` directory:

```
shell> cd memcached-1.2.5
```

3. Run `configure`

```
shell> ./configure
```

Some additional options you may want to specify to `configure`:

- `--prefix`

If you want to specify a different installation directory, use the `--prefix` option:

```
shell> ./configure --prefix=/opt
```

The default is to use the `/usr/local` directory.

- `--with-libevent`

If you have installed `libevent` and `configure` cannot find the library, use the `--with-libevent` option to specify the location of the installed library.

- `--enable-64bit`

To build a 64-bit version of `memcached` (which enables you to use a single instance with a large RAM allocation), use `--enable-64bit`.

- `--enable-threads`

To enable multi-threading support in `memcached`, which improves the response times on servers with a heavy load, use `--enable-threads`. You must have support for the POSIX threads within your operating system to enable thread support. For more information on the threading support, see [Section 14.5.2.7, “memcached thread Support”](#).

- `--enable-dtrace`

`memcached` includes a range of DTrace threads that can be used to monitor and benchmark a `memcached` instance. For more information, see [Section 14.5.2.5, “Using memcached and DTrace”](#).

4. Run `make` to build `memcached`:

```
shell> make
```

5. Run `make install` to install `memcached`:

```
shell> make install
```

## 14.5.2. Using `memcached`

To start using `memcached`, you must start the `memcached` service on one or more servers. Running `memcached` sets up the server, allocates the memory and starts listening for connections from clients.

### Note

You do not need to be privileged user (`root`) to run `memcached` unless you want to listen on one of the privileged TCP/IP ports (below 1024). You must, however, use a user that has not had their memory limits restricted using `setrlimit` or similar.

To start the server, run `memcached` as a nonprivileged (that is, non-`root`) user:

```
shell> memcached
```

By default, `memcached` uses the following settings:

- Memory allocation of 64MB
- Listens for connections on all network interfaces, using port 11211
- Supports a maximum of 1024 simultaneous connections

Typically, you would specify the full combination of options that you want when starting `memcached`, and normally provide a startup script to handle the initialization of `memcached`. For example, the following line starts `memcached` with a maximum of 1024MB RAM for the cache, listening on port 11211 on the IP address 192.168.0.110, running has a background daemon:

```
shell> memcached -d -m 1024 -p 11211 -l 192.168.0.110
```

To ensure that `memcached` is started up on boot, check the init script and configuration parameters.

`memcached` supports the following options:

- `-u user`

If you start `memcached` as `root`, use the `-u` option to specify the user for executing `memcached`:

```
shell> memcached -u memcache
```

- `-m memory`

Set the amount of memory allocated to `memcached` for object storage. Default is 64MB.

To increase the amount of memory allocated for the cache, use the `-m` option to specify the amount of RAM to be allocated (in megabytes). The more RAM you allocate, the more data you can store and therefore the more effective your cache is.

### Warning

Do not specify a memory allocation larger than your available RAM. If you specify too large a value, then some RAM allocated for `memcached` uses swap space, and not physical RAM. This may lead to delays when storing and retrieving values, because data is swapped to disk, instead of storing the data directly in RAM.

You can use the output of the `vmstat` command to get the free memory, as shown in `free` column:

```
shell> vmstat
 kthr memory page disk faults cpu
 r b w swap free re mf pi po fr de sr sl s2 -- -- in sy cs us sy id
 0 0 0 5170504 3450392 2 7 2 0 0 0 0 4 0 0 0 0 0 296 54 199 0 0 100
```

For example, to allocate 3GB of RAM:

```
shell> memcached -m 3072
```

On 32-bit x86 systems where you are using PAE to access memory above the 4GB limit, you cannot allocate RAM beyond the maximum process size. You can get around this by running multiple instances of `memcached`, each listening on a different port:

```
shell> memcached -m 1024 -p11211
shell> memcached -m 1024 -p11212
shell> memcached -m 1024 -p11213
```

### Note

On all systems, particularly 32-bit, ensure that you leave enough room for both `memcached` application in addition to the memory setting. For example, if you have a dedicated `memcached` host with 4GB of RAM, do not set the memory size above 3500MB. Failure to do this may cause either a crash or severe performance issues.

- `-l interface`

Specify a network interface/address to listen for connections. The default is to listen on all available address ([INADDR\\_ANY](#)).

```
shell> memcached -l 192.168.0.110
```

Support for IPv6 address support was added in [memcached](#) 1.2.5.

- [-p port](#)

Specify the TCP port to use for connections. Default is 18080.

```
shell> memcached -p 18080
```

- [-U port](#)

Specify the UDP port to use for connections. Default is 11211, 0 switches UDP off.

```
shell> memcached -U 18080
```

- [-s socket](#)

Specify a Unix socket to listen on.

If you are running [memcached](#) on the same server as the clients, you can disable the network interface and use a local UNIX socket using the [-s](#) option:

```
shell> memcached -s /tmp/memcached
```

Using a UNIX socket automatically disables network support, and saves network ports (allowing more ports to be used by your web server or other process).

- [-a mask](#)

Specify the access mask to be used for the Unix socket, in octal. Default is 0700.

- [-c connections](#)

Specify the maximum number of simultaneous connections to the [memcached](#) service. The default is 1024.

```
shell> memcached -c 2048
```

Use this option, either to reduce the number of connections (to prevent overloading [memcached](#) service) or to increase the number to make more effective use of the server running [memcached](#) server.

- [-t threads](#)

Specify the number of threads to use when processing incoming requests.

By default, [memcached](#) is configured to use 4 concurrent threads. The threading improves the performance of storing and retrieving data in the cache, using a locking system to prevent different threads overwriting or updating the same values. You may want to increase or decrease the number of threads, use the [-t](#) option:

```
shell> memcached -t 8
```

- [-d](#)

Run [memcached](#) as a daemon (background) process:

```
shell> memcached -d
```

- [-r](#)

Maximize the size of the core file limit. In the event of a failure, this attempts to dump the entire memory space to disk as a core file, up to any limits imposed by [setrlimit](#).

- [-M](#)

Return an error to the client when the memory has been exhausted. This replaces the normal behavior of removing older items from the cache to make way for new items.

- [-k](#)

Lock down all paged memory. This reserves the memory before use, instead of allocating new slabs of memory as new items are stored in the cache.

### Note

There is a user-level limit on how much memory you can lock. Trying to allocate more than the available memory fails. You can set the limit for the user you started the daemon with (not for the [-u user](#) user) within the shell by using `ulimit -S -l NUM_KB`

- [-v](#)

Verbose mode. Prints errors and warnings while executing the main event loop.

- [-vv](#)

Very verbose mode. In addition to information printed by [-v](#), also prints each client command and the response.

- [-vvv](#)

Extremely verbose mode. In addition to information printed by [-vv](#), also show the internal state transitions.

- [-h](#)

Print the help message and exit.

- [-i](#)

Print the `memcached` and `libevent` license.

- [-I mem](#)

Specify the maximum size permitted for storing an object within the `memcached` instance. The size supports a unit postfix (`k` for kilobytes, `m` for megabytes). For example, to increase the maximum supported object size to 32MB:

```
shell> memcached -I 32m
```

The maximum object size you can specify is 128MB, the default remains at 1MB.

This option was added in 1.4.2.

- [-b](#)

Set the backlog queue limit. The backlog queue configures how many network connections can be waiting to be processed by `memcached`. Increasing this limit may reduce errors received by the client that it is not able to connect to the `memcached` instance, but does not improve the performance of the server. The default is 1024.

- [-P pidfile](#)

Save the process ID of the `memcached` instance into `file`.

- [-f](#)

Set the chunk size growth factor. When allocating new memory chunks, the allocated size of new chunks is determined by multiplying the default slab size by this factor.

To see the effects of this option without extensive testing, use the [-vv](#) command-line option to show the calculated slab sizes. For more information, see [Section 14.5.2.8, “memcached Logs”](#).

- [-n bytes](#)

The minimum space allocated for the key+value+flags information. The default is 48 bytes.

- [-L](#)

On systems that support large memory pages, enables large memory page use. Using large memory pages enables `memcached` to allocate the item cache in one large chunk, which can improve the performance by reducing the number misses when accessing memory.

- [-C](#)

Disable the use of compare and swap (CAS) operations.

This option was added in `memcached` 1.3.x.

- `-D char`

Set the default character to be used as a delimiter between the key prefixes and IDs. This is used for the per-prefix statistics reporting (see [Section 14.5.4, “Getting memcached Statistics”](#)). The default is the colon (:). If this option is used, statistics collection is turned on automatically. If not used, you can enable stats collection by sending the `stats detail on` command to the server.

This option was added in `memcached` 1.3.x.

- `-R num`

Sets the maximum number of requests per event process. The default is 20.

- `-B protocol`

Set the binding protocol, that is, the default `memcached` protocol support for client connections. Options are `ascii`, `binary` or `auto`. Automatic (`auto`) is the default.

This option was added in `memcached` 1.4.0.

### 14.5.2.1. `memcached` Deployment

When using `memcached` you can use a number of different potential deployment strategies and topologies. The exact strategy to use depends on your application and environment. When developing a system for deploying `memcached` within your system, keep in mind the following points:

- `memcached` is only a caching mechanism. It shouldn't be used to store information that you cannot otherwise afford to lose and then load from a different location.
- There is no security built into the `memcached` protocol. At a minimum, make sure that the servers running `memcached` are only accessible from inside your network, and that the network ports being used are blocked (using a firewall or similar). If the information on the `memcached` servers that is being stored is any sensitive, then encrypt the information before storing it in `memcached`.
- `memcached` does not provide any sort of failover. Because there is no communication between different `memcached` instances. If an instance fails, your application must capable of removing it from the list, reloading the data and then writing data to another `memcached` instance.
- Latency between the clients and the `memcached` can be a problem if you are using different physical machines for these tasks. If you find that the latency is a problem, move the `memcached` instances to be on the clients.
- Key length is determined by the `memcached` server. The default maximum key size is 250 bytes.
- Using a single `memcached` instance, especially for multiple clients, is generally a bad idea as it introduces a single point of failure. Instead provide at least two `memcached` instances so that a failure can be handled appropriately. If possible, you should create as many `memcached` nodes as possible. When adding and removing `memcached` instances from a pool, the hashing and distribution of key/value pairs may be affected. For information on how to avoid problems, see [Section 14.5.2.4, “memcached Hashing/Distribution Types”](#).

### 14.5.2.2. Using namespaces

The `memcached` cache is a very simple massive key/value storage system, and as such there is no way of compartmentalizing data automatically into different sections. For example, if you are storing information by the unique ID returned from a MySQL database, then storing the data from two different tables could run into issues because the same ID might be valid in both tables.

Some interfaces provide an automated mechanism for creating *namespaces* when storing information into the cache. In practice, these namespaces are merely a prefix before a given ID that is applied every time a value is stored or retrieve from the cache.

You can implement the same basic principle by using keys that describe the object and the unique identifier within the key that you supply when the object is stored. For example, when storing user data, prefix the ID of the user with `user:` or `user-`.

#### Note

Using namespaces or prefixes only controls the keys stored/retrieved. There is no security within `memcached`, and therefore no way to enforce that a particular client only accesses keys with a particular namespace. Namespaces are only useful as a method of identifying data and preventing corruption of key/value pairs.

### 14.5.2.3. Data Expiry

There are two types of data expiry within a `memcached` instance. The first type is applied at the point when you store a new key/value pair into the `memcached` instance. If there is not enough space within a suitable slab to store the value, then an existing least recently used (LRU) object is removed (evicted) from the cache to make room for the new item.

The LRU algorithm ensures that the object that is removed is one that is either no longer in active use or that was used so long ago that its data is potentially out of date or of little value. However, in a system where the memory allocated to `memcached` is smaller than the number of regularly used objects required in the cache, a lot of expired items could be removed from the cache even though they are in active use. You use the statistics mechanism to get a better idea of the level of evictions (expired objects). For more information, see [Section 14.5.4, “Getting memcached Statistics”](#).

You can change this eviction behavior by setting the `-M` command-line option when starting `memcached`. This option forces an error to be returned when the memory has been exhausted, instead of automatically evicting older data.

The second type of expiry system is an explicit mechanism that you can set when a key/value pair is inserted into the cache, or when deleting an item from the cache. Using an expiration time can be a useful way of ensuring that the data in the cache is up to date and in line with your application needs and requirements.

A typical scenario for explicitly setting the expiry time might include caching session data for a user when accessing a Web site. `memcached` uses a lazy expiry mechanism where the explicit expiry time that has been set is compared with the current time when the object is requested. Only objects that have not expired are returned.

You can also set the expiry time when explicitly deleting an object from the cache. In this case, the expiry time is really a timeout and indicates the period when any attempts to set the value for a given key are rejected.

### 14.5.2.4. memcached Hashing/Distribution Types

The `memcached` client interface supports a number of different distribution algorithms that are used in multi-server configurations to determine which host should be used when setting or getting data from a given `memcached` instance. When you get or set a value, a hash is constructed from the supplied key and then used to select a host from the list of configured servers. Because the hashing mechanism uses the supplied key as the basis for the hash, the same server is selected during both set and get operations.

You can think of this process as follows. Given an array of servers (a, b, and c), the client uses a hashing algorithm that returns an integer based on the key being stored or retrieved. The resulting value is then used to select a server from the list of servers configured in the client. Most standard client hashing within `memcache` clients uses a simple modulus calculation on the value against the number of configured `memcached` servers. You can summarize the process in pseudocode as:

```
@memcservers = ['a.memc', 'b.memc', 'c.memc'];
$value = hash($key);
$chosen = $value % length(@memcservers);
```

Replacing the above with values:

```
@memcservers = ['a.memc', 'b.memc', 'c.memc'];
$value = hash('myid');
$chosen = 7009 % 3;
```

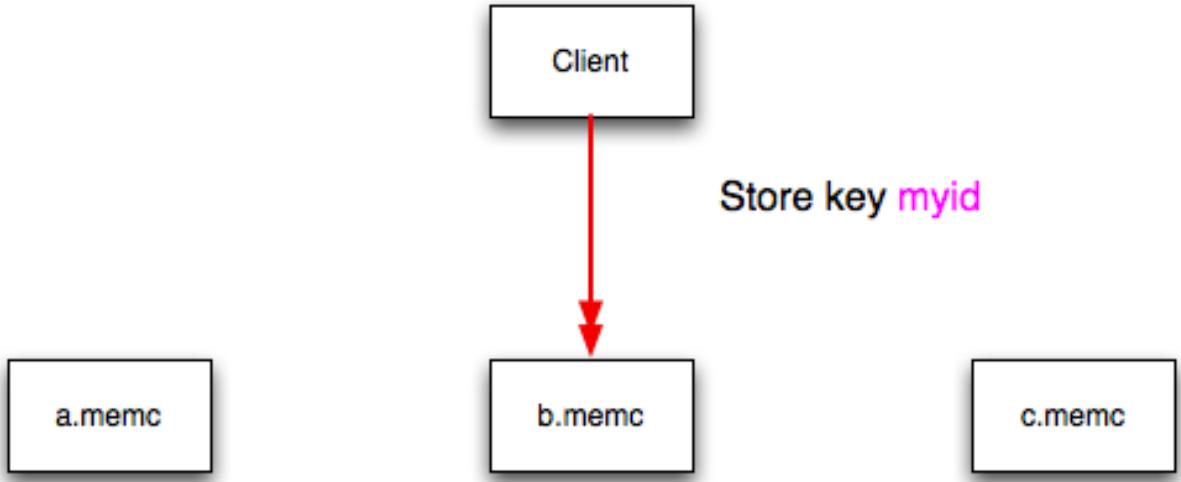

In the above example, the client hashing algorithm chooses the server at index 1 (`7009 % 3 = 1`), and store or retrieve the key and value with that server.

#### Note

This selection and hashing process is handled automatically by the `memcached` client you are using; you need only provide the list of `memcached` servers that you want to use.

You can see a graphical representation of this below in [Figure 14.5, “memcached Hash Selection”](#).

**Figure 14.5. memcached Hash Selection**

The same hashing and selection process takes place during any operation on the specified key within the `memcached` client.

Using this method provides a number of advantages:

- The hashing and selection of the server to contact is handled entirely within the client. This eliminates the need to perform network communication to determine the right machine to contact.
- Because the determination of the `memcached` server occurs entirely within the client, the server can be selected automatically regardless of the operation being executed (set, get, increment, etc.).
- Because the determination is handled within the client, the hashing algorithm returns the same value for a given key; values are not affected or reset by differences in the server environment.
- Selection is very fast. The hashing algorithm on the key value is quick and the resulting selection of the server is from a simple array of available machines.
- Using client-side hashing simplifies the distribution of data over each `memcached` server. Natural distribution of the values returned by the hashing algorithm means that keys are automatically spread over the available servers.

Providing that the list of servers configured within the client remains the same, the same stored key returns the same value, and therefore selects the same server.

However, if you do not use the same hashing mechanism then the same data may be recorded on different servers by different interfaces, both wasting space on your `memcached` and leading to potential differences in the information.

### Note

One way to use a multi-interface compatible hashing mechanism is to use the `libmemcached` library and the associated interfaces. Because the interfaces for the different languages (including C, Ruby, Perl and Python) use the same client library interface, they always generate the same hash code from the ID.

The problem with client-side selection of the server is that the list of the servers (including their sequential order) *must* remain consistent on each client using the `memcached` servers, and the servers must be available. If you try to perform an operation on a key when:

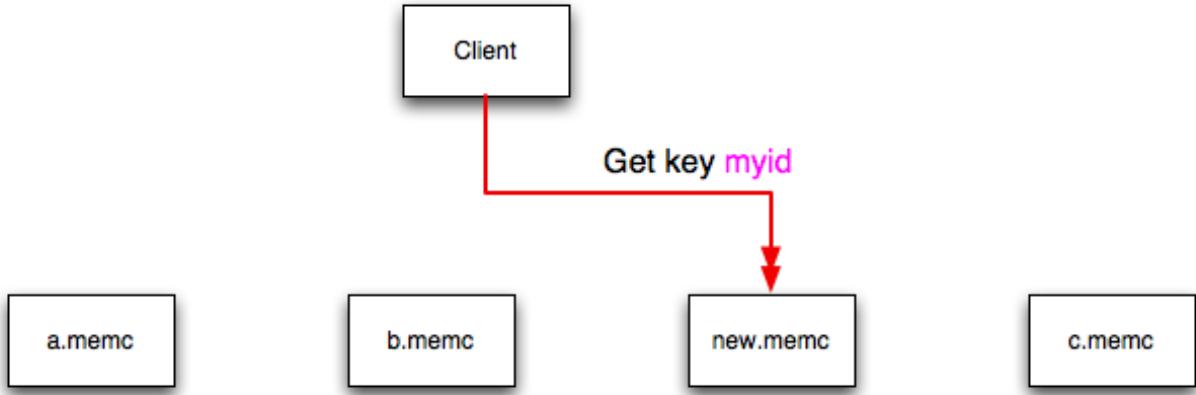

- A new `memcached` instance has been added to the list of available instances
- A `memcached` instance has been removed from the list of available instances
- The order of the `memcached` instances has changed

When the hashing algorithm is used on the given key, but with a different list of servers, the hash calculation may choose a different server from the list.

If a new `memcached` instance is added into the list of servers, as `new.memc` is in the example below, then a GET operation using

the same key, `myid`, can result in a cache-miss. This is because the same value is computed from the key, which selects the same index from the array of servers, but index 2 now points to the new server, not the server `c.memc` where the data was originally stored. This would result in a cache miss, even though the key exists within the cache on another `memcached` instance.

**Figure 14.6. `memcached` Hash Selection with New `memcached` instance**

This means that servers `c.memc` and `new.memc` both contain the information for key `myid`, but the information stored against the key in each server may be different in each instance. A more significant problem is a much higher number of cache-misses when retrieving data, as the addition of a new server changes the distribution of keys, and this in turn requires rebuilding the cached data on the `memcached` instances, causing an increase in database reads.

The same effect can occur if you actively manage the list of servers configured in your clients, adding and removing the configured `memcached` instances as each instance is identified as being available. For example, removing a `memcached` instance when the client notices that the instance can no longer be contacted can cause the server selection to fail as described here.

To prevent this causing significant problems and invalidating your cache, you can select the hashing algorithm used to select the server. There are two common types of hashing algorithm, *consistent* and *modula*.

With *consistent* hashing algorithms, the same key when applied to a list of servers always uses the same server to store or retrieve the keys, even if the list of configured servers changes. This means that you can add and remove servers from the configure list and always use the same server for a given key. There are two types of consistent hashing algorithms available, Ketama and Wheel. Both types are supported by `libmemcached`, and implementations are available for PHP and Java.

Any consistent hashing algorithm has some limitations. When you add servers to an existing list of configured servers, keys are distributed to the new servers as part of the normal distribution. When you remove servers from the list, the keys are re-allocated to another server within the list, meaning that the cache needs to be re-populated with the information. Also, a consistent hashing algorithm does not resolve the issue where you want consistent selection of a server across multiple clients, but where each client contains a different list of servers. The consistency is enforced only within a single client.

With a *modula* hashing algorithm, the client selects a server by first computing the hash and then choosing a server from the list of configured servers. As the list of servers changes, so the server selected when using a modula hashing algorithm also changes. The result is the behavior described above; changes to the list of servers mean that different servers are selected when retrieving data, leading to cache misses and increase in database load as the cache is re-seeded with information.

If you use only a single `memcached` instance for each client, or your list of `memcached` servers configured for a client never changes, then the selection of a hashing algorithm is irrelevant, as it has no noticeable effect.

If you change your servers regularly, or you use a common set of servers that are shared among a large number of clients, then using a consistent hashing algorithm should help to ensure that your cache data is not duplicated and the data is evenly distributed.

#### 14.5.2.5. Using `memcached` and DTrace

`memcached` includes a number of different DTrace probes that can be used to monitor the operation of the server. The probes included can monitor individual connections, slab allocations, and modifications to the hash table when a key/value pair is added, updated, or removed.

For more information on DTrace and writing DTrace scripts, read the [DTrace User Guide](#).

Support for DTrace probes was added to `memcached` 1.2.6 includes a number of DTrace probes that can be used to help monitor your application. DTrace is supported on Solaris 10, OpenSolaris, Mac OS X 10.5 and FreeBSD. To enable the DTrace probes in `memcached`, build from source and use the `--enable-dtrace` option. For more information, see [Section 14.5.1, “Installing](#)

`memcached`".

The probes supported by `memcached` are:

- `conn-allocate(connid)`

Fired when a connection object is allocated from the connection pool.

- `connid`: The connection ID

- `conn-release(connid)`

Fired when a connection object is released back to the connection pool.

Arguments:

- `connid`: The connection ID

- `conn-create(ptr)`

Fired when a new connection object is being created (that is, there are no free connection objects in the connection pool).

Arguments:

- `ptr`: A pointer to the connection object

- `conn-destroy(ptr)`

Fired when a connection object is being destroyed.

Arguments:

- `ptr`: A pointer to the connection object

- `conn-dispatch(connid, threadid)`

Fired when a connection is dispatched from the main or connection-management thread to a worker thread.

Arguments:

- `connid`: The connection ID

- `threadid`: The thread ID

- `slabs-allocate(size, slabclass, slabsizze, ptr)`

Allocate memory from the slab allocator

Arguments:

- `size`: The requested size

- `slabclass`: The allocation is fulfilled in this class

- `slabsizze`: The size of each item in this class

- `ptr`: A pointer to allocated memory

- `slabs-allocate-failed(size, slabclass)`

Failed to allocate memory (out of memory)

Arguments:

- `size`: The requested size

- `slabclass`: The class that failed to fulfill the request

- `slabs-slabclass-allocate(slabclass)`

Fired when a slab class needs more space

Arguments:

- `slabclass`: The class that needs more memory
- `slabs-slabclass-allocate-failed(slabclass)`

Failed to allocate memory (out of memory)

Arguments:

- `slabclass`: The class that failed to grab more memory
- `slabs-free(size, slabclass, ptr)`

Release memory

Arguments:

- `size`: The size of the memory
- `slabclass`: The class the memory belongs to
- `ptr`: A pointer to the memory to release
- `assoc-find(key, depth)`

Fired when we have searched the hash table for a named key. These two elements provide an insight in how well the hash function operates. Traversals are a sign of a less optimal function, wasting cpu capacity.

Arguments:

- `key`: The key searched for
- `depth`: The depth in the list of hash table
- `assoc-insert(key, nokeys)`

Fired when a new item has been inserted.

Arguments:

- `key`: The key just inserted
- `nokeys`: The total number of keys currently being stored, including the key for which insert was called.
- `assoc-delete(key, nokeys)`

Fired when a new item has been removed.

Arguments:

- `key`: The key just deleted
- `nokeys`: The total number of keys currently being stored, excluding the key for which delete was called.
- `item-link(key, size)`

Fired when an item is being linked in the cache

Arguments:

- `key`: The items key
- `size`: The size of the data
- `item-unlink(key, size)`

Fired when an item is being deleted

Arguments:

- `key`: The items key
- `size`: The size of the data
- `item-remove(key, size)`

Fired when the refcount for an item is reduced

Arguments:

- `key`: The items key
- `size`: The size of the data
- `item-update(key, size)`

Fired when the "last referenced" time is updated

Arguments:

- `key`: The items key
- `size`: The size of the data
- `item-replace(oldkey, oldsize, newkey, newsize)`

Fired when an item is being replaced with another item

Arguments:

- `oldkey`: The key of the item to replace
- `oldsize`: The size of the old item
- `newkey`: The key of the new item
- `newsizes`: The size of the new item
- `process-command-start(connid, request, size)`

Fired when the processing of a command starts

Arguments:

- `connid`: The connection ID
- `request`: The incoming request
- `size`: The size of the request
- `process-command-end(connid, response, size)`

Fired when the processing of a command is done

Arguments:

- `connid`: The connection ID
- `response`: The response to send back to the client
- `size`: The size of the response
- `command-get(connid, key, size)`

Fired for a get-command

Arguments:

- `connid`: The connection ID
- `key`: The requested key

- `size`: The size of the key's data (or -1 if not found)
- `command-gets(connid, key, size, casid)`

Fired for a gets command

Arguments:

- `connid`: The connection ID
- `key`: The requested key
- `size`: The size of the key's data (or -1 if not found)
- `casid`: The casid for the item
- `command-add(connid, key, size)`

Fired for a add-command

Arguments:

- `connid`: The connection ID
- `key`: The requested key
- `size`: The new size of the key's data (or -1 if not found)
- `command-set(connid, key, size)`

Fired for a set-command

Arguments:

- `connid`: The connection ID
- `key`: The requested key
- `size`: The new size of the key's data (or -1 if not found)
- `command-replace(connid, key, size)`

Fired for a replace-command

Arguments:

- `connid`: The connection ID
- `key`: The requested key
- `size`: The new size of the key's data (or -1 if not found)
- `command-prepend(connid, key, size)`

Fired for a prepend-command

Arguments:

- `connid`: The connection ID
- `key`: The requested key
- `size`: The new size of the key's data (or -1 if not found)
- `command-append(connid, key, size)`

Fired for a append-command

Arguments:

- `connid`: The connection ID

- `key`: The requested key
- `size`: The new size of the key's data (or -1 if not found)
- `command-cas(connid, key, size, casid)`

Fired for a cas-command

Arguments:

- `connid`: The connection ID
- `key`: The requested key
- `size`: The size of the key's data (or -1 if not found)
- `casid`: The cas ID requested
- `command-incr(connid, key, val)`

Fired for incr command

Arguments:

- `connid`: The connection ID
- `key`: The requested key
- `val`: The new value
- `command-decr(connid, key, val)`

Fired for decr command

Arguments:

- `connid`: The connection ID
- `key`: The requested key
- `val`: The new value
- `command-delete(connid, key, exptime)`

Fired for a delete command

Arguments:

- `connid`: The connection ID
- `key`: The requested key
- `exptime`: The expiry time

#### 14.5.2.6. Memory allocation within `memcached`

When you first start `memcached`, the memory that you have configured is not automatically allocated. Instead, `memcached` only starts allocating and reserving physical memory once you start saving information into the cache.

When you start to store data into the cache, `memcached` does not allocate the memory for the data on an item by item basis. Instead, a slab allocation is used to optimize memory usage and prevent memory fragmentation when information expires from the cache.

With slab allocation, memory is reserved in blocks of 1MB. The slab is divided up into a number of blocks of equal size. When you try to store a value into the cache, `memcached` checks the size of the value that you are adding to the cache and determines which slab contains the right size allocation for the item. If a slab with the item size already exists, the item is written to the block within the slab.

If the new item is bigger than the size of any existing blocks, then a new slab is created, divided up into blocks of a suitable size. If an existing slab with the right block size already exists, but there are no free blocks, a new slab is created. If you update an existing

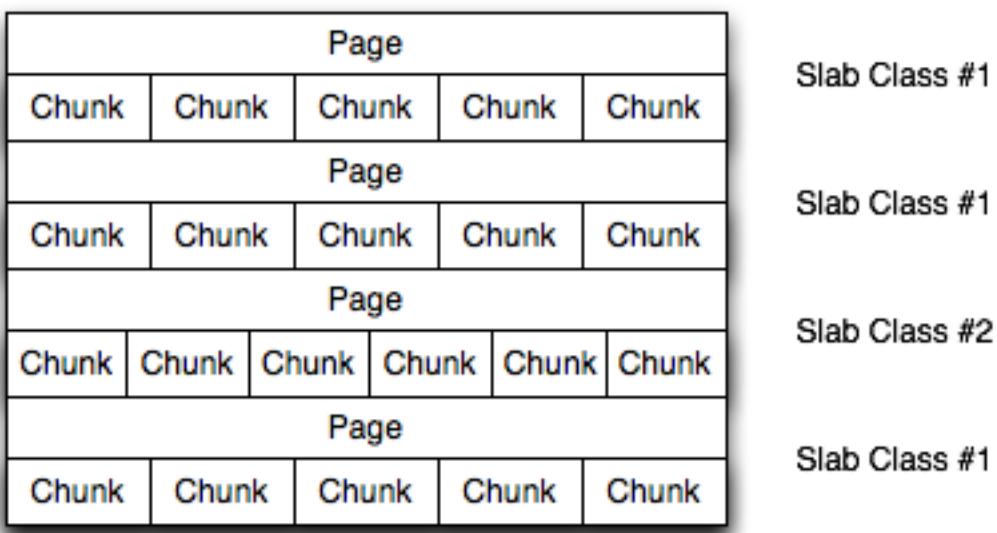

item with data that is larger than the existing block allocation for that key, then the key is re-allocated into a suitable slab.

For example, the default size for the smallest block is 88 bytes (40 bytes of value, and the default 48 bytes for the key and flag data). If the size of the first item you store into the cache is less than 40 bytes, then a slab with a block size of 88 bytes is created and the value stored.

If the size of the data that you want to store is larger than this value, then the block size is increased by the chunk size factor until a block size large enough to hold the value is determined. The block size is always a function of the scale factor, rounded up to a block size which is exactly divisible into the chunk size.

For a sample of the structure, see [Figure 14.7, “Memory Allocation in memcached”](#).

**Figure 14.7. Memory Allocation in memcached**

The result is that you have multiple pages allocated within the range of memory allocated to `memcached`. Each page is 1MB in size (by default), and is split into a different number of chunks, according to the chunk size required to store the key/value pairs. Each instance has multiple pages allocated, and a page is always created when a new item needs to be created requiring a chunk of a particular size. A slab may consist of multiple pages, and each page within a slab contains an equal number of chunks.

The chunk size of a new slab is determined by the base chunk size combined with the chunk size growth factor. For example, if the initial chunks are 104 bytes in size, and the default chunk size growth factor is used (1.25), then the next chunk size allocated would be the best power of 2 fit for  $104 * 1.25$ , or 136 bytes.

Allocating the pages in this way ensures that memory does not get fragmented. However, depending on the distribution of the objects that you want to store, it may lead to an inefficient distribution of the slabs and chunks if you have significantly different sized items. For example, having a relatively small number of items within each chunk size may waste a lot of memory with just few chunks in each allocated page.

You can tune the growth factor to reduce this effect by using the `-f` command line option, which adapts the growth factor applied to make more effective use of the chunks and slabs allocated. For information on how to determine the current slab allocation statistics, see [Section 14.5.4.2, “memcached Slabs Statistics”](#).

If your operating system supports it, you can also start `memcached` with the `-L` command line option. This option preallocates all the memory during startup using large memory pages. This can improve performance by reducing the number of misses in the CPU memory cache.

#### 14.5.2.7. memcached thread Support

If you enable the thread implementation within when building `memcached` from source, then `memcached` uses multiple threads in addition to the `libevent` system to handle requests.

When enabled, the threading implementation operates as follows:

- Threading is handled by wrapping functions within the code to provide basic protection from updating the same global structures at the same time.
- Each thread uses its own instance of the `libevent` to help improve performance.
- TCP/IP connections are handled with a single thread listening on the TCP/IP socket. Each connection is then distributed to one of the active threads on a simple round-robin basis. Each connection then operates solely within this thread while the connection remains open.
- For UDP connections, all the threads listen to a single UDP socket for incoming requests. Threads that are not currently dealing with another request ignore the incoming packet. One of the remaining, nonbusy, threads reads the request and sends the response. This implementation can lead to increased CPU load as threads wake from sleep to potentially process the request.

Using threads can increase the performance on servers that have multiple CPU cores available, as the requests to update the hash table can be spread between the individual threads. However, because of the locking mechanism employed you may want to experiment with different thread values to achieve the best performance based on the number and type of requests within your given workload.

#### 14.5.2.8. `memcached` Logs

If you enable verbose mode, using the `-v`, `-vv`, or `-vvv` options, then the information output by `memcached` includes details of the operations being performed.

Without the verbose options, `memcached` normally produces no output during normal operating.

- **Output when using `-v`**

The lowest verbosity level shows you:

- Errors and warnings
- Transient errors
- Protocol and socket errors, including exhausting available connections
- Each registered client connection, including the socket descriptor number and the protocol used.

For example:

```
32: Client using the ascii protocol
33: Client using the ascii protocol
```

Note that the socket descriptor is only valid while the client remains connected. Non-persistent connections may not be effectively represented.

Examples of the error messages output at this level include:

```
<%d send buffer was %d, now %d
Can't listen for events on fd %d
Can't read from libevent pipe
Catastrophic: event fd doesn't match conn fd!
Couldn't build response
Couldn't realloc input buffer
Couldn't update event
Failed to build UDP headers
Failed to read, and not due to blocking
Too many open connections
Unexpected state %d
```

- **Output when using `-vv`**

When using the second level of verbosity, you get more detailed information about protocol operations, keys updated, chunk and network operations and details.

During the initial start-up of `memcached` with this level of verbosity, you are shown the sizes of the individual slab classes, the chunk sizes, and the number of entries per slab. These do not show the allocation of the slabs, just the slabs that would be created when data is added. You are also given information about the listen queues and buffers used to send information. A sample of the output generated for a TCP/IP based system with the default memory and growth factors is given below:

```
shell> memcached -vv
slab class 1: chunk size 80 perslab 13107
slab class 2: chunk size 104 perslab 10082
```

```

slab class 3: chunk size 136 perslab 7710
slab class 4: chunk size 176 perslab 5957
slab class 5: chunk size 224 perslab 4681
slab class 6: chunk size 280 perslab 3744
slab class 7: chunk size 352 perslab 2978
slab class 8: chunk size 440 perslab 2383
slab class 9: chunk size 552 perslab 1899
slab class 10: chunk size 696 perslab 1506
slab class 11: chunk size 872 perslab 1202
slab class 12: chunk size 1096 perslab 956
slab class 13: chunk size 1376 perslab 762
slab class 14: chunk size 1720 perslab 609
slab class 15: chunk size 2152 perslab 487
slab class 16: chunk size 2696 perslab 388
slab class 17: chunk size 3376 perslab 310
slab class 18: chunk size 4224 perslab 248
slab class 19: chunk size 5280 perslab 198
slab class 20: chunk size 6600 perslab 158
slab class 21: chunk size 8256 perslab 127
slab class 22: chunk size 10320 perslab 101
slab class 23: chunk size 12904 perslab 81
slab class 24: chunk size 16136 perslab 64
slab class 25: chunk size 20176 perslab 51
slab class 26: chunk size 25224 perslab 41
slab class 27: chunk size 31536 perslab 33
slab class 28: chunk size 39424 perslab 26
slab class 29: chunk size 49280 perslab 21
slab class 30: chunk size 61600 perslab 17
slab class 31: chunk size 77000 perslab 13
slab class 32: chunk size 96256 perslab 10
slab class 33: chunk size 120320 perslab 8
slab class 34: chunk size 150400 perslab 6
slab class 35: chunk size 188000 perslab 5
slab class 36: chunk size 235000 perslab 4
slab class 37: chunk size 293752 perslab 3
slab class 38: chunk size 367192 perslab 2
slab class 39: chunk size 458992 perslab 2
<26 server listening (auto-negotiate)
<29 server listening (auto-negotiate)
<30 send buffer was 57344, now 2097152
<31 send buffer was 57344, now 2097152
<30 server listening (udp)
<30 server listening (udp)
<31 server listening (udp)
<30 server listening (udp)
<30 server listening (udp)
<31 server listening (udp)
<31 server listening (udp)
<31 server listening (udp)
<31 server listening (udp)

```

Using this verbosity level can be a useful way to check the effects of the growth factor used on slabs with different memory allocations, which in turn can be used to better tune the growth factor to suit the data you are storing in the cache. For example, if you set the growth factor to 4 (quadrupling the size of each slab):

```

shell> memcached -f 4 -m 1g -vv
slab class 1: chunk size 80 perslab 13107
slab class 2: chunk size 320 perslab 3276
slab class 3: chunk size 1280 perslab 819
slab class 4: chunk size 5120 perslab 204
slab class 5: chunk size 20480 perslab 51
slab class 6: chunk size 81920 perslab 12
slab class 7: chunk size 327680 perslab 3
...

```

During use of the cache, this verbosity level also prints out detailed information on the storage and recovery of keys and other information. An example of the output during a typical set/get and increment/decrement operation is shown below.

```

32: Client using the ascii protocol
<32 set my_key 0 0 10
>32 STORED
<32 set object_key 1 0 36
>32 STORED
<32 get my_key
>32 sending key my_key
>32 END
<32 get object_key
>32 sending key object_key
>32 END
<32 set key 0 0 6
>32 STORED
<32 incr key 1
>32 789544
<32 decr key 1
>32 789543
<32 incr key 2
>32 789545
<32 set my_key 0 0 10
>32 STORED
<32 set object_key 1 0 36
>32 STORED

```

```
<32 get my_key
>32 sending key my_key
>32 END
<32 get object_key
>32 sending key object_key1 1 36

>32 END
<32 set key 0 0 6
>32 STORED
<32 incr key 1
>32 789544
<32 decr key 1
>32 789543
<32 incr key 2
>32 789545
```

During client communication, for each line, the initial character shows the direction of flow of the information. The < for communication from the client to the `memcached` server and > for communication back to the client. The number is the numeric socket descriptor for the connection.

- **Output when using `-vvv`**

This level of verbosity includes the transitions of connections between different states in the event library while reading and writing content to/from the clients. It should be used to diagnose and identify issues in client communication. For example, you can use this information to determine if `memcached` is taking a long time to return information to the client, during the read of the client operation or before returning and completing the operation. An example of the typical sequence for a set operation is provided below:

```
<32 new auto-negotiating client connection
32: going from conn_new_cmd to conn_waiting
32: going from conn_waiting to conn_read
32: going from conn_read to conn_parse_cmd
32: Client using the ascii protocol
<32 set my_key 0 0 10
32: going from conn_parse_cmd to conn_nread
> NOT FOUND my_key
>32 STORED
32: going from conn_nread to conn_write
32: going from conn_write to conn_new_cmd
32: going from conn_new_cmd to conn_waiting
32: going from conn_waiting to conn_read
32: going from conn_read to conn_closing
<32 connection closed.
```

All of the verbosity levels in `memcached` are designed to be used during debugging or examination of issues. The quantity of information generated, particularly when using `-vvv`, is significant, particularly on a busy server. Also be aware that writing the error information out, especially to disk, may negate some of the performance gains you achieve by using `memcached`. Therefore, use in production or deployment environments is not recommended.

### 14.5.3. `memcached` Interfaces

A number of interfaces from different languages exist for interacting with `memcached` servers and storing and retrieving information. Interfaces for the most common language platforms including Perl, PHP, Python, Ruby, C and Java.

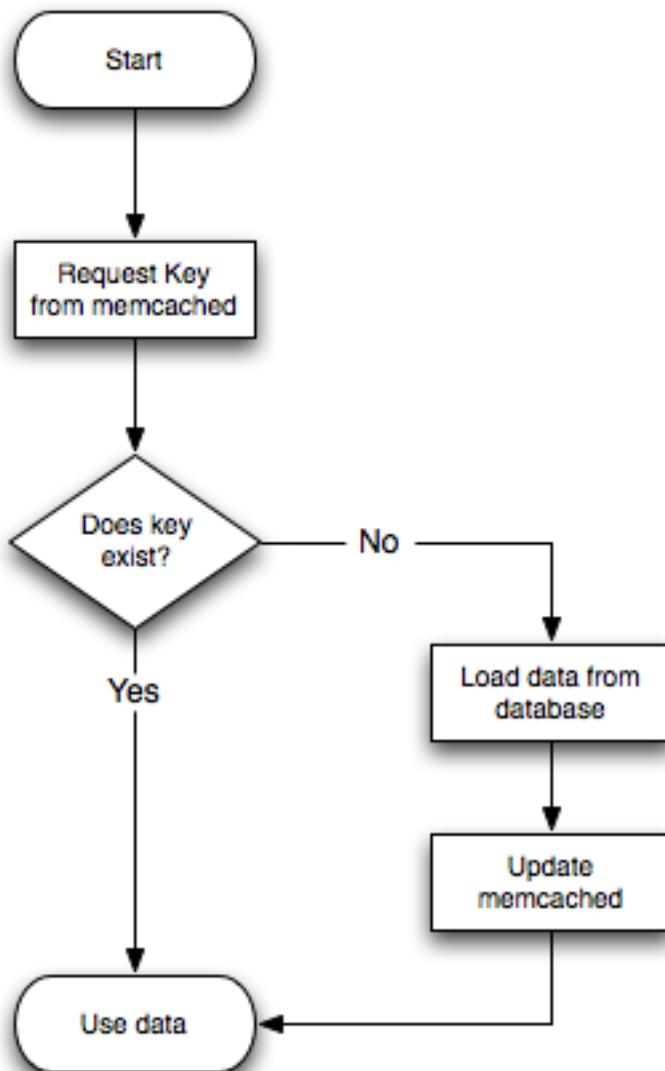

Data stored into a `memcached` server is referred to by a single string (the key), with storage into the cache and retrieval from the cache using the key as the reference. The cache therefore operates like a large associative array or hash. It is not possible to structure or otherwise organize the information stored in the cache. If you want to store information in a structured way, you must use 'formatted' keys.

The following tips may be useful to you when using `memcached`:

The general sequence for using `memcached` in any language as a caching solution is as follows:

1. Request the item from the cache.
2. If the item exists, use the item data.
3. If the item does not exist, load the data from MySQL, and store the value into the cache. This means the value is available to the next client that requests it from the cache.

For a flow diagram of this sequence, see [Figure 14.8, “Typical memcached Application Flowchart”](#).

**Figure 14.8. Typical memcached Application Flowchart**

The interface to `memcached` supports the following methods for storing and retrieving information in the cache, and these are consistent across all the different APIs, even though the language specific mechanics may be different:

- `get(key)`: Retrieves information from the cache. Returns the value if it exists, or `NULL`, `nil`, or `undefined` or the closest equivalent in the corresponding language, if the specified key does not exist.
- `set(key, value [, expiry])`: Sets the key in the cache to the specified value. Note that this either updates an existing key if it already exists, or adds a new key/value pair if the key doesn't exist. If the expiry time is specified, then the key expires (and is deleted) when the expiry time is reached. The time is specified in seconds, and is taken as a relative time if the value is less than 30 days ( $30*24*60*60$ ), or an absolute time (epoch) if larger than this value.
- `add(key, value [, expiry])`: Adds the key to the cache, if the specified key doesn't already exist.
- `replace(key, value [, expiry])`: Replaces the `value` of the specified `key`, only if the key already exists.
- `delete(key [, time])`: Deletes the `key` from the cache. If you supply a `time`, then adding a value with the specified `key` is blocked for the specified period.
- `incr(key [, value])`: Increments the specified `key` by one or the specified `value`.

- `decr(key [, value]):` Decrements the specified `key` by one or the specified `value`.
- `flush_all:` Invalidates (or expires) all the current items in the cache. Technically they still exist (they are not deleted), but they are silently destroyed the next time you try to access them.

In all implementations, most or all of these functions are duplicated through the corresponding native language interface.

For all languages and interfaces, use `memcached` to store full items, rather than simply caching single rows of information from the database. For example, when displaying a record about an object (invoice, user history, or blog post), load all the data for the associated entry from the database, and compile it into the internal structure that would normally be required by the application. You then save the complete object into the cache.

Complex data structures cannot be stored directly. Most interfaces serialize the data for you, that is, put it in a form that can reconstruct the original pointers and nesting. Perl uses `Storable`, PHP uses `serialize`, Python uses `cPickle` (or `Pickle`) and Java uses the `Serializable` interface. In most cases, the serialization interface used is customizable. To share data stored in `memcached` instances between different language interfaces, consider using a common serialization solution such as JSON (Javascript Object Notation).

#### 14.5.3.1. Using `libmemcached`

The `libmemcached` library provides both C and C++ interfaces to `memcached` and is also the basis for a number of different additional API implementations, including Perl, Python and Ruby. Understanding the core `libmemcached` functions can help when using these other interfaces.

The C library is the most comprehensive interface library for `memcached` and provides a wealth of functions and operational systems not always exposed in the other interfaces not based on the `libmemcached` library.

The different functions can be divided up according to their basic operation. In addition to functions that interface to the core API, there are a number of utility functions that provide extended functionality, such as appending and prepending data.

To build and install `libmemcached`, download the `libmemcached` package, run configure, and then build and install:

```
shell> tar xjf libmemcached-0.21.tar.gz
shell> cd libmemcached-0.21
shell> ./configure
shell> make
shell> make install
```

On many Linux operating systems, you can install the corresponding `libmemcached` package through the usual `yum`, `apt-get` or similar commands.

To build an application that uses the library, you need to first set the list of servers. You can do this either by directly manipulating the servers configured within the main `memcached_st` structure, or by separately populating a list of servers, and then adding this list to the `memcached_st` structure. The latter method is used in the following example. Once the server list has been set, you can call the functions to store or retrieve data. A simple application for setting a preset value to localhost is provided here:

```
#include <stdio.h>
#include <string.h>
#include <unistd.h>
#include <libmemcached/memcached.h>

int main(int argc, char *argv[])
{
 memcached_server_st *servers = NULL;
 memcached_st *memc;
 memcached_return rc;
 char *key= "keystring";
 char *value= "keyvalue";

 memcached_server_st *memcached_servers_parse (char *server_strings);
 memc= memcached_create(NULL);

 servers= memcached_server_list_append(servers, "localhost", 11211, &rc);
 rc= memcached_server_push(memc, servers);

 if (rc == MEMCACHED_SUCCESS)
 fprintf(stderr,"Added server successfully\n");
 else
 fprintf(stderr,"Couldn't add server: %s\n",memcached_strerror(memc, rc));

 rc= memcached_set(memc, key, strlen(key), value, strlen(value), (time_t)0, (uint32_t)0);

 if (rc == MEMCACHED_SUCCESS)
 fprintf(stderr,"Key stored successfully\n");
 else
 fprintf(stderr,"Couldn't store key: %s\n",memcached_strerror(memc, rc));

 return 0;
}
```

You can test the success of an operation by using the return value, or populated result code, for a given function. The value is always set to `MEMCACHED_SUCCESS` if the operation succeeded. In the event of a failure, use the `memcached_strerror()` function to translate the result code into a printable string.

To build the application, you must specify the `memcached` library:

```
shell> gcc -o memc_basic memc_basic.c -lmemcached
```

Running the above sample application, after starting a `memcached` server, should return a success message:

```
shell> memc_basic
Added server successfully
Key stored successfully
```

#### 14.5.3.1.1. libmemcached Base Functions

The base `libmemcached` functions enable you to create, destroy and clone the main `memcached_st` structure that is used to interface to the `memcached` servers. The main functions are defined below:

```
memcached_st *memcached_create (memcached_st *ptr);
```

Creates a new `memcached_st` structure for use with the other `libmemcached` API functions. You can supply an existing, static, `memcached_st` structure, or `NULL` to have a new structure allocated. Returns a pointer to the created structure, or `NULL` on failure.

```
void memcached_free (memcached_st *ptr);
```

Free the structure and memory allocated to a previously created `memcached_st` structure.

```
memcached_st *memcached_clone(memcached_st *clone, memcached_st *source);
```

Clone an existing `memcached` structure from the specified `source`, copying the defaults and list of servers defined in the structure.

#### 14.5.3.1.2. libmemcached Server Functions

The `libmemcached` API uses a list of servers, stored within the `memcached_server_st` structure, to act as the list of servers used by the rest of the functions. To use `memcached`, you first create the server list, and then apply the list of servers to a valid `libmemcached` object.

Because the list of servers, and the list of servers within an active `libmemcached` object can be manipulated separately, you can update and manage server lists while an active `libmemcached` interface is running.

The functions for manipulating the list of servers within a `memcached_st` structure are given below:

```
memcached_return
 memcached_server_add (memcached_st *ptr,
 char *hostname,
 unsigned int port);
```

Add a server, using the given `hostname` and `port` into the `memcached_st` structure given in `ptr`.

```
memcached_return
 memcached_server_add_unix_socket (memcached_st *ptr,
 char *socket);
```

Add a Unix socket to the list of servers configured in the `memcached_st` structure.

```
unsigned int memcached_server_count (memcached_st *ptr);
```

Return a count of the number of configured servers within the `memcached_st` structure.

```
memcached_server_st *
 memcached_server_list (memcached_st *ptr);
```

Returns an array of all the defined hosts within a `memcached_st` structure.

```
memcached_return
 memcached_server_push (memcached_st *ptr,
 memcached_server_st *list);
```

Pushes an existing list of servers onto list of servers configured for a current `memcached_st` structure. This adds servers to the end of the existing list, and duplicates are not checked.

The `memcached_server_st` structure can be used to create a list of `memcached` servers which can then be applied individually to `memcached_st` structures.

```
memcached_server_st *
 memcached_server_list_append (memcached_server_st *ptr,
 char *hostname,
 unsigned int port,
 memcached_return *error);
```

Add a server, with `hostname` and `port`, to the server list in `ptr`. The result code is handled by the `error` argument, which should point to an existing `memcached_return` variable. The function returns a pointer to the returned list.

```
unsigned int memcached_server_list_count (memcached_server_st *ptr);
```

Return the number of the servers in the server list.

```
void memcached_server_list_free (memcached_server_st *ptr);
```

Free up the memory associated with a server list.

```
memcached_server_st *memcached_servers_parse (char *server_strings);
```

Parses a string containing a list of servers, where individual servers are separated by a comma, space, or both, and where individual servers are of the form `server[:port]`. The return value is a server list structure.

#### 14.5.3.1.3. libmemcached Set Functions

The set related functions within `libmemcached` provide the same functionality as the core functions supported by the `memcached` protocol. The full definition for the different functions is the same for all the base functions (add, replace, prepend, append). For example, the function definition for `memcached_set()` is:

```
memcached_return
memcached_set (memcached_st *ptr,
 const char *key,
 size_t key_length,
 const char *value,
 size_t value_length,
 time_t expiration,
 uint32_t flags);
```

The `ptr` is the `memcached_st` structure. The `key` and `key_length` define the key name and length, and `value` and `value_length` the corresponding value and length. You can also set the expiration and optional flags. For more information, see Section 14.5.3.1.5, “[libmemcached Behaviors](#)”.

The following table outlines the remainder of the set-related functions.

| <code>libmemcached</code> Function                                                                                              | Equivalent to                                                                                                                                 |
|---------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| <code>memcached_set(memc, key, key_length, value, value_length, expiration, flags)</code>                                       | Generic <code>set()</code> operation.                                                                                                         |
| <code>memcached_add(memc, key, key_length, value, value_length, expiration, flags)</code>                                       | Generic <code>add()</code> function.                                                                                                          |
| <code>memcached_replace(memc, key, key_length, value, value_length, expiration, flags)</code>                                   | Generic <code>replace()</code> .                                                                                                              |
| <code>memcached_prepend(memc, key, key_length, value, value_length, expiration, flags)</code>                                   | Prepends the specified <code>value</code> before the current value of the specified <code>key</code> .                                        |
| <code>memcached_append(memc, key, key_length, value, value_length, expiration, flags)</code>                                    | Appends the specified <code>value</code> after the current value of the specified <code>key</code> .                                          |
| <code>memcached_cas(memc, key, key_length, value, value_length, expiration, flags, cas)</code>                                  | Overwrites the data for a given key as long as the corresponding <code>cas</code> value is still the same within the server.                  |
| <code>memcached_set_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)</code> | Similar to the generic <code>set()</code> , but has the option of an additional master key that can be used to identify an individual server. |
| <code>memcached_add_by_key(memc, master_key, mas-</code>                                                                        | Similar to the generic <code>add()</code> , but has the option of an addition-                                                                |

| libmemcached Function                                                                                                               | Equivalent to                                                                                                                                       |
|-------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>ter_key_length, key, key_length, value, value_length, expiration, flags)</code>                                               | al master key that can be used to identify an individual server.                                                                                    |
| <code>memcached_replace_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)</code> | Similar to the generic <code>replace()</code> , but has the option of an additional master key that can be used to identify an individual server.   |
| <code>memcached_prepend_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)</code> | Similar to the <code>memcached.prepend()</code> , but has the option of an additional master key that can be used to identify an individual server. |
| <code>memcached_append_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)</code>  | Similar to the <code>memcached.append()</code> , but has the option of an additional master key that can be used to identify an individual server.  |
| <code>memcached_cas_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)</code>     | Similar to the <code>memcached.cas()</code> , but has the option of an additional master key that can be used to identify an individual server.     |

The `by_key` methods add two further arguments, the master key, to be used and applied during the hashing stage for selecting the servers. You can see this in the following definition:

```
memcached_return
memcached_set_by_key(memcached_st *ptr,
 const char *master_key,
 size_t master_key_length,
 const char *key,
 size_t key_length,
 const char *value,
 size_t value_length,
 time_t expiration,
 uint32_t flags);
```

All the functions return a value of type `memcached_return`, which you can compare against the `MEMCACHED_SUCCESS` constant.

#### 14.5.3.1.4. libmemcached Get Functions

The `libmemcached` functions provide both direct access to a single item, and a multiple-key request mechanism that provides much faster responses when fetching a large number of keys simultaneously.

The main get-style function, which is equivalent to the generic `get()` is `memcached_get()`. The functions a string pointer to the returned value for a corresponding key.

```
char *memcached_get (memcached_st *ptr,
 const char *key, size_t key_length,
 size_t *value_length,
 uint32_t *flags,
 memcached_return *error);
```

A multi-key get, `memcached_mget()`, is also available. Using a multiple key get operation is much quicker to do in one block than retrieving the key values with individual calls to `memcached_get()`. To start the multi-key get, you need to call `memcached_mget()`:

```
memcached_return
memcached_mget (memcached_st *ptr,
 char **keys, size_t *key_length,
 unsigned int number_of_keys);
```

The return value is the success of the operation. The `keys` parameter should be an array of strings containing the keys, and `key_length` an array containing the length of each corresponding key. `number_of_keys` is the number of keys supplied in the array.

To fetch the individual values, you need to use `memcached_fetch()` to get each corresponding value.

```
char *memcached_fetch (memcached_st *ptr,
 const char *key, size_t *key_length,
 size_t *value_length,
 uint32_t *flags,
 memcached_return *error);
```

The function returns the key value, with the `key`, `key_length` and `value_length` parameters being populated with the corresponding key and length information. The function returns `NULL` when there are no more values to be returned. A full example,

including the populating of the key data and the return of the information is provided here.

```
#include <stdio.h>
#include <sstring.h>
#include <unistd.h>
#include <libmemcached/memcached.h>

int main(int argc, char *argv[])
{
 memcached_server_st *servers = NULL;
 memcached_st *memc;
 memcached_return rc;
 char *keys[] = {"huey", "dewey", "louie"};
 size_t key_length[3];
 char *values[] = {"red", "blue", "green"};
 size_t value_length[3];
 unsigned int x;
 uint32_t flags;

 char return_key[MEMCACHED_MAX_KEY];
 size_t return_key_length;
 char *return_value;
 size_t return_value_length;

 memc= memcached_create(NULL);

 servers= memcached_server_list_append(servers, "localhost", 11211, &rc);
 rc= memcached_server_push(memc, servers);

 if (rc == MEMCACHED_SUCCESS)
 fprintf(stderr,"Added server successfully\n");
 else
 fprintf(stderr,"Couldn't add server: %s\n",memcached_strerror(memc, rc));

 for(x= 0; x < 3; x++)
 {
 key_length[x] = strlen(keys[x]);
 value_length[x] = strlen(values[x]);

 rc= memcached_set(memc, keys[x], key_length[x], values[x],
 value_length[x], (time_t)0, (uint32_t)0);
 if (rc == MEMCACHED_SUCCESS)
 fprintf(stderr,"Key %s stored successfully\n",keys[x]);
 else
 fprintf(stderr,"Couldn't store key: %s\n",memcached_strerror(memc, rc));
 }

 rc= memcached_mget(memc, keys, key_length, 3);

 if (rc == MEMCACHED_SUCCESS)
 {
 while ((return_value= memcached_fetch(memc, return_key, &return_key_length,
 &return_value_length, &flags, &rc)) != NULL)
 {
 if (rc == MEMCACHED_SUCCESS)
 {
 fprintf(stderr,"Key %s returned %s\n",return_key, return_value);
 }
 }
 }
 return 0;
}
```

Running the above application:

```
shell> memo_multi_fetch
Added server successfully
Key huey stored successfully
Key dewey stored successfully
Key louie stored successfully
Key huey returned red
Key dewey returned blue
Key louie returned green
```

#### 14.5.3.1.5. libmemcached Behaviors

The behavior of `libmemcached` can be modified by setting one or more behavior flags. These can either be set globally, or they can be applied during the call to individual functions. Some behaviors also accept an additional setting, such as the hashing mechanism used when selecting servers.

To set global behaviors:

```
memcached_return
 memcached_behavior_set (memcached_st *ptr,
 memcached_behavior_flag,
 uint64_t data);
```

To get the current behavior setting:

```
uint64_t
memcached_behavior_get (memcached_st *ptr,
 memcached_behavior flag);
```

| Behavior                           | Description                                                                                                                                                                                                                                                                                                                                                                 |
|------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MEMCACHED_BEHAVIOR_NO_BLOCK        | Caused <code>libmemcached</code> to use asynchronous I/O.                                                                                                                                                                                                                                                                                                                   |
| MEMCACHED_BEHAVIOR_TCP_NODELAY     | Turns on no-delay for network sockets.                                                                                                                                                                                                                                                                                                                                      |
| MEMCACHED_BEHAVIOR_HASH            | Without a value, sets the default hashing algorithm for keys to use MD5. Other valid values include <code>MEMCACHED_HASH_DEFAULT</code> , <code>MEMCACHED_HASH_MD5</code> , <code>MEMCACHED_HASH_CRC</code> , <code>MEMCACHED_HASH_FNV1_64</code> , <code>MEMCACHED_HASH_FNV1A_64</code> , <code>MEMCACHED_HASH_FNV1_32</code> , and <code>MEMCACHED_HASH_FNV1A_32</code> . |
| MEMCACHED_BEHAVIOR_DISTRIBUTION    | Changes the method of selecting the server used to store a given value. The default method is <code>MEMCACHED_DISTRIBUTION_MODULA</code> . You can enable consistent hashing by setting <code>MEMCACHED_DISTRIBUTION_CONSISTENT</code> . <code>MEMCACHED_DISTRIBUTION_CONSISTENT</code> is an alias for the value <code>MEMCACHED_DISTRIBUTION_CONSISTENT_KETAMA</code> .   |
| MEMCACHED_BEHAVIOR_CACHE_LOOKUPS   | Cache the lookups made to the DNS service. This can improve the performance if you are using names instead of IP addresses for individual hosts.                                                                                                                                                                                                                            |
| MEMCACHED_BEHAVIOR_SUPPORT_CAS     | Support CAS operations. By default, this is disabled because it imposes a performance penalty.                                                                                                                                                                                                                                                                              |
| MEMCACHED_BEHAVIOR_KETAMA          | Sets the default distribution to <code>MEMCACHED_DISTRIBUTION_CONSISTENT_KETAMA</code> and the hash to <code>MEMCACHED_HASH_MD5</code> .                                                                                                                                                                                                                                    |
| MEMCACHED_BEHAVIOR_POLL_TIMEOUT    | Modify the timeout value used by <code>poll()</code> . Supply a <code>signed int</code> pointer for the timeout value.                                                                                                                                                                                                                                                      |
| MEMCACHED_BEHAVIOR_BUFFER_REQUESTS | Buffers IO requests instead of them being sent. A get operation, or closing the connection causes the data to be flushed.                                                                                                                                                                                                                                                   |
| MEMCACHED_BEHAVIOR_VERIFY_KEY      | Forces <code>libmemcached</code> to verify that a specified key is valid.                                                                                                                                                                                                                                                                                                   |
| MEMCACHED_BEHAVIOR_SORT_HOSTS      | If set, hosts added to the list of configured hosts for a <code>memcached_st</code> structure are placed into the host list in sorted order. This breaks consistent hashing if that behavior has been enabled.                                                                                                                                                              |
| MEMCACHED_BEHAVIOR_CONNECT_TIMEOUT | In nonblocking mode this changes the value of the timeout during socket connection.                                                                                                                                                                                                                                                                                         |

#### 14.5.3.1.6. `libmemcached` Command-line Utilities

In addition to the main C library interface, `libmemcached` also includes a number of command line utilities that can be useful when working with and debugging `memcached` applications.

All of the command line tools accept a number of arguments, the most critical of which is `servers`, which specifies the list of servers to connect to when returning information.

The main tools are:

- `memcat`: Display the value for each ID given on the command line:

```
shell> memcat --servers=localhost hwkey
Hello world
```

- `memcp`: Copy the contents of a file into the cache, using the file names as the key:

```
shell> echo "Hello World" > hwkey
shell> memcp --servers=localhost hwkey
shell> memcat --servers=localhost hwkey
Hello world
```

- `memrm`: Remove an item from the cache:

```
shell> memcat --servers=localhost hwkey
Hello world
shell> memrm --servers=localhost hwkey
shell> memcat --servers=localhost hwkey
```

- **memslap**: Test the load on one or more `memcached` servers, simulating get/set and multiple client operations. For example, you can simulate the load of 100 clients performing get operations:

```
shell> memslap --servers=localhost --concurrency=100 --flush --test=get
memslap --servers=localhost --concurrency=100 --flush --test=get Threads connecting to servers 100
Took 13.571 seconds to read data
```

- **memflush**: Flush (empty) the contents of the `memcached` cache.

```
shell> memflush --servers=localhost
```

### 14.5.3.2. Using MySQL and `memcached` with Perl

The `Cache::Memcached` module provides a native interface to the Memcache protocol, and provides support for the core functions offered by `memcached`. You should install the module using your hosts native package management system. Alternatively, you can install the module using [CPAN](#):

```
root-shell> perl -MCPAN -e 'install Cache::Memcached'
```

To use `memcached` from Perl through `Cache::Memcached` module, you first need to create a new `Cache::Memcached` object that defines the list of servers and other parameters for the connection. The only argument is a hash containing the options for the cache interface. For example, to create a new instance that uses three `memcached` servers:

```
use Cache::Memcached;
my $cache = new Cache::Memcached {
 'servers' => [
 '192.168.0.100:11211',
 '192.168.0.101:11211',
 '192.168.0.102:11211',
],
};
```

#### Note

When using the `Cache::Memcached` interface with multiple servers, the API automatically performs certain operations across all the servers in the group. For example, getting statistical information through `Cache::Memcached` returns a hash that contains data on a host by host basis, as well as generalized statistics for all the servers in the group.

You can set additional properties on the cache object instance when it is created by specifying the option as part of the option hash. Alternatively, you can use a corresponding method on the instance:

- `servers` or method `set_servers()`: Specifies the list of the servers to be used. The servers list should be a reference to an array of servers, with each element as the address and port number combination (separated by a colon). You can also specify a local connection through a UNIX socket (for example `/tmp/sock/memcached`). You can also specify the server with a weight (indicating how much more frequently the server should be used during hashing) by specifying an array reference with the `memcached` server instance and a weight number. Higher numbers give higher priority.
- `compress_threshold` or method `set_compress_threshold()`: Specifies the threshold when values are compressed. Values larger than the specified number are automatically compressed (using `zlib`) during storage and retrieval.
- `no_rehash` or method `set_norehash()`: Disables finding a new server if the original choice is unavailable.
- `readonly` or method `set_READONLY()`: Disables writes to the `memcached` servers.

Once the `Cache::Memcached` object instance has been configured you can use the `set()` and `get()` methods to store and retrieve information from the `memcached` servers. Objects stored in the cache are automatically serialized and deserialized using the `Storable` module.

The `Cache::Memcached` interface supports the following methods for storing/retrieving data, and relate to the generic methods as shown in the table.

| <code>Cache::Memcached</code> Function | Equivalent to                                                                                                    |
|----------------------------------------|------------------------------------------------------------------------------------------------------------------|
| <code>get()</code>                     | Generic <code>get()</code>                                                                                       |
| <code>get_multi(keys)</code>           | Gets multiple <code>keys</code> from memcache using just one query. Returns a hash reference of key/value pairs. |

| Cache::Memcached Function | Equivalent to     |
|---------------------------|-------------------|
| set()                     | Generic set()     |
| add()                     | Generic add()     |
| replace()                 | Generic replace() |
| delete()                  | Generic delete()  |
| incr()                    | Generic incr()    |
| decr()                    | Generic decr()    |

Below is a complete example for using memcached with Perl and the Cache::Memcached module:

```
#!/usr/bin/perl

use Cache::Memcached;
use DBI;
use Data::Dumper;

Configure the memcached server

my $cache = new Cache::Memcached {
 'servers' => [
 'localhost:11211',
],
};

Get the film name from the command line
memcached keys must not contain spaces, so create
a key name by replacing spaces with underscores

my $filmname = shift or die "Must specify the film name\n";
my $filmkey = $filmname;
$filmkey =~ s/ /_/;

Load the data from the cache

my $filmdata = $cache->get($filmkey);

If the data wasn't in the cache, then we load it from the database

if (!defined($filmdata))
{
 $filmdata = load_filmdata($filmname);

 if (defined($filmdata))
 {

Set the data into the cache, using the key

 if ($cache->set($filmkey,$filmdata))
 {
 print STDERR "Film data loaded from database and cached\n";
 }
 else
 {
 print STDERR "Couldn't store to cache\n";
 }
 }
 else
 {
 die "Couldn't find $filmname\n";
 }
}
else
{
 print STDERR "Film data loaded from Memcached\n";
}

sub load_filmdata
{
 my ($filmname) = @_;

 my $dsn = "DBI:mysql:database=sakila;host=localhost;port=3306";
 $dbh = DBI->connect($dsn, 'sakila', 'password');

 my ($filmbase) = $dbh->selectrow_hashref(sprintf('select * from film where title = %s',
 $dbh->quote($filmname)));

 if (!defined($filmname))
 {
 return (undef);
 }

 $filmbase->{stars} =
 $dbh->selectall_arrayref(sprintf('select concat(first_name, " ",last_name) ' .
 'from film_actor left join (actor) ' .
 'on (film_actor.actor_id = actor.actor_id) ' .
 'where film_id=%s',
 $filmname));
}
```

```

 $dbh->quote($filmbase->{film_id})));
 return($filmbase);
}

```

The example uses the Sakila database, obtaining film data from the database and writing a composite record of the film and actors to memcache. When calling it for a film does not exist, you get this result:

```

shell> memcached-sakila.pl "ROCK INSTINCT"
Film data loaded from database and cached

```

When accessing a film that has already been added to the cache:

```

shell> memcached-sakila.pl "ROCK INSTINCT"
Film data loaded from Memcached

```

### 14.5.3.3. Using MySQL and `memcached` with Python

The Python `memcache` module interfaces to `memcached` servers, and is written in pure python (that is, without using one of the C APIs). You can download and install a copy from [Python Memcached](#).

To install, download the package and then run the Python installer:

```

python setup.py install
running install
running bdist_egg
running egg_info
creating python_memcached.egg-info
...
removing 'build/bdist.linux-x86_64/egg' (and everything under it)
Processing python_memcached-1.43-py2.4.egg
creating /usr/lib64/python2.4/site-packages/python_memcached-1.43-py2.4.egg
Extracting python_memcached-1.43-py2.4.egg to /usr/lib64/python2.4/site-packages
Adding python-memcached 1.43 to easy-install.pth file

Installed /usr/lib64/python2.4/site-packages/python_memcached-1.43-py2.4.egg
Processing dependencies for python-memcached==1.43
Finished processing dependencies for python-memcached==1.43

```

Once installed, the `memcache` module provides a class-based interface to your `memcached` servers. Serialization of Python structures is handled by using the Python `cPickle` or `pickle` modules.

To create a new `memcache` interface, import the `memcache` module and create a new instance of the `memcache.Client` class:

```

import memcache
memc = memcache.Client(['127.0.0.1:11211'])

```

The first argument should be an array of strings containing the server and port number for each `memcached` instance you want to use. You can enable debugging by setting the optional `debug` parameter to 1.

By default, the hashing mechanism used is `crc32`. This provides a basic module hashing algorithm for selecting among multiple servers. You can change the function used by setting the value of `memcache.serverHashFunction` to the alternate function you want to use. For example:

```

from zlib import adler32
memcache.serverHashFunction = adler32

```

Once you have defined the servers to use within the `memcache` instance, the core functions provide the same functionality as in the generic interface specification. A summary of the supported functions is provided in the following table.

| Python <code>memcache</code> Function                  | Equivalent to                                                                                                    |
|--------------------------------------------------------|------------------------------------------------------------------------------------------------------------------|
| <code>get()</code>                                     | Generic <code>get()</code>                                                                                       |
| <code>get_multi(keys)</code>                           | Gets multiple values from the supplied array of <code>keys</code> . Returns a hash reference of key/value pairs. |
| <code>set()</code>                                     | Generic <code>set()</code>                                                                                       |
| <code>set_multi(dict [, expiry [, key_prefix]])</code> | Sets multiple key/value pairs from the supplied <code>dict</code> .                                              |
| <code>add()</code>                                     | Generic <code>add()</code>                                                                                       |
| <code>replace()</code>                                 | Generic <code>replace()</code>                                                                                   |
| <code>prepend(key, value [, expiry])</code>            | Prepends the supplied <code>value</code> to the value of the existing <code>key</code> .                         |

| Python <code>memcache</code> Function                     | Equivalent to                                                                            |
|-----------------------------------------------------------|------------------------------------------------------------------------------------------|
| <code>append(key, value [, expiry[]])</code>              | Appends the supplied <code>value</code> to the value of the existing <code>key</code> .  |
| <code>delete()</code>                                     | Generic <code>delete()</code>                                                            |
| <code>delete_multi(keys [, expiry [, key_prefix]])</code> | Deletes all the keys from the hash matching each string in the array <code>keys</code> . |
| <code>incr()</code>                                       | Generic <code>incr()</code>                                                              |
| <code>decr()</code>                                       | Generic <code>decr()</code>                                                              |

### Note

Within the Python `memcache` module, all the `*_multi()` functions support an optional `key_prefix` parameter. If supplied, then the string is used as a prefix to all key lookups. For example, if you call:

```
memc.get_multi(['a','b'], key_prefix='users:')
```

The function retrieves the keys `users:a` and `users:b` from the servers.

An example showing the storage and retrieval of information to a `memcache` instance, loading the raw data from MySQL, is shown below:

```
import sys
import MySQLdb
import memcache

memc = memcache.Client(['127.0.0.1:11211'], debug=1);

try:
 conn = MySQLdb.connect (host = "localhost",
 user = "sakila",
 passwd = "password",
 db = "sakila")
except MySQLdb.Error, e:
 print "Error %d: %s" % (e.args[0], e.args[1])
 sys.exit (1)

popularfilms = memc.get('top5films')

if not popularfilms:
 cursor = conn.cursor()
 cursor.execute('select film_id,title from film order by rental_rate desc limit 5')
 rows = cursor.fetchall()
 memc.set('top5films',rows,60)
 print "Updated memcached with MySQL data"
else:
 print "Loaded data from memcached"
 for row in popularfilms:
 print "%s, %s" % (row[0], row[1])
```

When executed for the first time, the data is loaded from the MySQL database and stored to the `memcached` server.

```
shell> python memc_python.py
Updated memcached with MySQL data
```

The data is automatically serialized using `cPickle/pickle`. This means when you load the data back from `memcached`, you can use the object directly. In the example above, the information stored to `memcached` is in the form of rows from a Python DB cursor. When accessing the information (within the 60 second expiry time), the data is loaded from `memcached` and dumped:

```
shell> python memc_python.py
Loaded data from memcached
2, ACE GOLDFINGER
7, AIRPLANE SIERRA
8, AIRPORT POLLOCK
10, ALADDIN CALENDAR
13, ALI FOREVER
```

The serialization and deserialization happens automatically, but be aware that serialization of Python data may be incompatible with other interfaces and languages. You can change the serialization module used during initialization, for example to use JSON, which is more easily exchanged.

#### 14.5.3.4. Using MySQL and `memcached` with PHP

PHP provides support for the Memcache functions through a PECL extension. To enable the PHP `memcache` extensions, you must build PHP using the `--enable-memcache` option to `configure` when building from source.

If you are installing on a RedHat based server, you can install the `php-pecl-memcache` RPM:

```
root-shell> yum --install php-pecl-memcache
```

On Debian based distributions, use the `php-memcache` package.

You can set global runtime configuration options by specifying the values in the following table within your `php.ini` file.

| Configuration option                        | Default  | Description                                                                                                                                                                                                                                                                                                       |
|---------------------------------------------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>memcache.allow_failover</code>        | 1        | Specifies whether another server in the list should be queried if the first server selected fails.                                                                                                                                                                                                                |
| <code>memcache.max_failover_attempts</code> | 20       | Specifies the number of servers to try before returning a failure.                                                                                                                                                                                                                                                |
| <code>memcache.chunk_size</code>            | 8192     | Defines the size of network chunks used to exchange data with the <code>memcached</code> server.                                                                                                                                                                                                                  |
| <code>memcache.default_port</code>          | 11211    | Defines the default port to use when communicating with the <code>memcached</code> servers.                                                                                                                                                                                                                       |
| <code>memcache.hash_strategy</code>         | standard | Specifies which hash strategy to use. Set to <code>consistent</code> to enable servers to be added or removed from the pool without causing the keys to be remapped to other servers. When set to <code>standard</code> , an older (modula) strategy is used that potentially uses different servers for storage. |
| <code>memcache.hash_function</code>         | crc32    | Specifies which function to use when mapping keys to servers. <code>crc32</code> uses the standard CRC32 hash. <code>fnv</code> uses the FNV-1a hashing algorithm.                                                                                                                                                |

To create a connection to a `memcached` server, you need to create a new `Memcache` object and then specifying the connection options. For example:

```
<?php
$cache = new Memcache;
$cache->connect('localhost',11211);
?>
```

This opens an immediate connection to the specified server.

To use multiple `memcached` servers, you need to add servers to the memcache object using `addServer()`:

```
bool Memcache::addServer (string $host [, int $port [, bool $persistent
[, int $weight [, int $timeout [, int $retry_interval
[, bool $status [, callback $failure_callback
]]]]]]])
```

The server management mechanism within the `php-memcache` module is a critical part of the interface as it controls the main interface to the `memcached` instances and how the different instances are selected through the hashing mechanism.

To create a simple connection to two `memcached` instances:

```
<?php
$cache = new Memcache;
$cache->addServer('192.168.0.100',11211);
$cache->addServer('192.168.0.101',11211);
?>
```

In this scenario the instance connection is not explicitly opened, but only opened when you try to store or retrieve a value. You can enable persistent connections to `memcached` instances by setting the `$persistent` argument to true. This is the default setting, and causes the connections to remain open.

To help control the distribution of keys to different instances, use the global `memcache.hash_strategy` setting. This sets the hashing mechanism used to select. You can also add another weight to each server, which effectively increases the number of times the instance entry appears in the instance list, therefore increasing the likelihood of the instance being chosen over other instances. To set the weight, set the value of the `$weight` argument to more than one.

The functions for setting and retrieving information are identical to the generic functional interface offered by `memcached`, as shown in this table.

| PECL <code>memcache</code> Function | Equivalent to                  |
|-------------------------------------|--------------------------------|
| <code>get()</code>                  | Generic <code>get()</code>     |
| <code>set()</code>                  | Generic <code>set()</code>     |
| <code>add()</code>                  | Generic <code>add()</code>     |
| <code>replace()</code>              | Generic <code>replace()</code> |
| <code>delete()</code>               | Generic <code>delete()</code>  |
| <code>increment()</code>            | Generic <code>incr()</code>    |
| <code>decrement()</code>            | Generic <code>decr()</code>    |

A full example of the PECL `memcache` interface is provided below. The code loads film data from the Sakila database when the user provides a film name. The data stored into the `memcached` instance is recorded as a `mysqli` result row, and the API automatically serializes the information for you.

```
<?php

$memc = new Memcache;
$memc->addServer('localhost','11211');
?>

<html xmlns="http://www.w3.org/1999/xhtml" xml:lang="en" lang="en">
<head>
<meta http-equiv="Content-Type" content="text/html; charset=utf-8" />
<title>Simple Memcache Lookup</title>
</head>
<body>
<form method="post">
 <p>Film: <input type="text" size="20" name="film"></p>
<input type="submit">
</form>
<hr/>

<?php

 echo "Loading data...\n";

$value = $memc->get($_REQUEST['film']);

if ($value)
{
 printf("<p>Film data for %s loaded from memcache</p>",$value['title']);

 foreach (array_keys($value) as $key)
 {
 printf("<p>%s: %s</p>",$key, $value[$key]);
 }
}
else
{
 $con = new mysqli('localhost','sakila','password','sakila') or
 die ("<h1>Database problem</h1>" . mysqli_connect_error());

$result = $con->query(sprintf('select * from film where title ="%s"',$_REQUEST['film']));

$row = $result->fetch_array(MYSQLI_ASSOC);

$memc->set($row['title'],$row);

printf("<p>Loaded %s from MySQL</p>",$row['title']);
}

?>
```

With PHP, the connections to the `memcached` instances are kept open as long as the PHP and associated Apache instance remain running. When adding or removing servers from the list in a running instance (for example, when starting another script that mentions additional servers), the connections are shared, but the script only selects among the instances explicitly configured within the script.

To ensure that changes to the server list within a script do not cause problems, make sure to use the consistent hashing mechanism.

#### 14.5.3.5. Using MySQL and `memcached` with Ruby

There are a number of different modules for interfacing to `memcached` within Ruby. The `Ruby-MemCache` client library provides a native interface to `memcached` that does not require any external libraries, such as `libmemcached`. You can obtain the installer package from <http://www.deveiate.org/projects/RMemCache>.

To install, extract the package and then run `install.rb`:

```
shell> install.rb
```

If you have RubyGems, you can install the `Ruby-MemCache` gem:

```
shell> gem install Ruby-MemCache
Bulk updating Gem source index for: http://gems.rubyforge.org
Install required dependency io-reactor? [Yn] y
Successfully installed Ruby-MemCache-0.0.1
Successfully installed io-reactor-0.05
Installing ri documentation for io-reactor-0.05...
Installing RDoc documentation for io-reactor-0.05...
```

To use a `memcached` instance from within Ruby, create a new instance of the `MemCache` object.

```
require 'memcache'
memc = MemCache::new '192.168.0.100:11211'
```

You can add a weight to each server to increase the likelihood of the server being selected during hashing by appending the weight count to the server host name/port string:

```
require 'memcache'
memc = MemCache::new '192.168.0.100:11211:3'
```

To add servers to an existing list, you can append them directly to the `MemCache` object:

```
memc += ["192.168.0.101:11211"]
```

To set data into the cache, you can just assign a value to a key within the new cache object, which works just like a standard Ruby hash object:

```
memc["key"] = "value"
```

Or to retrieve the value:

```
print memc["key"]
```

For more explicit actions, you can use the method interface, which mimics the main `memcached` API functions, as summarized in the following table.

| Ruby <code>MemCache</code> Method | Equivalent to                                                                                                    |
|-----------------------------------|------------------------------------------------------------------------------------------------------------------|
| <code>get()</code>                | Generic <code>get()</code>                                                                                       |
| <code>get_hash(keys)</code>       | Get the values of multiple <code>keys</code> , returning the information as a hash of the keys and their values. |
| <code>set()</code>                | Generic <code>set()</code>                                                                                       |
| <code>set_many(pairs)</code>      | Set the values of the keys and values in the hash <code>pairs</code> .                                           |
| <code>add()</code>                | Generic <code>add()</code>                                                                                       |
| <code>replace()</code>            | Generic <code>replace()</code>                                                                                   |
| <code>delete()</code>             | Generic <code>delete()</code>                                                                                    |
| <code>incr()</code>               | Generic <code>incr()</code>                                                                                      |
| <code>decr()</code>               | Generic <code>decr()</code>                                                                                      |

#### 14.5.3.6. Using MySQL and `memcached` with Java

The `com.danga.MemCached` class within Java provides a native interface to `memcached` instances. You can obtain the client from <http://whalin.com/memcached/>. The Java class uses hashes that are compatible with `libmemcached`, so you can mix and match Java and `libmemcached` applications accessing the same `memcached` instances. The serialization between Java and other interfaces are not compatible. If this is a problem, use JSON or a similar nonbinary serialization format.

On most systems you can download the package and use the `jar` directly.

To use the `com.danga.MemCached` interface, you create a `MemCachedClient` instance and then configure the list of servers by configuring the `SockIOPool`. Through the pool specification you set up the server list, weighting, and the connection parameters to optimized the connections between your client and the `memcached` instances that you configure.

Generally you can configure the `memcached` interface once within a single class and then use this interface throughout the rest of your application.

For example, to create a basic interface, first configure the `MemCachedClient` and base `SockIOPool` settings:

```
public class MyClass {
 protected static MemCachedClient mcc = new MemCachedClient();
 static {
 String[] servers =
 {
 "localhost:11211",
 };
 Integer[] weights = { 1 };
 SockIOPool pool = SockIOPool.getInstance();
 pool.setServers(servers);
 pool.setWeights(weights);
 }
}
```

In the above sample, the list of servers is configured by creating an array of the `memcached` instances that you want to use. You can then configure individual weights for each server.

The remainder of the properties for the connection are optional, but you can set the connection numbers (initial connections, minimum connections, maximum connections, and the idle timeout) by setting the pool parameters:

```
pool.setInitConn(5);
pool.setMinConn(5);
pool.setMaxConn(250);
pool.setMaxIdle(1000 * 60 * 60 * 6)
```

Once the parameters have been configured, initialize the connection pool:

```
pool.initialize();
```

The pool, and the connection to your `memcached` instances should now be ready to use.

To set the hashing algorithm used to select the server used when storing a given key you can use `pool.setHashingAlg()`:

```
pool.setHashingAlg(SockIOPool.NEW_COMPAT_HASH);
```

Valid values are `NEW_COMPAT_HASH`, `OLD_COMPAT_HASH` and `NATIVE_HASH` are also basic modula hashing algorithms. For a consistent hashing algorithm, use `CONSISTENT_HASH`. These constants are equivalent to the corresponding hash settings within `libmemcached`.

| Java <code>com.danga.MemCached</code> Method | Equivalent to                                                                                                                                                                                         |
|----------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>get()</code>                           | Generic <code>get()</code>                                                                                                                                                                            |
| <code>getMulti(keys)</code>                  | Get the values of multiple <code>keys</code> , returning the information as Hash map using <code>java.lang.String</code> for the keys and <code>java.lang.Object</code> for the corresponding values. |
| <code>set()</code>                           | Generic <code>set()</code>                                                                                                                                                                            |
| <code>add()</code>                           | Generic <code>add()</code>                                                                                                                                                                            |
| <code>replace()</code>                       | Generic <code>replace()</code>                                                                                                                                                                        |
| <code>delete()</code>                        | Generic <code>delete()</code>                                                                                                                                                                         |
| <code>incr()</code>                          | Generic <code>incr()</code>                                                                                                                                                                           |
| <code>decr()</code>                          | Generic <code>decr()</code>                                                                                                                                                                           |

#### 14.5.3.7. Using the MySQL `memcached` UDFs

The `memcached` MySQL User Defined Functions (UDFs) enable you to set and retrieve objects from within MySQL 5.0 or greater.

To install the MySQL `memcached` UDFs, download the UDF package from [http://tangent.org/586/Memcached\\_Functions\\_for\\_MySQL.html](http://tangent.org/586/Memcached_Functions_for_MySQL.html). Unpack the package and run `configure` to configure the build process. When running `configure`, use the `--with-mysql` option and specify the location of the `mysql_config` command. Note that you must be running :

```
shell> tar zxf memcached_functions_mysql-0.5.tar.gz
shell> cd memcached_functions_mysql-0.5
```

```
shell> ./configure --with-mysql-config=/usr/local/mysql/bin/mysql_config
```

Now build and install the functions:

```
shell> make
shell> make install
```

Copy the MySQL `memcached` UDFs into your MySQL plugins directory:

```
shell> cp /usr/local/lib/libmemcached_functions_mysql* /usr/local/mysql/lib/mysql/plugins/
```

The plugin directory is given by the value of the `plugin_dir` system variable. For more information, see [Section 22.3.2.5, “Compiling and Installing User-Defined Functions”](#).

Once installed, you must initialize the function within MySQL using `CREATE` and specifying the return value and library. For example, to add the `memc_get()` function:

```
mysql> CREATE FUNCTION memc_get RETURNS STRING SONAME "libmemcached_functions_mysql.so";
```

You must repeat this process for each function that you want to provide access to within MySQL. Once you have created the association, the information is retained, even over restarts of the MySQL server. You can simplify the process by using the SQL script provided in the `memcached` UDFs package:

```
shell> mysql <sql/install_functions.sql
```

Alternatively, if you have Perl installed, then you can use the supplied Perl script, which checks for the existence of each function and creates the function/library association if it is not already defined:

```
shell> utils/install.pl --silent
```

The `--silent` option installs everything automatically. Without this option, the script asks whether you want to install each of the available functions.

The interface remains consistent with the other APIs and interfaces. To set up a list of servers, use the `memc_servers_set()` function, which accepts a single string containing and comma-separated list of servers:

```
mysql> SELECT memc_servers_set('192.168.0.1:11211,192.168.0.2:11211');
```

## Note

The list of servers used by the `memcached` UDFs is not persistent over restarts of the MySQL server. If the MySQL server fails, then you must re-set the list of `memcached` servers.

To set a value, use `memc_set`:

```
mysql> SELECT memc_set('myid', 'myvalue');
```

To retrieve a stored value:

```
mysql> SELECT memc_get('myid');
```

The list of functions supported by the UDFs, in relation to the standard protocol functions, is shown in the following table.

| MySQL <code>memcached</code> UDF Function            | Equivalent to                                                                                       |
|------------------------------------------------------|-----------------------------------------------------------------------------------------------------|
| <code>memc_get()</code>                              | Generic <code>get()</code>                                                                          |
| <code>memc_get_by_key(master_key, key, value)</code> | Like the generic <code>get()</code> , but uses the supplied master key to select the server to use. |
| <code>memc_set()</code>                              | Generic <code>set()</code>                                                                          |
| <code>memc_set_by_key(master_key, key, value)</code> | Like the generic <code>set()</code> , but uses the supplied master key to select the server to use. |
| <code>memc_add()</code>                              | Generic <code>add()</code>                                                                          |
| <code>memc_add_by_key(master_key, key, value)</code> | Like the generic <code>add()</code> , but uses the supplied master key to select the server to use. |
| <code>memc_replace()</code>                          | Generic <code>replace()</code>                                                                      |

| MySQL memcached UDF Function                             | Equivalent to                                                                                                                                                   |
|----------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>memc_replace_by_key(master_key, key, value)</code> | Like the generic <code>replace()</code> , but uses the supplied master key to select the server to use.                                                         |
| <code>memcprepend(key, value)</code>                     | Prepend the specified <code>value</code> to the current value of the specified <code>key</code> .                                                               |
| <code>memcprepend_by_key(master_key, key, value)</code>  | Prepend the specified <code>value</code> to the current value of the specified <code>key</code> , but uses the supplied master key to select the server to use. |
| <code>memcappend(key, value)</code>                      | Append the specified <code>value</code> to the current value of the specified <code>key</code> .                                                                |
| <code>memcappend_by_key(master_key, key, value)</code>   | Append the specified <code>value</code> to the current value of the specified <code>key</code> , but uses the supplied master key to select the server to use.  |
| <code>memc_delete()</code>                               | Generic <code>delete()</code>                                                                                                                                   |
| <code>memc_delete_by_key(master_key, key, value)</code>  | Like the generic <code>delete()</code> , but uses the supplied master key to select the server to use.                                                          |
| <code>memc_increment()</code>                            | Generic <code>incr()</code>                                                                                                                                     |
| <code>memc_decrement()</code>                            | Generic <code>decr()</code>                                                                                                                                     |

The respective `*_by_key()` functions are useful when you want to store a specific value into a specific `memcached` server, possibly based on a differently calculated or constructed key.

The `memcached` UDFs include some additional functions:

- `memc_server_count()`

Returns a count of the number of servers in the list of registered servers.

- `memc_servers_set_behavior(behavior_type, value), memc_set_behavior(behavior_type, value)`

Set behaviors for the list of servers. These behaviors are identical to those provided by the `libmemcached` library. For more information on `libmemcached` behaviors, see [Section 14.5.3.1, “Using libmemcached”](#).

You can use the behavior name as the `behavior_type`:

```
mysql> SELECT memc_servers_behavior_set("MEMCACHED_BEHAVIOR_KETAMA", 1);
```

- `memc_servers_behavior_get(behavior_type), memc_get_behavior(behavior_type, value)`

Returns the value for a given behavior.

- `memc_list_behaviors()`

Returns a list of the known behaviors.

- `memc_list_hash_types()`

Returns a list of the supported key-hashing algorithms.

- `memc_list_distribution_types()`

Returns a list of the supported distribution types to be used when selecting a server to use when storing a particular key.

- `memc_libmemcached_version()`

Returns the version of the `libmemcached` library.

- `memc_stats()`

Returns the general statistics information from the server.

#### 14.5.3.8. memcached Protocol

Communicating with a `memcached` server can be achieved through either the TCP or UDP protocols. When using the TCP protocol you can use a simple text based interface for the exchange of information.

#### 14.5.3.8.1. Using the TCP text protocol

When communicating with `memcached` you can connect to the server using the port configured for the server. You can open a connection with the server without requiring authorization or login. As soon as you have connected, you can start to send commands to the server. When you have finished, you can terminate the connection without sending any specific disconnection command. Clients are encouraged to keep their connections open to decrease latency and improve performance.

Data is sent to the `memcached` server in two forms:

- Text lines, which are used to send commands to the server, and receive responses from the server.
- Unstructured data, which is used to receive or send the value information for a given key. Data is returned to the client in exactly the format it was provided.

Both text lines (commands and responses) and unstructured data are always terminated with the string `\r\n`. Because the data being stored may contain this sequence, the length of the data (returned by the client before the unstructured data is transmitted) should be used to determine the end of the data.

Commands to the server are structured according to their operation:

- **Storage commands:** `set`, `add`, `replace`, `append`, `prepend`, `cas`

Storage commands to the server take the form:

```
command key [flags] [exptime] length [noreply]
```

Or when using compare and swap (cas):

```
cas key [flags] [exptime] length [casunique] [noreply]
```

Where:

- **command:** The command name.
  - `set`: Store value against key
  - `add`: Store this value against key if the key does not already exist
  - `replace`: Store this value against key if the key already exists
  - `append`: Append the supplied value to the end of the value for the specified key. The `flags` and `exptime` arguments should not be used.
  - `prepend`: Append value currently in the cache to the end of the supplied value for the specified key. The `flags` and `exptime` arguments should not be used.
  - `cas`: Set the specified key to the supplied value, only if the supplied `casunique` matches. This is effectively the equivalent of change the information if nobody has updated it since I last fetched it.
- **key:** The key. All data is stored using a the specific key. The key cannot contain control characters or whitespace, and can be up to 250 characters in size.
- **flags:** The flags for the operation (as an integer). Flags in `memcached` are transparent. The `memcached` server ignores the contents of the flags. They can be used by the client to indicate any type of information. In `memcached` 1.2.0 and lower the value is a 16-bit integer value. In `memcached` 1.2.1 and higher the value is a 32-bit integer.
- **exptime:** The expiry time, or zero for no expiry.
- **length:** The length of the supplied value block in bytes, excluding the terminating `\r\n` characters.
- **casunique:** A unique 64-bit value of an existing entry. This is used to compare against the existing value. Use the value returned by the `gets` command when issuing `cas` updates.
- **noreply:** Tells the server not to reply to the command.

For example, to store the value `abcdef` into the key `xyzkey`, you would use:

```
set xyzkey 0 0 6\r\nabcdef\r\n
```

The return value from the server is one line, specifying the status or error information. For more information, see [Table 14.2, “memcached Protocol Responses”](#).

- **Retrieval commands:** `get`, `gets`

Retrieval commands take the form:

```
get key1 [key2 ... keyn]
gets key1 [key2 ... keyn]
```

You can supply multiple keys to the commands, with each requested key separated by whitespace.

The server responds with an information line of the form:

```
VALUE key flags bytes [casunique]
```

Where:

- `key`: The key name.
- `flags`: The value of the flag integer supplied to the `memcached` server when the value was stored.
- `bytes`: The size (excluding the terminating `\r\n` character sequence) of the stored value.
- `casunique`: The unique 64-bit integer that identifies the item.

The information line is immediately followed by the value data block. For example:

```
get xyzkey\r\n
VALUE xyzkey 0 6\r\n
abcdef\r\n
```

If you have requested multiple keys, an information line and data block is returned for each key found. If a requested key does not exist in the cache, no information is returned.

- **Delete commands:** `delete`

Deletion commands take the form:

```
delete key [time] [noreply]
```

Where:

- `key`: The key name.
- `time`: The time in seconds (or a specific Unix time) for which the client wishes the server to refuse `add` or `replace` commands on this key. All `add`, `replace`, `get`, and `gets` commands fail during this period. `set` operations succeed. After this period, the key is deleted permanently and all commands are accepted.

If not supplied, the value is assumed to be zero (delete immediately).

- `noreply`: Tells the server not to reply to the command.

Responses to the command are either `DELETED` to indicate that the key was successfully removed, or `NOT_FOUND` to indicate that the specified key could not be found.

- **Increment/Decrement:** `incr`, `decr`

The increment and decrement commands change the value of a key within the server without performing a separate get/set sequence. The operations assume that the currently stored value is a 64-bit integer. If the stored value is not a 64-bit integer, then the value is assumed to be zero before the increment or decrement operation is applied.

Increment and decrement commands take the form:

```
incr key value [noreply]
decr key value [noreply]
```

Where:

- **key**: The key name.
- **value**: An integer to be used as the increment or decrement value.
- **noreply**: Tells the server not to reply to the command.

The response is:

- **NOT\_FOUND**: The specified key could not be located.
- **value**: The new value of the specified key.

Values are assumed to be unsigned. For `decr` operations the value is never decremented below 0. For `incr` operations, the value wraps around the 64-bit maximum.

- **Statistics commands: `stats`**

The `stats` command provides detailed statistical information about the current status of the `memcached` instance and the data it is storing.

Statistics commands take the form:

```
STAT [name] [value]
```

Where:

- **name**: The optional name of the statistics to return. If not specified, the general statistics are returned.
- **value**: A specific value to be used when performing certain statistics operations.

The return value is a list of statistics data, formatted as follows:

```
STAT name value
```

The statistics are terminated with a single line, `END`.

For more information, see [Section 14.5.4, “Getting memcached Statistics”](#).

For reference, a list of the different commands supported and their formats is provided below.

**Table 14.1. memcached Command Reference**

| Command              | Command Formats                                                                                                                     |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| <code>set</code>     | <code>set key flags exptime length</code> , <code>set key flags exptime length noreply</code>                                       |
| <code>add</code>     | <code>add key flags exptime length</code> , <code>add key flags exptime length noreply</code>                                       |
| <code>replace</code> | <code>replace key flags exptime length</code> , <code>replace key flags exptime length noreply</code>                               |
| <code>append</code>  | <code>append key length</code> , <code>append key length noreply</code>                                                             |
| <code>prepend</code> | <code>prepend key length</code> , <code>prepend key length noreply</code>                                                           |
| <code>cas</code>     | <code>cas key flags exptime length casunique</code> , <code>cas key flags exptime length casunique noreply</code>                   |
| <code>get</code>     | <code>get key1 [key2 ... keyn]</code>                                                                                               |
| <code>gets</code>    |                                                                                                                                     |
| <code>delete</code>  | <code>delete key</code> , <code>delete key noreply</code> , <code>delete key expiry</code> , <code>delete key expiry noreply</code> |
| <code>incr</code>    | <code>incr key</code> , <code>incr key noreply</code> , <code>incr key value</code> , <code>incr key value noreply</code>           |
| <code>decr</code>    | <code>decr key</code> , <code>decr key noreply</code> , <code>decr key value</code> , <code>decr key value noreply</code>           |
| <code>stat</code>    | <code>stat</code> , <code>stat name</code> , <code>stat name value</code>                                                           |

When sending a command to the server, the response from the server is one of the settings in the following table. All response values from the server are terminated by `\r\n`:

**Table 14.2. memcached Protocol Responses**

| String                    | Description                                                                                                                                                                                                                             |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| STORED                    | Value has successfully been stored.                                                                                                                                                                                                     |
| NOT_STORED                | The value was not stored, but not because of an error. For commands where you are adding a or updating a value if it exists (such as <code>add</code> and <code>replace</code> ), or where the item has already been set to be deleted. |
| EXISTS                    | When using a <code>cas</code> command, the item you are trying to store already exists and has been modified since you last checked it.                                                                                                 |
| NOT_FOUND                 | The item you are trying to store, update or delete does not exist or has already been deleted.                                                                                                                                          |
| ERROR                     | You submitted a nonexistent command name.                                                                                                                                                                                               |
| CLIENT_ERROR error-string | There was an error in the input line, the detail is contained in <code>errorstring</code> .                                                                                                                                             |
| SERVER_ERROR error-string | There was an error in the server that prevents it from returning the information. In extreme conditions, the server may disconnect the client after this error occurs.                                                                  |
| VALUE keys flags length   | The requested key has been found, and the stored <code>key</code> , <code>flags</code> and data block are returned, of the specified <code>length</code> .                                                                              |
| DELETED                   | The requested key was deleted from the server.                                                                                                                                                                                          |
| STAT name value           | A line of statistics data.                                                                                                                                                                                                              |
| END                       | The end of the statistics data.                                                                                                                                                                                                         |

#### 14.5.4. Getting memcached Statistics

The `memcached` system has a built in statistics system that collects information about the data being stored into the cache, cache hit ratios, and detailed information on the memory usage and distribution of information through the slab allocation used to store individual items. Statistics are provided at both a basic level that provide the core statistics, and more specific statistics for specific areas of the `memcached` server.

This information can prove be very useful to ensure that you are getting the correct level of cache and memory usage, and that your slab allocation and configuration properties are set at an optimal level.

The stats interface is available through the standard `memcached` protocol, so the reports can be accessed by using `telnet` to connect to the `memcached`. The supplied `memcached-tool` includes support for obtaining the [Section 14.5.4.2, “memcached Slabs Statistics”](#) and [Section 14.5.4.1, “memcached General Statistics”](#) information. For more information, see [Section 14.5.4.6, “Using memcached-tool”](#).

Alternatively, most of the language API interfaces provide a function for obtaining the statistics from the server.

For example, to get the basic stats using `telnet`:

```
shell> telnet localhost 11211
Trying ::1...
Connected to localhost.
Escape character is '^]'.
stats
STAT pid 23599
STAT uptime 675
STAT time 1211439587
STAT version 1.2.5
STAT pointer_size 32
STAT rusage_user 1.404992
STAT rusage_system 4.694685
STAT curr_items 32
STAT total_items 56361
STAT bytes 2642
STAT curr_connections 53
STAT total_connections 438
STAT connection_structures 55
STAT cmd_get 113482
STAT cmd_set 80519
STAT get_hits 78926
STAT get_misses 34556
STAT evictions 0
STAT bytes_read 6379783
STAT bytes_written 4860179
STAT limit_maxbytes 67108864
STAT threads 1
END
```

When using Perl and the `Cache::Memcached` module, the `stats()` function returns information about all the servers currently configured in the connection object, and total statistics for all the `memcached` servers as a whole.

For example, the following Perl script obtains the stats and dumps the hash reference that is returned:

```
use Cache::Memcached;
use Data::Dumper;

my $memc = new Cache::Memcached;
$memc->set_servers(@ARGV);

print Dumper($memc->stats());
```

When executed on the same `memcached` as used in the `Telnet` example above we get a hash reference with the host by host and total statistics:

```
$VAR1 = {
 'hosts' => {
 'localhost:11211' => {
 'misc' => {
 'bytes' => '2421',
 'curr_connections' => '3',
 'connection_structures' => '56',
 'pointer_size' => '32',
 'time' => '1211440166',
 'total_items' => '410956',
 'cmd_set' => '588167',
 'bytes_written' => '35715151',
 'evictions' => '0',
 'curr_items' => '31',
 'pid' => '23599',
 'limit_maxbytes' => '67108864',
 'uptime' => '1254',
 'rusage_user' => '9.857805',
 'cmd_get' => '838451',
 'rusage_system' => '34.096988',
 'version' => '1.2.5',
 'get_hits' => '581511',
 'bytes_read' => '46665716',
 'threads' => '1',
 'total_connections' => '3104',
 'get_misses' => '256940'
 },
 'sizes' => {
 '128' => '16',
 '64' => '15'
 }
 },
 'self' => {},
 'total' => {
 'cmd_get' => 838451,
 'bytes' => 2421,
 'get_hits' => 581511,
 'connection_structures' => 56,
 'bytes_read' => 46665716,
 'total_items' => 410956,
 'total_connections' => 3104,
 'cmd_set' => 588167,
 'bytes_written' => 35715151,
 'curr_items' => 31,
 'get_misses' => 256940
 }
 };
};
```

The statistics are divided up into a number of distinct sections, and then can be requested by adding the type to the `stats` command. Each statistics output is covered in more detail in the following sections.

- General statistics, see [Section 14.5.4.1, “memcached General Statistics”](#).
- Slab statistics (`slabs`), see [Section 14.5.4.2, “memcached Slabs Statistics”](#).
- Item statistics (`items`), see [Section 14.5.4.3, “memcached Item Statistics”](#).
- Size statistics (`sizes`), see [Section 14.5.4.4, “memcached Size Statistics”](#).
- Detailed status (`detail`), see [Section 14.5.4.5, “memcached Detail Statistics”](#).

#### 14.5.4.1. memcached General Statistics

The output of the general statistics provides an overview of the performance and use of the `memcached` instance. The statistics returned by the command and their meaning is shown in the following table.

The following terms are used to define the value type for each statistics value:

- `32u`: 32-bit unsigned integer
- `64u`: 64-bit unsigned integer
- `32u32u`: Two 32-bit unsigned integers separated by a colon
- `String`: Character string

| Statistic             | Data type | Description                                                                                                               | Version |
|-----------------------|-----------|---------------------------------------------------------------------------------------------------------------------------|---------|
| pid                   | 32u       | Process ID of the <code>memcached</code> instance.                                                                        |         |
| uptime                | 32u       | Uptime (in seconds) for this <code>memcached</code> instance.                                                             |         |
| time                  | 32u       | Current time (as epoch).                                                                                                  |         |
| version               | string    | Version string of this instance.                                                                                          |         |
| pointer_size          | string    | Size of pointers for this host specified in bits (32 or 64).                                                              |         |
| rusage_user           | 32u:32u   | Total user time for this instance (seconds:microseconds).                                                                 |         |
| rusage_system         | 32u:32u   | Total system time for this instance (seconds:microseconds).                                                               |         |
| curr_items            | 32u       | Current number of items stored by this instance.                                                                          |         |
| total_items           | 32u       | Total number of items stored during the life of this instance.                                                            |         |
| bytes                 | 64u       | Current number of bytes used by this server to store items.                                                               |         |
| curr_connections      | 32u       | Current number of open connections.                                                                                       |         |
| total_connections     | 32u       | Total number of connections opened since the server started running.                                                      |         |
| connection_structures | 32u       | Number of connection structures allocated by the server.                                                                  |         |
| cmd_get               | 64u       | Total number of retrieval requests ( <code>get</code> operations).                                                        |         |
| cmd_set               | 64u       | Total number of storage requests ( <code>set</code> operations).                                                          |         |
| get_hits              | 64u       | Number of keys that have been requested and found present.                                                                |         |
| get_misses            | 64u       | Number of items that have been requested and not found.                                                                   |         |
| delete_hits           | 64u       | Number of keys that have been deleted and found present.                                                                  | 1.3.x   |
| delete_misses         | 64u       | Number of items that have been delete and not found.                                                                      | 1.3.x   |
| incr_hits             | 64u       | Number of keys that have been incremented and found present.                                                              | 1.3.x   |
| incr_misses           | 64u       | Number of items that have been incremented and not found.                                                                 | 1.3.x   |
| decr_hits             | 64u       | Number of keys that have been decremented and found present.                                                              | 1.3.x   |
| decr_misses           | 64u       | Number of items that have been decremented and not found.                                                                 | 1.3.x   |
| cas_hits              | 64u       | Number of keys that have been compared and swapped and found present.                                                     | 1.3.x   |
| cas_misses            | 64u       | Number of items that have been compared and swapped and not found.                                                        | 1.3.x   |
| cas_badvalue          | 64u       | Number of keys that have been compared and swapped, but the comparison (original) value did not match the supplied value. | 1.3.x   |
| evictions             | 64u       | Number of valid items removed from cache to free memory for new items.                                                    |         |
| bytes_read            | 64u       | Total number of bytes read by this server from network.                                                                   |         |
| bytes_written         | 64u       | Total number of bytes sent by this server to network.                                                                     |         |
| limit_maxbytes        | 32u       | Number of bytes this server is permitted to use for storage.                                                              |         |
| threads               | 32u       | Number of worker threads requested.                                                                                       |         |
| conn_yields           | 64u       | Number of yields for connections (related to the <code>-R</code> option).                                                 | 1.4.0   |

The most useful statistics from those given here are the number of cache hits, misses, and evictions.

A large number of `get_misses` may just be an indication that the cache is still being populated with information. The number

should, over time, decrease in comparison to the number of cache `get_hits`. If, however, you have a large number of cache misses compared to cache hits after an extended period of execution, it may be an indication that the size of the cache is too small and you either need to increase the total memory size, or increase the number of the `memcached` instances to improve the hit ratio.

A large number of `evictions` from the cache, particularly in comparison to the number of items stored is a sign that your cache is too small to hold the amount of information that you regularly want to keep cached. Instead of items being retained in the cache, items are being evicted to make way for new items keeping the turnover of items in the cache high, reducing the efficiency of the cache.

#### 14.5.4.2. `memcached` Slabs Statistics

To get the `slabs` statistics, use the `stats slabs` command, or the API equivalent.

The slab statistics provide you with information about the slabs that have created and allocated for storing information within the cache. You get information both on each individual slab-class and total statistics for the whole slab.

```
STAT 1:chunk_size 104
STAT 1:chunks_per_page 10082
STAT 1:total_pages 1
STAT 1:total_chunks 10082
STAT 1:used_chunks 10081
STAT 1:free_chunks 1
STAT 1:free_chunks_end 10079
STAT 9:chunk_size 696
STAT 9:chunks_per_page 1506
STAT 9:total_pages 63
STAT 9:total_chunks 94878
STAT 9:used_chunks 94878
STAT 9:free_chunks 0
STAT 9:free_chunks_end 0
STAT active_slabs 2
STAT total_malloced 67083616
END
```

Individual stats for each slab class are prefixed with the slab ID. A unique ID is given to each allocated slab from the smallest size up to the largest. The prefix number indicates the slab class number in relation to the calculated chunk from the specified growth factor. Hence in the example, 1 is the first chunk size and 9 is the 9th chunk allocated size.

The different parameters returned for each chunk size and the totals are shown in the following table.

| Statistic       | Description                                                             | Version |
|-----------------|-------------------------------------------------------------------------|---------|
| chunk_size      | Space allocated to each chunk within this slab class.                   |         |
| chunks_per_page | Number of chunks within a single page for this slab class.              |         |
| total_pages     | Number of pages allocated to this slab class.                           |         |
| total_chunks    | Number of chunks allocated to the slab class.                           |         |
| used_chunks     | Number of chunks allocated to an item..                                 |         |
| free_chunks     | Number of chunks not yet allocated to items.                            |         |
| free_chunks_end | Number of free chunks at the end of the last allocated page.            |         |
| get_hits        | Number of get hits to this chunk                                        | 1.3.x   |
| cmd_set         | Number of set commands on this chunk                                    | 1.3.x   |
| delete_hits     | Number of delete hits to this chunk                                     | 1.3.x   |
| incr_hits       | Number of increment hits to this chunk                                  | 1.3.x   |
| decr_hits       | Number of decrement hits to this chunk                                  | 1.3.x   |
| cas_hits        | Number of CAS hits to this chunk                                        | 1.3.x   |
| cas_badval      | Number of CAS hits on this chunk where the existing value did not match | 1.3.x   |
| mem_requested   | The true amount of memory of memory requested within this chunk         | 1.4.1   |

The following additional statistics cover the information for the entire server, rather than on a chunk by chunk basis:

| Statistic      | Description                                     | Version |
|----------------|-------------------------------------------------|---------|
| active_slabs   | Total number of slab classes allocated.         |         |
| total_malloced | Total amount of memory allocated to slab pages. |         |

The key values in the slab statistics are the `chunk_size`, and the corresponding `total_chunks` and `used_chunks` parameters. These give an indication of the size usage of the chunks within the system. Remember that one key/value pair is placed into a chunk of a suitable size.

From these stats, you can get an idea of your size and chunk allocation and distribution. If you store many items with a number of largely different sizes, then you may want to adjust the chunk size growth factor to increase in larger steps to prevent chunk and memory wastage. A good indication of a bad growth factor is a high number of different slab classes, but with relatively few chunks actually in use within each slab. Increasing the growth factor creates fewer slab classes and therefore makes better use of the allocated pages.

#### 14.5.4.3. memcached Item Statistics

To get the `items` statistics, use the `stats items` command, or the API equivalent.

The `items` statistics give information about the individual items allocated within a given slab class.

```
STAT items:2:number 1
STAT items:2:age 452
STAT items:2:evicted 0
STAT items:2:evicted_nonzero 0
STAT items:2:evicted_time 2
STAT items:2:outofmemory 0
STAT items:2:tailrepairs 0
...
STAT items:27:number 1
STAT items:27:age 452
STAT items:27:evicted 0
STAT items:27:evicted_nonzero 0
STAT items:27:evicted_time 2
STAT items:27:outofmemory 0
STAT items:27:tailrepairs 0
```

The prefix number against each statistics relates to the corresponding chunk size, as returned by the `stats slabs` statistics. The result is a display of the number of items stored within each chunk within each slab size, and specific statistics about their age, eviction counts, and out of memory counts. A summary of the statistics is given in the following table.

| Statistic                    | Description                                                                                                                                                |       |
|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|
| <code>number</code>          | The number of items currently stored in this slab class.                                                                                                   |       |
| <code>age</code>             | The age of the oldest item within the slab class, in seconds.                                                                                              |       |
| <code>evicted</code>         | The number of items evicted to make way for new entries.                                                                                                   |       |
| <code>evicted_time</code>    | The time of the last evicted entry                                                                                                                         |       |
| <code>evicted_nonzero</code> | The time of the last evicted non-zero entry                                                                                                                | 1.4.0 |
| <code>outofmemory</code>     | The number of items for this slab class that have triggered an out of memory error (only value when the <code>-M</code> command line option is in effect). |       |
| <code>tailrepairs</code>     | Number of times the entries for a particular ID need repairing                                                                                             |       |

Item level statistics can be used to determine how many items are stored within a given slab and their freshness and recycle rate. You can use this to help identify whether there are certain slab classes that are triggering a much larger number of evictions than others.

#### 14.5.4.4. memcached Size Statistics

To get size statistics, use the `stats sizes` command, or the API equivalent.

The size statistics provide information about the sizes and number of items of each size within the cache. The information is returned as two columns, the first column is the size of the item (rounded up to the nearest 32 byte boundary), and the second column is the count of the number of items of that size within the cache:

```
96 35
128 38
160 807
192 804
224 410
```

```
256 222
288 83
320 39
352 53
384 33
416 64
448 51
480 30
512 54
544 39
576 10065
```

### Caution

Running this statistic locks up your cache as each item is read from the cache and its size calculated. On a large cache, this may take some time and prevent any set or get operations until the process completes.

The item size statistics are useful only to determine the sizes of the objects you are storing. Since the actual memory allocation is relevant only in terms of the chunk size and page size, the information is only useful during a careful debugging or diagnostic session.

#### 14.5.4.5. memcached Detail Statistics

For `memcached` 1.3.x and higher, you can enable and obtain detailed statistics about the `get`, `set`, and `del` operations on the individual keys stored in the cache, and determine whether the attempts hit (found) a particular key. These operations are only recorded while the detailed stats analysis is turned on.

To enable detailed statistics, you must send the `stats detail on` command to the `memcached` server:

```
$ telnet localhost 11211
Trying 127.0.0.1...
Connected to tiger.
Escape character is '^]'.
stats detail on
OK
```

Individual statistics are recorded for every `get`, `set` and `del` operation on a key, including keys that are not currently stored in the server. For example, if an attempt is made to obtain the value of key `abckey` and it does not exist, the `get` operating on the specified key are recorded while detailed statistics are in effect, even if the key is not currently stored. The `hits`, that is, the number of `get` or `del` operations for a key that exists in the server are also counted.

To turn detailed statistics off, send the `stats detail off` command to the `memcached` server:

```
$ telnet localhost 11211
Trying 127.0.0.1...
Connected to tiger.
Escape character is '^]'.
stats detail on
OK
```

To obtain the detailed statistics recorded during the process, send the `stats detail dump` command to the `memcached` server:

```
stats detail dump
PREFIX hykkey get 0 hit 0 set 1 del 0
PREFIX xyzkey get 0 hit 0 set 1 del 0
PREFIX yukkey get 1 hit 0 set 0 del 0
PREFIX abckey get 3 hit 3 set 1 del 0
END
```

You can use the detailed statistics information to determine whether your `memcached` clients are using a large number of keys that do not exist in the server by comparing the `hit` and `get` or `del` counts. Because the information is recorded by key, you can also determine whether the failures or operations are clustered around specific keys.

#### 14.5.4.6. Using memcached-tool

The `memcached-tool`, located within the `scripts` directory within the `memcached` source directory. The tool provides convenient access to some reports and statistics from any `memcached` instance.

The basic format of the command is:

```
shell> ./memcached-tool hostname:port [command]
```

The default output produces a list of the slab allocations and usage. For example:

```
shell> memcached-tool localhost:11211 display
Item_Size Max_Age Pages Count Full? Evicted Evict_Time OOM
1 80B 93s 1 20 no 0 0 0 0
2 104B 93s 1 16 no 0 0 0 0
3 136B 1335s 1 28 no 0 0 0 0
4 176B 1335s 1 24 no 0 0 0 0
5 224B 1335s 1 32 no 0 0 0 0
6 280B 1335s 1 34 no 0 0 0 0
7 352B 1335s 1 36 no 0 0 0 0
8 440B 1335s 1 46 no 0 0 0 0
9 552B 1335s 1 58 no 0 0 0 0
10 696B 1335s 1 66 no 0 0 0 0
11 872B 1335s 1 89 no 0 0 0 0
12 1.1K 1335s 1 112 no 0 0 0 0
13 1.3K 1335s 1 145 no 0 0 0 0
14 1.7K 1335s 1 123 no 0 0 0 0
15 2.1K 1335s 1 198 no 0 0 0 0
16 2.6K 1335s 1 199 no 0 0 0 0
17 3.3K 1335s 1 229 no 0 0 0 0
18 4.1K 1335s 1 248 yes 36 2 0 0
19 5.2K 1335s 2 328 no 0 0 0 0
20 6.4K 1335s 2 316 yes 387 1 0 0
21 8.1K 1335s 3 381 yes 492 1 0 0
22 10.1K 1335s 3 303 yes 598 2 0 0
23 12.6K 1335s 5 405 yes 605 1 0 0
24 15.8K 1335s 6 384 yes 766 2 0 0
25 19.7K 1335s 7 357 yes 908 170 0 0
26 24.6K 1336s 7 287 yes 1012 1 0 0
27 30.8K 1336s 7 231 yes 1193 169 0 0
28 38.5K 1336s 4 104 yes 1323 169 0 0
29 48.1K 1336s 1 21 yes 1287 1 0 0
30 60.2K 1336s 1 17 yes 1093 169 0 0
31 75.2K 1337s 1 13 yes 713 168 0 0
32 94.0K 1337s 1 10 yes 278 168 0 0
33 117.5K 1336s 1 3 no 0 0 0 0
```

This output is the same if you specify the `command` as `display`:

```
shell> memcached-tool localhost:11211 display
Item_Size Max_Age Pages Count Full? Evicted Evict_Time OOM
1 80B 93s 1 20 no 0 0 0 0
2 104B 93s 1 16 no 0 0 0 0
...
...
```

The output shows a summarized version of the output from the `slabs` statistics. The columns provided in the output are shown below:

- `#`: The slab number
- `Item_Size`: The size of the slab
- `Max_age`: The age of the oldest item in the slab
- `Pages`: The number of pages allocated to the slab
- `Count`: The number of items in this slab
- `Full?`: Whether the slab is fully populated
- `Evicted`: The number of objects evicted from this slab
- `Evict_Time`: The time (in seconds) since the last eviction
- `OOM`: The number of items that have triggered an out of memory error

You can also obtain a dump of the general statistics for the server using the `stats` command:

```
shell> memcached-tool localhost:11211 stats
#localhost:11211 Field Value
accepting_conns 1
bytes 162
bytes_read 485
bytes_written 6820
cas_badval 0
cas_hits 0
cas_misses 0
cmd_flush 0
cmd_get 4
cmd_set 2
conn_yields 0
connection_structures 11
curr_connections 10
```

```

curr_items 2
decr_hits 0
decr_misses 1
delete_hits 0
delete_misses 0
evictions 0
get_hits 4
get_misses 0
incr_hits 0
incr_misses 2
limit_maxbytes 67108864
listen_disabled_num 0
pid 12981
pointer_size 32
rusage_system 0.013911
rusage_user 0.011876
threads 4
time 1255518565
total_connections 20
total_items 2
uptime 880
version 1.4.2

```

The `memcached-tool` provides

## 14.5.5. memcached FAQ

### Questions

- [15.5.5.1:](#) If I have an object larger then a MB, do I have to manually split it or can I configure `memcached` to handle larger objects?
- [15.5.5.2:](#) Is the data inside of `memcached` secure?
- [15.5.5.3:](#) How are auto-increment columns in the MySQL database coordinated across multiple instances of memcached?
- [15.5.5.4:](#) How will the data will be handled when the `memcached` server is down?
- [15.5.5.5:](#) How does an event such as a crash of one of the `memcached` servers handled by the `memcached` client?
- [15.5.5.6:](#) What is the max size of an object you can store in memcache and is that configurable?
- [15.5.5.7:](#) Do the memcache UDFs work under 5.1?
- [15.5.5.8:](#) How easy is it to introduce `memcached` to an existing enterprise application instead of inclusion at project design?
- [15.5.5.9:](#) Is memcached more effective for video and audio as opposed to textual read/writes
- [15.5.5.10:](#) Can we implement different types of `memcached` as different nodes in the same server - so can there be deterministic and non deterministic in the same server?
- [15.5.5.11:](#) What are best practices for testing an implementation, to ensure that it is an improvement over the MySQL query cache, and to measure the impact of `memcached` configuration changes? And would you recommend keeping the configuration very simple to start?
- [15.5.5.12:](#) Can memcached be run on a Windows environment?
- [15.5.5.13:](#) What speed trade offs is there between `memcached` vs MySQL Query Cache? Where you check `memcached`, and get data from MySQL and put it in `memcached` or just make a query and results are put into MySQL Query Cache.

## Questions and Answers

### **15.5.5.1: If I have an object larger then a MB, do I have to manually split it or can I configure `memcached` to handle larger objects?**

You would have to manually split it. `memcached` is very simple, you give it a key and some data, it tries to cache it in RAM. If you try to store more than the default maximum size, the value is just truncated for speed reasons.

### **15.5.5.2: Is the data inside of `memcached` secure?**

No, there is no security required to access or update the information within a `memcached` instance, which means that anybody with access to the machine has the ability to read, view and potentially update the information. If you want to keep the data secure, you can encrypt and decrypt the information before storing it. If you want to restrict the users capable of connecting to the server, your only choice is to either disable network access, or use IPTables or similar to restrict access to the `memcached` ports to a select set of hosts.

### **15.5.5.3: How are auto-increment columns in the MySQL database coordinated across multiple instances of memcached?**

They aren't. There is no relationship between MySQL and `memcached` unless your application (or, if you are using the MySQL UDFs for `memcached`, your database definition) creates one.

If you are storing information based on an auto-increment key into multiple instances of `memcached` then the information will only be stored on one of the `memcached` instances anyway. The client uses the key value to determine which `memcached` instance to store the information, it doesn't store the same information across all the instances, as that would be a waste of cache memory.

### **15.5.5.4: How will the data will be handled when the `memcached` server is down?**

The behavior is entirely application dependent. Most applications will fall back to loading the data from the database (just as if they were updating the `memcached`) information. If you are using multiple `memcached` servers, you may also want to remove a server from the list to prevent the missing server affecting performance. This is because the client will still attempt to communicate the `memcached` that corresponds to the key you are trying to load.

### **15.5.5.5: How does an event such as a crash of one of the `memcached` servers handled by the `memcached` client?**

There is no automatic handling of this. If your client fails to get a response from a server then it should fall back to loading the data from the MySQL database.

The client APIs all provide the ability to add and remove `memcached` instances on the fly. If within your application you notice that `memcached` server is no longer responding, your can remove the server from the list of servers, and keys will automatically be redistributed to another `memcached` server in the list. If retaining the cache content on all your servers is important, make sure you use an API that supports a consistent hashing algorithm. For more information, see [Section 14.5.2.4, “`memcached` Hashing/Distribution Types”](#).

**15.5.5.6: What is the max size of an object you can store in memcache and is that configurable?**

The default maximum object size is 1MB. In `memcached` 1.4.2 and later you can change the maximum size of an object using the `-I` command line option.

For versions before this, to increase this size, you have to re-compile `memcached`. You can modify the value of the `POWER_BLOCK` within the `slabs.c` file within the source.

In `memcached` 1.4.2 and higher you can configure the maximum supported object size by using the `-I` command-line option. For example, to increase the maximum object size to 5MB:

```
$ memcached -I 5m
```

**15.5.5.7: Do the memcache UDFs work under 5.1?**

Yes.

**15.5.5.8: How easy is it to introduce `memcached` to an existing enterprise application instead of inclusion at project design?**

In general, it is very easy. In many languages and environments the changes to the application will be just a few lines, first to attempt to read from the cache when loading data and then fall back to the old method, and to update the cache with information once the data has been read.

`memcached` is designed to be deployed very easily, and you shouldn't require significant architectural changes to your application to use `memcached`.

**15.5.5.9: Is memcached more effective for video and audio as opposed to textual read/writes**

`memcached` doesn't care what information you are storing. To `memcached`, any value you store is just a stream of data. Remember, though, that the maximum size of an object you can store in `memcached` is 1MB, but can be configured to be larger by using the `-I` option in `memcached` 1.4.2 and later, or by modifying the source in versions before 1.4.2. If you plan on using `memcached` with audio and video content you will probably want to increase the maximum object size. Also remember that `memcached` is a solution for caching information for reading. It shouldn't be used for writes, except when updating the information in the cache.

**15.5.5.10: Can we implement different types of `memcached` as different nodes in the same server - so can there be deterministic and non deterministic in the same server?**

Yes. You can run multiple instances of `memcached` on a single server, and in your client configuration you choose the list of servers you want to use.

**15.5.5.11: What are best practices for testing an implementation, to ensure that it is an improvement over the MySQL query cache, and to measure the impact of `memcached` configuration changes? And would you recommend keeping the configuration very simple to start?**

The best way to test the performance is to start up a `memcached` instance. First, modify your application so that it stores the data just before the data is about to be used or displayed into `memcached`. Since the APIs handle the serialization of the data, it should just be a one line modification to your code. Then, modify the start of the process that would normally load that information from MySQL with the code that requests the data from `memcached`. If the data cannot be loaded from `memcached`, default to the MySQL process.

All of the changes required will probably amount to just a few lines of code. To get the best benefit, make sure you cache entire objects (for example, all the components of a web page, blog post, discussion thread, etc.), rather than using `memcached` as a simple cache of individual rows of MySQL tables. You should see performance benefits almost immediately.

Keeping the configuration very simple at the start, or even over the long term, is very easy with `memcached`. Once you have the basic structure up and running, the only change you may want to make is to add more servers into the list of servers used by your clients. You don't need to manage the `memcached` servers, and there is no complex configuration, just add more servers to the list and let the client API and the `memcached` servers make the decisions.

**15.5.5.12: Can memcached be run on a Windows environment?**

No. Currently `memcached` is available only on the Unix/Linux platform. There is an unofficial port available, see <http://www.codeplex.com/memcachedproviders>.

**15.5.5.13: What speed trade offs is there between `memcached` vs MySQL Query Cache? Where you check `memcached`, and get data from MySQL and put it in `memcached` or just make a query and results are put into MySQL Query Cache.**

In general, the time difference between getting data from the MySQL Query Cache and getting the exact same data from `memcached` is very small.

However, the benefit of `memcached` is that you can store any information, including the formatted and processed results of many queries into a single `memcached` key. Even if all the queries that you executed could be retrieved from the Query Cache without having to go to disk, you would still be running multiple queries (with network and other overhead) compared to just one for the `memcached` equivalent. If your application uses objects, or does any kind of processing on the information, with `memcached` you can store the post-processed version, so the data you load is immediately available to be used. With data loaded from the Query Cache, you would still have to do that processing.

In addition to these considerations, keep in mind that keeping data in the MySQL Query Cache is difficult as you have no control over the queries that are stored. This means that a slightly unusual query can temporarily clear a frequently used (and normally cached) query, reducing the effectiveness of your Query Cache. With `memcached` you can specify which objects are stored, when they are stored, and when they should be deleted giving you much more control over the information stored in the cache.

#### **15.5.5.14: Can `memcached` work with `ASPX`?**

There are ports and interfaces for many languages and environments. `ASPX` relies on an underlying language such as C# or Visual-Basic, and if you are using `ASP.NET` then there is a C# `memcached` library. For more information, see [.NET](#).

#### **15.5.5.15: How does `memcached` compare to `nCache`?**

The main benefit of `memcached` is that it is very easy to deploy and works with a wide range of languages and environments, including .NET, Java, Perl, Python, PHP, even MySQL. `memcached` is also very lightweight in terms of systems and requirements, and you can easily add as many or as few `memcached` servers as you need without changing the individual configuration. `memcached` does require additional modifications to the application to take advantage of functionality such as multiple `memcached` servers.

#### **15.5.5.16: File socket support for `memcached` from the localhost use to the local `memcached` server?**

You can use the `-s` option to `memcached` to specify the location of a file socket. This automatically disables network support.

#### **15.5.5.17: How expensive is it to establish a memcache connection? Should those connections be pooled?**

Opening the connection is relatively inexpensive, because there is no security, authentication or other handshake taking place before you can start sending requests and getting results. Most APIs support a persistent connection to a `memcached` instance to reduce the latency. Connection pooling would depend on the API you are using, but if you are communicating directly over TCP/IP, then connection pooling would provide some small performance benefit.

#### **15.5.5.18: If you log a complex class (with methods that do calculation etc) will the get from Memcache re-create the class on the way out?**

In general, yes. If the serialization method within the API/language that you are using supports it, then methods and other information will be stored and retrieved.

#### **15.5.5.19: Can MySQL actually trigger/store the changed data to memcached?**

Yes. You can use the MySQL UDFs for `memcached` and either write statements that directly set the values in the `memcached` server, or use triggers or stored procedures to do it for you. For more information, see [Section 14.5.3.7, “Using the MySQL memcached UDFs”](#).

#### **15.5.5.20: What are the advantages of using UDFs when the get/sets are manageable from within the client code rather than the db?**

Sometimes you want to be able to update the information within `memcached` based on a generic database activity, rather than relying on your client code. For example, you may want to update status or counter information in `memcached` through the use of a trigger or stored procedure. For some situations and applications the existing use of a stored procedure for some operations means that updating the value in `memcached` from the database is easier than separately loading and communicating that data to the client just so the client can talk to `memcached`.

In other situations, when you are using a number of different clients and different APIs, you don't want to have to write (and maintain) the code required to update `memcached` in all the environments. Instead, you do this from within the database and the client never gets involved.

#### **15.5.5.21: Is `memcached` typically a better solution for improving speed than MySQL Cluster and/or MySQL Proxy?**

Both MySQL Cluster and MySQL Proxy still require access to the underlying database to retrieve the information. This implies both a parsing overhead for the statement and, often, disk based access to retrieve the data you have selected.

The advantage of `memcached` is that you can store entire objects or groups of information that may require multiple SQL statements to obtain. Restoring the result of 20 SQL statements formatted into a structure that your application can use directly without requiring any additional processing is always going to be faster than building that structure by loading the rows from a database.

#### **15.5.5.22: Are there any, or are there any plans to introduce, a framework to hide the interaction of memcached from the**

**application; that is, within hibernate?**

There are lots of projects working with `memcached`. There is a Google Code implementation of Hibernate and `memcached` working together. See <http://code.google.com/p/hibernate-memcached/>.

**15.5.5.23: `memcached` is fast - is there any overhead in not using persistent connections? If persistent is always recommended, what are the downsides (for example, locking up)?**

If you don't use persistent connections when communicating with `memcached` then there will be a small increase in the latency of opening the connection each time. The effect is comparable to use nonpersistent connections with MySQL.

In general, the chance of locking or other issues with persistent connections is minimal, because there is very little locking within `memcached`. If there is a problem then eventually your request will timeout and return no result so your application will need to load from MySQL again.

**15.5.5.24: We are caching XML by serialising using `saveXML()`, because PHP cannot serialise DOM objects; Some of the XML is variable and is modified per-request. Do you recommend caching then using XPath, or is it better to rebuild the DOM from separate node-groups?**

You would need to test your application using the different methods to determine this information. You may find that the default serialization within PHP may allow you to store DOM objects directly into the cache.

**15.5.5.25: Is it true `memcached` will be much more effective with db-read-intensive applications than with db-write-intensive applications?**

Yes. `memcached` plays no role in database writes, it is a method of caching data already read from the database in RAM.

**15.5.5.26: Does the `-l` flag automatically sense how much memory is being used by other `memcached`?**

No. There is no communication or sharing of information between `memcached` instances.

**15.5.5.27: What's a recommended hardware config for a `memcached` server? Linux or Windows?**

`memcached` is only available on Unix/Linux, so using a Windows machine is not an option. Outside of this, `memcached` has a very low processing overhead. All that is required is spare physical RAM capacity. The point is not that you should necessarily deploy a dedicated `memcached` server. If you have web, application, or database servers that have spare RAM capacity, then use them with `memcached`.

If you want to build and deploy a dedicated `memcached` servers, then you use a relatively low-power CPU, lots of RAM and one or more Gigabit Ethernet interfaces.

**15.5.5.28: Doing a direct telnet to the `memcached` port, is that just for that one machine, or does it magically apply across all nodes?**

Just one. There is no communication between different instances of `memcached`, even if each instance is running on the same machine.

**15.5.5.29: Is compression available?**

Yes. Most of the client APIs support some sort of compression, and some even allow you to specify the threshold at which a value is deemed appropriate for compression during storage.

**15.5.5.30: So the responsibility lies with the application to populate and get records from the database as opposed to being a transparent cache layer for the db?**

Yes. You load the data from the database and write it into the cache provided by `memcached`. Using `memcached` as a simple database row cache, however, is probably inefficient. The best way to use `memcached` is to load all of the information from the database relating to a particular object, and then cache the entire object. For example, in a blogging environment, you might load the blog, associated comments, categories and so on, and then cache all of the information relating to that blog post. The reading of the data from the database will require multiple SQL statements and probably multiple rows of data to complete, which is time consuming. Loading the entire blog post and the associated information from `memcached` is just one operation and doesn't involve using the disk or parsing the SQL statement.

## 14.6. MySQL Proxy

The MySQL Proxy is an application that communicates over the network using the MySQL Network Protocol and provides communication between one or more MySQL servers and one or more MySQL clients. In the most basic configuration, MySQL Proxy simply passes on queries from the client to the MySQL Server and returns the responses from the MySQL Server to the client.

Because MySQL Proxy uses the MySQL network protocol, any MySQL compatible client (include the command line client, any clients using the MySQL client libraries, and any connector that supports the MySQL network protocol) can connect to the proxy

without modification.

In addition to the basic pass-through configuration, the MySQL Proxy is also capable of monitoring and altering the communication between the client and the server. This interception of the queries enables you to add profiling, and the interception of the exchanges is scriptable using the Lua scripting language.

By intercepting the queries from the client, the proxy can insert additional queries into the list of queries sent to the server, and remove the additional results when they are returned by the server. Using this functionality you can add informational statements to each query, for example to monitor their execution time or progress, and separately log the results, while still returning the results from the original query to the client.

The proxy enables you to perform additional monitoring, filtering or manipulation on queries without you having to make any modifications to the client and without the client even being aware that it is communicating with anything but a genuine MySQL server.

This documentation covers MySQL Proxy 0.8.0.

### **Warning**

MySQL Proxy is currently an Alpha release and should not be used within production environments.

### **Important**

MySQL Proxy is compatible with MySQL 5.0.x or later. Testing has not been performed with Version 4.1. Please provide feedback on your experiences using the [MySQL Proxy Forum](#).

## **14.6.1. MySQL Proxy Supported Platforms**

MySQL Proxy is currently available as a pre-compiled binary for the following platforms:

- Linux (including RedHat, Fedora, Debian, SuSE) and derivatives
- Mac OS X
- FreeBSD
- IBM AIX
- Sun Solaris
- Microsoft Windows (including Microsoft Windows XP, Microsoft Windows Vista, Microsoft Windows Server 2003, Microsoft Windows Server 2008)

### **Note**

You must have the .NET Framework 1.1 or higher installed.

Other Unix/Linux platforms not listed should be compatible by using the source package and building MySQL Proxy locally.

System requirements for the MySQL Proxy application are the same as the main MySQL server. Currently MySQL Proxy is compatible only with MySQL 5.0.1 and later. MySQL Proxy is provided as a standalone, statically linked binary. You do not need to have MySQL or Lua installed.

## **14.6.2. Installing MySQL Proxy**

You have three choices for installing MySQL Proxy:

- Pre-compiled binaries are available for a number of different platforms. See [Section 14.6.2.1, “Installing MySQL Proxy from a Binary Distribution”](#).
- You can install from the source code if you want to build on an environment not supported by the binary distributions. See [Section 14.6.2.2, “Installing MySQL Proxy from a Source Distribution”](#).
- The latest version of the MySQL proxy source code is available through a development repository is the best way to stay up to date with the latest fixes and revisions. See [Section 14.6.2.3, “Installing MySQL Proxy from the Bazaar Repository”](#).

### 14.6.2.1. Installing MySQL Proxy from a Binary Distribution

If you download the binary packages, then you need to extract the package and copy the contents of the package to your desired installation directory. Files required by MySQL Proxy, including additional Lua scripts and other components required for execution.

To install, unpack the archive into the desired directory, and then modify your `PATH` environment variable so that you can use the `mysql-proxy` command directly:

```
shell> cd /usr/local
shell> tar zxf mysql-proxy-0.7.2-osx10.5.tar.gz
shell> PATH=$PATH:/usr/local/mysql-proxy-0.7.2-osx10.5-x86/sbin
```

If you want to update the path globally on a system, you may need administrator privileges to modify the appropriate `/etc/profile`, `/etc/bashrc`, or other system configuration file.

On Windows, you can update the `PATH` environment variable by:

- On the Windows desktop, right-click the My Computer icon, and select Properties.
- Next select the Advanced tab from the `SYSTEM PROPERTIES` menu that appears, and click the ENVIRONMENT VARIABLES button.
- Under `SYSTEM VARIABLES`, select Path, and then click the EDIT button. The `EDIT SYSTEM VARIABLE` dialogue should appear.

### 14.6.2.2. Installing MySQL Proxy from a Source Distribution

If you have downloaded the source package then you will need to compile the MySQL Proxy before using it. To build you will need to have the following installed:

- libevent 1.x or higher (1.3b or later is preferred)
- lua 5.1.x or higher
- glib2 2.6.0 or higher
- pkg-config
- libtool 1.5 or higher
- MySQL 5.0.x or higher developer files

#### Note

On some operating systems you may need to manually build the required components to get the latest version. If you are having trouble compiling MySQL Proxy then consider using one of the binary distributions.

Once these components are installed, you need to configure and then build:

```
shell> tar zxf mysql-proxy-0.7.2.tar.gz
shell> cd mysql-proxy-0.7.2
shell> ./configure
shell> make
```

If you want to test the build, then use the `check` target to `make`:

```
shell> make check
```

The tests try to connect to `localhost` using the `root` user. If you need to provide a password, set the `MYSQL_PASSWORD` environment variable:

```
shell> MYSQL_PASSWORD=root_pwd make check
```

You can install using the `install` target:

```
shell> make install
```

By default `mysql-proxy` is installed into `/usr/local/sbin/mysql-proxy`. The Lua example scripts are copied into `/`

`usr/local/share`.

### 14.6.2.3. Installing MySQL Proxy from the Bazaar Repository

The MySQL Proxy source is available through a public Bazaar repository and is the quickest way to get hold of the latest releases and fixes.

To build from the Bazaar repository, you need the following components already installed:

- Bazaar 1.10.0 or later
- `libtool` 1.5 or higher
- `autoconf` 2.56 or higher
- `automake` 1.10 or higher
- `libevent` 1.x or higher (1.3b or later is preferred)
- `lua` 5.1.x or higher
- `glib2` 2.4.0 or higher
- `pkg-config`
- MySQL 5.0.x or higher developer files

The `mysql-proxy` source is hosted on Launchpad. To checkout a local copy of the Bazaar repository, use `bzr`:

```
shell> bzr branch lp:mysql-proxy
```

The above command will download a complete version of the Bazaar repository for `mysql-proxy`. The main source files are located within the `trunk` subdirectory. The configuration scripts need to be generated before you can configure and build `mysql-proxy`. The `autogen.sh` script will generate the configuration scripts for you:

```
shell> sh ./autogen.sh
```

The script creates the standard `configure` script, which you can then use to configure and build with `make`:

```
shell> ./configure
shell> make
shell> make install
```

If you want to create a standalone source distribution, identical to the source distribution available for download:

```
shell> make distcheck
```

The above will create the file `mysql-proxy-0.7.2.tar.gz` (with the corresponding current version) within the current directory.

### 14.6.3. MySQL Proxy Configuration Options

To start `mysql-proxy` you can just run the command directly. However, for most situations you will want to specify at the very least the address/host name and port number of the backend MySQL server to which the MySQL Proxy should pass on queries.

You can specify options to `mysql-proxy` either on the command line, or by using a configuration file and the `-defaults-file` command-line option to specify the file location.

If you want to use a configuration file, then the file should be formatted as follows:

- Options must be specified within a configuration group named `mysql-proxy`. For example:

```
[mysql-proxy]
admin-address = host:port
```

- All configuration options should be specified in the form of a configuration name and the value you want to set.

- For options that are a simple toggle on the command-line (for example `--proxy-skip-profiling`, you must use `true` or `false`. For example, the following is invalid:

```
[mysql-proxy]
proxy-skip-profiling
```

But this is valid:

```
[mysql-proxy]
proxy-skip-profiling = true
```

- The configuration file should have permissions of `0660` (readable and writable by user and group, no access for everybody).

Failure to adhere to any of these requirements will trigger an error during startup.

A list of the supported configuration file and command line options are given in the tables below.

**Table 14.3. mysql-proxy Help Options**

| Format                    | Config File             | Description                       | Introduction | Deprecated | Removed |
|---------------------------|-------------------------|-----------------------------------|--------------|------------|---------|
| <code>--help</code>       | <code>help</code>       | Show help options                 | 0.8.0        |            |         |
| <code>--help-admin</code> | <code>help-admin</code> | Show options for the admin-module | 0.8.0        |            |         |
| <code>--help-all</code>   | <code>help-all</code>   | Show all help options             | 0.8.0        |            |         |
| <code>--help-proxy</code> | <code>help-proxy</code> | Show options for the proxy-module | 0.8.0        |            |         |

**Table 14.4. mysql-proxy Admin Options**

| Format                          | Config File                   | Description                                                 | Introduction | Deprecated | Removed |
|---------------------------------|-------------------------------|-------------------------------------------------------------|--------------|------------|---------|
| <code>--admin-address</code>    | <code>admin-address</code>    | Defines the listening address and port for the admin module | 0.8.0        |            |         |
| <code>--admin-lua-script</code> | <code>admin-lua-script</code> | Script to execute by the admin module                       | 0.8.0        |            |         |
| <code>--admin-password</code>   | <code>admin-password</code>   | Password for authentication for admin module                | 0.8.0        |            |         |
| <code>--admin-username</code>   | <code>admin-username</code>   | Username for authentication for admin module                | 0.8.0        |            |         |
| <code>--proxy-address</code>    | <code>proxy-address</code>    | Listening address:port of the proxy server                  | 0.8.0        |            |         |

**Table 14.5. mysql-proxy Proxy Options**

| Format                                   | Config File                            | Description                                                                                     | Introduction | Deprecated | Removed |
|------------------------------------------|----------------------------------------|-------------------------------------------------------------------------------------------------|--------------|------------|---------|
| <code>--no-proxy</code>                  | <code>no-proxy</code>                  | Don't start the proxy module                                                                    | 0.8.0        |            |         |
| <code>--proxy-backend-addresses</code>   | <code>proxy-backend-addresses</code>   | Address:port of the remote MySQL server                                                         | 0.8.0        |            |         |
| <code>--proxy-fix-bug-25371</code>       | <code>proxy-fix-bug-25371</code>       | Enable the fix for Bug#25371 (for mysqld > 0.8.0.12) for older libmysql versions                | 0.8.0        |            |         |
| <code>--proxy-lua-script</code>          | <code>proxy-lua-script</code>          | Filename for Lua script for proxy operations                                                    | 0.8.0        |            |         |
| <code>--proxy-pool-no-change-user</code> | <code>proxy-pool-no-change-user</code> | Don't use the protocol CHANGE_USER to reset the connection when coming from the connection pool | 0.8.0        |            |         |
| <code>--proxy-</code>                    | <code>proxy-</code>                    | Address:port of the remote MySQL server (read                                                   | 0.8.0        |            |         |

| Format                              | Config File                 | Description                   | Introduction | Deprecated | Removed |
|-------------------------------------|-----------------------------|-------------------------------|--------------|------------|---------|
| - proxy-read-only-backend-addresses | read-only-backend-addresses | only)                         |              |            |         |
| --proxy-skip-profiling              | proxy-skip-profiling        | Disabled profiling of queries | 0.8.0        |            |         |

**Table 14.6. mysql-proxy Applications Options**

| Format                    | Config File             | Description                                                  | Introduction | Deprecated | Removed |
|---------------------------|-------------------------|--------------------------------------------------------------|--------------|------------|---------|
| --basedir                 | basedir                 | Specify the base directory to prepend to paths in the config | 0.8.0        |            |         |
| --daemon                  | daemon                  | Start in daemon-mode                                         | 0.8.0        |            |         |
| --defaults-file           | defaults-file           | Specify the configuration file                               | 0.8.0        |            |         |
| --event-threads           | event-threads           | The number of event-handling threads                         | 0.8.0        |            |         |
| --keepalive               | keepalive               | Try to restart the proxy if a crash occurs                   | 0.8.0        |            |         |
| --log-back-trace-on-crash | log-back-trace-on-crash | Try to invoke the debug and generate a backtrace on crash    | 0.8.0        |            |         |
| --log-file                | log-file                | Specify the file for logging error messages                  | 0.8.0        |            |         |
| --log-level               | log-level               | Logging level                                                | 0.8.0        |            |         |
| --log-use-syslog          | log-use-syslog          | Log errors to syslog                                         | 0.8.0        |            |         |
| --lua-cpath               | lua-cpath               | Set the LUA_CPATH                                            | 0.8.0        |            |         |
| --lua-path                | lua-path                | Set the LUA_PATH                                             | 0.8.0        |            |         |
| --max-open-files          | max-open-files          | Specify the maximum number of open files to support          | 0.8.0        |            |         |
| --pid-file                | pid-file                | PID file to store the process ID (when in daemon mode)       | 0.8.0        |            |         |
| --plugin-dir              | plugin-dir              | Path to the plugin files                                     | 0.8.0        |            |         |
| --plugins                 | plugins                 | List of plugins to load                                      | 0.8.0        |            |         |
| --user                    | user                    | Specify the user to use when running mysql-proxy             | 0.8.0        |            |         |
| --version                 | version                 | Show the version information                                 | 0.8.0        |            |         |

Except as noted in the details below, all of the options can be used within the configuration file by supplying the option and the corresponding value. For example:

```
log-file = /var/log/mysql-proxy.log
log-level = message
```

- `--help`

|                            |                     |
|----------------------------|---------------------|
| <b>Version Introduced</b>  | 0.8.0               |
| <b>Command-Line Format</b> | <code>--help</code> |
|                            | <code>-?</code>     |
| <b>Config-File Format</b>  | <code>help</code>   |

Show available help options.

- [--help-all](#)

|                            |                            |
|----------------------------|----------------------------|
| <b>Version Introduced</b>  | 0.8.0                      |
| <b>Command-Line Format</b> | <a href="#">--help-all</a> |
| <b>Config-File Format</b>  | <a href="#">help-all</a>   |

Show all help options.

- [--help-admin](#)

|                            |                              |
|----------------------------|------------------------------|
| <b>Version Introduced</b>  | 0.8.0                        |
| <b>Command-Line Format</b> | <a href="#">--help-admin</a> |
| <b>Config-File Format</b>  | <a href="#">help-admin</a>   |

Show options for the admin-module.

- [--help-proxy](#)

|                            |                              |
|----------------------------|------------------------------|
| <b>Version Introduced</b>  | 0.8.0                        |
| <b>Command-Line Format</b> | <a href="#">--help-proxy</a> |
| <b>Config-File Format</b>  | <a href="#">help-proxy</a>   |

Show options for the proxy-module.

- [--admin-address=host:port](#)

|                            |                                 |

| <b>Version Introduced</b>  | 0.8.0                           |
| <b>Command-Line Format</b> | <a href="#">--admin-address</a> |
| <b>Config-File Format</b>  | <a href="#">admin-address</a>   |
|                            | <b>Permitted Values</b>         |
|                            | Type <a href="#">string</a>     |
|                            | Default <a href="#">:4041</a>   |

The host name (or IP address) and port for the administration port. The default is [localhost:4041](#).

- [--admin-lua-script=script](#)

|                            |                                    |
|----------------------------|------------------------------------|
| <b>Version Introduced</b>  | 0.8.0                              |
| <b>Command-Line Format</b> | <a href="#">--admin-lua-script</a> |
| <b>Config-File Format</b>  | <a href="#">admin-lua-script</a>   |
|                            | <b>Permitted Values</b>            |
|                            | Type <a href="#">filename</a>      |
|                            | Default                            |

The script to use for the administration module for the proxy.

- [--admin-password=pass](#)

|                            |                                  |
|----------------------------|----------------------------------|
| <b>Version Introduced</b>  | 0.8.0                            |
| <b>Command-Line Format</b> | <a href="#">--admin-password</a> |
| <b>Config-File Format</b>  | <a href="#">admin-password</a>   |
|                            | <b>Permitted Values</b>          |
|                            | Type <a href="#">string</a>      |
|                            | Default                          |

The password to use to authenticate users wanting to connect to the administration module of `mysql-proxy`. The administration module uses the MySQL protocol to request a username and password for connections.

- `--admin-username=user`

|                            |                                  |
|----------------------------|----------------------------------|
| <b>Version Introduced</b>  | 0.8.0                            |
| <b>Command-Line Format</b> | <code>--admin-username</code>    |
| <b>Config-File Format</b>  | <code>admin-username</code>      |
|                            | <b>Permitted Values</b>          |
|                            | <b>Type</b> <code>string</code>  |
|                            | <b>Default</b> <code>root</code> |

The username to use to authenticate users wanting to connect to the administration module of `mysql-proxy`. The default username is `root`. The administration module uses the MySQL protocol to request a username and password for connections.

- `--basedir`

|                            |                                   |
|----------------------------|-----------------------------------|
| <b>Version Introduced</b>  | 0.8.0                             |
| <b>Command-Line Format</b> | <code>--basedir</code>            |
| <b>Config-File Format</b>  | <code>basedir</code>              |
|                            | <b>Permitted Values</b>           |
|                            | <b>Type</b> <code>filename</code> |

The base directory that will be prepended to all other filename configuration options. The base name should be an absolute (not relative) directory. If you specify a relative directory, `mysql-proxy` will generate an error during startup.

- `--defaults-file`

|                            |                              |
|----------------------------|------------------------------|
| <b>Version Introduced</b>  | 0.8.0                        |
| <b>Command-Line Format</b> | <code>--defaults-file</code> |
| <b>Config-File Format</b>  | <code>defaults-file</code>   |

The file to use as the file with configuration information. If not specified, configuration options are only taken from the command line.

- `--event-threads=#`

|                            |                                  |
|----------------------------|----------------------------------|
| <b>Version Introduced</b>  | 0.8.0                            |
| <b>Command-Line Format</b> | <code>--event-threads</code>     |
| <b>Config-File Format</b>  | <code>event-threads</code>       |
|                            | <b>Permitted Values</b>          |
|                            | <b>Type</b> <code>numeric</code> |
|                            | <b>Default</b> <code>1</code>    |

The number of event threads reserved to handle incoming requests.

- `--keepalive`

|                            |                          |
|----------------------------|--------------------------|
| <b>Version Introduced</b>  | 0.8.0                    |
| <b>Command-Line Format</b> | <code>--keepalive</code> |
| <b>Config-File Format</b>  | <code>keepalive</code>   |

Creates a process surrounding the main `mysql-proxy` which will attempt to restart the true `mysql-proxy` process in the event a crash or other failure.

**Note**

The `--keepalive` option is not available on Microsoft Windows. When running as a service, the `mysql-proxy` service will automatically restart.

- `--log-backtrace-on-crash`

|                            |                                       |
|----------------------------|---------------------------------------|
| <b>Version Introduced</b>  | 0.8.0                                 |
| <b>Command-Line Format</b> | <code>--log-backtrace-on-crash</code> |
| <b>Config-File Format</b>  | <code>log-backtrace-on-crash</code>   |

Logs the backtrace to the error log and tries to initialize the debugger in the event of a failure.

- `--log-file=filename`

|                            |                            |
|----------------------------|----------------------------|
| <b>Version Introduced</b>  | 0.8.0                      |
| <b>Command-Line Format</b> | <code>--log-file</code>    |
| <b>Config-File Format</b>  | <code>log-file</code>      |
|                            | <b>Permitted Values</b>    |
|                            | Type <code>filename</code> |

The name of a file to be used to record log information.

- `--log-level=level`

|                            |                                                                |
|----------------------------|----------------------------------------------------------------|
| <b>Version Introduced</b>  | 0.8.0                                                          |
| <b>Command-Line Format</b> | <code>--log-level</code>                                       |
| <b>Config-File Format</b>  | <code>log-level</code>                                         |
|                            | <b>Permitted Values</b>                                        |
|                            | Type <code>enumeration</code>                                  |
|                            | Valid Values <code>error, warning, info, message, debug</code> |

The log level to be used when outputting error messages. The specification will output that level (or lower) of a given error message. For example, `message` will also output `info`, `warning`, and `error` messages.

- `--log-use-syslog`

|                            |                               |
|----------------------------|-------------------------------|
| <b>Version Introduced</b>  | 0.8.0                         |
| <b>Command-Line Format</b> | <code>--log-use-syslog</code> |
| <b>Config-File Format</b>  | <code>log-use-syslog</code>   |

Causes errors to be sent to the syslog (Unix/Linux only).

- `--lua-cpath=path`

|                            |                            |
|----------------------------|----------------------------|
| <b>Version Introduced</b>  | 0.8.0                      |
| <b>Command-Line Format</b> | <code>--lua-cpath</code>   |
| <b>Config-File Format</b>  | <code>lua-cpath</code>     |
|                            | <b>Permitted Values</b>    |
|                            | Type <code>filename</code> |

The `LUA_CPATH` to be used when loading compiled modules or libraries for Lua scripts.

- `--lua-path=path`

|                            |                                   |
|----------------------------|-----------------------------------|
| <b>Version Introduced</b>  | 0.8.0                             |
| <b>Command-Line Format</b> | <code>--lua-path</code>           |
| <b>Config-File Format</b>  | <code>lua-path</code>             |
|                            | <b>Permitted Values</b>           |
|                            | <b>Type</b> <code>filename</code> |

The `LUA_CPATH` to be used when loading modules for Lua.

- `--max-open-files=#`

|                            |                                  |
|----------------------------|----------------------------------|
| <b>Version Introduced</b>  | 0.8.0                            |
| <b>Command-Line Format</b> | <code>--max-open-files</code>    |
| <b>Config-File Format</b>  | <code>max-open-files</code>      |
|                            | <b>Permitted Values</b>          |
|                            | <b>Type</b> <code>numeric</code> |

The maximum number of open files and sockets supported by the `mysql-proxy` process. You may need to increase this with certain scripts.

- `--no-proxy`

|                            |                         |
|----------------------------|-------------------------|
| <b>Version Introduced</b>  | 0.8.0                   |
| <b>Command-Line Format</b> | <code>--no-proxy</code> |
| <b>Config-File Format</b>  | <code>no-proxy</code>   |

Disable the proxy module.

- `--plugin-dir=path`

|                            |                                   |
|----------------------------|-----------------------------------|
| <b>Version Introduced</b>  | 0.8.0                             |
| <b>Command-Line Format</b> | <code>--plugin-dir</code>         |
| <b>Config-File Format</b>  | <code>plugin-dir</code>           |
|                            | <b>Permitted Values</b>           |
|                            | <b>Type</b> <code>filename</code> |

The directory to use when loading plugins for `mysql-proxy`.

- `--plugins=plugin,...`

|                            |                                 |
|----------------------------|---------------------------------|
| <b>Version Introduced</b>  | 0.8.0                           |
| <b>Command-Line Format</b> | <code>--plugins</code>          |
| <b>Config-File Format</b>  | <code>plugins</code>            |
|                            | <b>Permitted Values</b>         |
|                            | <b>Type</b> <code>string</code> |

A comma-separated list of the plugins to be loaded.

- `--proxy-address=host:port`

|                            |                              |
|----------------------------|------------------------------|
| <b>Version Introduced</b>  | 0.8.0                        |
| <b>Command-Line Format</b> | <code>--proxy-address</code> |
|                            | <code>-P</code>              |
| <b>Config-File Format</b>  | <code>proxy-address</code>   |

| Permitted Values |        |
|------------------|--------|
| Type             | string |
| Default          | :4040  |

The listening host name (or IP address) and port of the proxy server. The default is :4040 (all IPs on port 4040).

- `--proxy-read-only-backend-addresses=host:port`

| Version Introduced  | 0.8.0                                            |
|---------------------|--------------------------------------------------|
| Command-Line Format | <code>--proxy-read-only-backend-addresses</code> |
| Config-File Format  | <code>proxy-read-only-backend-addresses</code>   |
|                     | Permitted Values                                 |
|                     | Type string                                      |

The listening host name (or IP address) and port of the proxy server for read-only connections. The default is for this information not to be set.

### Note

Setting this value only configures the servers within the corresponding internal structure (see `proxy.global.backends`). You can determine the backend type by checking the `type` field for each connection.

You should therefore only use this option in combination with a script designed to make use of the different backend types.

When using this option on the command-line, you can specify the option and the server multiple times to specify multiple backends. For example:

```
shell> mysql-proxy --proxy-read-only-backend-addresses 192.168.0.1:3306 --proxy-read-only-backend-addresses 192.168.0.2:3306
```

When using the option within the configuration file, you should separate multiple servers with a comma. The equivalent of the above example would be:

```
...
proxy-read-only-backend-addresses = 192.168.0.1:3306, 192.168.0.2:3306
```

- `--proxy-backend-addresses=host:port`

The host name (or IP address) and port of the MySQL server to connect to. You can specify multiple backend servers by supplying multiple options. Clients are connected to each backend server in round-robin fashion. For example, if you specify two servers A and B, the first client connection will go to server A; the second client connection to server B and the third client connection to server A.

When using this option on the command-line, you can specify the option and the server multiple times to specify multiple backends. For example:

```
shell> mysql-proxy --proxy-backend-addresses 192.168.0.1:3306 --proxy-backend-addresses 192.168.0.2:3306
```

When using the option within the configuration file, you should separate multiple servers with a comma. The equivalent of the above example would be:

```
...
proxy-backend-addresses = 192.168.0.1:3306, 192.168.0.2:3306
```

- `--proxy-pool-no-change-user`

| Version Introduced  | 0.8.0                                    |
|---------------------|------------------------------------------|
| Command-Line Format | <code>--proxy-pool-no-change-user</code> |
| Config-File Format  | <code>proxy-pool-no-change-user</code>   |

Disables the use of the MySQL protocol `CHANGE_USER` when reusing a connection from the pool of connections specified by the `proxy-backend-addresses` list.

- `--proxy-skip-profiling`

Disables profiling of queries (tracking time statistics). The default is for tracking to be enabled.

- `--proxy-fix-bug-25371`

|                            |                                    |
|----------------------------|------------------------------------|
| <b>Version Introduced</b>  | 0.8.0                              |
| <b>Command-Line Format</b> | <code>--proxy-fix-bug-25371</code> |
| <b>Config-File Format</b>  | <code>proxy-fix-bug-25371</code>   |

Gets round an issue when connecting to a MySQL server later than 5.1.12 when using a MySQL client library of any earlier version.

- `--proxy-lua-script=file`

|                            |                                 |
|----------------------------|---------------------------------|
| <b>Version Introduced</b>  | 0.8.0                           |
| <b>Command-Line Format</b> | <code>--proxy-lua-script</code> |
|                            | <code>-s</code>                 |
| <b>Config-File Format</b>  | <code>proxy-lua-script</code>   |
|                            | <b>Permitted Values</b>         |
|                            | Type <code>filename</code>      |

The Lua script file to be loaded. Note that the script file is not physically loaded and parsed until a connection is made. Also note that the specified Lua script is reloaded for each connection; if the content of the Lua script changes while `mysql-proxy` is running then the updated content will automatically be used when a new connection is made.

- `--daemon`

|                            |                       |
|----------------------------|-----------------------|
| <b>Version Introduced</b>  | 0.8.0                 |
| <b>Command-Line Format</b> | <code>--daemon</code> |
| <b>Config-File Format</b>  | <code>daemon</code>   |

Starts the proxy in daemon mode.

- `--pid-file=file`

|                            |                            |
|----------------------------|----------------------------|
| <b>Version Introduced</b>  | 0.8.0                      |
| <b>Command-Line Format</b> | <code>--pid-file</code>    |
| <b>Config-File Format</b>  | <code>pid-file</code>      |
|                            | <b>Permitted Values</b>    |
|                            | Type <code>filename</code> |

Sets the name of the file to be used to store the process ID.

- `--user=user`

|                            |                          |
|----------------------------|--------------------------|
| <b>Version Introduced</b>  | 0.8.0                    |
| <b>Command-Line Format</b> | <code>--user</code>      |
| <b>Config-File Format</b>  | <code>user</code>        |
|                            | <b>Permitted Values</b>  |
|                            | Type <code>string</code> |

Run `mysql-proxy` as the specified `user`.

- `--version`

|                            |                        |
|----------------------------|------------------------|
| <b>Version Introduced</b>  | 0.8.0                  |
| <b>Command-Line Format</b> | <code>--version</code> |
|                            | <code>-V</code>        |
| <b>Config-File Format</b>  | <code>version</code>   |

Show the version number.

The most common usage is as a simple proxy service (that is, without addition scripting). For basic proxy operation you must specify at least one `proxy-backend-addresses` option to specify the MySQL server to connect to by default:

```
shell> mysql-proxy
--proxy-backend-addresses=MySQL.example.com:3306
```

The default proxy port is `4040`, so you can connect to your MySQL server through the proxy by specifying the host name and port details:

```
shell> mysql --host=localhost --port=4040
```

If your server requires authentication information then this will be passed through natively without alteration by `mysql-proxy`, so you must also specify the authentication information if required:

```
shell> mysql --host=localhost --port=4040 \
--user=username --password=password
```

You can also connect to a read-only port (which filters out `UPDATE` and `INSERT` queries) by connecting to the read-only port. By default the host name is the default, and the port is `4042`, but you can alter the host/port information by using the `--proxy-read-only-address` command-line option.

For more detailed information on how to use these command line options, and `mysql-proxy` in general in combination with Lua scripts, see [Section 14.6.5, “Using MySQL Proxy”](#).

### 14.6.3.1. Setting Up MySQL Proxy as a Windows Service

The MySQL distribution on Windows includes the `mysql-proxy-svc.exe` command, that enables a MySQL proxy instance to be managed by the Windows service control manager. This allows you to control the service without separately running the MySQL Proxy application, and allows for automatically starting and stopping the MySQL Proxy service during boot, reboot and shutdown.

To set up a MySQL Proxy service, you must use the `sc` command to create a new service using the MySQL Proxy service command. To create, use `sc` to specify the MySQL Proxy options on the command-line, and identify the service with a unique name. For example, to configure a new MySQL Proxy instance that will automatically start when your system boots, redirecting queries to the local MySQL server:

```
C:\> sc create "Proxy" DisplayName= "MySQL Proxy" start= "auto" >
binPath= "C:\Program Files\MySQL\mysql-proxy-0.8.0\bin\mysql-proxy-svc.exe" >
--proxy-backend-addresses=127.0.0.1:3306"
```

#### Note

The spaces are the equals sign after each property is required; failure to include it will result in an error.

The above creates a new service called `Proxy`. You can start and stop the service using the `net start|stop` with the service name. The service is not automatically started after it has been created. To start the service:

```
C:\> net start proxy
The MySQL Proxy service is starting.
The MySQL Proxy service was started successfully.
```

You can specify any additional command line options you need to the `sc` command. You can also set up multiple MySQL Proxy services on the same machine (providing they are configured to listen on different ports and/or IP addresses).

You can delete a service that you have created using:

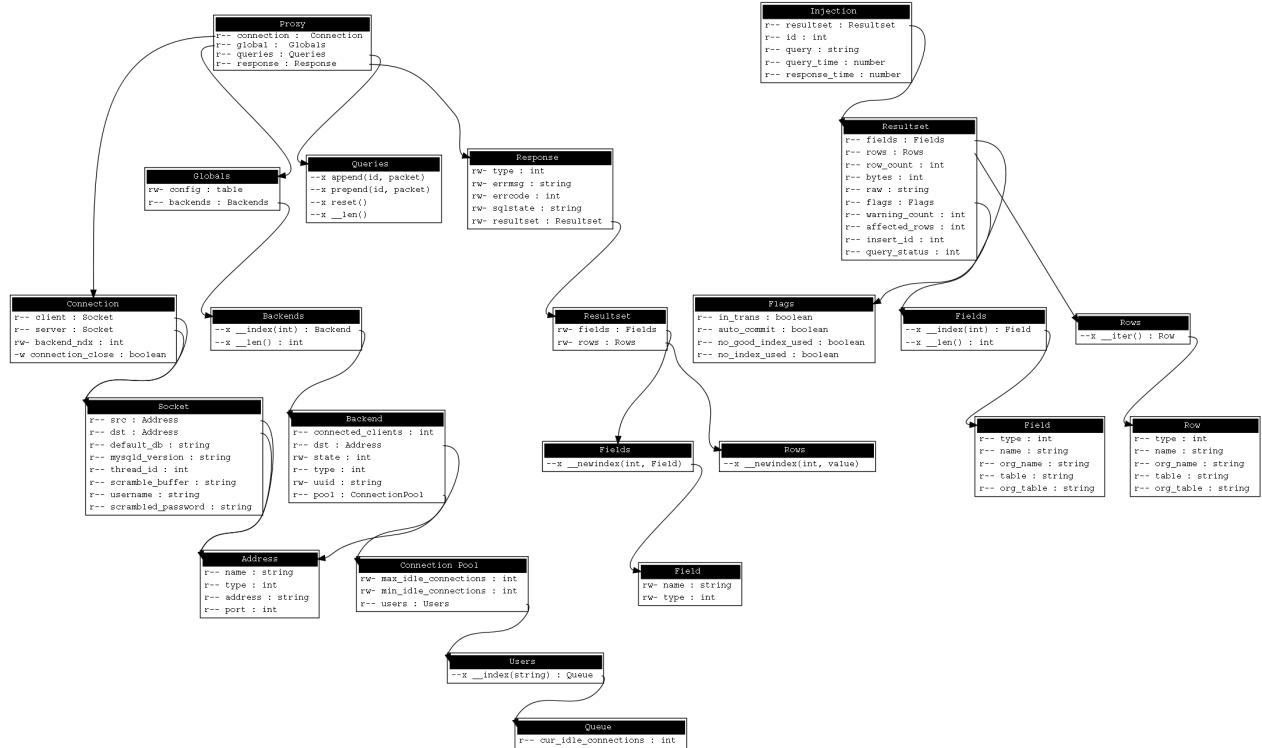

```
C:\> sc delete proxy
```

For more information on creating services using `sc`, see [How to create a Windows service by using Sc.exe](#).

## 14.6.4. MySQL Proxy Scripting

You can control how MySQL Proxy manipulates and works with the queries and results that are passed on to the MySQL server through the use of the embedded Lua scripting language. You can find out more about the Lua programming language from the [Lua Website](#).

An overview of the classes exposed by MySQL Proxy is shown in the diagram below:

The primary interaction between MySQL Proxy and the server is provided by defining one or more functions through an Lua script. A number of functions are supported, according to different events and operations in the communication sequence between a client and one or more backend MySQL servers:

- `connect_server()`: This function is called each time a connection is made to MySQL Proxy from a client. You can use this function during load-balancing to intercept the original connection and decide which server the client should ultimately be attached to. If you do not define a special solution, then a simple round-robin style distribution is used by default.
- `read_handshake()`: This function is called when the initial handshake information is returned by the server. You can capture the handshake information returned and provide additional checks before the authorization exchange takes place.
- `read_auth()`: This function is called when the authorization packet (user name, password, default database) are submitted by the client to the server for authentication.
- `read_auth_result()`: This function is called when the server returns an authorization packet to the client indicating whether the authorization succeeded.
- `read_query()`: This function is called each time a query is sent by the client to the server. You can use this to edit and manipulate the original query, including adding new queries before and after the original statement. You can also use this function to return information directly to the client, bypassing the server, which can be useful to filter unwanted queries or queries that exceed known limits.
- `read_query_result()`: This function is called each time a result is returned from the server, providing you have manually injected queries into the query queue. If you have not explicitly inject queries within the `read_query()` function then this function is not triggered. You can use this to edit the result set, or to remove or filter the result sets generated from additional

queries you injected into the queue when using `read_query()`.

The table below describes the direction of flow of information at the point when the function is triggered.

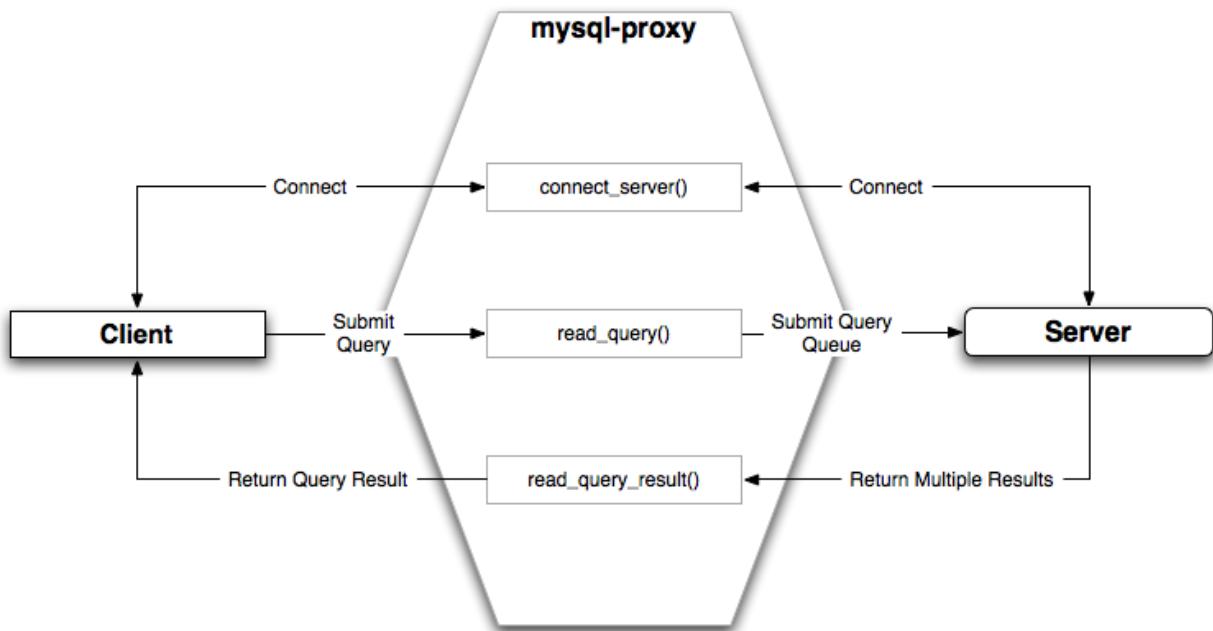

| Function                         | Supplied Information | Direction        |
|----------------------------------|----------------------|------------------|
| <code>connect_server()</code>    | None                 | Client to Server |
| <code>read_handshake()</code>    | None                 | Server to Client |
| <code>read_auth()</code>         | None                 | Client to Server |
| <code>read_auth_result()</code>  | None                 | Server to Client |
| <code>read_query()</code>        | Query                | Client to Server |
| <code>read_query_result()</code> | Query result         | Server to Client |

By default, all functions return a result that indicates that the data should be passed on to the client or server (depending on the direction of the information being transferred). This return value can be overridden by explicitly returning a constant indicating that a particular response should be sent. For example, it is possible to construct result set information by hand within `read_query()` and to return the resultset directly to the client without ever sending the original query to the server.

In addition to these functions, a number of built-in structures provide control over how MySQL Proxy forwards queries and returns the results by providing a simplified interface to elements such as the list of queries and the groups of result sets that are returned.

#### 14.6.4.1. Proxy Scripting Sequence During Query Injection

The figure below gives an example of how the proxy might be used when injecting queries into the query queue. Because the proxy sits between the client and MySQL server, what the proxy sends to the server, and the information that the proxy ultimately returns to the client do not have to match or correlate. Once the client has connected to the proxy, the following sequence occurs for each individual query sent by the client.

1. The client submits one query to the proxy, the `read_query()` function within the proxy is triggered. The function adds the query to the query queue.
2. Once manipulation by `read_query()` has completed, the queries are submitted, sequentially, to the MySQL server.
3. The MySQL server returns the results from each query, one result set for each query submitted. The `read_query_result()` function is triggered for each result set, and each invocation can decide which result set to return to the client

For example, you can queue additional queries into the global query queue to be processed by the server. This can be used to add

statistical information by adding queries before and after the original query, changing the original query:

```
SELECT * FROM City;
```

Into a sequence of queries:

```
SELECT NOW();
SELECT * FROM City;
SELECT NOW();
```

You can also modify the original statement, for example to add `EXPLAIN` to each statement executed to get information on how the statement was processed, again altering our original SQL statement into a number of statements:

```
SELECT * FROM City;
EXPLAIN SELECT * FROM City;
```

In both of these examples, the client would have received more result sets than expected. Regardless of how you manipulate the incoming query and the returned result, the number of queries returned by the proxy must match the number of original queries sent by the client.

You could adjust the client to handle the multiple result sets sent by the proxy, but in most cases you will want the existence of the proxy to remain transparent. To ensure that the number of queries and result sets match, you can use the MySQL Proxy `read_query_result()` to extract the additional result set information and return only the result set the client originally requested back to the client. You can achieve this by giving each query that you add to the query queue a unique ID, and then filter out queries that do not match the original query ID when processing them with `read_query_result()`.

#### 14.6.4.2. Internal Structures

There are a number of internal structures within the scripting element of MySQL Proxy. The primary structure is `proxy` and this provides an interface to the many common structures used throughout the script, such as connection lists and configured backend servers. Other structures, such as the incoming packet from the client and result sets are only available within the context of one of the scriptable functions.

| Attribute                  | Description                                                                                                                                                                                                                                                                                       |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>connection</code>    | A structure containing the active client connections. For a list of attributes, see <code>proxy.connection</code> .                                                                                                                                                                               |
| <code>servers</code>       | A structure containing the list of configured backend servers. For a list of attributes, see <code>proxy.global.backends</code> .                                                                                                                                                                 |
| <code>queries</code>       | A structure containing the queue of queries that will be sent to the server during a single client query. For a list of attributes, see <code>proxy.queries</code> .                                                                                                                              |
| <code>PROXY_VERSION</code> | The version number of MySQL Proxy, encoded in hex. You can use this to check that the version number supports a particular option from within the Lua script. Note that the value is encoded as a hex value, so to check the version is at least 0.5.1 you compare against <code>0x00501</code> . |

##### `proxy.connection`

The `proxy.connection` object is read only, and provides information about the current connection, and is split into a `client` and `server` tables. This enables you to examine information about both the incoming client connections to the proxy (`client`), and to the backend servers (`server`).

| Attribute                              | Description                                                                                                                                         |
|----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>client.default_db</code>         | Default database request by the client                                                                                                              |
| <code>client.username</code>           | Username used to authenticate                                                                                                                       |
| <code>client.scrambled_password</code> | The scrambled version of the password used to authenticate                                                                                          |
| <code>client.dst.name</code>           | The combined <code>address:port</code> of the Proxy port used by this client (should match the <code>-proxy-address</code> configuration parameter) |
| <code>client.dst.address</code>        | The IP address of the of the Proxy port used by this client                                                                                         |
| <code>client.dst.port</code>           | The port number of the of the Proxy port used by this client                                                                                        |
| <code>client.src.name</code>           | The combined <code>address:port</code> of the client (originating) TCP/IP endpoint                                                                  |
| <code>client.src.address</code>        | The IP address of the client (originating) TCP/IP port                                                                                              |
| <code>client.src.port</code>           | The port of the client (originating) TCP/IP endpoint                                                                                                |

| Attribute                           | Description                                                                                                                        |
|-------------------------------------|------------------------------------------------------------------------------------------------------------------------------------|
| <code>server.scramble_buffer</code> | The scramble buffer used to scramble the password                                                                                  |
| <code>server.mysql_version</code>   | The MySQL version number of the server                                                                                             |
| <code>server.thread_id</code>       | The ID of the thread handling the connection to the current server                                                                 |
| <code>server.dst.name</code>        | The combined <code>address:port</code> for the backend server for the current connection (i.e. the connection to the MySQL server) |
| <code>server.dst.address</code>     | The address for the backend server                                                                                                 |
| <code>server.dst.port</code>        | The port for the backend server                                                                                                    |
| <code>server.src.name</code>        | The combined <code>address:port</code> for the TCP/IP endpoint used by the Proxy to connect to the backend server                  |
| <code>server.src.address</code>     | The address of the endpoint for the proxy-side connection to the MySQL server                                                      |
| <code>server.src.port</code>        | The port of the endpoint for the proxy-side connection to the MySQL server                                                         |

#### `proxy.global.backends`

The `proxy.global.backends` table is partially writable and contains an array of all the configured backend servers and the server metadata (IP address, status, etc.). You can determine the array index of the current connection using `proxy.connection[ "backend_ndx" ]` which is the index into this table of the backend server being used by the active connection.

The attributes for each entry within the `proxy.global.backends` table are shown in this table.

| Attribute                      | Description                                                                                                                                                                                                                                                            |
|--------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>dst.name</code>          | The combined <code>address:port</code> of the backend server                                                                                                                                                                                                           |
| <code>dst.address</code>       | The IP address of the backend server                                                                                                                                                                                                                                   |
| <code>dst.port</code>          | The port of the backend server                                                                                                                                                                                                                                         |
| <code>connected_clients</code> | The number of clients currently connected.                                                                                                                                                                                                                             |
| <code>state</code>             | The status of the backend server. See <a href="#">Backend State/Type Constants [1293]</a>                                                                                                                                                                              |
| <code>type</code>              | The type of the backend server. You can use this to identify whether the backed was configured as a standard read/write backend, or a read-only backend. You can compare this value to the <code>proxy.BACKEND_TYPE_RW</code> and <code>proxy.BACKEND_TYPE_RO</code> . |

#### `proxy.queries`

The `proxy.queries` object is a queue representing the list of queries to be sent to the server. The queue is not populated automatically, but if you do not explicitly populate the queue then queries are passed on to the backend server verbatim. Also, if you do not populate the query queue by hand, then the `read_query_result()` function is not triggered.

The following methods are supported for populating the `proxy.queries` object.

| Function                                 | Description                                                                                                                                                                                                                                                                                                                                   |
|------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>append(id,packet,[options])</code> | Appends a query to the end of the query queue. The <code>id</code> is an integer identifier that you can use to recognize the query results when they are returned by the server. The packet should be a properly formatted query packet. The optional <code>options</code> should be a table containing the options specific to this packet. |
| <code>prepend(id,packet)</code>          | Prepends a query to the query queue. The <code>id</code> is an identifier that you can use to recognize the query results when they are returned by the server. The packet should be a properly formatted query packet.                                                                                                                       |
| <code>reset()</code>                     | Empties the query queue.                                                                                                                                                                                                                                                                                                                      |
| <code>len()</code>                       | Returns the number of query packets in the queue.                                                                                                                                                                                                                                                                                             |

For example, you could append a query packet to the `proxy.queries` queue by using the `append()`:

```
proxy.queries.append(1,packet)
```

The optional third argument to `append()` should contain the options for the packet. If you want to have access to the result set through the `read_query_result()` function, you must set the `resultset_is_needed` flag to true:

```
proxy.queries:append(1, packet, { resultset_is_needed = true })
```

If that flag is false (the default), proxy will:

- Send the resultset to the client as soon as the resultset is received
- Reduce memory usage (because the resultset is not stored internally for processing)
- Lower latency of results back to the client
- Pass on data from server to client unaltered

The default mode is therefore quicker and useful if you only want to monitor the queries sent, and the basic statistics.

If, however, you want to perform any kind of manipulation on the returned data, you must set the flag to true, which will:

- Store the resultset so that it can be processed
- Enable modification of the resultset before it is returned to the client
- Enable you to discard the resultset in place of returning it to the client

#### **proxy.response**

The `proxy.response` structure is used when you want to return your own MySQL response, instead of forwarding a packet that you have received a backend server. The structure holds the response type information, an optional error message, and the result set (rows/columns) that you want to return.

| Attribute              | Description                                                                                                                                                                                                                                                        |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>type</code>      | The type of the response. The type must be either <code>MYSQLD_PACKET_OK</code> or <code>MYSQLD_PACKET_ERR</code> . If the <code>MYSQLD_PACKET_ERR</code> , then you should set the value of the <code>mysql.response errmsg</code> with a suitable error message. |
| <code>errmsg</code>    | A string containing the error message that will be returned to the client.                                                                                                                                                                                         |
| <code>resultset</code> | A structure containing the result set information (columns and rows), identical to what would be returned when returning a results from a <code>SELECT</code> query.                                                                                               |

When using `proxy.response` you either set `proxy.response.type` to `proxy.MYSQLD_PACKET_OK` and then build `resultset` to contain the results that you want to return, or set `proxy.response.type` to `proxy.MYSQLD_PACKET_ERR` and set the `proxy.response errmsg` to a string with the error message. To send the completed resultset or error message, you should return the `proxy.PROXY_SEND_RESULT` to trigger the return of the packet information.

An example of this can be seen in the `tutorial-resultset.lua` script within the MySQL Proxy package:

```
if string.lower(command) == "show" and string.lower(option) == "querycounter" then
 --
 -- proxy.PROXY_SEND_RESULT requires
 --
 -- proxy.response.type to be either
 -- * proxy.MYSQLD_PACKET_OK or
 -- * proxy.MYSQLD_PACKET_ERR
 --
 -- for proxy.MYSQLD_PACKET_OK you need a resultset
 -- * fields
 -- * rows
 --
 -- for proxy.MYSQLD_PACKET_ERR
 -- * errmsg
 proxy.response.type = proxy.MYSQLD_PACKET_OK
 proxy.response.resultset = {
 fields = {
 { type = proxy.MYSQL_TYPE_LONG, name = "global_query_counter", },
 { type = proxy.MYSQL_TYPE_LONG, name = "query_counter", },
 },
 rows = {
 { proxy.global.query_counter, query_counter }
 }
 }

 -- we have our result, send it back
 return proxy.PROXY_SEND_RESULT
elseif string.lower(command) == "show" and string.lower(option) == "myerror" then
 proxy.response.type = proxy.MYSQLD_PACKET_ERR
```

```

proxy.response errmsg = "my first error"
return proxy.PROXY_SEND_RESULT

```

#### **proxy.response.resultset**

The `proxy.response.resultset` structure should be populated with the rows and columns of data that you want to return. The structure contains the information about the entire result set, with the individual elements of the data shown in the table below.

| Attribute                  | Description                                                                                                                                                                                                                                                                                                 |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>fields</code>        | The definition of the columns being returned. This should be a dictionary structure with the <code>type</code> specifying the MySQL data type, and the <code>name</code> specifying the column name. Columns should be listed in the order of the column data that will be returned.                        |
| <code>flags</code>         | A number of flags related to the resultset. Valid flags include <code>auto_commit</code> (whether an automatic commit was triggered), <code>no_good_index_used</code> (the query executed without using an appropriate index), and <code>no_index_used</code> (the query executed without using any index). |
| <code>rows</code>          | The actual row data. The information should be returned as an array of arrays. Each inner array should contain the column data, with the outer array making up the entire result set.                                                                                                                       |
| <code>warning_count</code> | The number of warnings for this result set.                                                                                                                                                                                                                                                                 |
| <code>affected_rows</code> | The number of rows affected by the original statement.                                                                                                                                                                                                                                                      |
| <code>insert_id</code>     | The last insert ID for an auto-incremented column in a table.                                                                                                                                                                                                                                               |
| <code>query_status</code>  | The status of the query operation. You can use the <code>MYSQLD_PACKET_OK</code> or <code>MYSQLD_PACKET_ERR</code> constants to populate this parameter.                                                                                                                                                    |

For an example of the population of this table, see `proxy.response`.

#### **Proxy Return State Constants**

The following constants are used internally by the proxy to specify the response to send to the client or server. All constants are exposed as values within the main `proxy` table.

| Constant                         | Description                                                                       |
|----------------------------------|-----------------------------------------------------------------------------------|
| <code>PROXY_SEND_QUERY</code>    | Causes the proxy to send the current contents of the queries queue to the server. |
| <code>PROXY_SEND_RESULT</code>   | Causes the proxy to send a result set back to the client.                         |
| <code>PROXY_IGNORE_RESULT</code> | Causes the proxy to drop the result set (nothing is returned to the client).      |

As constants, these entities are available without qualification in the Lua scripts. For example, at the end of the `read_query_result()` you might return `PROXY_IGNORE_RESULT`:

```

return proxy.PROXY_IGNORE_RESULT

```

#### **Packet State Constants**

The following states describe the status of a network packet. These items are entries within the main `proxy` table.

| Constant                       | Description                            |
|--------------------------------|----------------------------------------|
| <code>MYSQLD_PACKET_OK</code>  | The packet is OK.                      |
| <code>MYSQLD_PACKET_ERR</code> | The packet contains error information. |
| <code>MYSQLD_PACKET_RAW</code> | The packet contains raw data.          |

#### **Backend State/Type Constants**

The following constants are used either to define the status of the backend server (the MySQL server to which the proxy is connected) or the type of backend server. These items are entries within the main `proxy` table.

| Constant                           | Description                                |
|------------------------------------|--------------------------------------------|
| <code>BACKEND_STATE_UNKNOWN</code> | The current status is unknown.             |
| <code>BACKEND_STATE_UP</code>      | The backend is known to be up (available). |

| Constant             | Description                                    |
|----------------------|------------------------------------------------|
| BACKEND_STATE_DOWN   | The backend is known to be down (unavailable). |
| BACKEND_TYPE_UNKNOWN | Backend type is unknown.                       |
| BACKEND_TYPE_RW      | Backend is available for read/write.           |
| BACKEND_TYPE_RO      | Backend is available only for read-only use.   |

### Server Command Constants

The following values are used in the packets exchanged between the client and server to identify the information in the rest of the packet. These items are entries within the main `proxy` table. The packet type is defined as the first character in the sent packet. For example, when intercepting packets from the client to edit or monitor a query you would check that the first byte of the packet was of type `proxy.COM_QUERY`.

| Constant                | Description                   |
|-------------------------|-------------------------------|
| COM_SLEEP               | Sleep                         |
| COM_QUIT                | Quit                          |
| COM_INIT_DB             | Initialize database           |
| COM_QUERY               | Query                         |
| COM_FIELD_LIST          | Field List                    |
| COM_CREATE_DB           | Create database               |
| COM_DROP_DB             | Drop database                 |
| COM_REFRESH             | Refresh                       |
| COM_SHUTDOWN            | Shutdown                      |
| COM_STATISTICS          | Statistics                    |
| COM_PROCESS_INFO        | Process List                  |
| COM_CONNECT             | Connect                       |
| COM_PROCESS_KILL        | Kill                          |
| COM_DEBUG               | Debug                         |
| COM_PING                | Ping                          |
| COM_TIME                | Time                          |
| COM_DELAYED_INSERT      | Delayed insert                |
| COM_CHANGE_USER         | Change user                   |
| COM_BINLOG_DUMP         | Binlog dump                   |
| COM_TABLE_DUMP          | Table dump                    |
| COM_CONNECT_OUT         | Connect out                   |
| COM_REGISTER_SLAVE      | Register slave                |
| COM_STMT_PREPARE        | Prepare server-side statement |
| COM_STMT_EXECUTE        | Execute server-side statement |
| COM_STMT_SEND_LONG_DATA | Long data                     |
| COM_STMT_CLOSE          | Close server-side statement   |
| COM_STMT_RESET          | Reset statement               |
| COM_SET_OPTION          | Set option                    |
| COM_STMT_FETCH          | Fetch statement               |
| COM_DAEMON              | Daemon (MySQL 5.1 only)       |
| COM_ERROR               | Error                         |

### MySQL Type Constants

These constants are used to identify the field types in the query result data returned to clients from the result of a query. These items are entries within the main `proxy` table.

| Constant                            | Field Type                                                      |
|-------------------------------------|-----------------------------------------------------------------|
| <code>MYSQL_TYPE_DECIMAL</code>     | Decimal                                                         |
| <code>MYSQL_TYPE_NEWDECIMAL</code>  | Decimal (MySQL 5.0 or later)                                    |
| <code>MYSQL_TYPE_TINY</code>        | Tiny                                                            |
| <code>MYSQL_TYPE_SHORT</code>       | Short                                                           |
| <code>MYSQL_TYPE_LONG</code>        | Long                                                            |
| <code>MYSQL_TYPE_FLOAT</code>       | Float                                                           |
| <code>MYSQL_TYPE_DOUBLE</code>      | Double                                                          |
| <code>MYSQL_TYPE_NULL</code>        | Null                                                            |
| <code>MYSQL_TYPE_TIMESTAMP</code>   | Timestamp                                                       |
| <code>MYSQL_TYPE_LONGLONG</code>    | Long long                                                       |
| <code>MYSQL_TYPE_INT24</code>       | Integer                                                         |
| <code>MYSQL_TYPE_DATE</code>        | Date                                                            |
| <code>MYSQL_TYPE_TIME</code>        | Time                                                            |
| <code>MYSQL_TYPE_DATETIME</code>    | Datetime                                                        |
| <code>MYSQL_TYPE_YEAR</code>        | Year                                                            |
| <code>MYSQL_TYPE_NEWDATE</code>     | Date (MySQL 5.0 or later)                                       |
| <code>MYSQL_TYPE_ENUM</code>        | Enumeration                                                     |
| <code>MYSQL_TYPE_SET</code>         | Set                                                             |
| <code>MYSQL_TYPE_TINY_BLOB</code>   | Tiny Blob                                                       |
| <code>MYSQL_TYPE_MEDIUM_BLOB</code> | Medium Blob                                                     |
| <code>MYSQL_TYPE_LONG_BLOB</code>   | Long Blob                                                       |
| <code>MYSQL_TYPE_BLOB</code>        | Blob                                                            |
| <code>MYSQL_TYPE_VAR_STRING</code>  | Varstring                                                       |
| <code>MYSQL_TYPE_STRING</code>      | String                                                          |
| <code>MYSQL_TYPE_TINY</code>        | Tiny (compatible with <code>MYSQL_TYPE_CHAR</code> )            |
| <code>MYSQL_TYPE_ENUM</code>        | Enumeration (compatible with <code>MYSQL_TYPE_INTERVAL</code> ) |
| <code>MYSQL_TYPE_GEOGRAPHY</code>   | Geometry                                                        |
| <code>MYSQL_TYPE_BIT</code>         | Bit                                                             |

#### 14.6.4.3. Capturing a Connection with `connect_server()`

When the proxy accepts a connection from a MySQL client, the `connect_server()` function is called.

There are no arguments to the function, but you can use and if necessary manipulate the information in the `proxy.connection` table, which is unique to each client session.

For example, if you have multiple backend servers then you can set the server to be used by that connection by setting the value of `proxy.connection.backend_ndx` to a valid server number. The code below will choose between two servers based on whether the current time in minutes is odd or even:

```
function connect_server()
 print("--> a client really wants to talk to a server")
 if (tonumber(os.date("%M")) % 2 == 0) then
 proxy.connection.backend_ndx = 2
 print("Choosing backend 2")
 else
 proxy.connection.backend_ndx = 1
 print("Choosing backend 1")
 end
 print("Using " .. proxy.global.backends[proxy.connection.backend_ndx].dst.name)
end
```

In this example the IP address/port combination is also displayed by accessing the information from the internal `proxy.global.backends` table.

#### 14.6.4.4. Examining the Handshake with `read_handshake()`

Handshake information is sent by the server to the client after the initial connection (through `connect_server()`) has been made. The handshake information contains details about the MySQL version, the ID of the thread that will handle the connection information, and the IP address of the client and server. This information is exposed through the `proxy.connection` structure.

- `proxy.connection.server.mysql_version`: The version of the MySQL server.
- `proxy.connection.server.thread_id`: The thread ID.
- `proxy.connection.server.scramble_buffer`: The password scramble buffer.
- `proxy.connection.server.dst.name`: The IP address of the server.
- `proxy.connection.client.src.name`: The IP address of the client.

For example, you can print out the handshake data and refuse clients by IP address with the following function:

```
function read_handshake()
 print("<-- let's send him some information about us")
 print(" mysqld-version: " .. proxy.connection.server.mysql_version)
 print(" thread-id : " .. proxy.connection.server.thread_id)
 print(" scramble-buf : " .. string.format("%q", proxy.connection.server.scramble_buffer))
 print(" server-addr : " .. proxy.connection.server.dst.name)
 print(" client-addr : " .. proxy.connection.client.dst.name)

 if not proxy.connection.client.src.name:match("^127.0.0.1:") then
 proxy.response.type = proxy.MYSQLD_PACKET_ERR
 proxy.response errmsg = "only local connects are allowed"

 print("we don't like this client");
 end
 return proxy.PROXY_SEND_RESULT
end
end
```

Note that you have to return an error packet to the client by using `proxy.PROXY_SEND_RESULT`.

#### 14.6.4.5. Examining the Authentication Credentials with `read_auth()`

The `read_auth()` function is triggered when an authentication handshake is initiated by the client. In the execution sequence, `read_auth()` occurs immediately after `read_handshake()`, so the server selection has already been made, but the connection and authorization information has not yet been provided to the backend server.

You can obtain the authentication information by examining the `proxy.connection.client` structure. For more information, see `proxy.connection`.

For example, you can print the user name and password supplied during authorization using:

```
function read_auth()
 print(" username : " .. proxy.connection.client.username)
 print(" password : " .. string.format("%q", proxy.connection.client.scrambled_password))
end
```

You can interrupt the authentication process within this function and return an error packet back to the client by constructing a new packet and returning `proxy.PROXY_SEND_RESULT`:

```
proxy.response.type = proxy.MYSQLD_PACKET_ERR
proxy.response errmsg = "Logins are not allowed"
return proxy.PROXY_SEND_RESULT
```

#### 14.6.4.6. Accessing Authentication Information with `read_auth_result()`

The return packet from the server during authentication is captured by `read_auth_result()`. The only argument to this function is the authentication packet returned by the server. As the packet is a raw MySQL network protocol packet, you must access the first byte to identify the packet type and contents. The `MYSQLD_PACKET_ERR` and `MYSQLD_PACKET_OK` constants can be used to identify whether the authentication was successful:

```
function read_auth_result(auth)
 local state = auth.packet:byte()

 if state == proxy.MYSQLD_PACKET_OK then
 print("<-- auth ok");
 elseif state == proxy.MYSQLD_PACKET_ERR then
 print("<-- auth failed");
 else
 print("<-- auth ... don't know: " .. string.format("%q", auth.packet));
 end
end
```

```
end
```

If a long-password capable client tries to authenticate to a server that supports long passwords, but the user password provided is actually short, then `read_auth_result()` will be called twice. The first time, `auth.packet:byte()` will equal 254, indicating that the client should try again using the old password protocol. The second time `read_auth_result()` is called, `auth.packet:byte()` will indicate whether the authentication actually succeeded.

#### 14.6.4.7. Manipulating Queries with `read_query()`

The `read_query()` function is called once for each query submitted by the client and accepts a single argument, the query packet that was provided. To access the content of the packet you must parse the packet contents manually.

For example, you can intercept a query packet and print out the contents using the following function definition:

```
function read_query(packet)
 if packet:byte() == proxy.COM_QUERY then
 print("we got a normal query: " .. packet:sub(2))
 end
end
```

This example checks the first byte of the packet to determine the type. If the type is `COM_QUERY` (see [Server Command Constants \[1294\]](#)), then we extract the query from the packet and print it out. The structure of the packet type supplied is important. In the case of a `COM_QUERY` packet, the remaining contents of the packet are the text of the query string. In this example, no changes have been made to the query or the list of queries that will ultimately be sent to the MySQL server.

To modify a query, or add new queries, you must populate the query queue (`proxy.queries`) and then execute the queries that you have placed into the queue. If you do not modify the original query or the queue, then the query received from the client is sent to the MySQL server verbatim.

When adding queries to the queue, you should follow these guidelines:

- The packets inserted into the queue must be valid query packets. For each packet, you must set the initial byte to the packet type. If you are appending a query, you can append the query statement to the rest of the packet.
- Once you add a query to the queue, the queue is used as the source for queries sent to the server. If you add a query to the queue to add more information, you must also add the original query to the queue or it will not be executed.
- Once the queue has been populated, you must set the return value from `read_query()` to indicate whether the query queue should be sent to the server.
- When you add queries to the queue, you should add an ID. The ID you specify is returned with the result set so that you identify each query and corresponding result set. The ID has no other purpose than as an identifier for correlating the query and result set. When operating in a passive mode, during profiling for example, you want to identify the original query and the corresponding resultset so that the results expect by the client can be returned correctly.
- Unless your client is designed to cope with more result sets than queries, you should ensure that the number of queries from the client match the number of results sets returned to the client. Using the unique ID and removing result sets you inserted will help.

Normally, the `read_query()` and `read_query_result()` function are used in conjunction with each other to inject additional queries and remove the additional result sets. However, `read_query_result()` is only called if you populate the query queue within `read_query()`.

#### 14.6.4.8. Manipulating Results with `read_query_result()`

The `read_query_result()` is called for each result set returned by the server only if you have manually injected queries into the query queue. If you have not manipulated the query queue then this function is not called. The function supports a single argument, the result packet, which provides a number of properties:

- `id`: The ID of the result set, which corresponds to the ID that was set when the query packet was submitted to the server when using `append(id)` on the query queue. You must have set the `resultset_is_needed` flag to `append` to intercept the resultset before it is returned to the client. See [proxy.queries \[1291\]](#).
- `query`: The text of the original query.
- `query_time`: The number of microseconds required to receive the first row of a result set.
- `response_time`: The number of microseconds required to receive the last row of the result set.

- `resultset`: The content of the result set data.

By accessing the result information from the MySQL server you can extract the results that match the queries that you injected, return different result sets (for example, from a modified query), and even create your own result sets.

The Lua script below, for example, will output the query, followed by the query time and response time (that is, the time to execute the query and the time to return the data for the query) for each query sent to the server:

```
function read_query(packet)
 if packet:byte() == proxy.COM_QUERY then
 print("we got a normal query: " .. packet:sub(2))

 proxy.queries:append(1, packet)
 return proxy.PROXY_SEND_QUERY
 end
end

function read_query_result(inj)
 print("query-time: " .. (inj.query_time / 1000) .. "ms")
 print("response-time: " .. (inj.response_time / 1000) .. "ms")
end
```

You can access the rows of returned results from the resultset by accessing the `rows` property of the `resultset` property of the result that is exposed through `read_query_result()`. For example, you can iterate over the results showing the first column from each row using this Lua fragment:

```
for row in inj.resultset.rows do
 print("injected query returned: " .. row[1])
end
```

Just like `read_query()`, `read_query_result()` can return different values for each result according to the result returned. If you have injected additional queries into the query queue, for example, then you will want to remove the results returned from those additional queries and only return the results from the query originally submitted by the client.

The example below injects additional `SELECT NOW()` statements into the query queue, giving them a different ID to the ID of the original query. Within `read_query_result()`, if the ID for the injected queries is identified, we display the result row, and return the `proxy.PROXY_IGNORE_RESULT` from the function so that the result is not returned to the client. If the result is from any other query, we print out the query time information for the query and return the default, which passes on the result set unchanged. We could also have explicitly returned `proxy.PROXY_IGNORE_RESULT` to the MySQL client.

```
function read_query(packet)
 if packet:byte() == proxy.COM_QUERY then
 proxy.queries:append(2, string.char(proxy.COM_QUERY) .. "SELECT NOW()", {resultset_is_needed = true})
 proxy.queries:append(1, packet, {resultset_is_needed = true})
 proxy.queries:append(2, string.char(proxy.COM_QUERY) .. "SELECT NOW()", {resultset_is_needed = true})

 return proxy.PROXY_SEND_QUERY
 end
end

function read_query_result(inj)
 if inj.id == 2 then
 for row in inj.resultset.rows do
 print("injected query returned: " .. row[1])
 end
 return proxy.PROXY_IGNORE_RESULT
 else
 print("query-time: " .. (inj.query_time / 1000) .. "ms")
 print("response-time: " .. (inj.response_time / 1000) .. "ms")
 end
end
```

For further examples, see [Section 14.6.5, “Using MySQL Proxy”](#).

## 14.6.5. Using MySQL Proxy

There are a number of different ways to use MySQL Proxy. At the most basic level, you can allow MySQL Proxy to pass on queries from clients to a single server. To use MySQL proxy in this mode, you just have to specify the backend server that the proxy should connect to on the command line:

```
shell> mysql-proxy --proxy-backend-addresses=sakila:3306
```

If you specify multiple backend MySQL servers then the proxy will connect each client to each server in a round-robin fashion. For example, imagine you have two MySQL servers, A and B. The first client to connect will be connected to server A, the second to server B, the third to server C. For example:

```
shell> mysql-proxy \
--proxy-backend-addresses=narcissus:3306 \
--proxy-backend-addresses=nostromo:3306
```

When you have specified multiple servers in this way, the proxy will automatically identify when a MySQL server has become unavailable and mark it accordingly. New connections will automatically be attached to a server that is available, and a warning will be reported to the standard output from `mysql-proxy`:

```
network-mysqld.c.367: connect(nostromo:3306) failed: Connection refused
network-mysqld-proxy.c.2405: connecting to backend (nostromo:3306) failed, marking it as down for ...
```

Lua scripts enable a finer level of control, both over the connections and their distribution and how queries and result sets are processed. When using an Lua script, you must specify the name of the script on the command line using the `--proxy-lua-script` option:

```
shell> mysql-proxy --proxy-lua-script=mc.lua --proxy-backend-addresses=sakila:3306
```

When you specify a script, the script is not executed until a connection is made. This means that faults with the script will not be raised until the script is executed. Script faults will not affect the distribution of queries to backend MySQL servers.

### Note

Because the script is not read until the connection is made, you can modify the contents of the Lua script file while the proxy is still running and the script will automatically be used for the next connection. This ensures that MySQL Proxy remains available because it does not have to be restarted for the changes to take effect.

## 14.6.5.1. Using the Administration Interface

The `mysql-proxy` administration interface can be accessed using any MySQL client using the standard protocols. You can use the administration interface to gain information about the proxy server as a whole - standard connections to the proxy are isolated to operate as if you were connected directly to the backend MySQL server.

In `mysql-proxy` 0.8.0 and earlier, a rudimentary interface was built into the proxy. In later versions this was replaced so that you must specify an administration script to be used when users connect to the administration interface.

To use the administration interface, you should specify the username and password required to connect to the admin point (using the `--admin-username` and `--admin-password` options). You must also specify the Lua script to be used as the interface to the administration service by using the `admin-lua-script` script option to point to a Lua script.

For example, you can create a basic interface to the internal components of the `mysql-proxy` system using the following script, written by Diego Medina:

```

proxy.global.query_counter = proxy.global.query_counter or 0

function proxy.global.initialize_process_table()
 if proxy.global.process == nil then
 proxy.global.process = {}
 end
 if proxy.global.process[proxy.connection.server.thread_id] == nil then
 proxy.global.process[proxy.connection.server.thread_id] = {}
 end
end

function read_auth_result(auth)
 local state = auth.packet:byte()
 if state == proxy.MYSQLD_PACKET_OK then
 proxy.global.initialize_process_table()
 table.insert(proxy.global.process[proxy.connection.server.thread_id],
 { ip = proxy.connection.client.src.name, ts = os.time() })
 end
end

function disconnect_client()
 local connection_id = proxy.connection.server.thread_id
 if connection_id then
 -- client has disconnected, set this to nil
 proxy.global.process[connection_id] = nil
 end
end

-- read_query() can return a resultset
--
-- You can use read_query() to return a result-set.
--
-- @param packet the mysql-packet sent by the client
--
-- @return
-- * nothing to pass on the packet as is,
-- * proxy.PROXY_SEND_QUERY to send the queries from the proxy.queries queue
-- * proxy.PROXY_SEND_RESULT to send your own result-set
--
function read_query(packet)
 -- a new query came in in this connection
 -- using proxy.global.* to make it available to the admin plugin
 proxy.global.query_counter = proxy.global.query_counter + 1
end

```

To use the script, save the first script to a file (`admin.lua` in the example below) and the other to `reporter.lua`, and then run `mysql-proxy` specifying the admin script and a backend MySQL server:

```
shell> mysql-proxy --admin-lua-script=admin.lua --admin-password=password \
--admin-username=root --proxy-backend-addresses=127.0.0.1:3306 -proxy-lua-script=reporter.lua
```

In a separate window, connect to the MySQL server through the proxy:

```
shell> mysql --user=root --password=password --port=4040
Welcome to the MySQL monitor. Commands end with ; or \g.
Your MySQL connection id is 1798669
Server version: 5.0.70-log Gentoo Linux mysql-5.0.70-r1

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql>
```

In another different window, connect to the `mysql-proxy` admin service using the specified username and password:

```
shell> mysql --user=root --password=password --port=4041 --host=localhost
Welcome to the MySQL monitor. Commands end with ; or \g.
Your MySQL connection id is 1
Server version: 5.0.99-agent-admin

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql>
```

You can monitor the status of the proxy by asking for a list of the current active processes:

```
mysql> show proxy processlist;
+-----+-----+-----+
| Id | IP Address | Time |
+-----+-----+-----+
```

```
| 1798669 | 192.168.0.112:52592 | Wed Jan 20 16:58:00 2010 |
+-----+-----+
1 row in set (0.00 sec)

mysql>
```

For more information on the example, see [MySQL Proxy Admin Example](#).

## 14.6.6. MySQL Proxy FAQ

### Questions

- [15.6.6.1:](#) Is the system context switch expensive, how much overhead does the lua script add?

### Questions and Answers

#### **15.6.6.1: Is the system context switch expensive, how much overhead does the lua script add?**

Lua is fast and the overhead should be small enough for most applications. The raw packet-overhead is around 400 microseconds.

#### **15.6.6.2: Can I use MySQL Proxy with all versions of MySQL?**

MySQL Proxy is designed to work with MySQL 5.0 or higher, and supports the MySQL network protocol for 5.0 and higher.

#### **15.6.6.3: If MySQL Proxy has to live on same machine as MySQL, are there any tuning considerations to ensure both perform optimally?**

MySQL Proxy can live on any box: application, db or its own box. MySQL Proxy uses comparatively little CPU or RAM, so additional requirements or overhead is negligible.

#### **15.6.6.4: Do proxy applications run on a separate server? If not, what is the overhead incurred by Proxy on the DB server side?**

You can run the proxy on the application server, on its own box or on the DB-server depending on the use-case

#### **15.6.6.5: Can MySQL Proxy handle SSL connections?**

No, being the man-in-the-middle, Proxy can't handle encrypted sessions because it cannot share the SSL information.

#### **15.6.6.6: In load balancing, how can I separate reads from writes?**

There is no automatic separation of queries that perform reads or writes to the different backend servers. However, you can specify to `mysql-proxy` that one or more of the 'backend' MySQL servers are read only.

```
$ mysql-proxy \
--proxy-backend-addresses=10.0.1.2:3306 \
--proxy-read-only-backend-addresses=10.0.1.3:3306 &
```

#### **15.6.6.7: What is the limit for `max-connections` on the server?**

Around 1024 connections the MySQL Server may run out of threads it can spawn. Leaving it at around 100 is advised.

**15.6.6.8: As the script is re-read by proxy, does it cache this or is it looking at the file system with each request?**

It looks for the script at client-connect and reads it if it has changed, otherwise it uses the cached version.

**15.6.6.9: With load balancing, what happen to transactions ? Are all queries sent to the same server ?**

Without any special customization the whole connection is sent to the same server. That keeps the whole connection state intact.

**15.6.6.10: Can I run MySQL Proxy as a daemon?**

Starting from version 0.6.0, the Proxy is launched as a daemon by default. If you want to avoid this, use the `-D` or `--no-daemon` option. To keep track of the process ID, the daemon can be started with the additional option `--pid-file=file`, to save the PID to a known file name. On version 0.5.x, the Proxy can't be started natively as a daemon

**15.6.6.11: What about caching the authorization info so clients connecting are given back-end connections that were established with identical authorization information, thus saving a few more round trips?**

There is an option that provides this functionality `--proxy-pool-no-change-user`.

**15.6.6.12: Would the Java-only connection pooling solution work for multiple web servers? With this, I'd assume you can pool across many web servers at once?**

Yes. But you can also start one proxy on each application server to get a similar behavior as you have it already.

**15.6.6.13: Could MySQL Proxy be used to capture passwords?**

The MySQL network protocol does not allow passwords to be sent in clear-text, all you could capture is the encrypted version.

**15.6.6.14: Can MySQL Proxy be used on slaves and intercept binlog messages?**

We are working on that. See <http://jan.kneschke.de/2008/5/30/mysql-proxy-rbr-to-sbr-decoding> for an example.

**15.6.6.15: MySQL Proxy can handle about 5000 connections, what is the limit on a MySQL server?**

See your `max-connections` settings. By default the setting is 150, the proxy can handle a lot more.

**15.6.6.16: How does MySQL Proxy compare to DBSlayer ?**

DBSlayer is a REST->MySQL tool, MySQL Proxy is transparent to your application. No change to the application is needed.

**15.6.6.17: How do I use a socket with MySQL Proxy? Proxy change logs mention that support for UNIX sockets has been added.**

Just specify the path to the socket:

```
--proxy-backend-addresses=/path/to/socket
```

**15.6.6.18: I currently use SQL Relay for efficient connection pooling with a number of apache processes connecting to a MySQL server. Can MySQL proxy currently accomplish this. My goal is to minimize connection latency while keeping temporary tables available.**

Yes.

**15.6.6.19: The global namespace variable example with quotas does not persist after a reboot, is that correct?**

Yes. if you restart the proxy, you lose the results, unless you save them in a file.

**15.6.6.20: I tried using MySQL Proxy without any Lua script to try a round-robin type load balancing. In this case, if the first database in the list is down, MySQL Proxy would not connect the client to the second database in the list.**

This issue is fixed in version 0.7.0.

**15.6.6.21: If you have multiple databases on the same box, can you use proxy to connect to databases on default port 3306?**

Yes, MySQL Proxy can listen on any port. Providing none of the MySQL servers are listening on the same port.

**15.6.6.22: Will Proxy be deprecated for use with connection pooling once MySQL 6.x comes out? Or will 6.x integrate proxy more deeply?**

The logic about the pooling is controlled by the lua scripts, you can enable and disable it if you like. There are no plans to embed the current MySQL Proxy functionality into the MySQL Server.

**15.6.6.23: We've looked at using MySQL Proxy but we're concerned about the alpha status - when do you think the proxy would be considered production ready?**

We are on the road to the next feature release: 0.7.0. It will improve the performance quite a bit. After that we may be able to enter the beta phase.

**15.6.6.24: Will the proxy road map involve moving popular features from lua to C? For example Read/Write splitting**

We will keep the high-level parts in the Lua layer to be able to adjust to special situations without a rebuild. Read/Write splitting sometimes needs external knowledge that may only be available by the DBA.

**15.6.6.25: Are these reserved function names (for example, error\_result) that get automatically called?**

Only functions and values starting with `proxy . *` are provided by the proxy. All others are provided by you.

**15.6.6.26: Can you explain the status of your work with memcached and MySQL Proxy?**

There are some ideas to integrate proxy and `memcache` a bit, but no code yet.

**15.6.6.27: Is the MySQL Proxy an API ?**

No, MySQL Proxy is an application that forwards packets from a client to a server using the MySQL network protocol. The MySQL proxy provides a API allowing you to change its behavior.

**15.6.6.28: Is there any big web site using MySQL Proxy ? For what purpose and what transaction rate have they achieved.**

Yes, [gaiaonline](#). They have tested MySQL Proxy and seen it handle 2400 queries per second through the proxy.

**15.6.6.29: So the authentication when connection pooling has to be done at every connection? What's the authentication latency?**

You can skip the round-trip and use the connection as it was added to the pool. As long as the application cleans up the temporary tables it used. The overhead is (as always) around 400 microseconds.

**15.6.6.30: Is it possible to use the MySQL proxy w/ updating a Lucene index (or Solr) by making TCP calls to that server to update?**

Yes, but it isn't advised for now.

**15.6.6.31: Isn't MySQL Proxy similar to what is provided by Java connection pools?**

Yes and no. Java connection pools are specific to Java applications, MySQL Proxy works with any client API that talks the MySQL network protocol. Also, connection pools do not provide any functionality for intelligently examining the network packets and modifying the contents.

**15.6.6.32: Are there tools for isolating problems? How can someone figure out if a problem is in the client, in the db or in the proxy?**

You can set a debug script in the proxy, which is an exceptionally good tool for this purpose. You can see very clearly which component is causing the problem, if you set the right breakpoints.

**15.6.6.33: Can you dynamically reconfigure the pool of MySQL servers that MySQL Proxy will load balance to?**

Not yet, it is on the list. We are working on a administration interface for that purpose.

**15.6.6.34: Given that there is a `connect_server` function, can a Lua script link up with multiple servers?**

The proxy provides some tutorials in the source-package, one is [examples/tutorial-keepalive.lua](#).

**15.6.6.35: Adding a proxy must add latency to the connection, how big is that latency?**

In the range of 400microseconds

**15.6.6.36: In the quick poll, I see "Load Balancer: read-write splitting" as an option, so would it be correct to say that there are no scripts written for Proxy yet to do this?**

There is a proof of concept script for that included. But its far from perfect and may not work for you yet.

**15.6.6.37: Is it "safe" to use `LuaSocket` with proxy scripts?**

You can, but it is not advised as it may block.

**15.6.6.38: How different is MySQL Proxy from DBCP (Database connection pooling) for Apache in terms of connection pooling?**

Connection Pooling is just one use-case of the MySQL Proxy. You can use it for a lot more and it works in cases where you can't use DBCP (like if you don't have Java).

**15.6.6.39: Do you have make one large script and call at proxy startup, can I change scripts without stopping and restarting (interrupting) the proxy?**

You can just change the script and the proxy will reload it when a client connects.

---

# Chapter 15. MySQL Enterprise Monitor

## Note

MySQL Enterprise subscription, MySQL Enterprise Monitor, MySQL Replication Monitor, and MySQL Query Analyzer are only available to commercial customers. To learn more, see: <http://www.mysql.com/products/enterprise/features.html>.

The MySQL Enterprise Monitor serves as an automated assistant for MySQL database administrators. This service is designed to help administrators with their day-to-day tasks by monitoring MySQL servers and identifying potential problems. These features are designed to save the database administrator's time and effort by providing the information you need through a simplified interface.

An extension of existing MySQL Enterprise services, MySQL Enterprise Monitor monitors enterprise database environments and provides expert advice on how customers can tighten security and optimize the performance and uptime of their MySQL servers.

MySQL Enterprise Monitor helps administrators:

- Intelligently stay up to date with releases and bug fixes.
- Know what's going on with their system.
- Manage day-to-day database maintenance tasks.
- Improve the performance of their system.
- Manage and prevent crises.

The MySQL Enterprise Monitor was designed to tackle the job of managing the performance of any number of MySQL database servers, regardless of their physical or geographical location. Although MySQL Enterprise Monitor can easily track just a handful of MySQL servers, the service is specifically designed to greatly curtail the time it takes to get a handle on the availability and performance levels of many database servers at once.

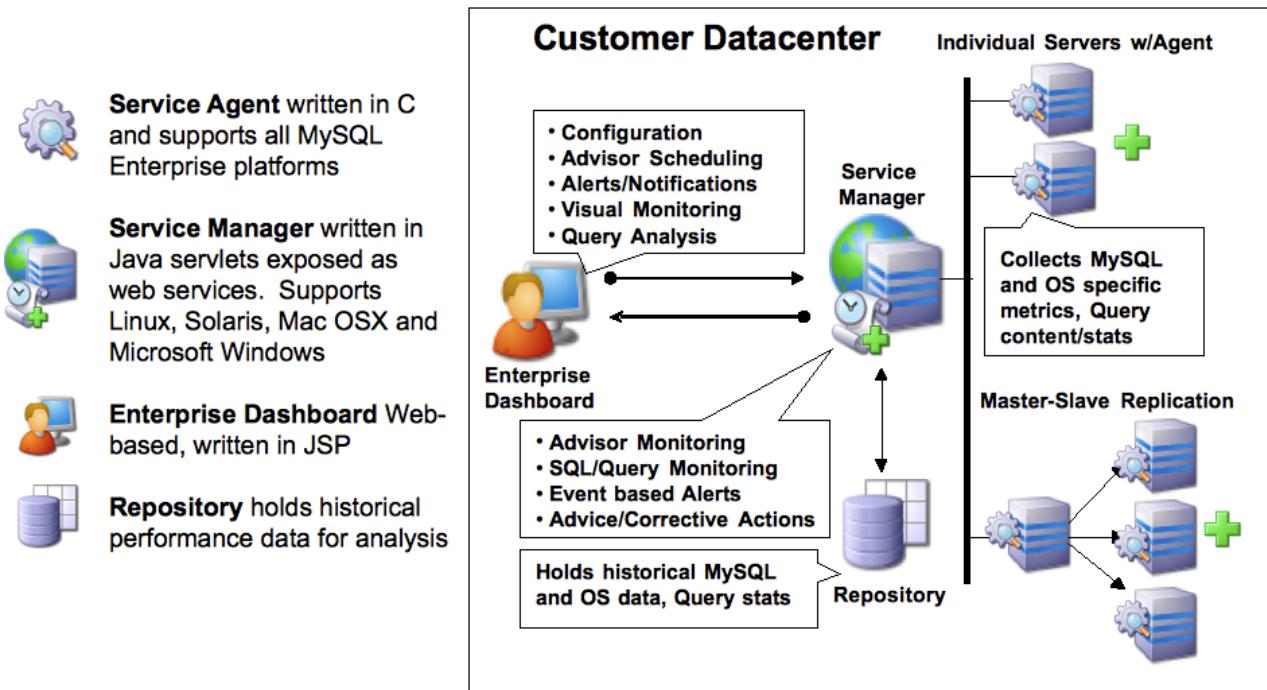

The MySQL Enterprise Monitor does this by providing a web-based interface—called the Enterprise Dashboard—that serves as the portal for viewing information about your MySQL database servers. MySQL professionals can manage all their servers by group or individually if need be.

The Enterprise Dashboard web interface does not have to be installed on individual desktops, but is instead available from a centrally located machine that serves as the main location for the Monitoring and Advisory service.

## 15.1. Overview of the Service

The MySQL Enterprise Monitor is a collection of components that work together to monitor and help administer your MySQL server installations. This service includes server management agents, advisors, and a central MySQL Enterprise Service Manager, all working in tandem with the MySQL Enterprise to keep your MySQL servers secure and up to date. All of this is controlled through the MySQL Enterprise Dashboard—a lightweight web-based interface that gives you complete control of your MySQL servers from any location.

**Figure 15.1. MySQL Enterprise Monitor Architecture**

The service is made up of a number of components, including the Monitor Agent (MySQL Enterprise Monitor Agent), the Service Manager (MySQL Enterprise Service Manager), the Enterprise Dashboard, the Repository and the Advisors.

### 15.1.1. The Service Architecture

The MySQL Enterprise Monitor is powered by a distributed web-based application that is deployed within the confines of the corporate firewall. The Enterprise Dashboard provides the interface to the server data, advisor notifications, live information and communication with the MySQL Enterprise Update Service.

Subscribers are kept up to date about the latest releases of the MySQL server or issues that may affect their specific implementation of MySQL by using the MySQL Enterprise Update Service. This same mechanism is used to notify MySQL Enterprise Monitor users of updates to the application or to the MySQL Advisors and Rules. The various components are described below.

- **Monitor Agent**

Monitor Agents are the foot soldiers of the MySQL Enterprise Monitor; they monitor each MySQL server. Running as a Windows service or Unix daemon, the Agent uses a combination of MySQL specific commands, SQL queries, and custom scripts to collect and report MySQL server or operating system (OS) specific data. The Monitor Agent initiates a “heartbeat” to the Service Manager on a regular basis to ensure specific MySQL server and OS level data collections are current.

In the overall architecture, the Monitor Agent is the only component of the MySQL Enterprise Monitor that establishes or maintains a connection with the monitored MySQL Server. As with any MySQL client, the Monitor Agent is authenticated on the monitored MySQL server and requires a user name and password to establish a connection.

In addition, the MySQL Enterprise Monitor Agent also provides a proxy service that allows for information about queries to be captured and reported as part of the Query Analyzer functionality. The MySQL Enterprise Monitor Agent accepts client connections and forwards the SQL statements on to the server and returns the results. In the background, the agent is collecting information about the query execution, row counts, times and other data so that queries and their execution can be monitored.

- **Service Manager**

The Service Manager is the heart and soul of the MySQL Enterprise Monitor. It is built on a collection of Java services hosted on a single Windows or Unix server. The Service Manager interacts with all of the Monitor Agents under its domain to collect MySQL server and OS level data for each of the monitored MySQL servers.

The Service Manager performs many duties including:

- Enterprise Dashboard, the main interface to the MySQL Enterprise Service Manager.
- Autodiscovery of monitored MySQL Servers.

- Creation and management of Monitor Agent tasks.
  - Storage of data collections from Monitor Agents.
  - Monitoring of key MySQL server and OS level metric data collections.
  - Reporting MySQL best practice events and violations.
  - Providing MySQL expert advice for MySQL best practice violations.
  - Autodiscovery of replication topology (Not available for all subscription levels)
- **The Repository**

The Repository is built on MySQL 5.0.[x](#) and is used to store MySQL server and OS level data collections for each of the monitored MySQL Servers. This information is used by the Service Manager to evaluate and report the health and status of the monitored MySQL environment(s).

- **The Enterprise Dashboard**

The MySQL Enterprise web client provides the graphical user interface (GUI) for the MySQL Enterprise Monitor. This interface is the primary means of monitoring the state of your MySQL servers, identifying rule violations and providing advice on how best to address and correct any underlying issues.

This interface also provides an easy means of configuring advisors, adding users, creating notification groups, and receiving updates from MySQL Enterprise.

## 15.1.2. Service Features

The key features of the MySQL Enterprise Monitor can be summarized as follows:

- Group-level or Server-level management options
- Enterprise Dashboard for managing all MySQL Servers from a consolidated console
- Monitoring page for “at a glance” global health check of key systems
- MySQL-provided Advisors and Advisor Rules for enforcing MySQL Best Practices
- Advisor Rule Scheduling for unattended operations
- Customizable Thresholds and Alerts for identifying Advisor Rule violations
- User-Defined Advisor Rules
- Event/Alert History browser for researching advisor-specific events and annotations
- Query Analyzer functionality allowing you to monitor the execution times, row counts and other data about queries executed on your MySQL server.

These features are presented through the MySQL Enterprise Dashboard which is made up of six main pages:

- The **MONITOR** page comprises:
  - The **SERVER TREE**: Easily navigate monitored servers
  - The **GRAPHING**: This capability is built in so you can quickly assess critical functions such as activity, performance metrics, and number of connections
  - The **HEAT CHART**: Color-coded buttons provide key operating system and database metrics
- The **ADVISORS** page

This page shows the advisors that are currently scheduled. There are advisors for a variety of topics such as security and indexing. Users can add, edit, or create their own advisors.

- The **EVENTS** page

This page shows rule violations, indicating the server, severity, and time of occurrence. A number of filter options are available, allowing various views of events.

- The **GRAPHS** page

Use this page to view all the available graphs and to adjust the scale of the graphs, for a more or less detailed view as the situation requires.

- The **QUERY ANALYZER** page

- The **REPLICATION** page

Use this page to keep track of your masters and their slaves (Not available for all subscription levels)

- The **SETTINGS** page

On this page you configure servers, users, email addresses, and notification groups. Entering a user name and password for MySQL Enterprise provides automatic updates.

### 15.1.3. Security

Using the Tomcat/Apache web server for the user interface allows an administrator to configure the web server to meet any security regulations. The MySQL Enterprise Monitor architecture is designed to be as secure as possible, even when monitoring systems outside of the local network.

Communications between the MySQL Enterprise Monitor Agent and MySQL Enterprise Service Manager can be protected by Secure Socket Layer (SSL) encryption and server and agent can use SSL certificates to provide authentication and prevent spoofing.

The MySQL Enterprise Monitor Agent is like a web browser — it is an HTTP client application that initiates all communication with the MySQL Enterprise Service Manager. If the server requires action from the agent, it must wait until the agent next initiates contact and sends its request in a response. This means you do not need to open an inbound port on the machine on which the agent is running because it does not listen for requests. However, an outbound port must be open for the agent to contact the MySQL Enterprise Service Manager.

As an additional security feature, each Agent can have a separate Advisory Service login which minimizes exposure should any one agent be compromised.

## 15.2. Conventions Used in This Document

This document uses certain typographical conventions:

- **Text in this style** is used for SQL statements; database, table, and column names; program listings and source code; and environment variables. Example: “To reload the grant tables, use the `FLUSH PRIVILEGES` statement.”
- **Text in this style** indicates input that you type in examples.
- **Text in this style** indicates the names of executable programs and scripts, examples being `mysql` (the MySQL command line client program) and `mysqld` (the MySQL server executable).
- **Text in this style** is used for variable input for which you should substitute a value of your own choosing.
- File names and directory names are written like this: “The global `my.cnf` file is located in the `/etc` directory.”
- Character sequences are written like this: “To specify a wildcard, use the ‘%’ character.”
- **Text in this style** is used for emphasis.
- **Text in this style** is used in table headings and to convey especially strong emphasis.

When commands are shown that are meant to be executed from within a particular program, the prompt shown preceding the command indicates which command to use. For example, `shell>` indicates a command that you execute from your login shell or from the command line in Windows:

```
shell> type a shell command here
```

The “shell” is your command interpreter. On Unix, this is typically a program such as `sh`, `csh`, or `bash`. On Windows, the equivalent program is `command.com` or `cmd.exe`, typically run in a console window.

When you enter a command or statement shown in an example, do not type the prompt shown in the example.

Sometimes, what appears on one line in a console window cannot be represented in the documentation on a single line. In cases such as this the character ‘`>`’ is used. For example:

```
Please specify the directory where the MySQL Enterprise Monitor >
will be installed.
```

Where Unix commands are concerned, the continuation character ‘`\`’ is used. Doing this allows commands to be copied and pasted to the command line verbatim. For example:

```
shell> /opt/mysql/enterprise/agent/bin/mysql-monitor-agent -f \
/opt/mysql/enterprise/agent/etc/mysql-monitor-agent.ini
```

SQL keywords are not case sensitive and may be written in either case. This document uses uppercase.

In syntax descriptions, square brackets (‘`[`’ and ‘`]`’) indicate optional words or clauses. For example, in the following statement, `IF EXISTS` is optional:

```
DROP TABLE [IF EXISTS] tbl_name
```

When a syntax element consists of a number of alternatives, the alternatives are separated by vertical bars (‘`|`’). When one member from a set of choices *may* be chosen, the alternatives are listed within square brackets (‘`[`’ and ‘`]`’):

```
TRIM([[BOTH | LEADING | TRAILING] [remstr] FROM] str)
```

When one member from a set of choices *must* be chosen, the alternatives are listed within braces (‘`{`’ and ‘`}`’):

```
{DESCRIBE | DESC} tbl_name [col_name | wild]
```

An ellipsis (‘`...`’) indicates the omission of a section of a statement, typically to provide a shorter version of more complex syntax. For example, `INSERT ... SELECT` is shorthand for the form of `INSERT` statement that is followed by a `SELECT` statement.

An ellipsis can also indicate that the preceding syntax element of a statement may be repeated. In the following example, multiple `reset_option` values may be given, with each of those after the first preceded by commas:

```
RESET reset_option [,reset_option] ...
```

Commands for setting shell variables are shown using Bourne shell syntax. For example, the sequence to set the `CC` environment variable and run the `configure` command looks like this in Bourne shell syntax:

```
shell> CC=gcc ./configure
```

If you are using `csh` or `tcsh`, you must issue commands somewhat differently:

```
shell> setenv CC gcc
shell> ./configure
```

Throughout this document the term ‘`Unix`’ is used to describe any Unix or Unix-like operating system. For an up-to-date list of operating systems supported by the MySQL Enterprise Monitor please see the <http://www.mysql.com/products/enterprise/>.

## 15.3. Installation and Upgrades

### Note

MySQL Enterprise subscription, MySQL Enterprise Monitor, MySQL Replication Monitor, and MySQL Query Analyzer are only available to commercial customers. To learn more, see: <http://www.mysql.com/products/enterprise/features.html>.

This chapter describes the process of installing the MySQL Enterprise Monitor on all operating systems. A working installation requires the installation of a MySQL Enterprise Service Manager, the MySQL Enterprise Advisors and one or more MySQL Enterprise Monitor Agents. Simply described, the agent inspects the MySQL server it is monitoring, reports to the Service Manager, and the results are interpreted by the advisors and displayed in the MySQL Enterprise Dashboard for viewing in a web browser.

One Monitor Agent is installed for each MySQL server that is being monitored. The Monitor Agent usually runs on the same machine that hosts the monitored MySQL server but it may run on any machine that has access to both the monitored MySQL server and the MySQL Enterprise Dashboard. The agent reports its findings to the Service Manager and these results are interpreted by Advisors and displayed in the dashboard. The end user opens a web browser to view the information presented in the dashboard. The Service Manager and dashboard run on the same machine and both have access to a local MySQL server installed as part of the MySQL Enterprise Monitor. This server is known as the repository and provides storage for the data provided by the agent.

Installation is a three step process:

1. Install and start the Service Manager on the monitoring system. See [Section 15.3.2, “Service Manager Installation”](#).
2. Configure the Service Manager, see [Section 15.3.3, “Monitor Agent Installation”](#).
3. Start the MySQL Enterprise Service Manager and MySQL Enterprise Monitor Agent instances, and then use the MySQL Enterprise Dashboard to install the Advisors and complete the configuration and installation. See [Section 15.3.2.7, “MySQL Enterprise Service Manager Configuration Settings and Advisor Installation”](#).

Depending on your configuration and environment, you will need to download a number of different components and files from [MySQL Enterprise website](#) available on the [download](#) page. These include:

- MySQL Enterprise Service Manager and MySQL Enterprise Dashboard for the platform that you intend to execute the MySQL Enterprise Service Manager on. These are named `mysqlmonitor-2.1.0.1096-linux-x86_64-installer.bin`, with the appropriate version and platform name. If you are performing an upgrade, download the upgrade installer, named `mysqlmonitor-2.1.0.1096-linux-x86_64-update-installer.bin`.
- One or more MySQL Enterprise Monitor Agent, one for each MySQL Server that you want to monitor. You should download an installer package for the right platform for the MySQL server you want to manage. Agent installers are available with the name `mysqlmonitoragent-2.1.0.1093-linux-debian3.1-powerpc-installer.bin`. Upgrade installers to update an existing MySQL Enterprise Monitor Agent installation are named `mysqlmonitoragent-2.1.0.1093-linux-debian3.1-powerpc-update-installer.bin`.
- *Optional*

A product key file for MySQL Enterprise Service Manager. If your MySQL Enterprise Service Manager has internet connectivity, your product key can be downloaded automatically during the initial phase of configuration directly from the MySQL Enterprise website. For more information, see [Section 15.3.2.7, “MySQL Enterprise Service Manager Configuration Settings and Advisor Installation”](#).

- *Optional*

An advisor bundle equal to the level of your MySQL Enterprise subscription (Platinum, Gold, or Silver), which is required for MySQL Enterprise Service Manager. If your MySQL Enterprise Service Manager has internet connectivity, your advisor bundle can be downloaded automatically during the initial phase of configuration directly from the MySQL Enterprise website. For more information, see [Section 15.3.2.7, “MySQL Enterprise Service Manager Configuration Settings and Advisor Installation”](#).

For information on the installation requirements for different platforms, see [Section 15.12.3, “Installation Requirements”](#).

## 15.3.1. User Roles

Prior to installation you will need to have at hand credentials for access to the MySQL server you plan to monitor and also your MySQL Enterprise credentials. *During* installation and when first logging in, you will set up a variety of users with different roles and credentials. This can become confusing. This section outlines the various users associated with the MySQL Enterprise Monitor and gives a brief description of their roles.

### 15.3.1.1. Existing Users

The **MySQL Enterprise user**: These are the credentials you use to log in to the MySQL Enterprise web site. You will need them to acquire the Advisor files and receive updates and, if necessary, acquire a product key.

The **MySQL user**: For Monitor Agents to report the status of a MySQL server they must have privileges on that server. To perform all functions an agent must have `SHOW DATABASES`, `REPLICATION CLIENT`, `SUPER`, `CREATE`, and `SELECT` privileges. In short, the Monitor Agent needs to have read access to all data. Details about this account are given in [Section 15.3.3.1, “Creating a MySQL User Account for the Monitor Agent”](#).

### 15.3.1.2. User Created During Installation

The **Repository user**: This user is the only user in the `user` table in the `mysql` database in the bundled MySQL server. To avoid confusion with monitored MySQL servers, this server is referred to throughout this document as the `repository`. The repository user can log in from `localhost` using the password specified during installation and has all privileges on all databases. These credentials are used to create the repository and its tables and to record data in them. During installation the default value for the user name for this role is `service_manager`. No default password is specified. You can use these credentials to manage the repository from the command line or when using a program such as MySQL Administrator.

During installation the file `configuration_report.txt` is created. Reference this file for the credentials of the repository manager. After the MySQL Enterprise Service Manager is installed, look for this file in the following directories:

- Windows: `C:\Program Files\MySQL\Enterprise\Monitor`
- Unix: `/opt/mysql/enterprise/monitor`
- Mac OS X: `/Applications/mysql/enterprise/monitor`

### 15.3.1.3. Users Created on First Log-in

The **Root user**: This user is the administrator of the dashboard. The first time you log in to the dashboard you must log in as this user. The default user name for this user is `admin`. There is no default password for this user.

The **Agent user**: The Monitor Agent needs to report the status of the MySQL server it is monitoring. For this reason it needs to log in to the dashboard. The default user name for this user is `agent`. There is no default password for this user.

#### Note

The Monitor Agent has two roles in the MySQL Enterprise Monitor; it must have access to the dashboard and to the MySQL server it is monitoring. For a description of the agent as a MySQL user see [Section 15.3.1.1, “Existing Users”](#).

### 15.3.2. Service Manager Installation

The MySQL Enterprise Service Manager is the core element of the MySQL Enterprise Monitor. The installation process for this element is completely self-contained, but the installation includes the following components:

- Apache Tomcat
- MySQL Server
- Java VM

#### Note

After installation you can determine the version number of the various components by entering `http://server_name:18080/main?command=list_versions` into the web browsers address bar.

During installation, versions of MySQL and Tomcat will be installed onto the machine. The installer automatically provides default network ports that are different from standard installation for these applications. You can change the ports during installation.

During installation, default values are shown for user names and ports. This is for your convenience only; you may choose different values. The installer detect ports that are already in use and allows you to select different ports.

#### Warning

The MySQL Enterprise Service Manager version 2.0 requires agents using 2.0 or higher.

All the installations share the same basic configuration parameters that you will be asked to confirm during installation. Before you start your installation, please review the section on these common parameters, then proceed to section specific to your installation platform. For details of the common parameters, see [Section 15.3.2.1, “Service Manager Installation Common Parameters”](#). For information on installation under Windows, see [Section 15.3.2.2, “Service Manager Installation on Windows”](#), for Mac OS X see [Section 15.3.2.3, “Service Manager Installation on Mac OS X”](#), and for Unix/Linux, see [Section 15.3.2.4, “Service Manager Installation on Unix”](#).

### 15.3.2.1. Service Manager Installation Common Parameters

All installations of the Service Manager install the Tomcat and MySQL applications using the same basic set of parameters. The

defaults provided by the installation process are designed to be unique so that they do not interfere with existing installations of either product. However, you should check these parameters before installation to ensure that you do not experience any problems.

The common parameters are divided into those applying to the Tomcat server, and the MySQL server (Repository Configuration):

- **Tomcat Server Options**

- Tomcat Server port: The default port that the Tomcat server will use when listening for connections. If you change this option, then the port that you need to use when connecting to the Service Manager must be modified accordingly. The default value is 18080.

**Note**

If you are not currently running a web server on port 80 you may find it more convenient to use the well known port rather than 18080. Since port 80 is the default for a web server, you can then open the dashboard without specifying a port.

- Tomcat Shutdown port: The port used by the management scripts that is used to shut the Tomcat server down when you need to stop the Service Manager. The default value is 18005.
- Tomcat SSL Port: The standard port used to connect to the Service Manager when you want to use Secure Sockets Layer (SSL) encrypted communication. The default value is 18443.

- **Repository Configuration (MySQL Server)**

- Repository Username: The user name created and used to store information within the MySQL server to hold the information used by the Service Manager. In normal use, you should not need to use or modify this information, but it may be required if you have a support issue. The default value is `service_manager`.
- Repository User password: The password to be used for the Repository Username. This should be set to a secure password so that the repository data is secure.

The information that you configure during installation will always be recorded within the `configuration_report.txt` file within the installation directory for the Service Manager.

**Caution**

Because the information stored within the `configuration_report.txt` file is in plain text, the Repository user name and password information are also exposed within this file. Make sure that the installation directory and file are secure that they can only be accessed by those users who would need to use the information.

### 15.3.2.2. Service Manager Installation on Windows

On Windows the installation modes are `win32` and `unattended` only. `unattended` mode is especially useful if you are doing multiple installations. For more information on this topic see [Section 15.3.4, “Unattended Installation”](#).

**Note**

To install the Service Manager as a Windows service, you must do the installation as a privileged user.

On Windows Vista or later, if user account control is on, an operating system dialog box requests confirmation of the installation.

To install the Service Manager on Windows, find the executable file named `mysqlmonitor-version-windows-installer.exe` (where `version` represents the three-part version number).

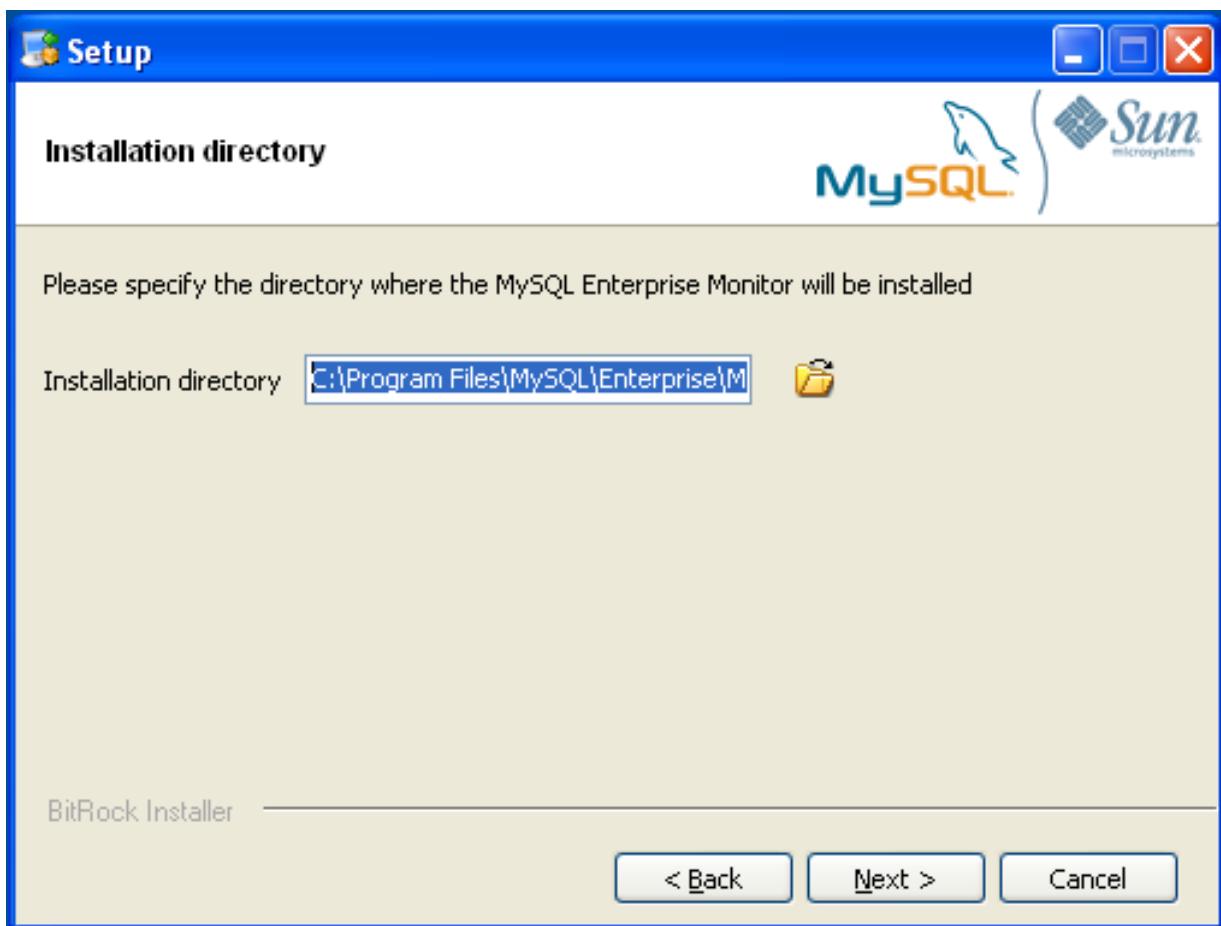

1. Double-click the MySQL Monitor installer. You should be presented with the Language Selection prompt. Select the language to use for the installer and then click OK.

**Figure 15.2. MySQL Enterprise Monitor: Installing Monitor on Windows: Language Selection**

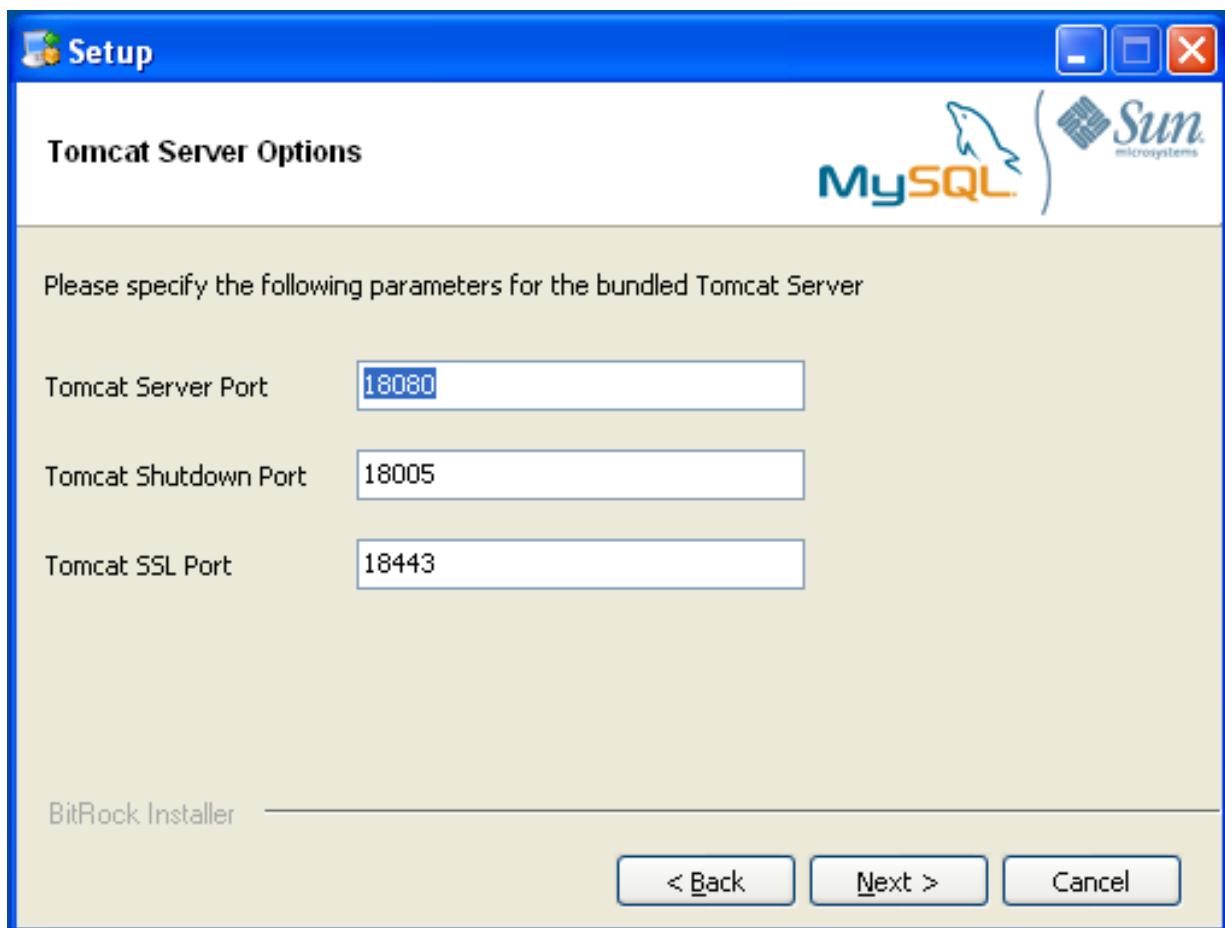

2. With the installation language selected, the remainder of the installation sets up the installation location and the main configuration parameters required by MySQL Enterprise Service Manager. Click NEXT to continue.
3. Select the installation directory where you want the MySQL Enterprise Service Manager components installed. By default on Windows the directory is `C:\Program Files\MySQL\Enterprise\Monitor`. You click the button next to the installation directory field to select a directory using the File chooser, or type the directory manually. Click NEXT to continue.

**Figure 15.3. MySQL Enterprise Monitor: Installing Monitor on Windows: Installation Directory**

4. Configure the options that set the network ports used by the Tomcat server. For more information, see [Section 15.3.2.1, “Service Manager Installation Common Parameters”](#). Click NEXT to continue.

**Figure 15.4. MySQL Enterprise Monitor: Installing Monitor on Windows: Tomcat Server Options**

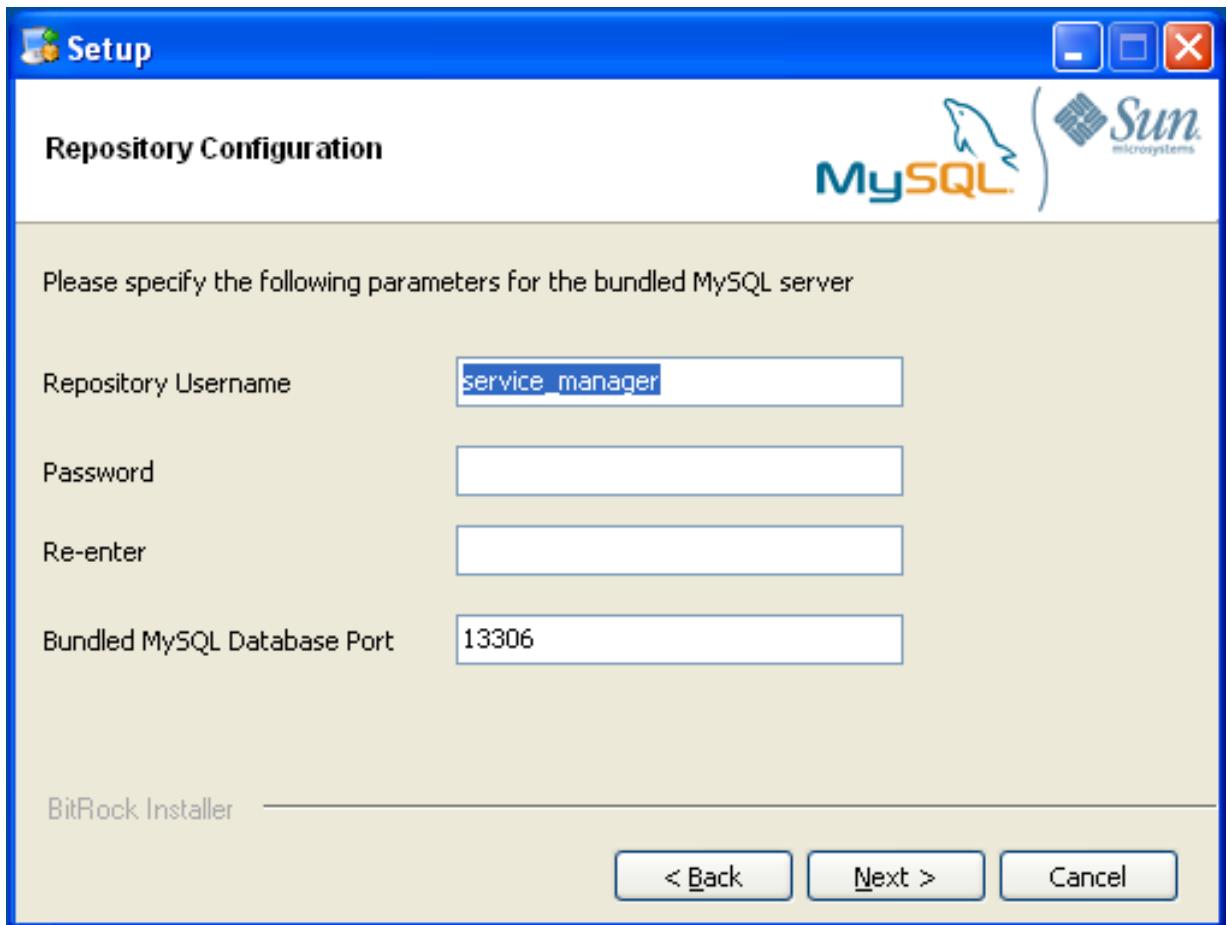

5. Configure the repository settings, setting the user name, password and port used to communicate with the bundled MySQL server that will be used to store the information and statistics for your installation. For more information, see [Section 15.3.2.1, “Service Manager Installation Common Parameters”](#). Click NEXT to continue.

**Note**

If the Windows firewall is enabled you will be asked to unblock ports for Apache/Tomcat and the MySQL server.

**Figure 15.5. MySQL Enterprise Monitor: Installing Monitor on Windows: Repository Configuration**

6. You will be provided with information and a warning about the configuration options and how they are stored in the [configuration\\_report.txt](#) file, and its location. Take a note of the full path to this file in case you need to look up the information later. Click NEXT to continue.
7. You should now be prompted to start the installation process. Click NEXT to continue.
8. Once the installation has been completed, you will be provided with the information on how to uninstall MySQL Enterprise Service Manager. Click NEXT to continue.
9. To complete the installation and set up your MySQL Enterprise Service Manager, you will need to log in to the Dashboard. You can do this automatically by checking the box on the final window before clicking FINISH. This checkbox is selected by default. If you do not want to run the Dashboard at this time, uncheck the box and click FINISH.

For instructions on starting the MySQL Enterprise Monitor services under Windows, see [Section 15.3.2.5, “Starting/Stopping the MySQL Enterprise Monitor Service on Windows”](#).

### 15.3.2.3. Service Manager Installation on Mac OS X

On Mac OS X there are three installation modes `osx`, `text`, and `unattended`. For more information on this topic see [Section 15.3.4, “Unattended Installation”](#). The `text` mode installation for Mac OS X is identical to `text` installation under Unix. For `text` mode installation instructions see [Section 15.3.2.4, “Service Manager Installation on Unix”](#).

Installing the MySQL Enterprise Service Manager on Mac OS X requires an existing installation of Java. The minimum required version is 1.5.0\_7. If this version is not installed on your machine you can download it from Apple. This version of Java requires Mac OS X version 10.4.5 as a minimum, so you may need to upgrade your operating system in order to install it.

For reasons of backward compatibility, Mac OS X is usually installed with multiple versions of Java. When installing in `osx` mode, version 1.5.0\_7 must be the default version. Upon installation, Java 1.5.0\_7 sets itself as the default so this is usually not a problem.

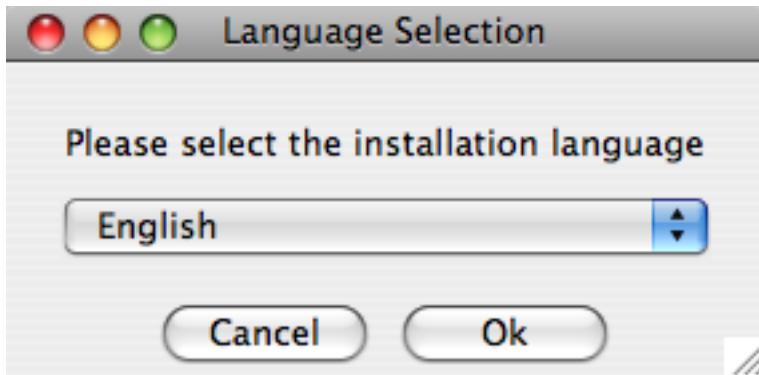

If you have changed the default you can reset it or you may install the MySQL Enterprise Service Manager in `text` mode, setting the environment variables to point to the correct version of Java. To install in `text` mode, find the `installbuilder` file in the

[Contents/MacOS](#) directory immediately below the `mysqlmonitor-version-osx-installer.app` directory. Installing the MySQL Enterprise Service Manager in `text` mode is identical to the procedure described in [Section 15.3.2.4, “Service Manager Installation on Unix”](#) with the minor differences noted above.

To install using the GUI (`osx`) installation, follow these instructions:

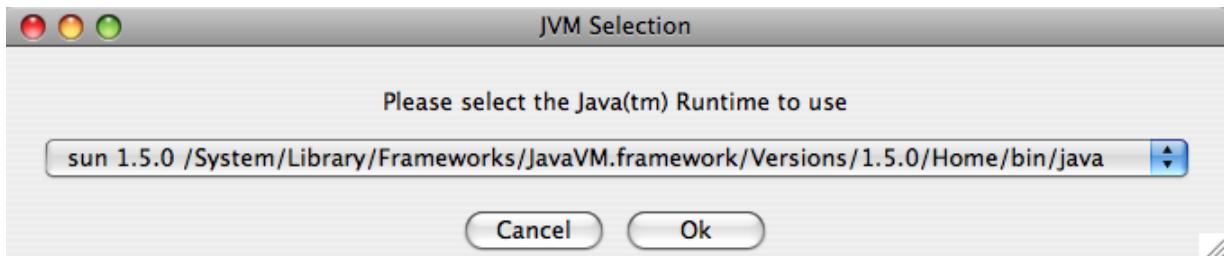

1. Double-click the MySQL Monitor installer. You should be presented with the Language Selection prompt. Select the language to use for the installer and then click OK.

**Figure 15.6. MySQL Enterprise Monitor: Installing Monitor on OS X: Language Selection**

2. If you have multiple Java installations on your machine, you will be asked to choose which Java to use with your MySQL Enterprise Service Manager installation. Choose the Java version you want to use (1.5.0 or later is required), and click OK.

**Figure 15.7. MySQL Enterprise Monitor: Installing Monitor on OS X: Java Selection**

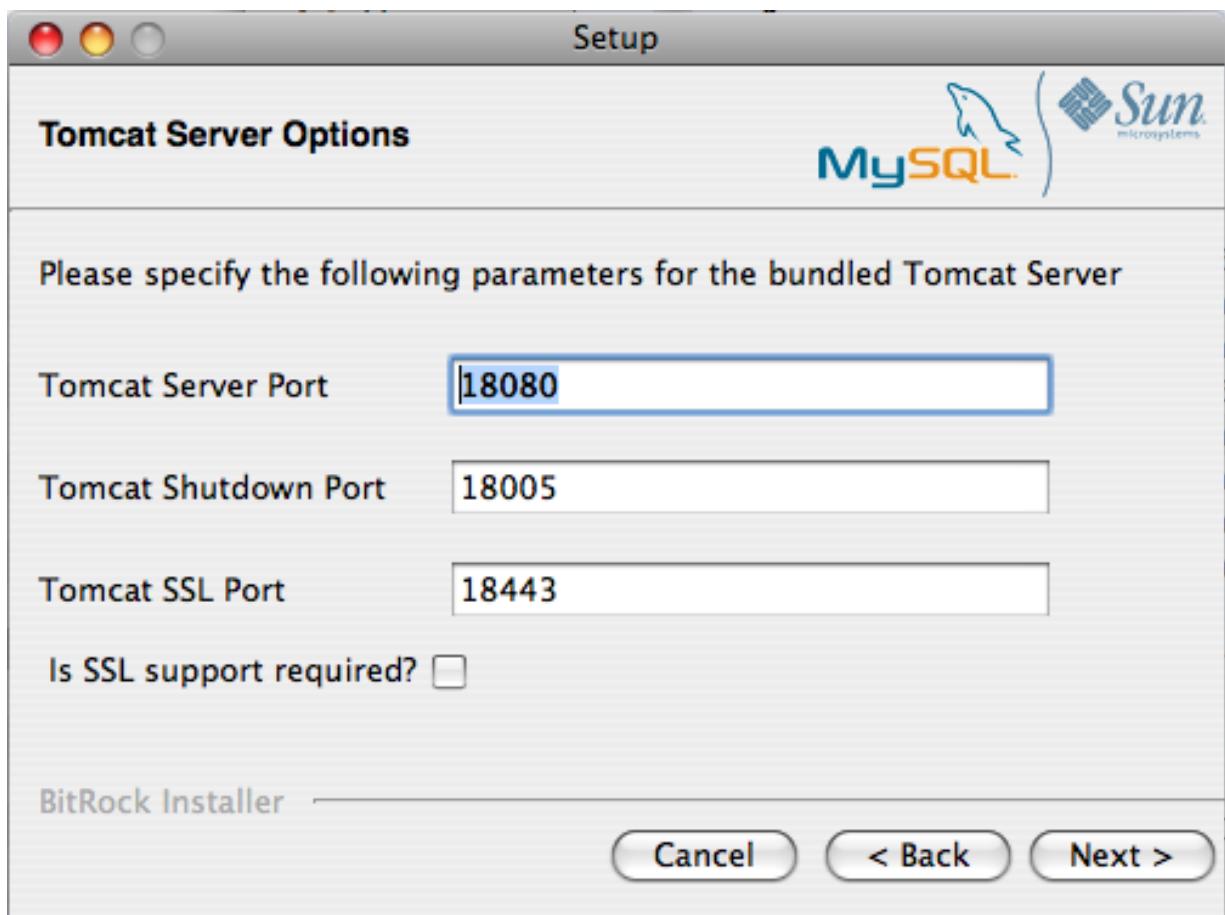

3. With the installation language and Java version selected, the remainder of the installation sets up the installation location and the main configuration parameters required by MySQL Enterprise Service Manager. Click NEXT to continue.
4. Select the installation directory where you want the MySQL Enterprise Service Manager components installed. By default on Mac OS X the directory is [/Applications/mysql/enterprise/monitor](#). You click the button next to the installation directory field to select a directory using the File chooser, or type the directory manually. Click NEXT to continue.

**Figure 15.8. MySQL Enterprise Monitor: Installing Monitor on OS X: Installation Directory**

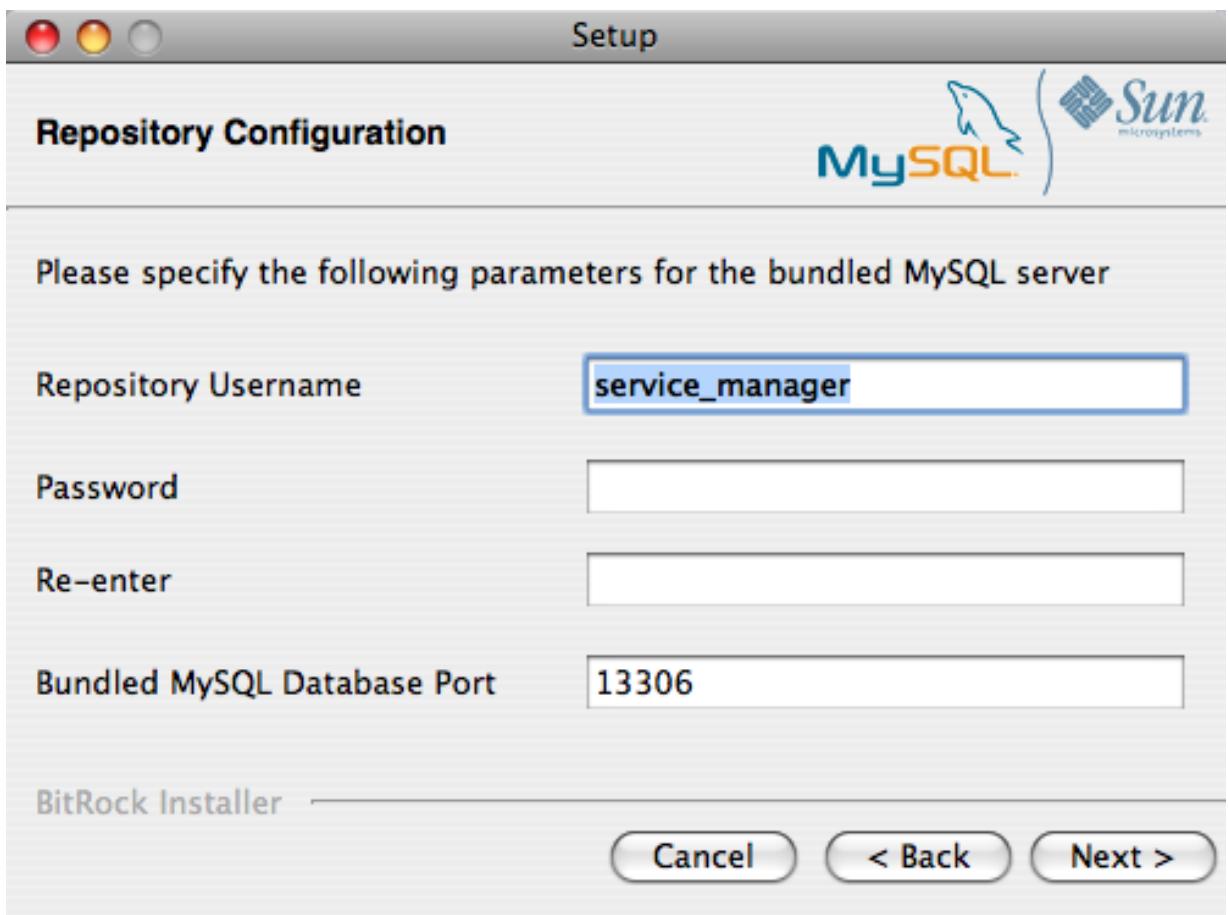

5. Configure the options that set the network ports used by the Tomcat server. For more information, see [Section 15.3.2.1, “Service Manager Installation Common Parameters”](#). Click NEXT to continue.

**Figure 15.9. MySQL Enterprise Monitor: Installing Monitor on OS X: Tomcat Server Options**

6. Configure the repository settings, setting the user name, password and port used to communicate with the bundled MySQL server that will be used to store the information and statistics for your installation. For more information, see [Section 15.3.2.1, "Service Manager Installation Common Parameters"](#). Click NEXT to continue.

**Figure 15.10. MySQL Enterprise Monitor: Installing Monitor on OS X: Repository Configuration**

7. You will be provided with information and a warning about the configuration options and how they are stored in the `configuration_report.txt` file, and its location. Take a note of the full path to this file in case you need to look up the information later. Click NEXT to continue.
8. You should now be prompted to start the installation process. Click NEXT to continue.
9. Once the installation has been completed, you will be provided with the information on how to uninstall MySQL Enterprise Service Manager. Click NEXT to continue.
10. To complete the installation and set up your MySQL Enterprise Service Manager, you will need to login to the Dashboard. You can do this automatically by checking the box on the final window before clicking FINISH. This checkbox is selected by default. If you do not want to run the Dashboard at this time, uncheck the box and click FINISH.

Your installation should now be complete. To continue with the configuration of MySQL Enterprise Service Manager, see [Section 15.3.2.7, “MySQL Enterprise Service Manager Configuration Settings and Advisor Installation”](#).

#### 15.3.2.4. Service Manager Installation on Unix

To install the Service Manager find the file named `mysqlmonitor-version-installer.bin` (where `version` indicates the version number, the OS, and the architecture). Ensure that this file is executable by typing:

```
shell> chmod +x mysqlmonitor-version-installer.bin
```

To install to the default directory (`/opt/mysql/enterprise/monitor`) you need to be logged in as `root`. Installing as an unprivileged user installs to the `/home/user_name/mysql/enterprise/monitor/` directory.

What follows describes installation from the command line. You may install the Service Manager graphically by running the installer from within a windows manager. In both cases the steps are identical. You may also install the Service Manager in `unattended` mode. This is especially useful if you are doing multiple installations. For more information on this topic see [Section 15.3.4, “Unattended Installation”](#).

1. Begin installation by typing:

```
shell> ./mysqlmonitor-version-installer.bin
```

2. First choose the language for the installation:

```
Language Selection
Please select the installation language
[1] English
[2] Japanese
Please choose an option [1] :
```

3. Throughout the installation process you will be asked the configuration questions for different options. Default values are shown between square brackets; to use the default press **Enter**. Otherwise, enter the new value and press **Enter**:

First, select the directory where you want MySQL Enterprise Service Manager to be installed. The default is `/opt/mysql/enterprise/monitor/`. Make sure that the location you choose has enough space to hold the installation files and the database information that will be created when MySQL Enterprise Service Manager is running.

```
Please specify the directory where the MySQL Enterprise Service Manager
will be installed.

Installation directory [/opt/mysql/enterprise/monitor/]:
```

4. Now set the Tomcat Server options. For more details on these parameters, see [Section 15.3.2.1, “Service Manager Installation Common Parameters”](#).

```

Tomcat Server Options
Please specify the following parameters for the bundled Tomcat Server
Tomcat Server Port [18080]:
Tomcat Shutdown Port [18005]:
Tomcat SSL Port [18443]:
```

You will also be asked if SSL support is required. SSL support allows your agents and monitor to communicate with each other using SSL. Using SSL means that the data exchanged by the agent and MySQL Enterprise Service Manager are secure and can be used to monitor servers securely, or to monitor agents over a public connection.

You can enable SSL by pressing **Y** when prompted during installation:

```
Is SSL support required? [y/N]:
```

5. Set the repository (embedded MySQL server) configuration options. For more details on these parameters, see [Section 15.3.2.1, “Service Manager Installation Common Parameters”](#).

```

Repository Configuration
Please specify the following parameters for the bundled MySQL server
Repository Username [service_manager]:
Password :
Re-enter :
Bundled MySQL Database Port [13306]:
```

6. Before the final installation process, you will be provided with the location of the file that contains a copy of all of the settings. Be sure to follow the instructions and store this report in a secure location. There is no password recovery feature.

```

Configuration Report
Note:
The settings you specified will be saved here:
/opt/mysql/enterprise/monitor/configuration_report.txt
```

```
IMPORTANT: This configuration report includes passwords stored in plain text; it
is intended to help you install and configure your agents. We strongly advise
you to secure or delete this text file immediately after installation.
```

```
Press [Enter] to continue :
```

7. You will now be asked to confirm the installation process.

```
Setup is now ready to begin installing MySQL Enterprise Monitor
on your computer.
```

```
Do you want to continue? [Y/n]: Y
```

```
Please wait while Setup installs MySQL Enterprise Monitor
on your computer.
```

The installation process may take a few minutes to complete. Upon completion you should see:

```
Completed installing files
Setup has completed installing MySQL Enterprise files on your computer
Uninstalling the MySQL Enterprise files can be done by invoking:
/opt/mysql/enterprise/monitor/uninstall
To complete the installation, launch the MySQL Enterprise Dashboard and complete
the initial setup and product activation information. Refer to the readme file
for additional information and a list of known issues.
```

```
Press [Enter] to continue :
```

8. Finally, you will be given the opportunity to read a supplied [Readme](#) file that is supplied with the installation. The [Readme](#) contains important information about how to use and start your MySQL Enterprise Service Manager.

```

Setup has finished installing MySQL Enterprise Monitor on your computer.
```

```
View Readme File [Y/n]: n
```

Once the [Readme](#) file has been displayed, or if you did not elect to read the file, the installation provides information about how to continue with your installation.

```
Info: To access the MySQL Enterprise Monitor please visit the
following page: http://localhost:18080/Auth.action
```

```
Press [Enter] to continue :
```

The Enterprise Dashboard will not start up automatically if you perform a [text](#) mode installation. For more information on starting and stopping MySQL Enterprise Service Manager, see [Section 15.3.2.6, “Starting/Stopping the MySQL Enterprise Monitor Service on Unix and Mac OS X”](#).

### 15.3.2.5. Starting/Stopping the MySQL Enterprise Monitor Service on Windows

You can choose to start up the MySQL Enterprise Service Manager on installation. The installed services are called:

- MySQL Enterprise Tomcat
- MySQL Enterprise MySQL

You can stop or start the services from the Microsoft Management Console Services window. Look for the [MySQL Enterprise Tomcat](#) and the [MySQL Enterprise MySQL](#) entries.

#### Note

On Windows Vista or later, starting these services requires administrative privileges—you must be logged in as an administrator. To start or stop a service right-click it and choose the [RUN AS ADMINISTRATOR](#) menu option. The same

restriction applies to using the menu options discussed in the following and to starting the services from the command line. To open an administrator cmd window right-click the cmd icon and choose the RUN AS ADMINISTRATOR menu option.

To start or stop a service, right-click it and choose from the options in the pop-up menu.

There is also a menu entry for starting and stopping the services. Navigate to the **Program, MySQL, MySQL Enterprise Monitor, Services** entry to stop or start the services.

You can also stop or start a service from the command line. To start the Tomcat service type:

```
shell> sc start MySQLEnterpriseTomcat
```

or:

```
shell> net start MySQLEnterpriseTomcat
```

To stop this service type:

```
shell> sc stop MySQLEnterpriseTomcat
```

or:

```
shell> net stop MySQLEnterpriseTomcat
```

In similar fashion, you may stop or start the MySQL server from the command line. The service name is **MySQLEnterpriseMySQL**.

You may also start, stop, and restart a specific service or both services using the **mysqlmonitorctl.bat** file. To execute this file, go to the command line and navigate to the **C:\Program Files\MySQL\Enterprise\Monitor** directory. Typing **mysqlmonitorctl.bat help** produces the following output:

```
usage: mysqlmonitorctl.bat help
 mysqlmonitorctl.bat (start|stop|restart|install|uninstall)
 mysqlmonitorctl.bat (start|stop|restart) tomcat
 mysqlmonitorctl.bat (start|stop|restart) mysql

help - this screen
start - start the service(s)
stop - stop the service(s)
restart - restart or start the service(s)
install - install the service(s)
uninstall - uninstall the service(s)
```

To stop a specific service, pass the argument **tomcat** or **mysql** in addition to the status change argument. If you wish to change the status of both services, do not specify a service name. You may also uninstall the services using this batch file.

Configuration of the dashboard begins immediately after the Service Manager is installed. To continue a Windows installation skip the next section and go to [Section 15.3.2.7, “MySQL Enterprise Service Manager Configuration Settings and Advisor Installation”](#).

### 15.3.2.6. Starting/Stopping the MySQL Enterprise Monitor Service on Unix and Mac OS X

The services incorporated into the MySQL Enterprise Service Manager are:

- The MySQL Server
- The Apache/Tomcat Server

Should you need to stop, start, or restart the MySQL Enterprise Service Manager call the **mysqlmonitorctl.sh** file located in the **/opt/mysql/enterprise/monitor/** directory on Unix or the **/Applications/mysql/enterprise/monitor/** on Mac OS X. To see all the available options navigate to the appropriate directory and type:

```
shell> /opt/mysql/enterprise/monitor/mysqlmonitorctl.sh help
```

Executing this script produces the following output:

```
usage: ./mysqlmonitorctl.sh help
./mysqlmonitorctl.sh (start|stop|status|restart)
./mysqlmonitorctl.sh (start|stop|status|restart) mysql
./mysqlmonitorctl.sh (start|stop|status|restart) tomcat
```

```
help - this screen
start - start the service(s)
stop - stop the service(s)
restart - restart or start the service(s)
status - report the status of the service
```

Using this script you can stop, start, or restart all the Service Manager components. To do this make a call to `mysqlmonit-orctl.sh start` from your start-up script.

To start the service:

```
shell> ./mysqlmonitorctl.sh start
./mysqlmonitorctl.sh : mysql started
nohup: redirecting stderr to stdout
Starting mysqld daemon with databases from /opt/mysql/enterprise/monitor/mysql/data/
Using CATALINA_BASE: /opt/mysql/enterprise/monitor/apache-tomcat
Using CATALINA_HOME: /opt/mysql/enterprise/monitor/apache-tomcat
Using CATALINA_TMPDIR: /opt/mysql/enterprise/monitor/apache-tomcat/temp
Using JRE_HOME: /opt/mysql/enterprise/monitor/java
```

If you try to start the service and it is already running, you will be warned that the services are already running:

```
shell> ./mysqlmonitorctl.sh start
./mysqlmonitorctl.sh : mysql (pid 18403) already running
./mysqlmonitorctl.sh : tomcat (pid 18480) already running
```

To stop the service:

```
shell> ./mysqlmonitorctl.sh stop
Using CATALINA_BASE: /Applications/mysql/enterprise/monitor/apache-tomcat
Using CATALINA_HOME: /Applications/mysql/enterprise/monitor/apache-tomcat
Using CATALINA_TMPDIR: /Applications/mysql/enterprise/monitor/apache-tomcat/temp
Using JRE_HOME: /System/Library/Frameworks/JavaVM.framework/Versions/1.5.0/Home
Stopping tomcat service ... [OK]
STOPPING server from pid file /Applications/mysql/enterprise/monitor/mysql/data/mysqld.pid
090209 15:37:09 mysqld ended
```

The `restart` command is equivalent to executing a `stop` and then `start` operation.

This script can also be used to check the status of the Tomcat web server or the MySQL repository.

```
shell> ./mysqlmonitorctl.sh status
MySQL Network MySQL is running
MySQL Network Tomcat is running
```

Configuration of the dashboard begins immediately after the MySQL Enterprise Service Manager is installed.

### 15.3.2.7. MySQL Enterprise Service Manager Configuration Settings and Advisor Installation

The Enterprise Dashboard is the web-based interface to the Service Manager so the procedure for starting the dashboard is identical for all platforms. From the dashboard you can configure the settings necessary for receiving updates from MySQL Enterprise and for the initial installation of the Advisors.

If you installed the Service Manager using a graphical interface, you have the option of launching the dashboard on the final install-ation screen (as long as the LAUNCH MYSQL ENTERPRISE MONITOR NOW checkbox is checked).

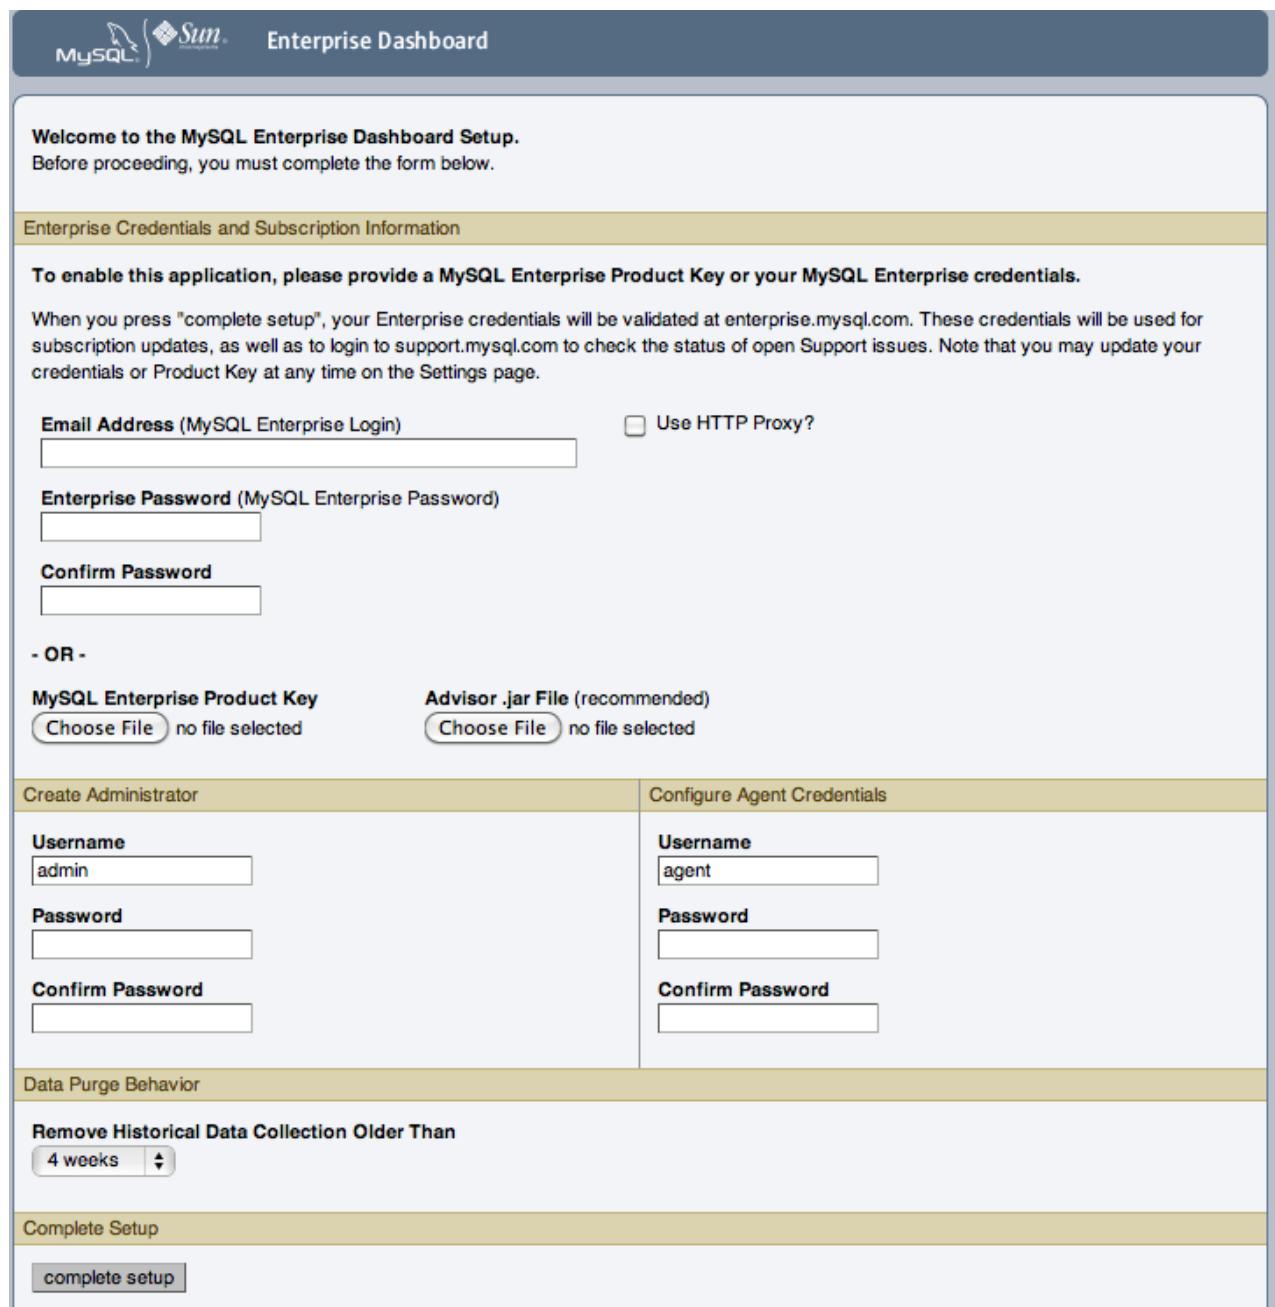

Otherwise, you can view the dashboard by typing `http://localhost:18080/Auth.action` into the address bar of your web browser. If you are unsure of the host name and port to use, check the `configuration_report.txt` file.

Under Windows it is also possible to open the dashboard by choosing the `MySQL` menu item and finding the `MySQL Enterprise Monitor` entry. Under this entry choose `Start Service Manager`.

#### 15.3.2.7.1. Initial Dashboard Log-In

If this is the first time that you have attempted to log in to the dashboard you should see a screen similar to the following:

**Figure 15.11. MySQL Enterprise Monitor: Initial Dashboard Log-In**

Welcome to the MySQL Enterprise Dashboard Setup.  
Before proceeding, you must complete the form below.

**Enterprise Credentials and Subscription Information**

To enable this application, please provide a MySQL Enterprise Product Key or your MySQL Enterprise credentials.

When you press "complete setup", your Enterprise credentials will be validated at enterprise.mysql.com. These credentials will be used for subscription updates, as well as to login to support.mysql.com to check the status of open Support issues. Note that you may update your credentials or Product Key at any time on the Settings page.

|                                                             |                                                             |
|-------------------------------------------------------------|-------------------------------------------------------------|
| Email Address (MySQL Enterprise Login)                      | <input type="checkbox"/> Use HTTP Proxy?                    |
| <input type="text"/>                                        |                                                             |
| Enterprise Password (MySQL Enterprise Password)             |                                                             |
| <input type="password"/>                                    |                                                             |
| Confirm Password                                            |                                                             |
| <input type="password"/>                                    |                                                             |
| <b>- OR -</b>                                               |                                                             |
| MySQL Enterprise Product Key                                | Advisor .jar File (recommended)                             |
| <input type="button" value="Choose File"/> no file selected | <input type="button" value="Choose File"/> no file selected |
| <b>Create Administrator</b>                                 |                                                             |
| Username                                                    | Configure Agent Credentials                                 |
| <input type="text" value="admin"/>                          | <input type="text" value="agent"/>                          |
| Password                                                    |                                                             |
| <input type="password"/>                                    | <input type="password"/>                                    |
| Confirm Password                                            |                                                             |
| <input type="password"/>                                    | <input type="password"/>                                    |
| <b>Data Purge Behavior</b>                                  |                                                             |
| Remove Historical Data Collection Older Than                |                                                             |
| <input type="button" value="4 weeks"/>                      |                                                             |
| <b>Complete Setup</b>                                       |                                                             |
| <input type="button" value="complete setup"/>               |                                                             |

Use this screen to perform the following tasks:

- Install the Advisors
- Set up your MySQL Enterprise credentials
- Create a user name and password for the dashboard administrator
- Create a user name and password for the Monitor Agent

If you have been provided with a [MySQL Enterprise Product Key](#) and an Advisors file click the BROWSE button and locate these files. The advisor file bears the name, [AdvisorScript-version.jar](#) and the product key, [Subscription-level\\_date.xml](#). If you do not allow Internet access from the dashboard you must install the advisors in this way. It is strongly recommended that you install the Advisors at this point, but you may do so later. For instructions on doing this see, [Section 15.3.2.7.3, “Installing Advisors After Initial Log-in”](#). If the product key that you provide is invalid a notification appears and you will be unable to import the advisors.

**Note**

If you are activating the MySQL Enterprise Monitor using a product key *do not* enter your MySQL credentials; entering both produces an error message.

If you have Internet access from the dashboard, activate MySQL Enterprise Monitor by supplying your MySQL Enterprise credentials. Enter your email address as the [MySQL Enterprise Login](#) and enter and confirm your MySQL Enterprise password. If you specify incorrect credentials, you receive the error message, “Unable to connect to verify credentials.”

In the **CREATE ADMINISTRATOR** section of this screen, enter credentials for the dashboard administrator. This creates the [root user](#) described in [Section 15.3.1.3, “Users Created on First Log-in”](#). Make note of the user name and password as these credentials are required for any future login.

In the **CONFIGURE AGENT CREDENTIALS** section of this screen enter the credentials for the agent. This is the [agent user](#) also described in [Section 15.3.1.3, “Users Created on First Log-in”](#). The agent needs to log in to report its findings. Make note of the agent's credentials; this information is required when installing the agent.

When all the settings have been specified, click the COMPLETE SETUP button. If you log in successfully you should see a message displaying the number of graphs and advisors that have been imported. This number varies depending upon your subscription level.

If importation of the advisor files fails, you will see the message:

Unable to import Advisor Jar. You may download the jar manually from the Enterprise Portal and import it from the 'Check For Updates' page.

In this case you may download the advisor file from the Enterprise website and install it as described in [Section 15.3.2.7.3, “Installing Advisors After Initial Log-in”](#).

### 15.3.2.7.2. Setting the Timezone and Locale

If this is the first time that you have launched the dashboard you are asked to set your time zone and locale. Choose the appropriate values from the drop-down list boxes. Setting the time zone ensures that you have an accurate time reference for any notifications from the MySQL Enterprise Advisors.

**Warning**

It is especially important that the time zone be set correctly as this may also affect the way the graphs display. For this reason, also ensure that the time reported by the operating system is correct. To change the time zone or locale see [Section 15.5.2, “User Preferences”](#).

The locale chosen determines the user's default language when logging in to the Dashboard. Note that this will override the default browser settings whenever this specific user logs in.

After specifying your time zone and locale, the dashboard opens on the [Monitor](#) page. For a detailed examination of the [Monitor or Screen](#) see, [Section 15.4, “MySQL Enterprise Dashboard”](#).

### 15.3.2.7.3. Installing Advisors After Initial Log-in

The Advisors interpret the data sent by the Monitor Agents and display the results in the dashboard. A minimal set of Advisors are preinstalled with the Service Manager. To obtain the full set of Advisors and get the most value from the MySQL Enterprise Monitor, you must download Advisors from MySQL Enterprise.

If you did not install the Advisors when you first logged in to the MySQL Enterprise Dashboard, open the dashboard, find the [Advisors](#) tab, and choose the [Check for Updates](#) link. Doing this downloads the latest version of the Advisors from the MySQL Enterprise web site. In order to install the advisors in this fashion you must specify your MySQL Enterprise credentials. Find instructions for doing this in [Section 15.5.1, “Global Settings”](#).

If you do not allow Internet access from the dashboard, you must install the Advisors from a local file. To do this you need an advisor file bearing the name, [AdvisorScript-version.jar](#). If you don't already have this file, you can find it on the MySQL Enterprise downloads page. Download the Advisors file to a location that is accessible from the dashboard. Use the BROWSE button to find the Advisors file and then choose IMPORT to load the advisors.

### 15.3.2.7.4. Upgrading and Updating Advisors

The process for upgrading advisors is exactly the same as the initial installation. Advisors are updated by choosing the UPDATE button on the [Check for Updates](#) page. If you do not have Internet access from the dashboard you can import the Advisors from a local file as described in [Section 15.3.2.7.3, “Installing Advisors After Initial Log-in”](#).

**Note**

You may choose to upgrade your MySQL Enterprise Monitor subscription level at any time.

### 15.3.2.7.5. Outgoing Email Settings

Alert notification through email is a key component of the MySQL Enterprise Monitor Advisor solution. For this reason you may want to immediately configure an SMTP account for at least one recipient.

To do this choose the [Settings](#) tab and go to the [Global Settings](#) screen by clicking the appropriate link. Here you can configure the email settings. These settings apply to the currently logged-in user.

Find the [Outgoing Email Settings](#) on the left of this page.

**Figure 15.12. MySQL Enterprise Monitor: Outgoing Email Settings**

Outgoing Email Settings

**Enable Email Notifications**

From Address (ex. 'MySQL Dashboard' <name@domain.com>)

**SMTP Server**

**SMTP Server Login**

**Disable JavaMail TLS/SSL**

**Update Password On Save**

**SMTP Server Password**  **Confirm Password**

**On Save, Send Test Email Message to (optional)**

**save**

Ensure that the [Enable Email Notifications](#) checkbox is checked and enter information as appropriate.

The default value for the SMTP port is [25](#). If your mail server runs on a different port simply specify it, separating it from the server name using a colon. For example, if your mail server runs on port 587 enter [email.myserver.com:587](#) into the **SMTP SERVER** text box.

#### Note

An email server must be available for sending email alerts.

The SMTP client uses Transport Layer Security (TLS) if the SMTP server supports it.

If your SMTP server incorrectly indicates that it supports TLS, check the **DISABLE JAVAMAIL TLS/SSL** check box.

The email settings page is dealt with in more detail in [Section 15.5, “The Settings Page”](#).

## 15.3.3. Monitor Agent Installation

A MySQL Enterprise Monitor Agent monitors a MySQL server and sends data to the Advisors. These data are interpreted and displayed in the dashboard. The Monitor Agent is installed on all platforms using the steps described in the next section.

### Warning

The MySQL Enterprise Service Manager version 2.0 or higher requires agents with a version number of 2.0 or higher.

### 15.3.3.1. Creating a MySQL User Account for the Monitor Agent

Before setting up an agent to monitor a MySQL server you need to ensure that there is a user account for the agent on that server.

The privileges required for this user account vary depending on the information you wish to gather using the MySQL Enterprise Monitor Agent. The following privileges allow the Monitor Agent to perform its assigned duties without limitation:

- **SHOW DATABASES**: Allows the MySQL Enterprise Monitor Agent to gather inventory about the monitored MySQL server.
- **REPLICATION CLIENT**: Allows the MySQL Enterprise Monitor Agent to gather Replication master/slave status data. This privilege is only needed if the MySQL Replication Advisor Rules are employed.
- **SELECT**: Allows the MySQL Enterprise Monitor Agent to collect statistics for table objects.
- **SUPER**: Allows the MySQL Enterprise Monitor Agent to execute **SHOW ENGINE INNODB STATUS** to collect data about InnoDB tables. This privilege is also required to obtain replication information using **SHOW MASTER STATUS**.
- **PROCESS**: When monitoring a MySQL server running MySQL 5.1.24 or above with **InnoDB**, the **PROCESS** privilege is required to execute **SHOW ENGINE INNODB STATUS**.
- **INSERT**: Required to create the UUID required by the agent.
- **CREATE**: Allows the MySQL Enterprise Monitor Agent to create tables. During discovery, the agent creates the table **inventory** within the **mysql** database that is used to the UUID for the server. Without this table, the agent cannot determine the UUID of the server and therefore use this when sending information to MySQL Enterprise Service Manager.

For example, the following **GRANT** statement will give the agent the required **SELECT**, **REPLICATION CLIENT**, **SHOW DATABASES** and **SUPER** rights:

```
GRANT SELECT, REPLICATION CLIENT, SHOW DATABASES, SUPER, PROCESS
ON *.*
TO 'mysqluser'@'localhost'
IDENTIFIED BY 'agent_password';
```

For security reasons, you may wish to limit the **CREATE** and **INSERT** privileges to the agent so that it can only create tables within the **mysql** database:

```
GRANT CREATE, INSERT
ON mysql.*
TO 'mysqluser'@'localhost'
IDENTIFIED BY 'agent_password';
```

To enable replication discovery to work, you should also grant the **SELECT** privilege on the **mysql.inventory** table for each user with replication privileges on the corresponding replication master. This is required to let the MySQL Enterprise Monitor Agent read the replication master UUID. For example:

```
GRANT SELECT
ON mysql.inventory
TO 'replicationuser'@'%'
IDENTIFIED BY 'replication_password';
```

### Note

You should perform this step *after* after having run the agent on the corresponding MySQL server to ensure that the **mysql.inventory** table has been correctly created. You can do this by running the agent, shutting the agent down, running the above **GRANT** statement, and then restarting the agent.

If the agent is unable to access the information from the table then a warning containing this information will be written to the agent log.

### Note

You may want to disable logging for the grant statement to prevent the grant information being replicated to the slaves. If this is the case, execute the statement `SET SQL_LOG_BIN=0` before you execute the above `GRANT` statement.

In a typical configuration, the agent runs on the same machine as the MySQL server it is monitoring so the host name will be `localhost`. However, this will change if the agent is running on a machine other than the one that hosts the monitored MySQL server. In this case, change `localhost` to the appropriate value. For more information about remote monitoring see [Section 15.3.3.6.4, “Configuring an Agent to Monitor a Remote MySQL Server”](#).

### 15.3.3.2. Installing the Agent on Microsoft Windows

To install the MySQL Enterprise Monitor Agent on Windows, double-click the `mysqlmonitoragent-version-windows-installer.exe` (where `version` indicates the three-part version number) installer.

#### Note

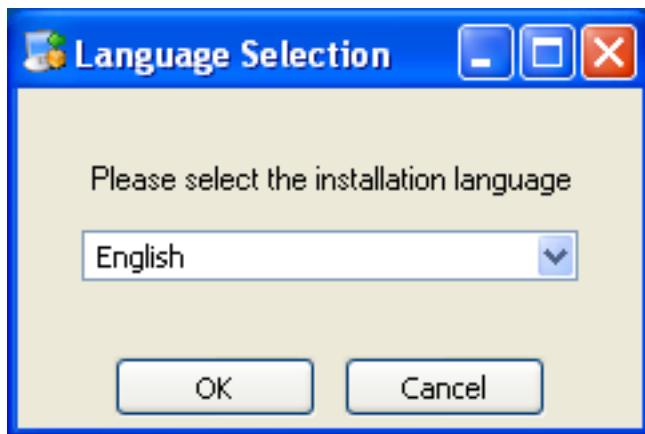

To install the agent as a Windows service, you must do the installation as a privileged user.

On Windows Vista or later, if user account control is on, an operating system dialog box requests confirmation of the installation.

You may also install the Monitor Agent in `unattended` mode. This is especially useful if you are doing multiple installations. For more information on this topic see, [Section 15.3.4, “Unattended Installation”](#).

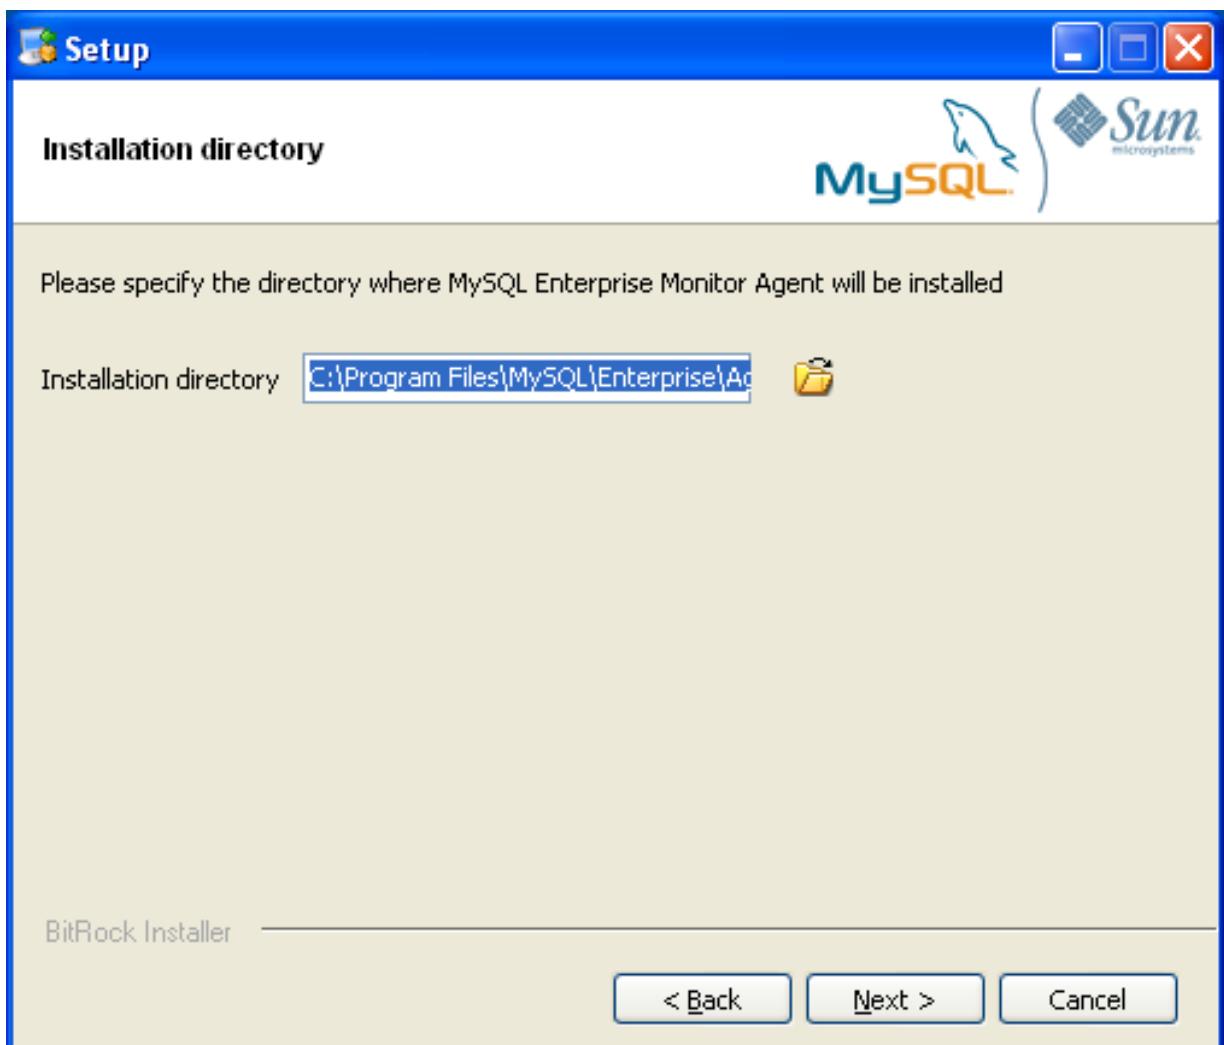

1. First, select the language for the MySQL Enterprise Monitor Agent installation. Click OK to continue installation.

**Figure 15.13. MySQL Enterprise Monitor: Installing Agent on Windows: Language Selection**

2. Click NEXT to start the installation process.
3. Select the installation directory. The default installation directory is `C:\Program Files\MySQL\Enterprise\Agent`. Select the installation directory, or type the new directory location. Click NEXT to continue the installation process.

**Figure 15.14. MySQL Enterprise Monitor: Installing Agent on Windows: Installation Directory**

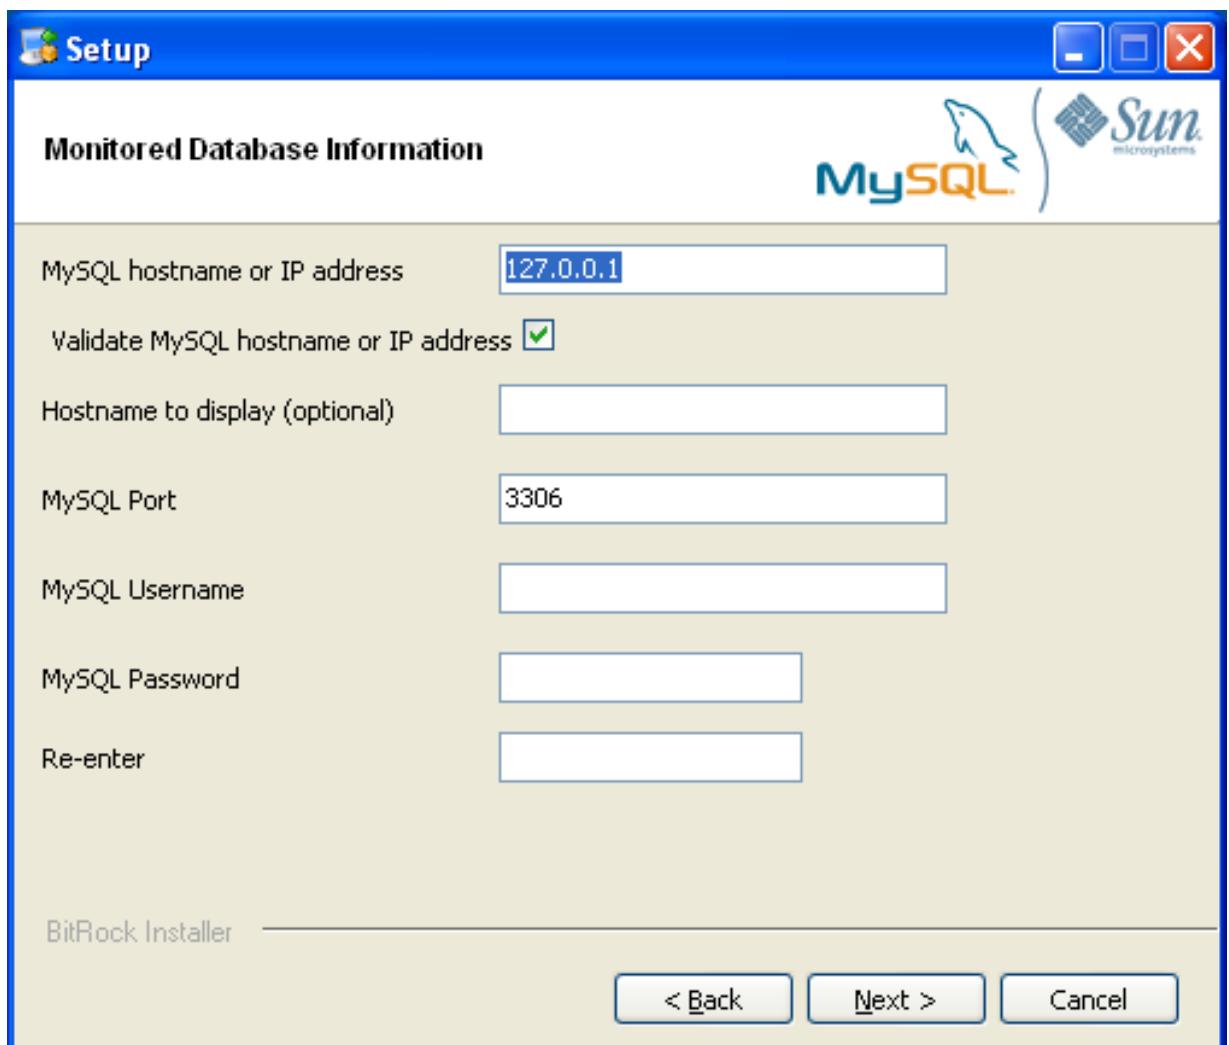

4. You need to specify the information about the MySQL server that you want to monitor. You must enter the IP address or host name of the host you want to monitor, and the port, user name and password that you will use to connect to the MySQL server. If you want to confirm that the MySQL server is currently reachable using the information, ensure that the **VALIDATE MySQL HOST NAME OR IP ADDRESS** checkbox is selected.

#### Note

Currently, on Windows, the monitor agent only includes support for connecting to the server to be monitored using TCP/IP, so if the server has been started with `--skip-networking` it cannot be monitored.

If the MySQL server to be monitored has been started using the command option `--bind-address` then the server will only listen for connections on the IP address specified, that is, the IP address of the MySQL server. If the monitor agent has been started using TCP/IP networking and the default address of 127.0.0.1 it will not be able to connect to the server to be monitored. Also, if "localhost" is specified as the host name during agent configuration, a connection will not be established, as the server will be listening for connections on the address specified with the `-bind-address` option, not 127.0.0.1.

**Figure 15.15. MySQL Enterprise Monitor: Installing Agent on Windows: Monitored Database Information**

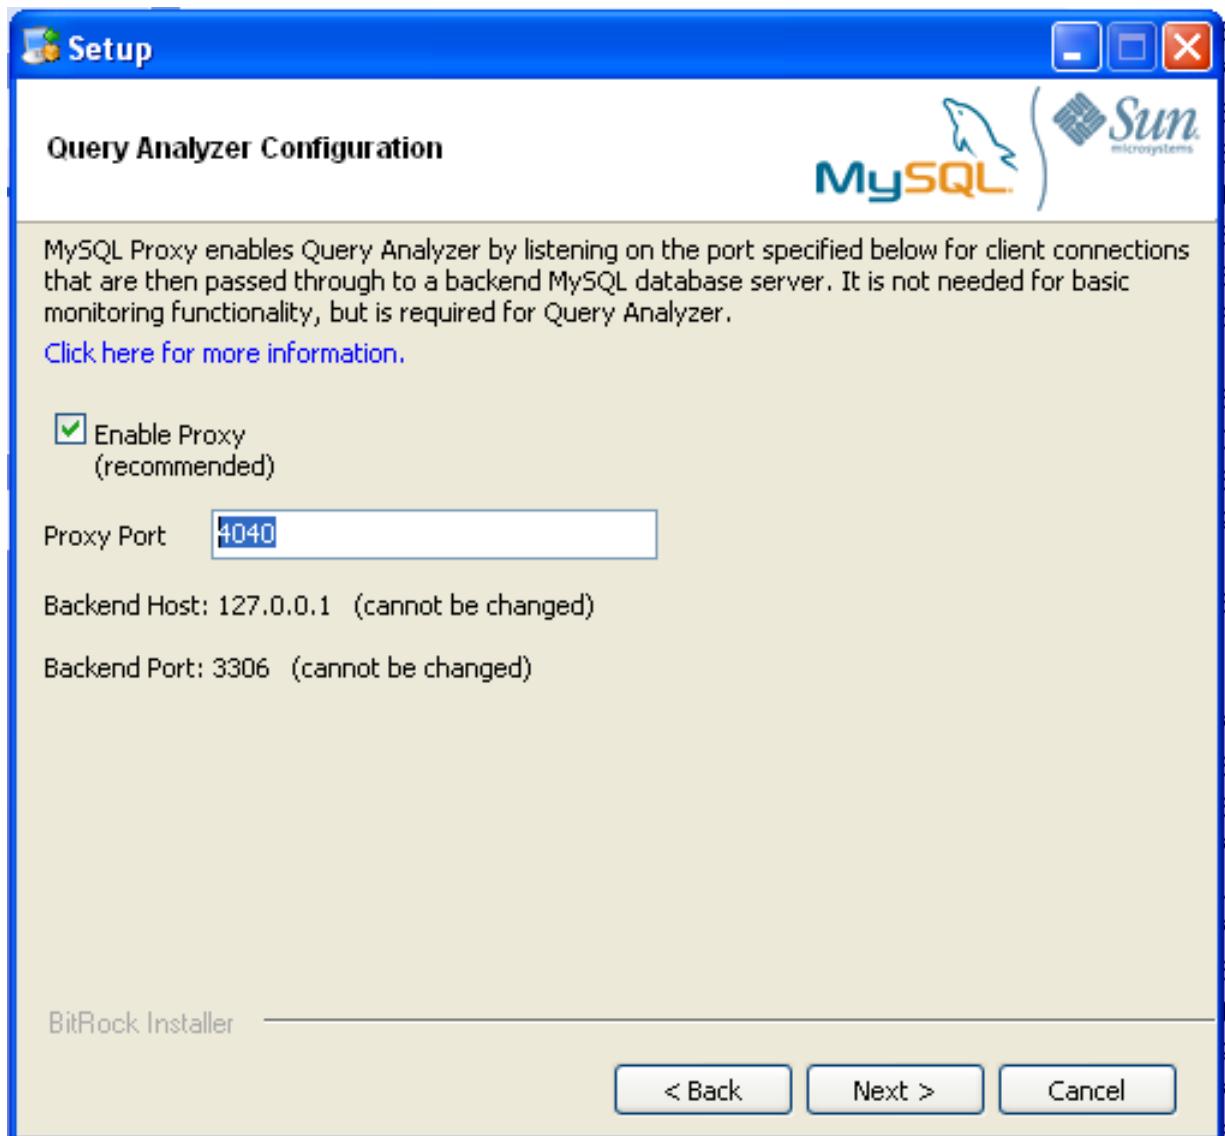

Click **NEXT** to continue the installation.

5. If you want to use Query Analyzer, then you need to enable the MySQL Enterprise Monitor Agent Proxy. The Proxy is enabled by default. If you disable the Proxy during installation, you will need to enable it later before you are able to use Query Analyzer. For more information on Query Analyzer, see [Section 15.10, “The Query Analyzer Page”](#).

When Proxy is enabled, MySQL Enterprise Monitor Agent listens on a network port for client applications, and forwards the connections to the backend MySQL server. You can change the port number that MySQL Enterprise Monitor Agent listens for connections.

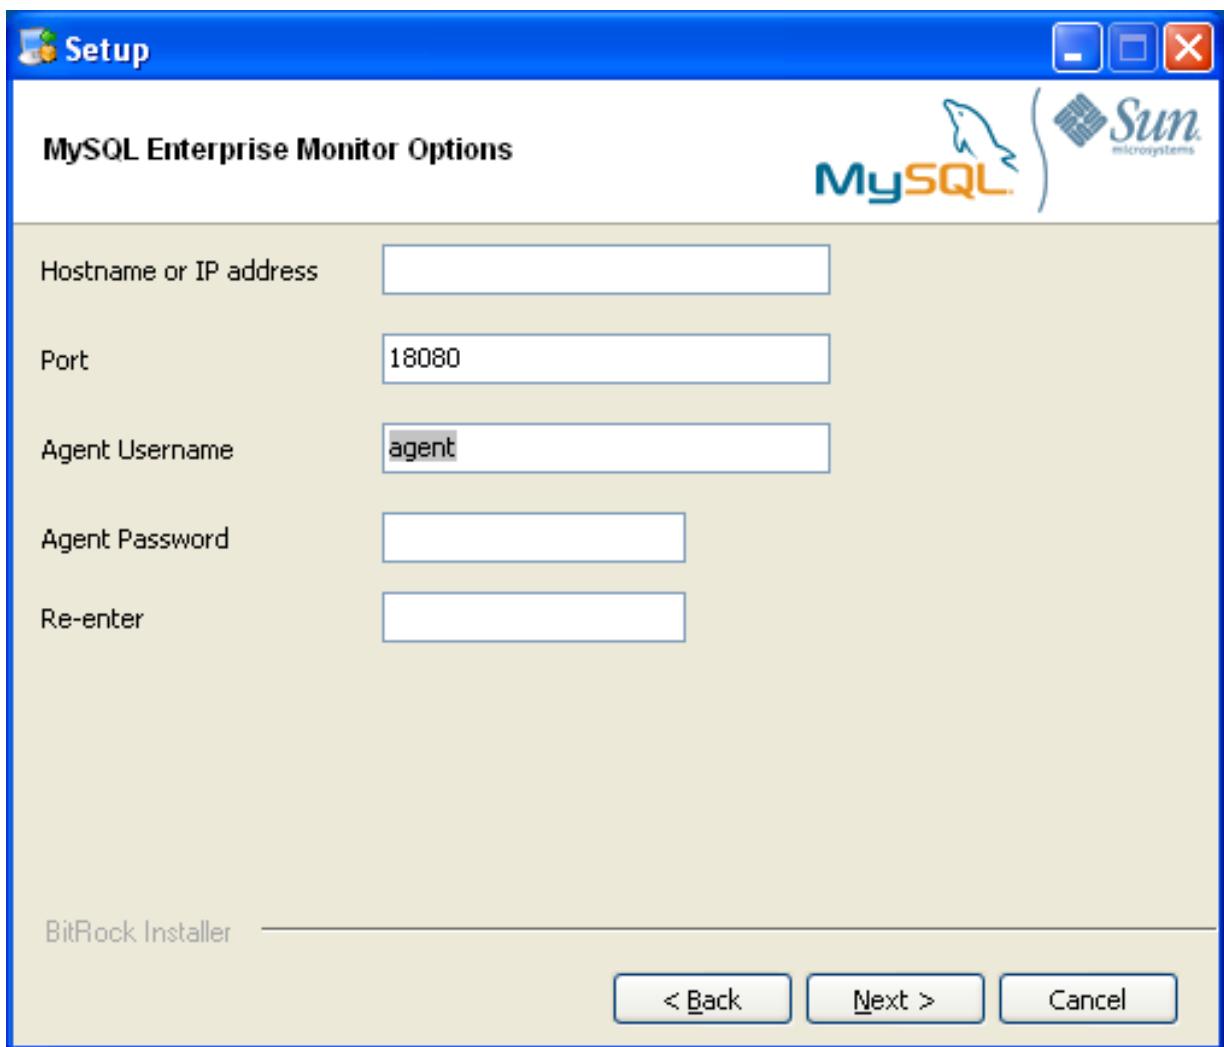

The default port is 6446.

**Figure 15.16. MySQL Enterprise Monitor: Installing Agent on Windows: Query Analyzer Configuration**

6. The MySQL Enterprise Service Manager that you want to use must be configured during installation. The host name, port and agent authentication information must be entered. If you have already installed MySQL Enterprise Service Manager then you can locate the information in the installation report file created during installation. Enter the required information and then click NEXT to continue.

**Figure 15.17. MySQL Enterprise Monitor: Installing Agent on Windows: MySQL Enterprise Service Manager Options**

7. You will be provided with a Configuration Report containing the information that you have entered during the installation. Check the information provided in the report. If you see a problem, use BACK to go back to the configuration screen and change the information. If the information is correct, click NEXT to continue.
8. You are given a final opportunity to change the installation parameters. Click NEXT to start the installation process.
9. Once the agent has been installed, you will get a confirmation message. Click NEXT to finalize the installation.
10. You can start the MySQL Enterprise Monitor Agent automatically now the installation has been completed. To allow the agent to be started, leave the checkbox selected. To start the agent separately, uncheck the checkbox. Click FINISH to exit the installation.

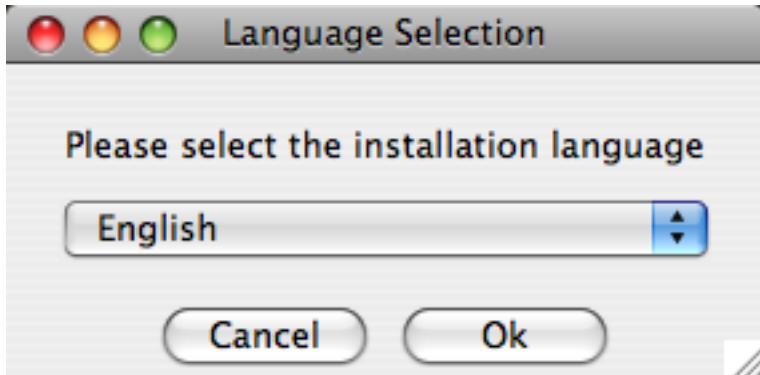

Once the Monitor Agent is installed, it needs to be started. For information on how to start and stop the Agent, see [Section 15.3.3.5.1, “Starting/Stopping the Agent on Windows”](#).

### 15.3.3.3. Installing the Agent on Mac OS X

To install the MySQL Enterprise Monitor Agent on Mac OS X, decompress the `mysqlmonitoragent-version-installer.app.zip` and then run the `mysqlenterpriseagent-version-installer` application.

1. First, select the language for the MySQL Enterprise Monitor Agent installation. Click OK to continue installation.

**Figure 15.18. MySQL Enterprise Monitor: Installing Agent on Mac OS X: Language Selection**

2. Click NEXT to start the installation process.
3. Select the installation directory. The default installation directory is `/Applications/mysql/enterprise/agent`. Select the installation directory, or type the new directory location.

You also need to select the method that the agent will use to communicate with the MySQL server. You can choose either to use a TCP/IP (network) connection, or a Socket (local) connection. Choose the connection method, and click NEXT.

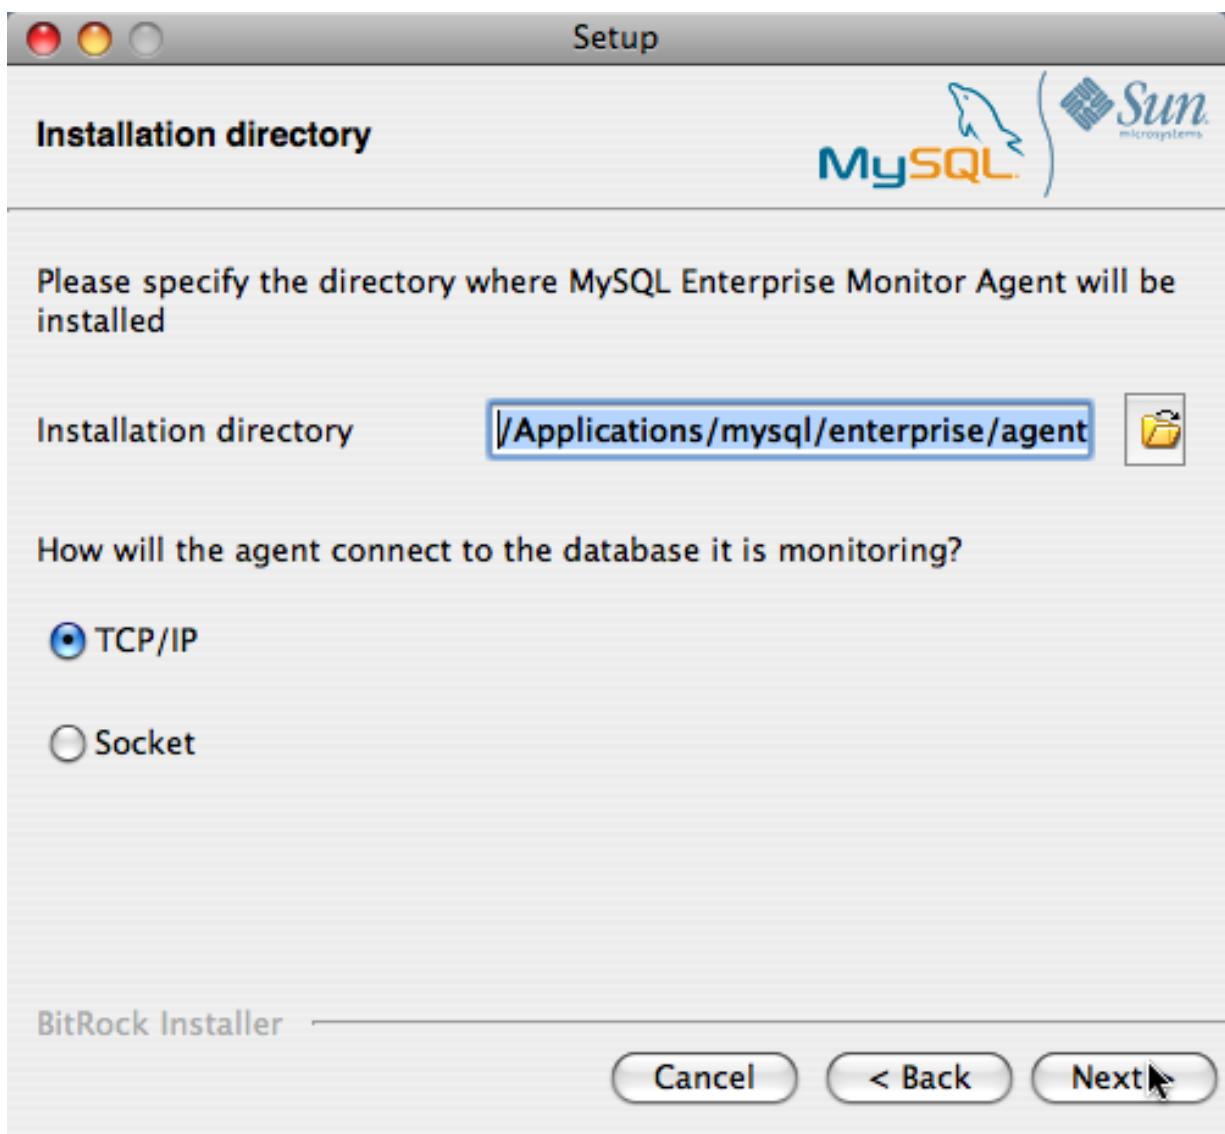

#### Note

The monitor agent always associates “localhost” with the TCP/IP address 127.0.0.1, not the MySQL socket. This is in contrast to the MySQL Command Line Tool, which connects using the MySQL socket by default on Unix, if the host-name “localhost” is specified.

If the MySQL server you wish to monitor has been started with the `--skip-networking` command option then you will not be able to connect to it using TCP/IP, as the server will not listen for TCP/IP connections. In this case the monitor agent will need to be configured to use the MySQL socket. This can be done during installation by selecting “socket” rather than “TCP/IP” and then specifying the MySQL socket name. This can also be configured after installation by editing the `agent-instance.ini` configuration file, for further information on this refer to [Section 15.3.3.6.2, “MySQL Server \(agent-instance.ini\) Configuration”](#).

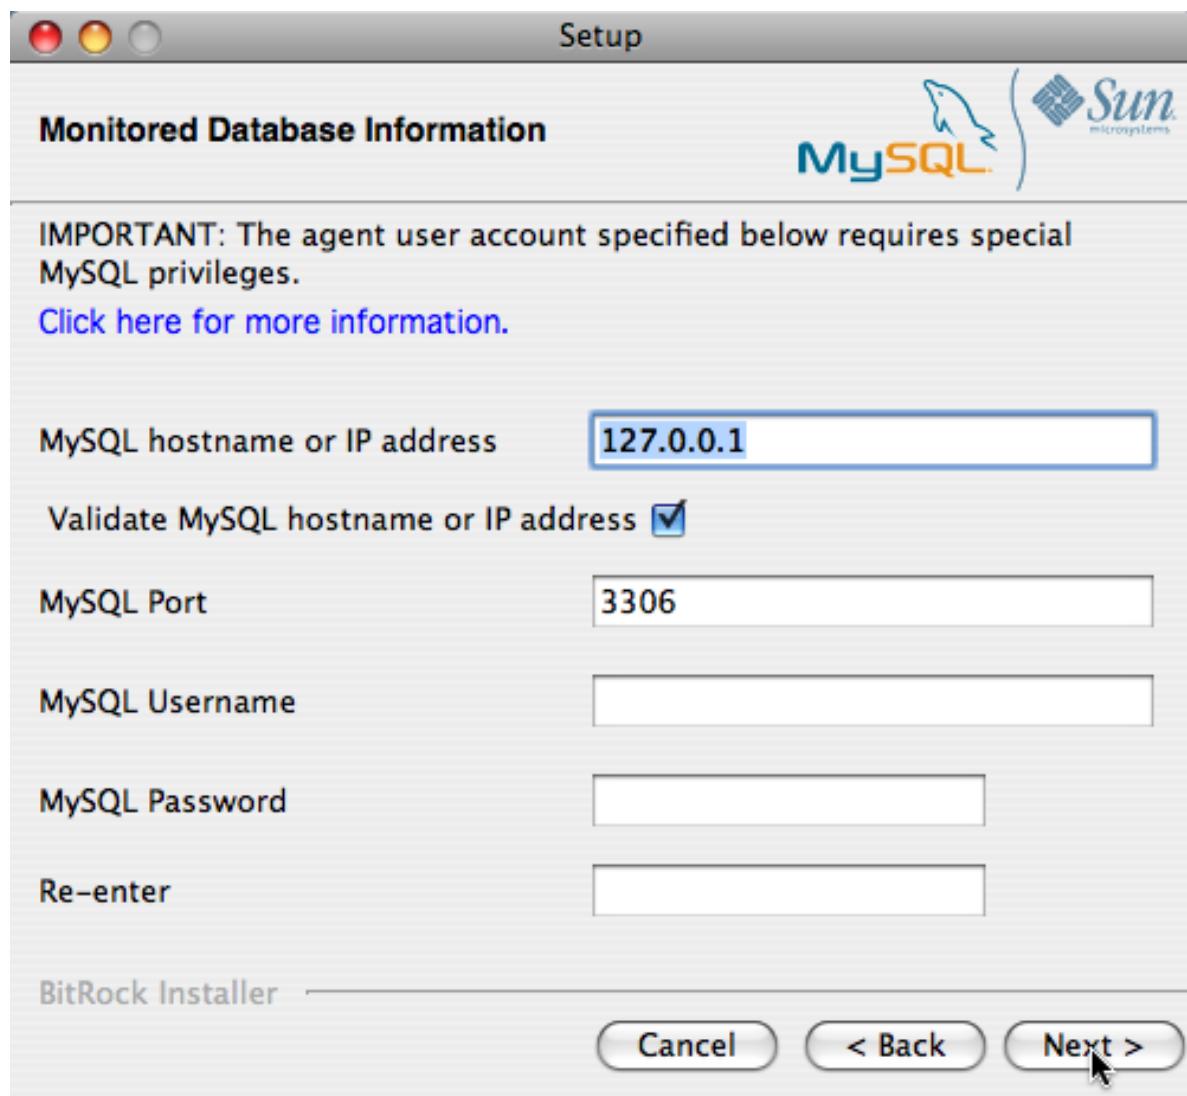

If the MySQL server to be monitored has been started using the command option `--bind-address` then the server will only listen for connections on the IP address specified, that is, the IP address of the MySQL server. If the monitor agent has been started using TCP/IP networking and the default address of 127.0.0.1 it will not be able to connect to the server to be monitored. Also, if “localhost” is specified as the host name during agent configuration, a connection will not be established, as the server will be listening for connections on the address specified with the `--bind-address` option, not 127.0.0.1.

**Figure 15.19. MySQL Enterprise Monitor: Installing Agent on Mac OS X: Installation Directory**

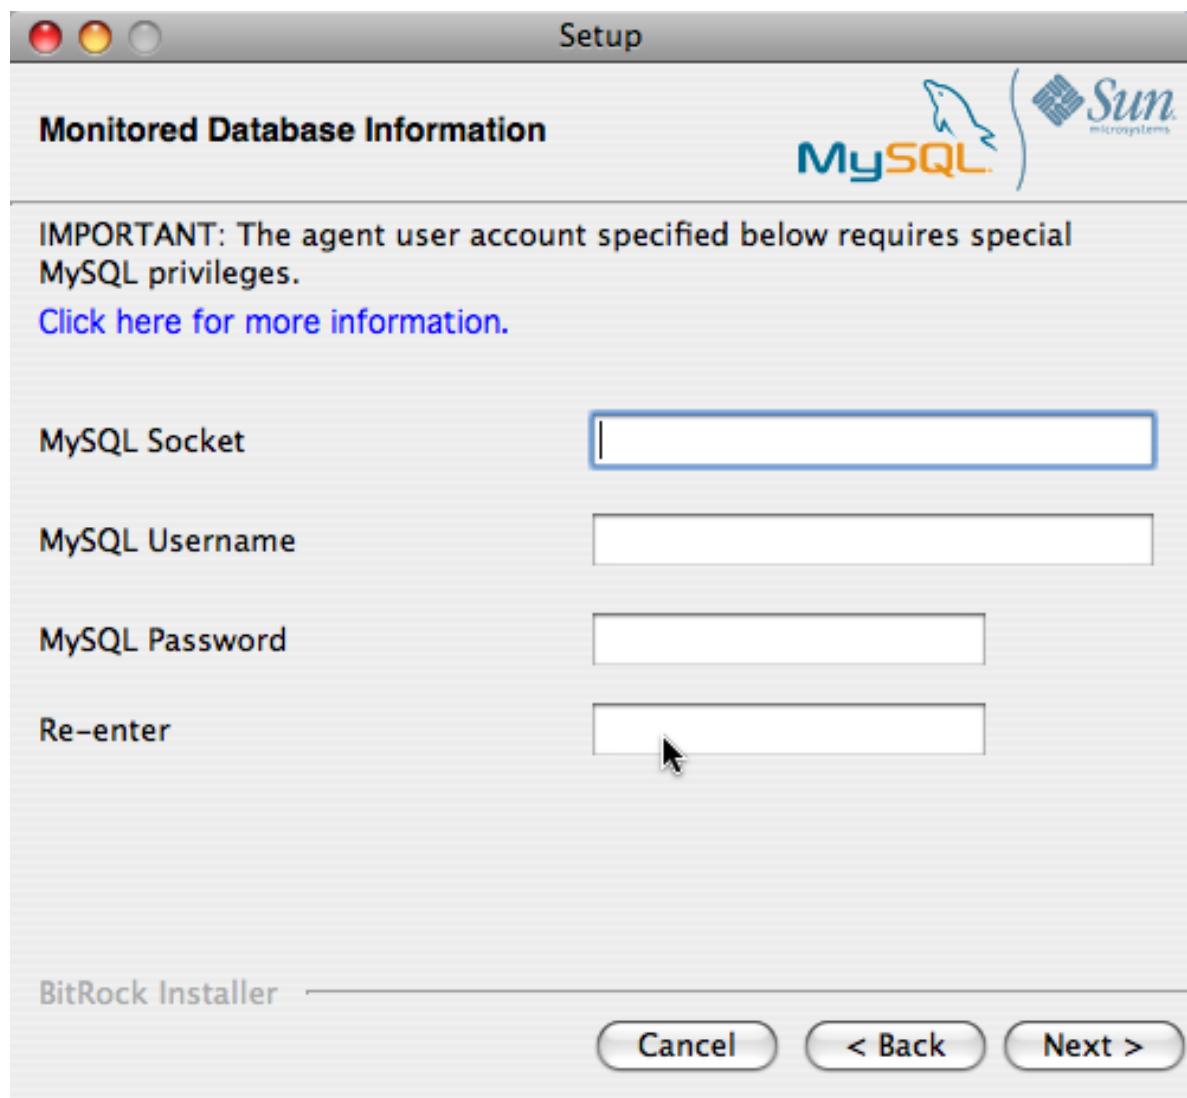

4. You need to specify the information about the MySQL server that you want to monitor. The configuration information you enter will depend on the connection method selected in the previous screen.
  - If you chose TCP/IP as the connection method, you must enter the IP address or host name of the host you want to monitor, and the port, user name and password that you will use to connect to the MySQL server. If you want to confirm that the MySQL server is currently reachable using the information, ensure that the **VALIDATE MYSQL HOST NAME OR IP ADDRESS** checkbox is selected.

**Figure 15.20. MySQL Enterprise Monitor: Installing Agent on Mac OS X: Monitored Database Information**

- If you chose Socket as the connection method, you must enter the full path name to the Unix socket created by your MySQL server, and the user name and password that will be used to authenticate with the server. Typical values include `/tmp/mysql.sock` and `/var/mysql/mysql.sock`.

**Figure 15.21. MySQL Enterprise Monitor: Installing Agent on Mac OS X: Monitored Database Information**

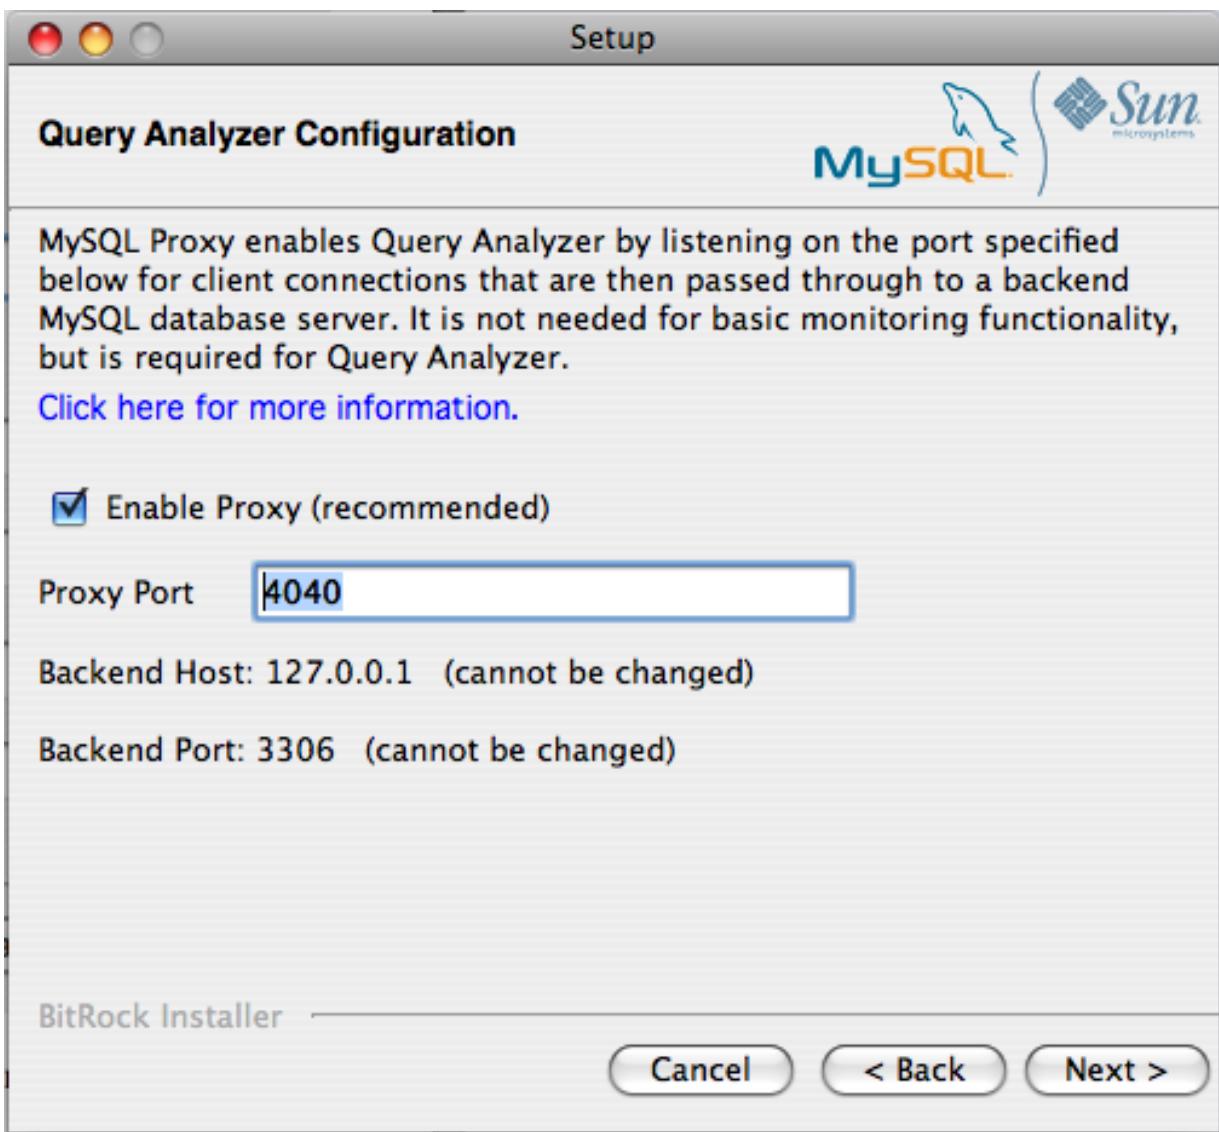

Click NEXT to continue the installation.

5. If you want to use Query Analyzer, then you need to enable the MySQL Enterprise Monitor Agent Proxy. The Proxy is enabled by default. If you disable the Proxy during installation, you will need to enable it later before you are able to use Query Analyzer. For more information on Query Analyzer, see [Section 15.10, “The Query Analyzer Page”](#).

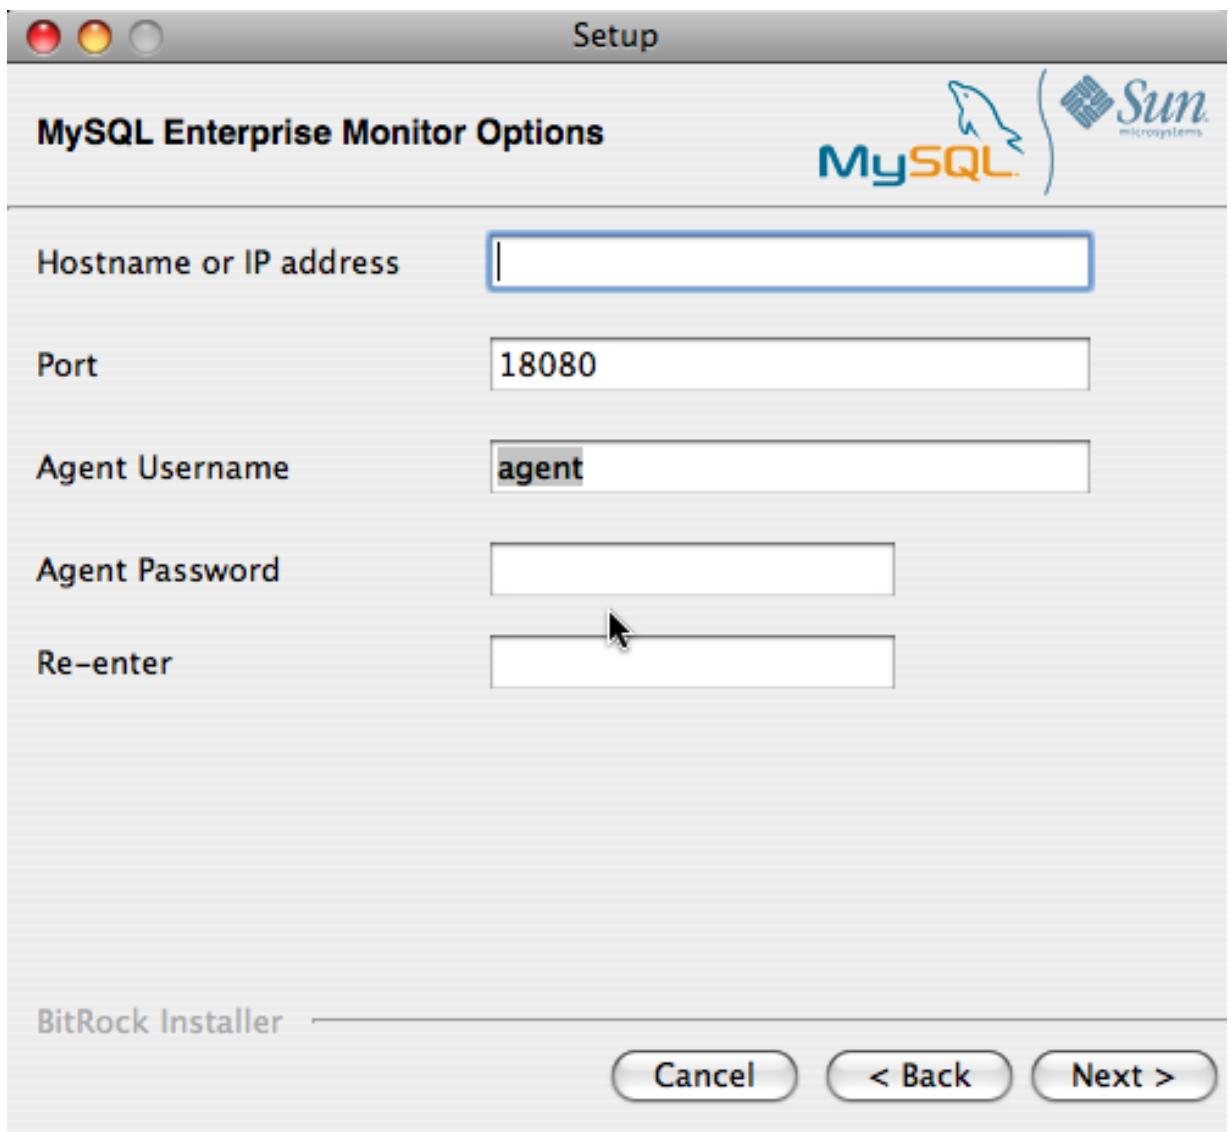

When Proxy is enabled, MySQL Enterprise Monitor Agent listens on a network port for client applications, and forwards the connections to the backend MySQL server. You can change the port number that MySQL Enterprise Monitor Agent listens for connections. The default port is 6446.

**Figure 15.22. MySQL Enterprise Monitor: Installing Agent on Mac OS X: Query Analyzer Configuration**

6. The MySQL Enterprise Service Manager that you want to use must be configured during installation. The host name, port and agent authentication information must be entered. If you have already installed MySQL Enterprise Service Manager then you can locate the information in the installation report file created during installation. Enter the required information and then click NEXT to continue.

**Figure 15.23. MySQL Enterprise Monitor: Installing Agent on Mac OS X: MySQL Enterprise Service Manager Options**

7. You will be provided with a Configuration Report containing the information that you have entered during the installation. Check the information provided in the report. If you see a problem, use BACK to go back to the configuration screen and change the information. If the information is correct, click NEXT to continue.
8. You are given a final opportunity to change the installation parameters. Click NEXT to start the installation process.
9. Once the agent has been installed, you will get a confirmation message. Click NEXT to finalize the installation.
10. You can start the MySQL Enterprise Monitor Agent automatically now the installation has been completed. To allow the agent to be started, leave the checkbox selected. To start the agent separately, uncheck the checkbox. Click FINISH to exit the installation.

Once the Monitor Agent is installed, it needs to be started. For information on how to start and stop the Agent, see [Section 15.3.3.5.2, “Starting/Stopping the Agent on Mac OS X”](#).

#### 15.3.3.4. Installing the Monitor Agent on Unix

As a prerequisite for installing the MySQL Enterprise Monitor Agent on Linux systems you must have the Linux Standards Base (LSB) initialization functions installed.

##### Note

You can check the existence of the LSB components by looking for an LSB package within your Linux package management environment. For example, on RedHat and other RPM-based distributions:

```
shell> rpm -qa | grep -i lsb
redhat-lsb-3.1-19.fc8.x86_64
```

Under Debian/Ubuntu:

```
shell> dpkg -l|grep -i lsb
ii lsb-base 3.2-20ubuntu4
 Linux Standard Base 3.2 init script function
ii lsb-release 3.2-20ubuntu4
 Linux Standard Base version reporting utilit
```

Alternatively, you can use the `lsb_release` command. Existence of this command normally indicates that the current distribution is LSB compliant.

To install the agent navigate to the directory that contains the file, `mysqlmonitoragent-version-installer.bin` (where `version` indicates the three-part version number, the OS, and the architecture). Ensure that this file is executable by typing:

```
shell> chmod +x mysqlmonitoragent-version-installer.bin
```

To install to the default directory (`/opt/mysql/enterprise/agent`) you need to be logged in as `root`. Installing as an unprivileged user installs to the `/home/user_name/mysql/enterprise/agent` directory.

### Note

If you install the agent as an unprivileged user, it will not automatically start up on rebooting.

What follows describes installation from the command line. You may install the Monitor Agent graphically by running the installer from within a windows manager. In both cases the steps are identical. You may also install the Monitor Agent in `unattended` mode. This is especially useful if you are doing multiple installations. For more information on this topic see [Section 15.3.4, “Unattended Installation”](#).

Begin installation from the command line by typing:

```
shell> ./mysqlmonitoragent-version-installer.bin --mode text
```

The various options are shown in what follows. Default values are indicated by square brackets; to select them press ENTER. Otherwise enter a value of your choosing.

- First, you must select the Language you want to use during the installation process:

```
Language Selection
Please select the installation language
[1] English
[2] Japanese
Please choose an option [1] :
```

- Next, specify the directory where you want the agent installed:

```

Welcome to the MySQL Enterprise Monitor Agent Setup Wizard.

Please specify the directory where MySQL Enterprise Monitor Agent will be installed
Installation directory [/opt/mysql/enterprise/agent]:
```

- Specify the MySQL server that you want to monitor. First, you must specify whether you want to use a TCP/IP or socket-based connection to communicate with the MySQL Server:

```
How will the agent connect to the database it is monitoring?

[1] TCP/IP
[2] Socket
Please choose an option [1] :
```

If you select TCP/IP, then you will be asked to enter the TCP/IP address and port number:

```

Monitored Database Information

IMPORTANT: The agent user account specified below requires special MySQL privileges.
```

```

Visit the following URL for more information:
https://enterprise.mysql.com/docs/monitor/2.0/en/mem-install.html#mem-agent-rights

MySQL hostname or IP address [127.0.0.1]:

Validate MySQL hostname or IP address [Y/n]:
```

MySQL Port [3306]:

If you select Socket, then you will be asked to provide the path name to the MySQL socket. Typical values are `/tmp/mysql.sock`, `/var/lib/mysql.sock`, or `/var/run/mysql.sock`.

```

Monitored Database Information

IMPORTANT: The agent user account specified below requires special MySQL privileges.

Visit the following URL for more information:

https://enterprise.mysql.com/docs/monitor/2.0/en/mem-install.html#mem-agent-rights

MySQL Socket []:
```

### Note

The monitor agent always associates “localhost” with the TCP/IP address 127.0.0.1, not the MySQL socket. This is in contrast to the MySQL Command Line Tool, which connects using the MySQL socket by default on Unix, if the host-name “localhost” is specified.

If the MySQL server you wish to monitor has been started with the `--skip-networking` command option then you will not be able to connect to it using TCP/IP, as the server will not listen for TCP/IP connections. In this case the monitor agent will need to be configured to use the MySQL socket. This can be done during installation by selecting “socket” rather than “TCP/IP” and then specifying the MySQL socket name. This can also be configured after installation by editing the `agent-instance.ini` configuration file, for further information on this refer to [Section 15.3.3.6.2, “MySQL Server \(agent-instance.ini\) Configuration”](#).

If the MySQL server to be monitored has been started using the command option `--bind-address` then the server will only listen for connections on the IP address specified, that is, the IP address of the MySQL server. If the monitor agent has been started using TCP/IP networking and the default address of 127.0.0.1 it will not be able to connect to the server to be monitored. Also, if “localhost” is specified as the host name during agent configuration, a connection will not be established, as the server will be listening for connections on the address specified with the `-bind-address` option, not 127.0.0.1.

- Specify the user credentials for the MySQL server that you want to monitor:

```

MySQL Username []: service_agent
MySQL Password :
Re-enter :
```

- Select whether you want to enable Query Analyzer. If you disable the Query Analyzer during installation, you will need to manually edit the configuration file to re-enable the Query Analyzer functionality. If you enable Query Analyzer (Proxy), you must specify the port on which the agent will listen for queries.

```

Query Analyzer Configuration

MySQL Proxy enables query monitoring and analysis by listening on a specified port for client connections that are

Click here for more information.

[Y/n]:

Enable Proxy (recommended) [Y/n]:

Proxy Port [6446]:

Backend Host: 127.0.0.1 (cannot be changed)

Backend Port: 3306 (cannot be changed)
```

For more information on enabling Query Analyzer if you disabled it during installation, see [Section 15.10, “The Query Ana-](#)

lyzer Page”.

6. Enter the details of the MySQL Enterprise Service Manager that you want to use with this agent. The configuration information required is available within the installation report generated when you installed MySQL Enterprise Service Manager

```

MySQL Enterprise Monitor Options

Hostname or IP address []: 192.168.0.197
Tomcat Server Port [18080]:
Tomcat SSL Port [18443]:
```

The agent and MySQL Enterprise Service Manager support using SSL for communication. If you want to enable SSL communication between the agent and the MySQL Enterprise Service Manager, you must reply **Y** to the following question.

```
Use SSL? [y/N]:
Agent Username [agent]:
Agent Password :
Re-enter :
```

7. Before installation starts, you will be provided with a summary of the installation settings that you have specified:

```
Here are the settings you specified:

Installation directory: /opt/mysql/enterprise/agent

Monitored MySQL Database:

Hostname or IP address: 127.0.0.1
Port: 3306
MySQL username: mysql_user
MySQL password: password

Query Analyzer Configuration

Proxy Enabled: yes
Proxy Port: 6446

MySQL Enterprise Manager:

Hostname or IP address: 192.168.0.197
Tomcat Server Port: 18080
Tomcat SSL Port: 18443
Use SSL: 0
Agent username: agent

Press [Enter] to continue :

Setup is now ready to begin installing MySQL Enterprise Monitor Agent on your computer.
Do you want to continue? [Y/n]: y
```

8. The installer will copy the necessary files and create the configuration file required to run the agent:

```

Please wait while Setup installs MySQL Enterprise Monitor Agent on your computer.

Installing
0% _____ 50% _____ 100%
#####

Info to start MySQL Agent

The MySQL agent was successfully installed. To start the MySQL Agent please
invoke:
/opt/mysql/enterprise/agent/etc/init.d/mysql-monitor-agent start
Press [Enter] to continue :

Setup has finished installing MySQL Enterprise Monitor Agent on your computer.
```

9. Finally, you can read the supplied `README` file when prompted. The file is provided within the `share/doc/README_en.txt` file within the agent installation directory if you would like to read this file separately.

For information on starting the agent, see [Section 15.3.3.5.3, “Starting/Stopping the Agent on Unix”](#).

### 15.3.3.5. Starting/Stopping the MySQL Enterprise Monitor Agent

The MySQL Enterprise Monitor Agent can be started and stopped at any time. When not running, information about the current status of your server will not be available, and MySQL Enterprise Service Manager will provide a warning if an agent and the MySQL server that it monitors is unavailable.

#### Warning

If you are using Query Analyzer, then turning off the agent will prevent your applications from communicating with the MySQL server. See [Section 15.10, “The Query Analyzer Page”](#).

#### 15.3.3.5.1. Starting/Stopping the Agent on Windows

You have the option of starting the Monitor Agent from the final installation screen. Otherwise you can do this by going to the `Start Menu` and under `Programs` find `MySQL` and then the `MySQL Enterprise Monitor Agent` entry. Simply select the `Start MySQL Enterprise Monitor Agent` option.

#### Note

On Windows Vista or later, starting the agent requires administrative privileges—you must be logged in as an administrator. To start or stop the agent right-click the menu item and choose the `RUN AS ADMINISTRATOR` menu option. The same restriction applies to starting the agent from the command line. To open an administrator `cmd` window right-click the `cmd` icon and choose the `RUN AS ADMINISTRATOR` menu option.

#### Warning

To report its findings, the agent needs to be able to connect to the dashboard through the port specified during installation. The default value for this port is `18080`; ensure that this port is not blocked. If you need help troubleshooting the agent installation see, [Section 15.3.7, “Troubleshooting the Agent”](#).

Alternately, you can start the agent from the command line by entering:

```
shell> sc start MySQLEnterpriseMonitorAgent
```

or:

```
shell> net start MySQLEnterpriseMonitorAgent
```

You can also start the agent by issuing the command, `agentctl.bat start`. Stop the agent by passing the argument, `stop`. This batch file is found in the `Agent` directory.

For confirmation that the service is running you can open the Microsoft Management Console Services window. To do this go to the Control Panel, find `Administrative Tools` and click the link to `Services`. Locate the service named `MySQL Enterprise Monitor Agent` and look under the `STATUS` column.

You may also start the agent from this window rather than from the `Start` menu or the command line. Simply right-click `MySQL Enterprise Monitor Agent` and choose `Start` from the pop-up menu. Starting the agent from this window opens an error dialog box if the agent cannot connect to the MySQL server it is monitoring. No error is displayed if the agent is unable to connect to the MySQL Enterprise Service Manager.

The pop-up menu for starting the agent also offers the option of stopping the agent. To stop the agent from the command line you only need type:

```
shell> sc stop MySQLEnterpriseMonitorAgent
```

or:

```
shell> net stop MySQLEnterpriseMonitorAgent
```

#### Note

`MySQLEnterpriseMonitorAgent` is the default name of the Monitor Agent service. If you have added an additional agent as described in [Section 15.3.3.6.2, “MySQL Server \(agent-instance.ini\) Configuration”](#), replace `MySQLEnterpriseMonitorAgent` with the appropriate agent name.

### 15.3.3.5.2. Starting/Stopping the Agent on Mac OS X

The script to start the agent on Mac OS X is located in the `/Applications/mysql/enterprise/agent/etc/init.d` directory. To start the agent navigate to this directory and at the command line type:

```
shell> ./mysql-monitor-agent start
```

To stop the agent, use the `stop` command:

```
shell> ./mysql-monitor-agent stop
```

If the agent cannot be stopped because the `pid` file that contains the agent's process ID cannot be found, you can use `kill` to send a `TERM` signal to the running process:

```
shell> kill -TERM PID
```

If you are running more than one agent on a specific machine, you must also specify the path to the `ini` file when you are stopping the agent. Executing `mysql-monitor-agent stop` without an `ini` file will only stop the agent associated with the default `ini` file.

To verify that the agent is running use the following command:

```
shell> ./mysql-monitor-agent status
```

The resulting message indicates whether the agent is running or not. If the agent is not running, use the following command to view the last ten entries in the agent log file:

```
shell> tail /Applications/mysql/enterprise/agent/log/mysql-monitor-agent.log
```

For further information on troubleshooting the agent see [Section 15.3.3.7, “Troubleshooting the Agent”](#).

Installation creates the directory `/Applications/mysql/enterprise/agent` with the settings stored in the `mysql-monitor-agent.ini` file located directly below this directory in the `etc` directory. The `log` directory is also located immediately below the `agent` directory.

To see all the command-line options available when running the monitor agent, navigate to the `/Applications/mysql/enterprise/agent/etc/init.d` directory and execute `mysql-monitor-agent help`. You should see the message:

```
Usage: ./mysql-monitor-agent {start|stop|restart|status} [ini-file-name]
```

The `ini-file-name` option only needs to be used if the `ini` file is not installed to the default location or you have changed the name of the `ini` file. You will need to use this option if you are installing more than one agent on the same machine. Pass the full path to the `ini` file. For example, after navigating to the `/Applications/mysql/enterprise/agent/etc/init.d` directory, issue the command:

```
shell> ./mysql-monitor-agent start /Applications/mysql/enterprise/agent/etc/new-mysql-monitor-agent.ini
```

If you installed the agent as `root`, on reboot the `mysql-monitor-agent` daemon will start up automatically. If you installed the agent as an unprivileged user, you must manually start the agent on reboot or write a script to perform this task. Likewise, if you have added an additional agent as described in [Section 15.3.3.6.2, “MySQL Server \(agent-instance.ini\) Configuration”](#), and you wish to start this agent on reboot, create a system initialization script appropriate to your operating system. To determine whether the agent is running or not navigate to the `init.d` directory and issue the command

`./mysql-monitor-agent status`.

#### Warning

To report its findings, the agent needs to be able to connect to the dashboard through the port specified during installation. The default value for this port is `18080`; ensure that this port is not blocked. If you need help troubleshooting the agent installation see, [Section 15.3.3.7, “Troubleshooting the Agent”](#).

### 15.3.3.5.3. Starting/Stopping the Agent on Unix

When installation is finished, you can start the monitor agent from the command line by typing:

```
shell> /opt/mysql/enterprise/agent/etc/init.d/mysql-monitor-agent start
```

For a non-`root` installation the command would be:

```
shell> /home/<user name>/mysql/enterprise/agent/etc/init.d/mysql-monitor-agent start
```

To stop the agent, use the `stop` command:

```
shell> ./mysql-monitor-agent stop
```

If the agent cannot be stopped because the `pid` file that contains the agent's process ID cannot be found, you can use `kill` to send a `TERM` signal to the running process:

```
shell> kill -TERM PID
```

If you are running more than one agent on a specific machine, you must also specify the path to the `ini` file when you are stopping the agent. Executing `mysql-monitor-agent stop` without an `ini` file will only stop the agent associated with the default `ini` file. Likewise, when checking the status of an agent specify its `ini` file.

To verify that the agent is running use the following command:

```
shell> ./mysql-monitor-agent status
```

The resulting message indicates whether the agent is running or not. If the agent is not running, use the following command to view the last ten entries in the agent log file:

```
shell> tail /opt/mysql/enterprise/agent/log/mysql-monitor-agent.log
```

For further information on troubleshooting the agent see [Section 15.3.3.7, “Troubleshooting the Agent”](#).

Installation creates the directory `/opt/mysql/enterprise/agent` with the settings stored in the `mysql-monitor-agent.ini` file located directly below this directory in the `etc` directory. The `log` directory is also located immediately below the `agent` directory.

To see all the command-line options available when running the monitor agent, navigate to the `/opt/mysql/enterprise/agent/etc/init.d` directory and execute `mysql-monitor-agent help`. You should see the message:

```
Usage: ./mysql-monitor-agent {start|stop|restart|status} [ini-file-name]
```

The `ini-file-name` option only needs to be used if the `ini` file is not installed to the default location or you have changed the name of the `ini` file. You will need to use this option if you are installing more than one agent on the same machine. Pass the full path to the `ini` file. For example, after navigating to the `/opt/mysql/enterprise/agent/etc/init.d` directory, issue the command:

```
shell> ./mysql-monitor-agent start /opt/mysql/enterprise/agent/etc/new-mysql-monitor-agent.ini
```

If you installed the agent as `root`, on reboot the `mysql-monitor-agent` daemon will start up automatically. If you installed the agent as an unprivileged user, you must manually start the agent on reboot or write a script to perform this task. Likewise, if you have added an additional agent as described in [Section 15.3.3.6.2, “MySQL Server \(agent-instance.ini\) Configuration”](#), and you wish to start this agent on reboot, create a system initialization script appropriate to your operating system. To determine whether the agent is running or not navigate to the `init.d` directory and issue the command

```
./mysql-monitor-agent status.
```

### Warning

To report its findings, the agent needs to be able to connect to the dashboard through the port specified during installation. The default value for this port is `18080`; ensure that this port is not blocked. If you need help troubleshooting the agent installation see, [Section 15.3.3.7, “Troubleshooting the Agent”](#).

## 15.3.3.6. Advanced Agent Configuration

The MySQL Enterprise Monitor Agent is configured through files located within the `etc` directory within the directory where you installed the agent.

Configuration is stored in multiple files, according to a predetermined file and directory layout. The primary configuration file contains specific information about the agent and how the agent communicates with MySQL Enterprise Service Manager. The main configuration is located within the `mysql-monitor-agent.ini` file.

Additional configuration files contain information about the MySQL server that is being monitored. You can configure which directory is used for storing this information within the `mysql-monitor-agent.ini` file. The default location is the `etc/instances` directory within the MySQL Enterprise Monitor Agent directory.

The server you want to monitor should have a directory within the specified location, optionally using the name of the server you are monitoring, and within that directory, an `agent-instance.ini` file. This file contains the configuration information for connecting to the MySQL server, including the host name, port, user credentials and display name.

You can see an example of the file layout of the `etc` directory:

```
./init.d
./init.d/mysql-monitor-agent
./instances
./instances/agent
./instances/agent/agent-instance.ini
./mysql-monitor-agent.ini
```

For more information on the configuration of the `mysql-monitor-agent.ini` file, see [Section 15.3.3.6.1, “MySQL Enterprise Monitor Agent \(`mysql-monitor-agent.ini`\) Configuration”](#). For details on the content of the individual MySQL instance configuration files, see [Section 15.3.3.6.2, “MySQL Server \(`agent-instance.ini`\) Configuration”](#).

### 15.3.3.6.1. MySQL Enterprise Monitor Agent (`mysql-monitor-agent.ini`) Configuration

The `mysql-monitor-agent.ini` files contains the base configuration information for the MySQL Enterprise Monitor Agent. The file sets the core information about the supported functionality for the entire agent.

You can see a sample of the configuration file below:

```
WARNING - the UUID defined below must be unique for each agent.
#
To use this .ini file as a template for configuring additional
agents, do not simply copy and start a new agent without first
modifying the UUID.
#
Refer to the documentation for more detailed information and
instructions.
#
Version: 20080718_230416_r7011

[mysql-proxy]

plugins=proxy,agent
agent-mgmt-hostname = http://agent:password@monitor-server:18080/heartbeat
mysqld-instance-dirs etc/instances
agent-item-files = share/mysql-proxy/items/quan.lua,share/mysql-proxy/items/items-mysql-monitor.xml
proxy-address=:6446
proxy-backend-addresses = 127.0.0.1:3306
proxy-lua-script = share/mysql-proxy/quan.lua

agent-uuid = 8770ead5-3632-4b29-a413-4a7c92437e26
log-file = mysql-monitor-agent.log
pid-file=/Applications/mysql/enterprise/agent/mysql-monitor-agent.pid
```

#### Note

Do not copy the agent configuration information from one machine to another without changing the `agent-uuid`. Each agent instance must have a unique agent id.

The main configuration information must be located within the `[mysql-proxy]` section of the configuration file. The main configurable parameters within this file are:

- `plugins`: Configures the plugins to be used by the agent. When monitoring servers you must have the `agent` plugin configured. If you want to support Query Analyzer then you must also have the `proxy` module enabled. Plugins should be specified as a comma separated list of plugin names.

If you selected to support Query Analyzer during installation of the agent, the default value will be `proxy,agent`. If you disabled Query Analysis during installation, the default value will be `agent`.

- `log-level`: Sets the logging level of the agent. The default level is `critical`.

Valid values for `log-level` are as follows:

- **debug**: Provides detailed information about what the agent is doing and the information being provided by the agent to the MySQL Enterprise Service Manager.
- **critical**: Lists critical messages highlighting problems with the agent.
- **error**: Lists error messages.
- **warning**: Provides only warning messages generated by the agent.
- **message**: Provides information about the agent and basic processing information.
- **info**: Provides messages used for informational purposes.

### Warning

Be careful when setting the `log-level` to `debug`. Doing this will rapidly increase the size of your `mysql-monitor-agent.log` file. To avoid disk space problems, put the log files on a different drive from your MySQL server and the MySQL Enterprise Dashboard.

It is strongly recommended that you use a `log-level` of `critical` or `error` in a production server. Use the higher-levels to provide more detailed information only for debugging problems with your agent.

Under Windows, if you restart the agent from the command line after setting the `log-level` to `debug`, extensive debug information is displayed to the console as well as to the log file.

- **agent-mgmt-hostname**: Sets the URL to use when reporting information. This value will be automatically set to your MySQL Enterprise Service Manager during installation.
- **mysqld-instance-dir**: Sets the directory where the configuration files that specify the MySQL servers to be monitored can be located.
- **agent-item-files**: Sets the information that is provided up to the MySQL Enterprise Service Manager when the agent is reporting status information. You should leave this item with the default setting of the `share/mysql-proxy/items/quan.lua` (which provides Query Analyzer data) and `share/mysql-proxy/items/items-mysql-monitor.xml` (which provides the core agent monitoring data).
- **proxy-address**: Sets the address, port number, or both for the proxy to listen to for connections. The setting is used when employing Query Analysis as the address/port that you must configure your application to use in place of your normal MySQL server. By default this item is set during installation.

The default value is 6446. If you want to support a different local host name/IP address and port, specify the host name and the port number, separated by a colon.

- **proxy-backend-addresses**: Sets the host name and port number to be used when communicating the backend MySQL server when employing query analyzer. This is the MySQL server where packets from the client are sent when communicating with the proxy on the host name/port set by the `proxy-address`.
- **proxy-lua-script**: Sets the Lua script to be used by the proxy when forwarding queries. To use Query Analyzer, this parameter should be set to `share/mysql-proxy/quan.lua`. This is the default value.
- **agent-uuid**: Sets the UUID (Universally Unique ID) of the agent. This value should be unique for all agents communicating with the same server, as the UUID is used to uniquely ID the agent within MySQL Enterprise Service Manager

If you are setting up multiple hosts and copying the configuration between hosts, make sure that the `agent-uuid` is unique. You can have the agent create a new UUID by leaving this configuration property blank.

- **log-file**: Sets the location of the log file used to record information about the agent when it is running. If you do not specify a full path name, then the log file location is considered to be relative to the installation directory of the agent.
- **pid-file**: Sets the location of the file used to record the Process ID of the agent. This is used by the script that shuts down the agent to identify the process to be shutdown. The default value is the `mysql-monitor-agent.pid` file within the base installation directory as created by the agent installer.

### 15.3.3.6.2. MySQL Server (`agent-instance.ini`) Configuration

For the MySQL server that you want to monitor, you must create an `agent-instance.ini` within the directory specified by the `mysqld-instance-dir` configuration parameter within the main `mysql-monitor-agent.ini` file.

The `agent-instance.ini` file contains the host name and user credentials for connecting to the MySQL server that you want

the agent to monitor. The format of the file is as follows:

```
To use this .ini file as a template for configuring additional
instances to monitor, do not simply copy and start a new agent
without first modifying the displayname.
#
Refer to the documentation for more detailed information and
instructions.
#
Version: 20080718_230416_r7011

[mysqld]
hostname = 127.0.0.1
port = 3306
user = root
password =
```

The individual configuration parameters can be defined as follows:

- **hostname**: The host name of the MySQL server that you want to monitor.
- **port**: The TCP/IP port of the MySQL server that you want to monitor.
- **user**: The user to use when connecting to the MySQL server that you want to monitor.
- **password**: The corresponding password to use when connecting to the MySQL server that you want to monitor.

It is also possible to configure the agent to use sockets. This can be done during installation by selecting “socket” rather than “TCP/IP” from the menu and then specifying the socket name. This can also be configured after installation by editing the **agent-instance.ini** configuration file, and adding the line:

```
socket = /full/path/to/mysql.sock
```

### 15.3.3.6.3. Monitoring Multiple MySQL Servers

You can monitor multiple MySQL servers (either on the same machine, or across different machines) using two different methods:

- By using a single agent instance to monitor multiple MySQL servers. You can use this method if you want to monitor multiple servers, but do not want or need to support Query Analysis on the additional servers.
- By using multiple copies of the MySQL Enterprise Monitor Agent to monitor each server individually. Using this method requires additional overhead to monitor each server, while also allowing you to supply Query Analyzer data.

#### Using a Single Agent Instance

##### **Warning**

Do not use the single agent instance method if you want to use Query Analyzer. If you set your application to use the proxy port provided by the single instance then the queries may not be directed to the correct server. Using Query Analyzer, the proxy, and the single agent instance method is not supported.

##### **Warning**

When using the single agent instance method, the agent will attempt to determine the right information about the backend server that it is monitoring to use the information when applying rule and advisor information. Currently, this operation is performed for only one of the servers in the list of configured servers. If the servers being monitoring are using different MySQL versions then the rules applied to the servers may be incorrect, and you could get wrong or misleading advice about issues or problems on a given server.

To use a single agent to monitor multiple instances, you can create additional directories and configuration files within the **instances** directory for the agent. For example, you can see the default structure of the agent configuration directory:

```
./init.d
./init.d/mysql-monitor-agent
./instances
./instances/agent
./instances/agent/agent-instance.ini
./mysql-monitor-agent.ini
```

Within the **instances** directory, you can add further directories, one for each monitored server. Each additional directory must have a suitable **agent-instance.ini** file containing the connection information for the new MySQL server instance. For ex-

ample, the following structure demonstrates an agent monitoring four MySQL servers:

```
./init.d
./init.d/mysql-monitor-agent
./instances
./instances/agent
./instances/agent/agent-instance.ini
./instances/mysql12
./instances/mysql12/agent-instance.ini
./instances/mysql12-rep
./instances/mysql12-rep/agent-instance.ini
./instances/mysql1-backup
./instances/mysql1-backup/agent-instance.ini
./mysql-monitor-agent.ini
```

To add another MySQL monitored server, follow these steps:

1. Make sure that the MySQL instance that you want to monitor has a suitable user to use for connecting to the server. For more information, see [Section 15.3.3.1, “Creating a MySQL User Account for the Monitor Agent”](#).
2. Copy an existing configuration directory and configuration files to the new directory:
 

```
shell> cp -R etc/instances/agent etc/instances/mysql12
```
3. Edit the configuration file within the new directory, for example `mysql12/agent-instance.ini`, and set the `user`, `password` and either the `hostname` and `port`, or `socket` parameters.
4. Restart the agent:
 

```
shell> mysql-monitor-agent restart
```

### Using Multiple Agent Instances

To use multiple agents to monitor multiple MySQL servers you need to create a new configuration structure for both the agent and the MySQL server instances you need to monitor, including the binaries and configuration files, and then update the configuration to set the corresponding parameters to monitor the new server. Using this method allows you to enable query analysis by redirecting requests to the target server using the built-in proxy service within the agent.

For example, the directory structure below shows the configuration directory for two agents monitoring a single MySQL server each:

```
./init.d
./init.d/mysql-monitor-agent
./instances
./instances/agent
./instances/agent/agent-instance.ini
./instances-second/agent
./instances-second/agent/agent-instance.ini
./mysql-monitor-agent.ini
./mysql-second-agent.ini
```

The `mysql-monitor-agent.ini` file contains the configuration for the first agent, with the MySQL servers monitored defined within the `instances` directory. The `mysql-second-agent.ini` file contains the configuration information for the second agent, with the MySQL servers monitor defined within the `instances-second` directory.

To set up multiple agents:

1. Make sure that the MySQL instance that you want to monitor has a suitable user to use for connecting to the server. For more information, see [Section 15.3.3.1, “Creating a MySQL User Account for the Monitor Agent”](#).
2. You need to generate a new UUID for the new agent:

```
shell> /opt/mysql/enterprise/agent/bin/mysql-monitor-agent --agent-generate-uuid
ee9296d7-f7cd-4fee-8b26-ead884ebf398
2009-03-05 11:49:37: (critical) shutting down normally
```

Keep a record of the UUID to update the configuration file.

Note, the agent should not be running when the UUID is generated.

3. Copy the main agent configuration file, which is by default in `/opt/mysql/enterprise/agent/etc/mysql-monitor-agent.ini`:

```
shell> cp mysql-monitor-agent.ini mysql-second-agent.ini
```

4. Edit the new configuration file, changing the following settings:
  - Change the `mysqld-instance-dir` to the new directory that will contain the individual MySQL server configuration files.
  - Change the `proxy-address` to a different value than the first agent configuration.
  - Change the `proxy-backend-addresses` to specify the IP address and MySQL port number for the MySQL server.
  - Change the `agent-uuid` to the new value obtained in an earlier step.
  - Change the `log-file` parameter to specify a different file to use when logging errors and problems. You cannot log to the same file from two different agents.
  - Change the `pid-file` parameter to specify the file that will be used to store the process ID of the agent.
5. Copy an existing configuration directory and configuration files to the new directory:

```
shell> cp -R etc/instances etc/instances-second
```

6. Edit the configuration file, `instances/second/agent/agent-instance.ini` within the new directory, and set the `user`, `password` and either the `hostname` and `port`, or `socket` parameters.
7. With multiple instances, you must start each agent individually, specifying the location of the main configuration file. For example, to start the original (default) service:

```
shell> /opt/mysql/enterprise/agent/etc/init.d/mysql-monitor-agent start /opt/mysql/monitor/agent/etc/mysql-monitor-
```

To start the second instance:

```
shell> /opt/mysql/enterprise/agent/etc/init.d/mysql-monitor-agent start /opt/mysql/monitor/agent/etc/mysql-second-
```

#### 15.3.3.6.4. Configuring an Agent to Monitor a Remote MySQL Server

Typically, the agent runs on the same machine as the MySQL server it is monitoring. Fortunately, this is not a requirement. If you want to monitor a MySQL server running on an operating system for which there is no agent available, you can install the agent on a machine other than the one hosting the MySQL server.

The process for installing an agent to monitor a MySQL server on a remote machine is identical to the process described in [Section 15.3.3, “Monitor Agent Installation”](#). Follow the directions given there, being careful to specify the correct IP address or host name for the MySQL Enterprise Service Manager and likewise for the MySQL server—since the agent is not running on the same machine as the MySQL server, it cannot be the default, `localhost`.

Don't forget that the agent must be given rights to log in to the MySQL server from a host other than `localhost` and that the port used by the MySQL server, typically `3306` must be open for remote access. For more information about the database credentials required by agents see, [Section 15.3.3.1, “Creating a MySQL User Account for the Monitor Agent”](#).

The agent also needs to be able to log in to the MySQL Enterprise Service Manager, typically using port `18080`, so ensure that the appropriate port is open.

##### Note

Remote agents do not report the OS information for either the host or the agent.

If your subscription level entitles you to replication autodiscovery, do **not** use remote monitoring with replication slaves or masters. The agent must be installed on the same machine as the server you are monitoring for discovery to work properly. For more information, see [Section 15.11, “The Replication Page”](#).

#### 15.3.3.6.5. Monitoring Outside the Firewall with an SSH Tunnel

If you run an SSH server on the machine that hosts the MySQL Enterprise Service Manager and an SSH client on the machine that hosts the agent, you can create an SSH tunnel so that the agent can bypass your firewall. First, you need to make an adjustment to the `hostname` value specified in the `[mysql-proxy]` section of the `.ini` file. (For more information about the contents and location of the `.ini` file see [Section 15.3.3.6.1, “MySQL Enterprise Monitor Agent \(`mysql-monitor-agent.ini`\) Configuration”](#).) Stop the agent and change the `hostname` value as shown in the following:

```
hostname = http://agent_name:password@localhost:18080/heartbeat
```

Replace the `agent_name` and `password` with suitable values. Likewise replace port `18080` if you are not running the dashboard on this port. Use `localhost` for the host name, since the agent is connecting through an SSH tunnel.

Next, execute the following command on the machine where the agent is running:

```
shell> ssh -L 18080:Dashboard_Host:18080 -l user_name -N Dashboard_Host
```

When prompted, enter the password for `user_name`.

If you are not running the MySQL Enterprise Service Manager on port `18080`, substitute the appropriate port number. Likewise, replace `Dashboard_Host` with the correct value. `user_name` represents a valid operating system user on the machine that hosts the MySQL Enterprise Service Manager.

Be sure to restart the agent so that the new value for the `hostname` takes effect. For instructions on restarting the agent see:

- Under Windows see, [Section 15.3.3.5.1, “Starting/Stopping the Agent on Windows”](#).
- Under Unix see, [Section 15.3.3.5.3, “Starting/Stopping the Agent on Unix”](#).
- Under Mac OS X see, [Section 15.3.3.5.2, “Starting/Stopping the Agent on Mac OS X”](#).

### 15.3.3.6. Generating a new UUID

For MySQL Enterprise Monitor to operate correctly, each agent must have a unique UUID to uniquely identify the agent with the MySQL Enterprise Service Manager.

#### Warning

Ensure that you do not reuse or duplicate a UUID. Running two agents with the same identification number yields unpredictable results

In Unix go to the command line and type:

```
shell> /opt/mysql/enterprise/agent/bin/mysql-monitor-agent --agent-generate-uuid
```

In Mac OS X go to the command line and type:

```
shell> /Applications/mysql/enterprise/agent/bin/mysql-monitor-agent --agent-generate-uuid
```

This should display a line similar to the following:

```
ee9296d7-f7cd-4fee-8b26-ead884ebf398
```

Paste this line into the `[mysql-proxy]` section of the `mysql-monitor-agent.ini` file for the `agent-uuid` parameter:

```
[mysql-proxy]
...
agent-uuid=ee9296d7-f7cd-4fee-8b26-ead884ebf398
```

In Windows, go to the command line and change to the MySQL Enterprise Monitor Agent installation directory and update the UUID by executing `mysql-monitor-agent -uf mysql-monitor-agent-3307.ini`. For example:

```
C:\> cd C:\Program Files\MySQL\Enterprise\Agent
C:\> mysql-monitor-agent -uf mysql-monitor-agent.ini (or your .ini file name)
```

This updates the configuration file directly with the new UUID.

### 15.3.3.7. Troubleshooting the Agent

The first step in troubleshooting the agent is finding out whether it is running or not. To do this see:

- Windows: [Section 15.3.3.5.1, “Starting/Stopping the Agent on Windows”](#)
- Unix: [Section 15.3.3.5.3, “Starting/Stopping the Agent on Unix”](#)

- Mac OS X: [Section 15.3.3.5.2, “Starting/Stopping the Agent on Mac OS X”](#)

If incorrect credentials are specified for the agent login to the MySQL server that it is monitoring, then the agent will not run on start-up. Log in to the monitored MySQL server and check the agent's credentials. Compare the values of the `Host`, `User`, and `Password` fields in the `mysql.user` table with the values shown in the `[mysqld]` section of the `etc/instances/mysql/agent-instance.ini`. If incorrect credentials are specified in the `ini` file, simply correct them and restart the agent. Remember, changes to the `ini` file do not take effect until the agent is restarted.

The agent will not start up if incorrect credentials are specified for the service manager login. Using incorrect credentials for logging in to the service manager creates an entry in the agent log file. For the location of this log file see [Agent Log and PID Files](#).

If the agent starts up but no server appears in the dashboard, check the `hostname` specified in the `[mysql-proxy]` portion of the `mysql-monitor-agent.ini` file. Incorrect credentials, IP address, or port will all cause the MySQL server to fail to appear in the dashboard. Also, ensure that the port specified in this file is not blocked on the machine hosting the MySQL Enterprise Service Manager.

An easy way to confirm that the agent can log in to the service manager is to type `http://Dashboard Host:18080/heartbeat` into the address bar of your web browser, substituting the appropriate host name and port. When the HTTP authentication dialog box opens, enter the agent user name and password. If you log in successfully, you should see the following message:

```
<exceptions>
<error>E1031: Agent payload parameter NULL.</error>
</exceptions>
```

### Note

Despite the fact that the preceding listing shows an error, you have logged in successfully. This error appears *because* you have logged in but with no “payload”.

If you can log in successfully in the way described above and the agent is running, then there are errors in the `mysql-monitor-agent.ini` file. Compare the host name, port, agent name, and password found in the `ini` file with the values you entered into the address bar of your web browser.

If HTTP authentication fails then you are using incorrect credentials for the agent. Attempting to log in to the service manager using incorrect credentials creates an entry in the agent log file. For the location of this log file see [Agent Log and PID Files](#).

If no HTTP authentication dialog box appears, and you are unable to connect at all, then you may have specified an incorrect host name or port. Confirm the values you entered against those described as the `Application hostname and port`: in the `configuration_report.txt` file. Failure to connect could also indicate that the port is blocked on the machine hosting the MySQL Enterprise Service Manager.

To check if a blocked port is the problem, temporarily bring down your firewall. If the agent is then able to connect, open up the port specified during installation and restart the agent. If necessary you can monitor outside the firewall using an SSH tunnel. For more information, see [Section 15.3.3.6.5, “Monitoring Outside the Firewall with an SSH Tunnel”](#).

You can also check the agent error log file to help determine any problems. An error such as the following might indicate a blocked port:

```
(critical) connection to merlin-server
'http://agent:test@172.11.1.1:18080/heartbeat' failed:
"connect() timed out!" error.
```

For the location of the agent error log file see, [Agent Log and PID Files](#).

Setting the `log-level` entry in your `ini` file is also a good debugging technique. For more information on this subject see, [Section 15.3.3.6.1, “MySQL Enterprise Monitor Agent \(`mysql-monitor-agent.ini`\) Configuration”](#).

Running the agent from the command line sometimes displays errors that fail to appear in the log file or on the screen when the agent is started from a menu option. To start the agent from the command line see the instructions given at the start of this section.

If you have more than one agent running on the same machine, the `UUID` must be unique and the `log-file` and `pid-file` values must be different. For more information, see [Section 15.3.3.6.2, “MySQL Server \(`agent-instance.ini`\) Configuration”](#).

If the agent is not running on the same machine that hosts the MySQL server it is monitoring, then you must ensure that the correct `host` is specified for the agent account. The correct port, typically 3306, must also be open for remote login. For more information about remote monitoring see, [Section 15.3.3.6.4, “Configuring an Agent to Monitor a Remote MySQL Server”](#).

If the MySQL Enterprise Monitor Agent has been ungracefully terminated and restarted (for example after being terminated using `kill`), then you may see a `DuplicateAgentUuidException` error until the original registration of the previous instance of the agent has expired.

## 15.3.4. Unattended Installation

It is possible to install the MySQL Enterprise Monitor without any direct user interaction. This is done by passing the command-line option `--mode unattended` to the installation file.

Using this mode and other command-line parameters means the user will not be prompted for input during installation. This is especially useful when doing multiple installations of the MySQL Enterprise Monitor.

However, rather than passing numerous parameters from the command line, it is usually more convenient to save your options in a text file and invoke the installer using the `optionfile` option. This is a more reusable and less error-prone solution.

Before attempting an unattended installation, it is recommended that you install the MySQL Enterprise Monitor interactively at least once. Failing this, as a minimum, read the regular installation instructions since some tasks still remain after an unattended installation; you must configure the MySQL Enterprise settings, import the advisors, and start up all the services/daemons.

### 15.3.4.1. Command-Line Options

To view the available options for the monitor installer or for the agent installer, at the command line type the executable file name along with the `--help` option.

On each platform, for each installer, the installer supports a number of different installation modes. Some of these are unique to an individual platform, others are available on all platforms. The table below summarizes the different options available for each platform.

Platform	Default Mode	win32	gtk	xwindow	osx	text	unattended
Windows	win32	Y	N	N	N	N	Y
Unix	gtk	N	Y	Y	N	Y	Y
Linux	gtk	N	Y	Y	N	Y	Y
Mac OS X	win32	N	N	N	Y	Y	Y

#### 15.3.4.1.1. MySQL Enterprise Service Manager Options

The following listing shows the command line options for the MySQL Enterprise Service Manager.

```
--help Display the list of valid options
--version Display product information
--optionfile <optionfile> Installation option file
 Default:
--mode <mode> Installation mode
 Default: win32
 Allowed: win32 unattended
--debugtrace <debugtrace> Debug filename
 Default:
--installer-language <installer-language> Language selection
 Default:
 Allowed: en jp
--installdir <installdir> Installation directory
 Default:/opt/mysql/enterprise/monitor/
--tomcatport <tomcatport> Tomcat Server Port
 Default: 18080
--tomcatshutdownport <tomcatshutdownport> Tomcat Shutdown Port
 Default: 18005
--tomcatsslport <tomcatsslport>Tomcat SSL Port
 Default: 18443
--usessl <usessl> Should communication between the Dashboard »
 and Service Manager be encrypted?
 Default: 0
--adminuser <adminuser> Repository Username
 Default: service_manager
--adminpassword <adminpassword>Password
 Default:
--dbport <dbport> Bundled MySQL Database Port
```

Default: 13306

The options and their effect on installation are detailed below:

- **--help**  
Display the list of valid options.
- **--version**  
Display product and version information.
- **--optionfile**  
The path to the option file containing the information for the installation.
- **--mode**  
The installation mode to be used for this installation.
- **--debugtrace**  
The filename to be used for a debug trace of the installation.
- **--installer-language**  
The installer language; supported options are `en` for English and `jp` Japanese.
- **--installdir**  
The installation directory for MySQL Enterprise Service Manager.  
The default on Windows is `C:\Program Files\MySQL\Enterprise\Monitor`  
The default on Unix is `/opt/mysql/enterprise/monitor/`  
The default on Mac OS X is `/Applications/mysql/enterprise/monitor/`
- **--tomcatport**  
The MySQL Enterprise Service Manager port;  
The default is 18080.
- **--tomcatshutdownport**  
The MySQL Enterprise Service Manager Tomcat shutdown port.  
The default is 18005.
- **--tomcatsslport**  
The MySQL Enterprise Service Manager SSL port.  
The default is 18443.
- **--usessl**  
Enable support for SSL communication between the MySQL Enterprise Monitor Agent and MySQL Enterprise Service Manager.  
The default is 0.
- **--adminuser**  
The MySQL Enterprise Service Manager user name.  
The default is `service_manager`.

## Warning

The repository user name and password are stored in unencrypted form in the `config.properties` file. To locate this file on your operating system see [The config.properties File](#).

- `--adminpassword`

The MySQL Enterprise Service Manager password.

- `--dbport`

The TCP/IP port for the Bundled MySQL database.

The default is 13306.

#### 15.3.4.1.2. MySQL Enterprise Monitor Agent Options

To view all the options available for an unattended *agent* installation, invoke the agent installer file passing in the `help` option. (Under Windows you must redirect the output to a file. You should see a listing similar to the following:

**Note**

The exact options may vary depending on the operating system on which you are executing the installer.

```
Usage:
--help Display the list of valid options
--version Display product information
--optionfile <optionfile> Installation option file
 Default:
--unattendedmodeui <unattendedmodeui> Unattended Mode UI
 Default: none
 Allowed: none minimal minimalWithDialogs
--mode <mode> Installation mode
 Default: osx
 Allowed: osx text unattended
--debugtrace <debugtrace> Debug filename
 Default:
--installer-language <installer-language> Language selection
 Default:
 Allowed: en ja
--installdir <installdir> Installation directory
 Default:
--mysqlconnmethod <mysqlconnmethod>
 Default: tcpip
 Allowed: tcpip socket
--mysqlhost <mysqlhost> MySQL hostname or IP address
 Default: 127.0.0.1
--checkmysqlhost <checkmysqlhost> Validate MySQL hostname or IP address
 Default: yes
--mysqlport <mysqlport> MySQL Port
 Default: 3306
--mysqlsocket <mysqlsocket> MySQL Socket
 Default:
--mysqluser <mysqluser> MySQL Username
 Default:
--mysqlpassword <mysqlpassword> Password for mysql user
 Default:
--enableproxy <enableproxy> Enable Proxy (recommended)
 Default: 1
--proxyport <proxyport> Proxy Port
 Default: 6446
--managerhost <managerhost> Hostname or IP address
 Default:
--managerport <managerport> Tomcat Server Port
 Default: 18080
--managersslport <managersslport> Tomcat SSL Port
 Default: 18443
```

```
--usessl <usessl> Use SSL?
 Default: 0
--agentuser <agentuser> Agent Username
 Default: agent
--agentpassword <agentpassword> Agent Password
 Default:
--proxyuser <proxyuser> User Account
 Default: root
```

The options and their effect on installation are detailed below:

- **--help**  
Display the list of valid options
- **--version**  
Display product information, including the version number of the installer.
- **--optionfile <optionfile>**  
Specify the location of an option file containing the configuration options for this installation.
- **--unattendedmodeui <unattendedmodeui>**  
The UI elements to use when performing an unattended installation. The options are **none**, show now UI elements during the installation; **minimal**, show minimal elements during installation; **minimalWithDialogs**, show minimal UI elements, but include the filled-dialog boxes.  
The default is **none**.
  - **--mode <mode>**  
Specify the installation mode to use for this installation.
  - **--debugtrace <debugtrace>**  
Set the filename to use when recording debug information during the installation.
  - **--installer-language <installer-language>**  
Set the language to be used for the installer.
  - **--installdir <installdir>**  
Specify the directory where the software will be installed.  
The default on Windows is **C:\Program Files\MySQL\Enterprise\Agent**  
The default on Unix is **/opt/mysql/enterprise/agent/**  
The default on Mac OS X is **/Applications/mysql/enterprise/agent/**
  - **--mysqlconnmethod <mysqlconnmethod>**  
Specify the connection method to use to connect to MySQL.  
Options are **tcpip** and **socket**.  
The default is **tcpip**.
  - **--mysqlhost <mysqlhost>**  
MySQL hostname or IP address  
The default is 127.0.0.1.
  - **--checkmysqlhost <checkmysqlhost>**  
Validate the MySQL hostname or IP address

The default is `yes`.

- `--mysqlport <mysqlport>`

Specify the TCP/IP port to use when connecting to MySQL.

The default is 3306.

- `--mysqlsocket <mysqlsocket>`

Specify the filename of the MySQL socket to use when communicating with the monitored MySQL instance.

- `--mysqluser <mysqluser>`

Specify the username to use when connecting to the MySQL instance.

- `--mysqlpassword <mysqlpassword>`

Specify the password to use when connecting to the MySQL instance.

- `--enableproxy <enableproxy>`

Enable the Proxy. This is recommended and is required if you want to use Query Analyzer.

The default is 1 (use the proxy).

- `--proxypport <proxypport>`

Specify the TCP/IP port to use for the proxy interface.

The default is 6446.

- `--managerhost <managerhost>`

The hostname or IP address of the MySQL Enterprise Service Manager.

- `--managerport <managerport>`

The port number of the MySQL Enterprise Service Manager.

The default is 18080.

- `--managersslport <managersslport>`

The port number of the MySQL Enterprise Service Manager for SSL-based communication

The default is 18443.

- `--usessl <usessl>`

Specifies whether SSL should be used to communicate with the MySQL Enterprise Service Manager.

- `--agentuser <agentuser>`

Specify the agent username to be used when communicating with the MySQL Enterprise Service Manager.

- `--agentpassword <agentpassword>`

Specify the agent password to be used when communicating with the MySQL Enterprise Service Manager.

- `--proxyuser <proxyuser>`

The user account for the proxy server.

The default is `root`.

### 15.3.4.2. Unattended Windows Installation

For unattended installation on Windows, create an option file named `options.server.txt`. The following is an example of what the contents of an option file might be.

```
debugtrace=C:\Program Files\MySQL\Enterprise\install.debugtrace.log
mode=unattended
installdir=C:\Program Files\MySQL\Enterprise
tomcatport=8080
tomcatshutdownport=8005
tomcatsslport=8443
adminpassword=myadminpassword
dbport=3300
```

This file identifies a directory and file name for a log file, sets the `mode` to `unattended`, and uses the `installdir` option to specify an installation directory. The meaning of the other options is fairly self-evident.

#### Note

Set the `installdir` and `debugtrace` options to values appropriate to your locale and operating system.

The only options that must be specified in an option file when installing the MySQL Enterprise Service Manager are `mode` (if not specified at the command line), `installdir`, and `adminpassword`.

Check the options in your option file closely before installation; no warnings will be issued if there are errors.

Ensure that the monitor installer file and the options file are in the same directory and, if you saved the options file as `options.server.txt`, you can invoke an unattended installation from the command line by typing:

```
C:\ mysqlmonitor-version-windows-installer.exe --optionfile options.server.txt
```

You can install the MySQL Enterprise Monitor Agent in exactly the same fashion. Create an agent option file and call the agent installer using the `optionfile` option.

As a minimum for the agent installation, you must specify the `mode` (if not specified at the command line), `mysqluser`, `installdir`, `mysqlpassword`, `installdir`, `managerhost`, and `agentpassword` options. Create a file containing these values and use it with the `optionfile` option for unattended agent installation.

If you wish, you can create one script that calls both the Service Manager and the Monitor Agent programs passing appropriate `optionfile` options.

### 15.3.4.3. Unattended Unix and Mac OS X Installation

For unattended installation on Unix, create an option file named `options.server.txt`. The following is an example of what the contents of an option file might be for installation on Unix.

```
debugtrace=/opt/mysql/enterprise/install.debugtrace.monitor.log
mode=unattended
installdir=/opt/mysql/enterprise/monitor
tomcatport=8080
tomcatshutdownport=8005
tomcatsslport=8443
adminpassword=myadminpassword
dbport=3300
```

This file identifies a directory and file name for a log file, sets the `mode` to `unattended`, and uses the `installdir` option to specify an installation directory. The meaning of the other options is fairly self-evident.

#### Note

Set the `installdir` and `debugtrace` options to values appropriate to your locale and operating system.

The only options that must be specified in an option file when installing the MySQL Enterprise Service Manager are `mode` (if not specified at the command line), `installdir`, and `adminpassword`.

Check the options in your option file closely before installation; no warnings will be issued if there are errors.

Ensure that the monitor installer file and the options file are in the same directory and, if you saved the options file as `options.server.txt`, you can invoke an unattended installation from the command line by typing:

```
shell> mysqlmonitor-version-installer.bin --optionfile options.server.txt
```

You can install the MySQL Enterprise Monitor Agent in exactly the same fashion. Create an agent option file and call the agent installer using the `optionfile` option.

As a minimum for the agent installation, you must specify the `mode` (if not specified at the command line), `mysqluser`, `installdir`, `mysqlpassword`, and `agentpassword` options. Create a file containing these values and use it with the `op-`

`tionfile` option for unattended agent installation.

If you wish, you can create one script that calls both the Service Manager and the Monitor Agent programs passing appropriate `optionfile` options.

#### Note

The Service Manager does not automatically start up on rebooting. For more information, see [Bug#31676](#).

The procedure for unattended agent installation under Mac OS X is identical to the procedure under Unix.

### 15.3.4.4. Starting the Services

For instructions on starting the services needed by the MySQL Enterprise Service Manager see, [Section 15.3.2.5, “Starting/Stopping the MySQL Enterprise Monitor Service on Windows”](#) for Windows and, [Section 15.3.2.6, “Starting/Stopping the MySQL Enterprise Monitor Service on Unix and Mac OS X”](#) for Unix and Mac OS X.

For instructions on starting the MySQL Enterprise Monitor Agent see:

- Windows: [Section 15.3.3.5.1, “Starting/Stopping the Agent on Windows”](#)
- Unix: [Section 15.3.3.5.3, “Starting/Stopping the Agent on Unix”](#)
- Mac OS X: [Section 15.3.3.5.2, “Starting/Stopping the Agent on Mac OS X”](#)

If you wish, you can script the startup of these services.

### 15.3.5. Post-Installation Considerations

Depending upon how you plan to use the MySQL Enterprise Monitor, there are some tasks you may want to perform after installation. Find some suggestions in the following list:

- **Email settings:** Test email notification by deliberately triggering an alert.
- **Auto Startup:** On Unix systems, the MySQL Enterprise Service Manager does not automatically restart when the system is rebooted. You may wish to create a system initialization script appropriate to your operating system.
- **Log files:** Check the log files for any irregularities. For the locations of the various log files see [Files Associated with The MySQL Enterprise Monitor](#).
- **Agent Log file rotation:** Implement log file rotation for the monitor agent.
- **Back up the repository:** For a back-up strategy suitable to your circumstances, see the [MySQL reference manual documentation](#).
- **Configuration backup:** Back up the `mysql-monitor-agent.ini` file and the associated `instances` directory and contents.

For more information about the `mysql-monitor-agent.ini` file see [Section 15.3.3.6, “Advanced Agent Configuration”](#).

- **Configuration file:** Store the `configuration_report.txt` in a safe place. There is no mechanism for retrieving the password stored in this file.
- **Repository credentials:** The repository user name and password are stored in unencrypted form in the `config.properties` file. Take care to protect this file.
- **Disk management:** Remove installation files, and monitor the space used by the repository. Ensure that you have adequate disk space by regularly purging data. For more information, see [Data Purge Behavior](#).
- **Firewall changes:** You may want to limit or expand access to the MySQL Enterprise Service Manager.
- **Open ports:** As with firewall changes, you may want to limit or expand access to the MySQL Enterprise Service Manager. The dashboard uses nonstandard ports, none of which are usually open by default.
- **Server upgrades:** See [Section 15.3.6.3.1, “Upgrading the Monitored MySQL Server”](#) for instructions on upgrading a server.
- **Repository access:** You may want to add other users.

## 15.3.6. Upgrading, Re-Installing or Changing Your Installation

You can upgrade MySQL Enterprise Monitor in a number of different ways:

- For instructions on upgrading your existing installation, see [Section 15.3.6.1, “Upgrading MySQL Enterprise Monitor”](#).
- For more information on re-installing an existing installation, see [Section 15.3.6.2, “Reinstalling MySQL Enterprise Monitor”](#).
- To change an existing installation, such as changing the monitored server, see [Section 15.3.6.3, “Changing Your MySQL Enterprise Monitor Installation”](#).

### 15.3.6.1. Upgrading MySQL Enterprise Monitor

From time to time there may be updates to the MySQL Enterprise Service Manager or the MySQL Enterprise Monitor Agent. This section describes how to perform an update for either of these components.

You cannot use the update installers to change to a different operating system or chip architecture. For example, you cannot update a 32-bit Linux installation to a 64-bit version using an update installer—in cases such as this you must do a fresh installation.

The installation and configuration of MySQL Enterprise Monitor Agent must be standard before you start the installation. The update installer will not upgrade agents where you have changed or modified the filenames or directory layout of the installed agent, configuration files, or the startup files.

The name of the update file varies but it shows the target operating system and the version the update applies to. If a specific component is being updated it may also appear in the file name. For example, a file named `mysqlenterprisemanager-2.0.0-windows-update-installer.exe` would indicate a Windows update to MySQL Enterprise Service Manager version 2.0.0.

You may install an update in the same way that you initially installed the service manager or the agent; in `win32` or `unattended` mode on Windows in `gtk`, `text`, `xwindow`, or `unattended` mode on Unix and in `osx`, `text`, or `unattended` mode on OS X.

#### Warning

The method you use for upgrading MySQL Enterprise Monitor components will depend on the upgrade you are performing.

- If you are upgrading between major versions (for example, from MySQL Enterprise Monitor 1.3 to merlin 2.0), you should shutdown the MySQL Enterprise Service Manager and each connected MySQL Enterprise Monitor Agent. Once you have shutdown each component, start by updating the MySQL Enterprise Service Manager, and then updating the MySQL Enterprise Monitor Agent on each monitored client.
- If you are upgrading between the same major version, for example, MySQL Enterprise Monitor 2.0 to MySQL Enterprise Monitor 2.1, or a minor version, such as MySQL Enterprise Monitor 2.1.1 to MySQL Enterprise Monitor 2.1.2, you can shutdown only the component (agent, or server) you are updating. Using this method, you can perform a ‘rolling’ upgrade, where you shutdown a single MySQL Enterprise Monitor Agent, upgrade it to the latest agent version, and then restart the agent before moving on to the next monitored instance.

#### Important

The upgrade installer will overwrite `items-mysql-monitor.xml`. On Windows this file is found in the `C:\Program Files\MySQL\Enterprise\Agent\share\mysql-monitor-agent` directory and on Unix in the `/opt/mysql/enterprise/agent/share/mysql-monitor-agent` directory. You should back this file up if you have made any changes to it.

#### Warning

If you use the Upgrade installer to update MySQL Enterprise Service Manager and you have made any changes to the `my.cnf` within your MySQL Enterprise Service Manager installation, any changes will be lost. You should copy the existing `my.cnf` file before starting the upgrade installer.

Otherwise, updating is a fairly straightforward process. Run the installation file and choose the directory of your current installation and whether or not you wish to back up your current installation. The time required to complete the process varies depending upon the nature of the update.

If you chose to back up your current installation, a directory named `backup` will be created in the current installation directory. This directory will contain copies of the directory or directories that were replaced during the update. In cases where only specific

files are replaced, the `backup` directory may contain only these files. If you are unhappy with the update simply overwrite the new files or directories with the originals found in the `backup` directory. Be sure to stop both the MySQL Enterprise Service Manager and MySQL Enterprise Monitor Agent before restoring the original files. You can delete or archive this directory when you are satisfied that the update was successful.

If you choose to back up your current installation, the installer checks that there is adequate disk space for your repository backup. If there is not enough space, you are given the option of choosing another location; you may also choose not to back up the repository.

To update your Advisors see, [Section 15.3.2.7.3, “Installing Advisors After Initial Log-in”](#).

### 15.3.6.1.1. Upgrading from MySQL Enterprise Monitor 1.3 to 2.0

To upgrade your existing installation from MySQL Enterprise Monitor 1.3 to MySQL Enterprise Monitor 2.0, you need to upgrade both your MySQL Enterprise Service Manager and your MySQL Enterprise Monitor Agent on each machine that you are monitoring.

To perform the update process you must use an `update` installer. This ensures that your current configuration information is migrated to the new version of MySQL Enterprise Service Manager.

Before you start the migration, shutdown your MySQL Enterprise Service Manager and MySQL Enterprise Monitor Agent on each monitored host. Then install the updated MySQL Enterprise Service Manager application to migrate the configuration and data of the main application and repository. Once the new MySQL Enterprise Service Manager is running, you can start to update and migrate each agent.

For more information on upgrading your MySQL Enterprise Service Manager, see [Section 15.3.6.1.1.1, “Upgrading to MySQL Enterprise Service Manager 2.0”](#). For more information on upgrading an MySQL Enterprise Monitor Agent, see [Section 15.3.6.1.1.2, “Upgrading to MySQL Enterprise Monitor 2.0”](#).

#### 15.3.6.1.1.1. Upgrading to MySQL Enterprise Service Manager 2.0

Upgrading MySQL Enterprise Service Manager requires you to use one of the `update` installers. The update installer performs a number of operations during installation:

- A new database, required to support 2.0 functionality, is created.
- Your core dashboard, user, and rule information is migrated from the old database to the new database.
- The core configuration parameters for the MySQL Enterprise Service Manager are migrated from MySQL Enterprise Monitor 1.3 to MySQL Enterprise Monitor 2.0.

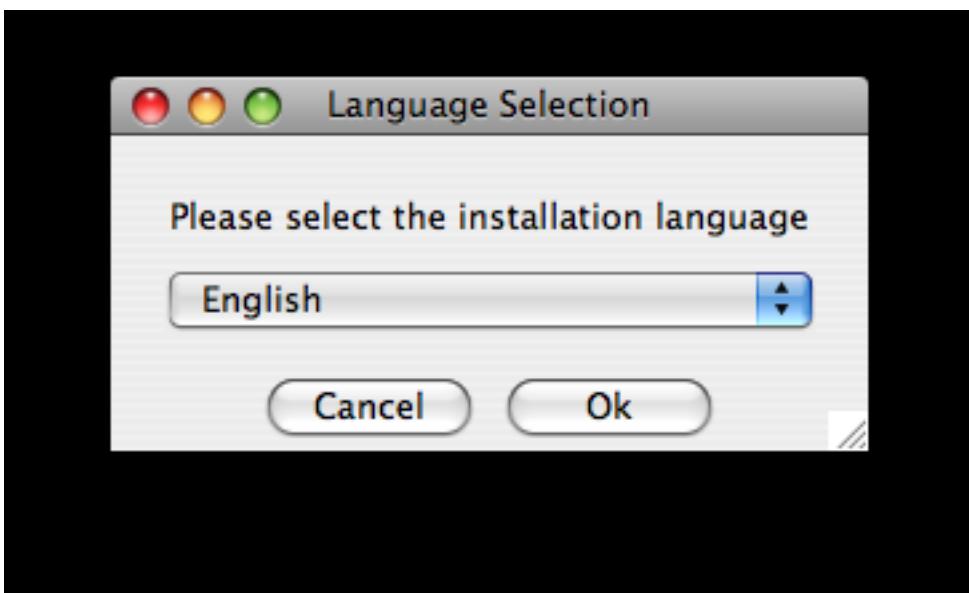

The installation of the new software using the update installer follows this basic sequence:

1. Request the installation language.
2. Confirm the location of the current MySQL Enterprise Service Manager installation.
3. Specify whether you want to keep a copy of the old server, application, and database files.
4. Configure the Tomcat server settings, including whether the new server should support SSL connections from agents.
5. If requested, the application and database information is backed up and upgraded, before the new application is installed.

The installation process is consistent for all platforms. A sample of the process for Mac OS X has been provided below:

1. Double-click the update installer. The update installer will have `update` in the file name. For example, `mysqlmonitor-2.0.0.7101-osx-update-installer.app`.
2. Confirm the language you want to use when installing the software.

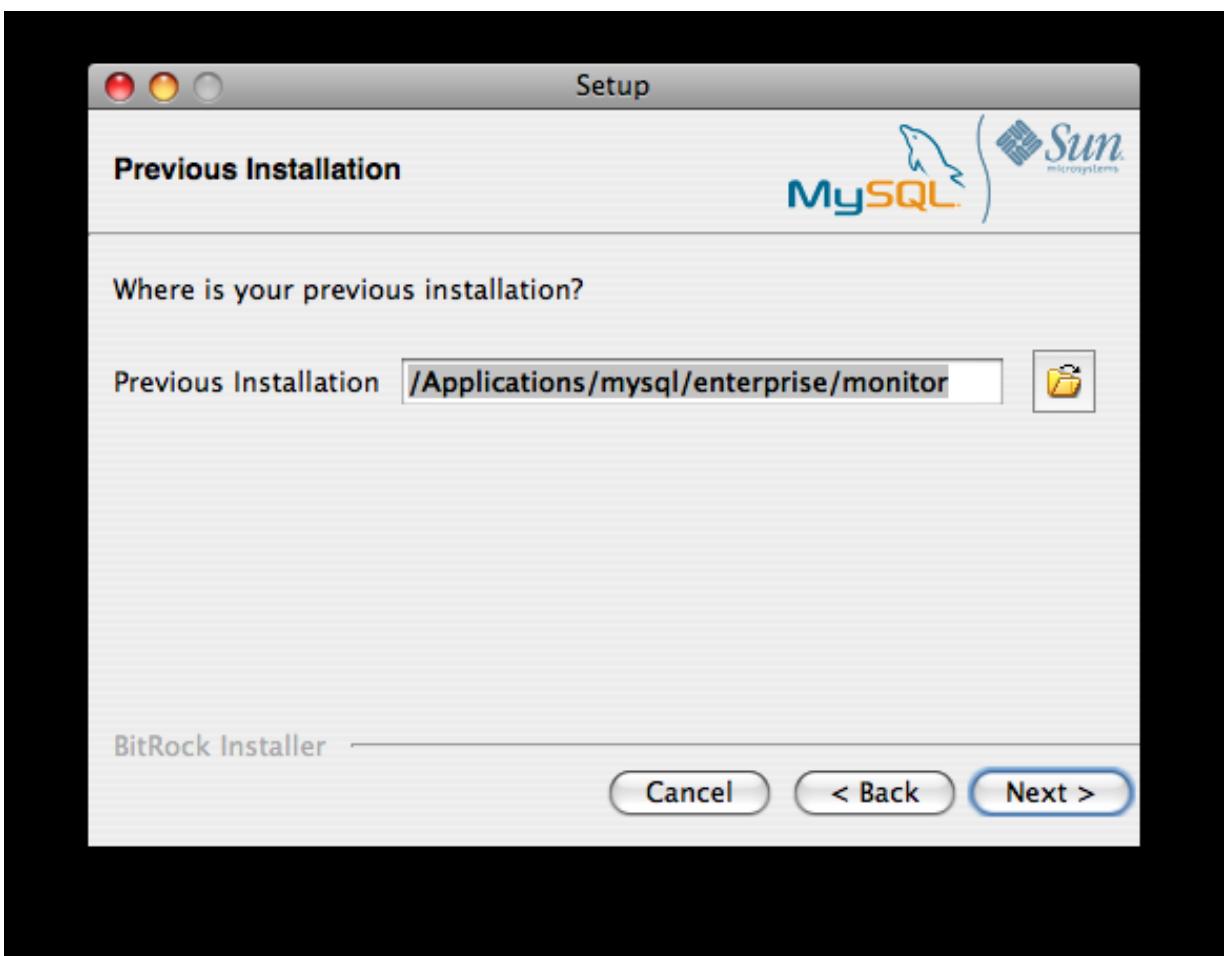

**Figure 15.24. MySQL Enterprise Monitor: Server Update: Language Selection**

Click OK

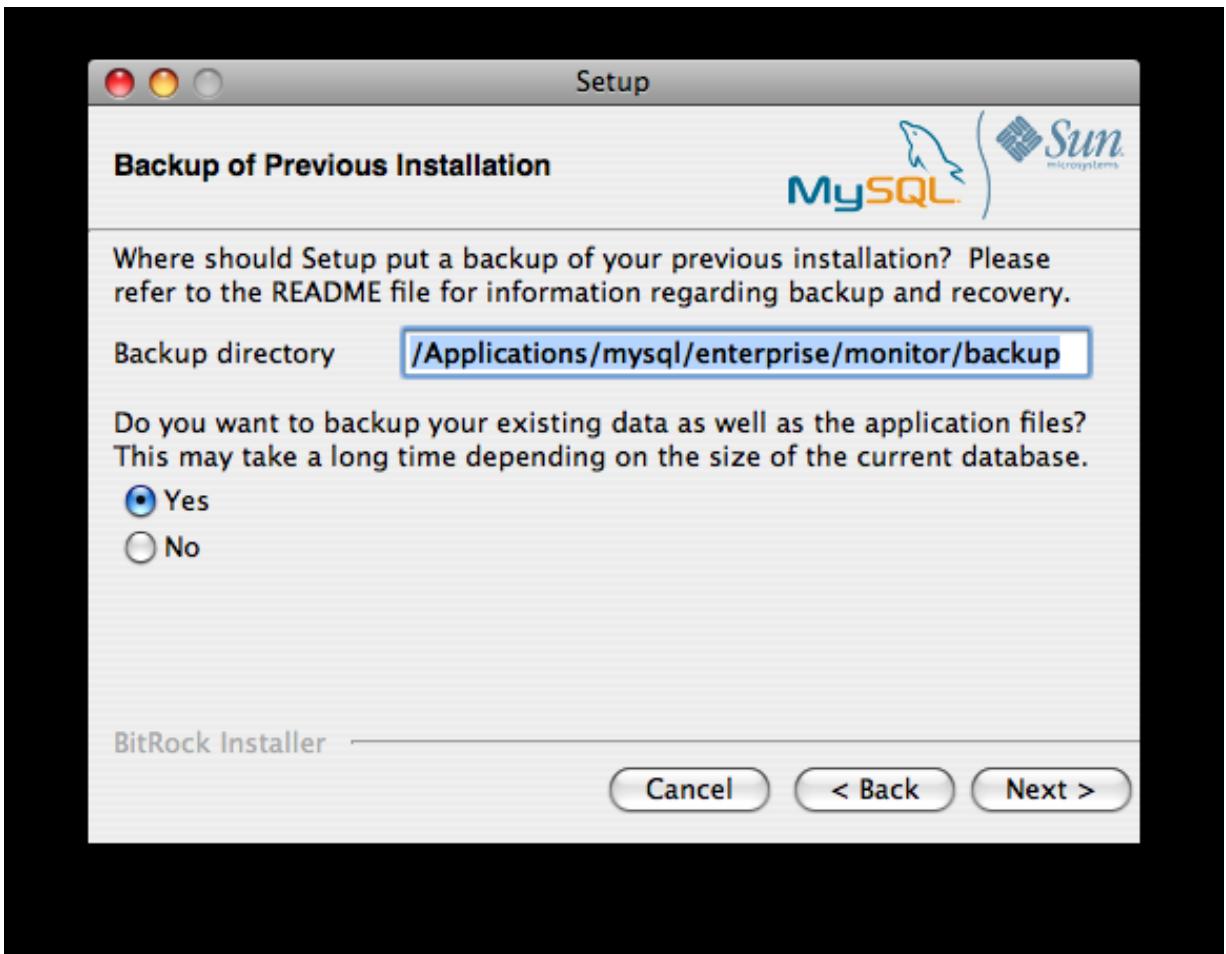

3. You will be presented with an information screen showing the application you are installing. Click NEXT to continue.
4. Specify, or locate, the previous installation of MySQL Enterprise Service Manager If you installed the server within the default location, the current version of the application should be located automatically.

**Figure 15.25. MySQL Enterprise Monitor: Server Update: Previous Installation**

5. The installer can keep a backup copy of your existing application, including keeping a complete backup of the data stored within your MySQL Enterprise Monitor repository database.

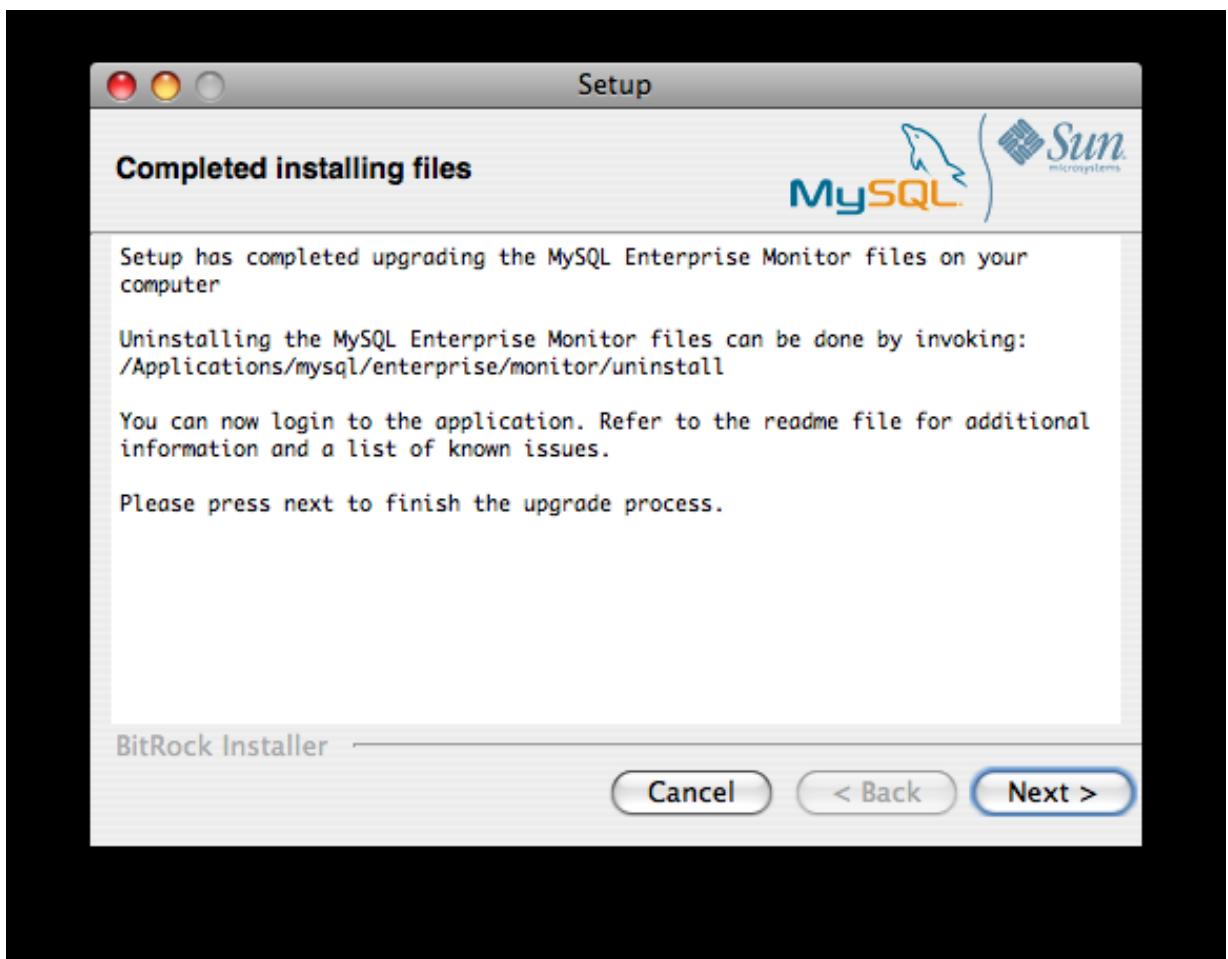

**Figure 15.26. MySQL Enterprise Monitor: Server Update: Backup of Previous Installation**

Specify the location of the backup (default is to use the **backup** directory within your installation directory). Note that backing up the database in addition to the main application will increase the installation time as the files have to be copied. The larger the size of your repository data, the longer the installation process will take.

6. Specify the Tomcat Server options. The Tomcat Server Port is the default port you will use to access the MySQL Enterprise Dashboard. If you want to support agents using SSL to communicate to MySQL Enterprise Service Manager, you must check the **IS SSL SUPPORT REQUIRED?**
7. Confirm that you want to continue the installation. Once installation has started, the backup of your existing application (and database) will start, although the process may take some time. Wait until the process completes.
8. Once the process has completed you will be provided with a notification of the installation process, including how to uninstall the application if you want to do so in the future. If any errors occurred, they will be reported here.

**Figure 15.27. MySQL Enterprise Monitor: Server Update: Completed installing files**

9. The installation has now completed. You can automatically start the MySQL Enterprise Service Manager and view the attached Readme file by ensuring the checkboxes on this page are selected.
10. You can now quit the installer.

Once the installation has completed, the first time you login to MySQL Enterprise Dashboard you will be asked to provide your login credentials, if they do not already exist in the server configuration, or to provide a copy of the Advisor jar suitable for your MySQL Enterprise Service Manager version.

**Figure 15.28. MySQL Enterprise Monitor: Server Update: Final Setup**

Welcome to the MySQL Enterprise Dashboard Setup.  
Before proceeding, you must complete the form below.

**Enterprise Credentials and Subscription Information**

To enable this application, please provide a MySQL Enterprise Product Key or your MySQL Enterprise credentials.  
When you press "complete setup", your Enterprise credentials will be validated at enterprise.mysql.com. These credentials will also be used for subscription updates. Note that you may update your credentials or Product Key at any time on the Settings page.

**Email Address (MySQL Enterprise Login)**

**Enterprise Password (MySQL Enterprise Password)**

**Confirm Password**

- OR -

**Import Advisors and Graphs from file (\*.jar)**

MySQL Enterprise © 2005-2008 MySQL AB, 2008 Sun Microsystems, Inc. All rights reserved. [Enterprise Software](#) | [Update Service](#) | [Knowledge Base](#) | [Technical Support](#) | [About](#) (Nov 19, 2008 11:25:51 AM)

MySQL Enterprise Monitor has now been updated. You must update each of your agents to MySQL Enterprise Monitor Agent 2.0 to ensure that they are providing the correct information to MySQL Enterprise Service Manager

### 15.3.6.1.1.2. Upgrading to MySQL Enterprise Monitor Agent 2.0

To upgrade an agent you should use a [update](#) installer. This will migrate your configuration information, simplifying the upgrade process significantly.

#### Note

The agent log file, `mysql-monitor-agent.log`, if it exists, will be retained during the upgrade. A new log file, `mysql-monitor-agent.log` is used by MySQL Enterprise Monitor Agent 2.0.

The core sequence is the same on all platforms, the update process on Linux is shown below:

1. Start the update installer.

```
shell> ./mysqlmonitoragent-2.0.0.7101-linux-glibc2.3-x86-32bit-update-installer.bin
```

2. Set the language for the installation process.

```
Language Selection
Please select the installation language
[1] English
[2] Japanese
Please choose an option [1] :
```

3. Confirm or update the location of the installation directory of the previous version.

```

Welcome to the setup wizard for the MySQL Enterprise Monitor Agent Update

Please specify the directory that contains the previous installation of
the MySQL Enterprise Monitor Agent
Installation directory [/opt/mysql/enterprise/agent]:
```

- Specify whether you want to create a backup of the current application and configuration information, and if so, where the backup directory should be created.

```

Current installation backup

Do you want to create a backup during the update process?

Backup the current installation [Y/n]: Y

Backup directory [/opt/mysql/enterprise/agent/patchbackup]:
```

- You will be asked whether you want to enable the Query Analyzer. The Query Analyzer enables you to monitor the execution stateistics for individual queries executed through your MySQL servers. To enable, you must specify the proxy port, MySQL server and MySQL server port that you want to use. If you do not enable Query Analyzer now, you can enable it later. See [Section 15.10, “The Query Analyzer Page”](#).

```

Query Analyzer Configuration

MySQL Proxy enables query monitoring and analysis by listening on the port
specified below for client connections that are then passed through to a
backend MySQL database server. It is not needed for basic monitoring
functionality, but is required for query monitoring and analysis.

Visit the following URL for more information:
https://enterprise.mysql.com/docs/monitor/2.0/en/mem-query-analyzer.html

Enable Proxy (recommended) [Y/n]: Y

Proxy Port [6446]:
Backend Host: 127.0.0.1 (cannot be changed)
Backend Port: 3306 (cannot be changed)
```

- You are now ready to complete the installation. Confirm that you want to continue.

```

Setup is now ready to begin installing MySQL Enterprise Monitor Agent Update on your computer.

Do you want to continue? [Y/n]: Y

Please wait while Setup installs MySQL Enterprise Monitor Agent Update on your computer.

Installing
0% 50% 100%
#####

Setup has finished installing MySQL Enterprise Monitor Agent Update on your computer.

Restart MySQL Enterprise Monitor Agent now [Y/n]: Y

View Readme File [Y/n]: n
```

Before connecting your MySQL Enterprise Monitor Agent to your MySQL server you must update the grants for the MySQL Enterprise Monitor Agent. Connect to the MySQL server and run this statement to update the required grants:

```
GRANT CREATE, INSERT
ON mysql.*
TO 'mysqluser'@'localhost'
IDENTIFIED BY 'agent_password';
```

Replacing the `mysqluser` and `agent_password` parameters with the values used for connecting your agent to your MySQL server.

Once the update agent has communicated with the MySQL Enterprise Service Manager the core information about the agent and the MySQL server it is monitoring will be migrated to the new data format required by MySQL Enterprise Service Manager 2.0. To migrate the existing stored data, see [Section 15.12.9, “Migrating 1.3.x Historical Data to MySQL Enterprise Monitor 2.0”](#).

### 15.3.6.1.2. Upgrading to MySQL Enterprise Monitor 2.1

When upgrading to MySQL Enterprise Monitor 2.1 you should be aware of the following issues:

- During the upgrade process, if you had previously set a Query Analyzer data purge value that was greater than the standard data purge value, the historical data collection purge period will be set to the Query Analyzer purge period. This will be logged in the upgrade log with the following notice:

```
getDataCollectionPurgeLifespan now: 4 weeks (was: 2 weeks)
```

### 15.3.6.1.3. Unattended MySQL Enterprise Monitor Update

The options available when performing an unattended MySQL Enterprise Service Manager update are as follows:

```
--help Display the list of valid options
--version Display product information
--optionfile <optionfile> Installation option file
 Default:
--mode <mode> Installation mode
 (Windows)Default: win32
 (Unix)Default: gtk
 (Mac OS X)Default: osx
 (Windows)Allowed: win32 unattended
 (Unix)Allowed: gtk text xwindow unattended
 (Mac OS X)Allowed: osx text unattended

--debugtrace <debugtrace> Debug filename
 Default:

--installer-language <installer-language> Language selection
 Default:
 Allowed: en jp

--installdir <installdir> Previous Installation
 Default:

--createDataBackup <createDataBackup>
 Default: 1

--backupDir <backupDir> Backup directory
 Default:
```

The options for an unattended update of the agent differ only in that the `createDataBackup` option is replaced by `createBackup`.

If you did not install the MySQL Enterprise Service Manager to the default directory the `installdir` option must be specified. `mode` must also be specified when performing an unattended update. Otherwise, performing an unattended update is identical to the process described in [Section 15.3.4, “Unattended Installation”](#).

### 15.3.6.2. Reinstalling MySQL Enterprise Monitor

In some cases you may want to reinstall MySQL Enterprise Monitor rather than updating your current installation. To reinstall rather than update MySQL Enterprise Monitor follow these steps:

1. Stop all the Monitor Agents
2. Run the `uninstall` programs for both the MySQL Enterprise Service Manager and the MySQL Enterprise Monitor Agent
3. Begin the new installation

To stop the Monitor Agents see:

- Windows: [Section 15.3.3.5.1, “Starting/Stopping the Agent on Windows”](#)
- Unix: [Section 15.3.3.5.3, “Starting/Stopping the Agent on Unix”](#)
- Mac OS X: [Section 15.3.3.5.2, “Starting/Stopping the Agent on Mac OS X”](#)

Instructions for removing the MySQL Enterprise Service Manager and the MySQL Enterprise Monitor Agent are given in [Section 15.3.4, “Unattended Installation”](#).

tion 15.3.7, “Uninstalling the MySQL Enterprise Monitor”.

### 15.3.6.3. Changing Your MySQL Enterprise Monitor Installation

This section describes the best practices to employ when changing your MySQL Enterprise Monitor installation.

#### 15.3.6.3.1. Upgrading the Monitored MySQL Server

When upgrading a monitored MySQL server first stop the agent. To stop the agent see:

- Windows: [Section 15.3.3.5.1, “Starting/Stopping the Agent on Windows”](#)
- Unix: [Section 15.3.3.5.3, “Starting/Stopping the Agent on Unix”](#)
- Mac OS X: [Section 15.3.3.5.2, “Starting/Stopping the Agent on Mac OS X”](#)

Stop the MySQL server and perform the upgrade. For instructions on stopping and restarting the MySQL service under Windows see [Section 15.3.2.5, “Starting/Stopping the MySQL Enterprise Monitor Service on Windows”](#).

To stop and restart the MySQL daemon under Unix and Mac OS X, see, [Section 15.3.2.6, “Starting/Stopping the MySQL Enterprise Monitor Service on Unix and Mac OS X”](#).

Once the service/daemon is stopped you may upgrade your server. For instructions on upgrading your MySQL server see the reference manual pertaining to your server version. When the upgrade is complete restart the MySQL server.

**Note**

The agent's log file will show that the server was down.

#### 15.3.6.3.2. Changing the Server That an Agent Monitors

You need not reinstall the MySQL Enterprise Monitor Agent to change the MySQL server that it monitors. It is possible to adapt an existing agent so that it monitors a different server.

To do this you must stop the monitor agent and then remove the server that it is monitoring. To stop the agent see:

- Windows: [Section 15.3.3.5.1, “Starting/Stopping the Agent on Windows”](#)
- Unix: [Section 15.3.3.5.3, “Starting/Stopping the Agent on Unix”](#)
- Mac OS X: [Section 15.3.3.5.2, “Starting/Stopping the Agent on Mac OS X”](#)

For instructions on removing a server see, [Section 15.5.3.3, “Removing a Server From the Dashboard”](#).

Once the agent is stopped and the server is removed from the Dashboard, changes may be made to the `mysql-monitor-or-agent.ini`, or the `agent-instance.ini` file within the agent `instances` instances directory. You can find the location of the directory by examining the content of the `mysql-monitor-agent.ini` and checking the value of the `mysqld-instance-dir` parameter.

If you want to make changes to the monitored MySQL server, edit the `agent-instance.ini` file. Change the `user`, `password`, `hostname`, and `port` values if required. For more information, see [Section 15.3.3.6.2, “MySQL Server \(agent-instance.ini\) Configuration”](#).

To change other settings, such as enabling proxy support (required for Query Analyzer), the management host, or the port number used by the agent, modify the `mysql-monitor-agent.ini` file. For more information, see [Section 15.3.3.6.1, “MySQL Enterprise Monitor Agent \(mysql-monitor-agent.ini\) Configuration”](#).

To restart the agent see:

- Windows: [Section 15.3.3.5.1, “Starting/Stopping the Agent on Windows”](#)
- Unix: [Section 15.3.3.5.3, “Starting/Stopping the Agent on Unix”](#)
- Mac OS X: [Section 15.3.3.5.2, “Starting/Stopping the Agent on Mac OS X”](#)

**Note**

If you are adapting an existing agent to monitor a remote server make sure that the agent has the credentials for remote access and that the port on the remote MySQL server instance is open. For more information, see [Section 15.3.3.6.4, “Configuring an Agent to Monitor a Remote MySQL Server”](#).

If you experience difficulties starting the agent, check [Section 15.3.3.7, “Troubleshooting the Agent”](#).

Log in to the Dashboard and you should find your new server in the [All Servers](#) group.

### 15.3.6.3.3. Temporarily Suspending the Agent

In some situations you may need to bring down a monitored server. When this is necessary, it is good practice to stop the agent first—doing so will avoid generating a “Server is unreachable” event.

For instance, suppose you need to stop the server to do a backup. The steps to follow are:

1. Stop the agent
2. Stop the service/daemon
3. Perform the backup
4. Restart the service/daemon
5. Restart the agent

To stop or start the agent see:

- Windows: see [Section 15.3.3.5.1, “Starting/Stopping the Agent on Windows”](#)
- Unix: see [Section 15.3.3.5.3, “Starting/Stopping the Agent on Unix”](#)
- Mac OS X: see [Section 15.3.3.5.2, “Starting/Stopping the Agent on Mac OS X”](#)

To stop the MySQL service/daemon see the MySQL reference manual for your server version. You can find the manual online at <http://dev.mysql.com/doc>.

Follow these steps and there will be no “noise” associated with backing up your server. In contrast, if you leave the agent running while bringing down the server, you will generate a “Server is unreachable” event.

As an alternative to stopping the agent, you can change the logic associated with a rule. For instance, you could alter the threshold of the rule “Server is unreachable”:

```
%server.reachable% == THRESHOLD
```

to:

```
%server.reachable% == THRESHOLD && CURTIME() NOT BETWEEN '22:00:00' AND '23:00:00'
```

This would effectively blackout the rule between 10 and 11 pm, during which time you could perform a backup.

For more information about editing rules see [Section 15.7.3, “Editing Built-in Rules”](#). To blackout all events associated with a specific server or group of servers see [Section 15.7.7, “Advisor Blackout Periods”](#).

### 15.3.7. Uninstalling the MySQL Enterprise Monitor

Removal of the MySQL Enterprise Monitor requires removal of the MySQL Enterprise Service Manager and the MySQL Enterprise Monitor Agent Service. In some circumstances, when running multiple agents on one machine for instance, you may not want to remove the entire MySQL Enterprise Monitor Agent Service but only a single monitored server.

#### 15.3.7.1. Removing the MySQL Enterprise Monitor: Windows

##### Removing the MySQL Enterprise Service Manager

Remove the MySQL Enterprise Service Manager by going to the [Control Panel](#) and choosing [Add or Remove Programs](#). Find the entry for [MySQL Enterprise Monitoring and Advisory Service](#) and remove it. During the uninstall process you will be given the option of saving existing data and log files. Choose this option if you plan to reinstall the

MySQL Enterprise Monitor.

If you are not saving existing data, after MySQL Enterprise Service Manager has been removed you may delete the `C:\Program Files\MySQL\Enterprise\Monitor` directory.

### Warning

If you chose not to remove existing data and log files when uninstalling MySQL Enterprise Service Manager do **not** remove the `C:\Program Files\MySQL\Enterprise\Monitor` directory. Doing so will delete these files.

If you added the Tomcat/Apache web server to the list of Windows firewall exceptions, remove this service by opening the `Windows Firewall` from the `Control Panel`. Choose the `Exceptions` tab and delete the `Tomcat/Apache` entry.

### Removing MySQL Enterprise Monitor Services Only

When the MySQL Enterprise Service Manager is installed, the Tomcat/Apache and MySQL server services are started. It is possible to remove these services without also removing your MySQL Enterprise Service Manager installation. For more information about these services see, [Section 15.3.2.5, “Starting/Stopping the MySQL Enterprise Monitor Service on Windows”](#).

Do this by finding the `MySQL Enterprise Monitor` menu option and choosing `Services` and then `Uninstall MySQL Enterprise Monitor Services`. This will remove all the services associated with MySQL Enterprise Service Manager.

You can confirm that these services have been removed by checking services in the Microsoft Management Console Services window.

If you wish to reinstall these services you can do this by using the `Install MySQL Enterprise Monitor Services` menu option.

It is also possible to remove services using the `mysqlmonitorctl.bat` file found in the `C:\Program Files\MySQL\Enterprise\Monitor` directory. To see the available options, go to the command line and type: `mysqlnet-workctrl help`. This batch file is discussed in more detail in [Section 15.3.2.5, “Starting/Stopping the MySQL Enterprise Monitor Service on Windows”](#).

### Removing the Monitor Agent

To remove the Monitor Agent itself, open the `Control Panel` and choose `Add or Remove Programs`. Find the entry for `MySQL Enterprise Monitor Agent` and remove it. This will execute the uninstall program located in the `C:\Program Files\MySQL\MySQL\Enterprise\Agent` directory.

### Warning

If you are running more than one agent on the same machine and wish to remove only one of the agents, do **not** remove the `MySQL Enterprise Monitor Agent` entry from the `Add or Remove Programs` menu. To remove a single agent see [Removing a Single Agent \[1372\]](#)

After removing the Monitor Agent you may also need to remove the directories, `C:\Program Files\MySQL\Enterprise` and `C:\Program Files\MySQL\Enterprise\Agent`.

Removing the Monitor Agent in this fashion will remove the default service. However, if you are running additional Monitor Agents as described in [Section 15.3.3.6.2, “MySQL Server \(agent-instance.ini\) Configuration”](#), you will have to remove those agents manually. See the next section for instructions on doing this.

### Removing a Single Agent

If you are running more than one agent on the same machine and wish to remove only one of the agents, do **not** remove the `MySQL Enterprise Monitor Agent` entry from the `Add or Remove Programs` menu. To remove a single agent and leave other agents intact follow these steps:

1. Stop the agent
2. Confirm the location of the log files
3. Remove the agent as a service
4. Remove/Archive the associated files

It is best to stop the agent before removing it; for instructions on stopping an agent see, [Section 15.3.3.5.1, “Starting/Stopping the Agent on Windows”](#).

You can confirm the location of the agent log files by checking the `ini` file. For more information on this topic see [Sec-](#)

tion 15.3.3.6.1, “MySQL Enterprise Monitor Agent (`mysql-monitor-agent.ini`) Configuration”.

Go to the command line and remove the MySQL Enterprise Monitor Agent as a Windows service by typing:

```
shell> sc delete AgentName
```

You can confirm that the agent has been removed by checking the Microsoft Management Console Services window. There should no longer be an entry for the removed agent.

You should also remove or archive any log or configuration files associated with this agent. If you have installed any additional agents, remove them in the same fashion.

## 15.3.7.2. Removing the MySQL Enterprise Monitor: Unix

### Removing the MySQL Enterprise Service Manager

To remove the MySQL Enterprise Service Manager, find the `uninstall` file in the `/opt/mysql/enterprise/monitor` directory.

Execute this file by typing:

```
shell> ./uninstall
```

During the uninstall process you will be given the option of saving existing data and log files. Choose this option if you plan to re-install the MySQL Enterprise Monitor.

If you are not saving existing data, after uninstalling the MySQL Enterprise Service Manager you may remove the `/opt/mysql/enterprise/monitor` directory.

#### Warning

If you chose not to remove existing data and log files when uninstalling the MySQL Enterprise Monitor do **not** remove the `/opt/mysql/enterprise/monitor` directory; doing so will delete these files.

On Red Hat Enterprise Linux 4 and Fedora Core 4, the uninstall script may not stop the Tomcat server. Do this manually if necessary. To do this see, [Section 15.3.2.6, “Starting/Stopping the MySQL Enterprise Monitor Service on Unix and Mac OS X”](#).

There may be other Java processes running on your system. Be careful not to accidentally stop them.

On some Unix platforms, including HP-UX, you may have to manually delete the `uninstall` application and the installation directory after you have execute the uninstall process.

### Removing the Monitor Agent

Prior to removal of the Monitor Agent Service you should stop any agents. Do this by changing to the `init.d` directory and issuing the command, `./mysql-monitor-agent stop`.

You will find the `uninstall` file in the `/opt/mysql/enterprise/agent` directory. Execute this file by navigating to this directory and typing:

```
shell> ./uninstall
```

After uninstalling the Monitor Agent you may remove the `/opt/mysql/enterprise/agent` directory.

Removing the Monitor Agent in this fashion will remove the default service, and all the configuration files for different instances.

### Removing a Single Agent

If you are running more than one agent on the same machine and wish to remove only one of the agents, do **not** run the uninstall program. To remove a single agent and leave other agents intact follow these steps:

1. Stop the agent
2. Confirm the location of the log files
3. Remove the agent as a service
4. Remove/Archive associated files

It is best to stop the agent before removing it; for instructions on stopping an agent see [Section 15.3.3.5.3, “Starting/Stopping the Agent on Unix”](#).

You can confirm the location of the agent log files by checking the `ini` file. For more information on this topic see [Section 15.3.6.1, “MySQL Enterprise Monitor Agent \(`mysql-monitor-agent.ini`\) Configuration”](#).

You may then remove the agent as a daemon by removing its entry in the `init.d` directory. You should also remove or archive any log or configuration files associated with this agent.

If you have installed any additional agents, remove them in the same fashion.

### 15.3.7.3. Removing the MySQL Enterprise Monitor Mac OS X

#### Removing the MySQL Enterprise Service Manager

To remove the MySQL Enterprise Service Manager, run the `uninstall.app` located in the `/Applications/mysql/enterprise/monitor/` directory, or the root directory of your MySQL Enterprise Service Manager installation.

During the uninstall process you will be given the option of saving existing data and log files. Choose this option if you plan to re-install the MySQL Enterprise Monitor.

If you are not saving existing data, after uninstalling the MySQL Enterprise Service Manager you may remove the `/Applications/mysql/enterprise/monitor` directory.

#### Warning

If you chose not to remove existing data and log files when uninstalling the MySQL Enterprise Monitor do not remove the `/Applications/mysql/enterprise/monitor` directory; doing so will delete these files.

#### Removing the Monitor Agent

Prior to removal of the MySQL Enterprise Monitor Agent you should stop any agents. Do this by changing to the `init.d` directory and issuing the command:

```
shell> ./mysql-monitor-agent stop
```

Run the `uninstall.app` file located in the `/Applications/mysql/enterprise/agent` directory.

After uninstalling the MySQL Enterprise Monitor Agent you may remove the `/Applications/mysql/enterprise/agent` directory.

Removing the MySQL Enterprise Monitor Agent in this fashion will remove the default service, and all the configuration files for different instances.

#### Removing a Single Agent

If you are running more than one agent on the same machine and wish to remove only one of the agents, do not run the `uninstall` program.

To remove a single agent and leave other agents intact follow these steps:

1. Stop the agent
2. Confirm the location of the log files
3. Remove the agent as a daemon
4. Remove/Archive associated files

It is best to stop the agent before removing it; for instructions on stopping an agent see [Section 15.3.3.5.2, “Starting/Stopping the Agent on Mac OS X”](#).

You can confirm the location of the agent log files by checking the `ini` file. For more information on this topic see [Section 15.3.6.1, “MySQL Enterprise Monitor Agent \(`mysql-monitor-agent.ini`\) Configuration”](#).

You may then remove the agent as a daemon by removing its entry in the `init.d` directory.

You should also remove or archive any log or configuration files associated with this agent.

If you have installed any additional agents, remove them in the same fashion.

## 15.4. MySQL Enterprise Dashboard

### Note

MySQL Enterprise subscription, MySQL Enterprise Monitor, MySQL Replication Monitor, and MySQL Query Analyzer are only available to commercial customers. To learn more, see: <http://www.mysql.com/products/enterprise/features.html>.

The purpose of the MySQL Enterprise Dashboard is to provide you with information about your MySQL servers. It provides a list of the latest MySQL Enterprise Advisor reports, server status information, MySQL Enterprise alerts, and updated views of monitored MySQL servers. The [Monitor](#) screen gives a quick overview of the status of your MySQL servers.

The MySQL Enterprise Dashboard interface is provided through a standard web browser. For more details on the supported browsers, see [Section 15.12.2, “Supported Browsers”](#).

You can open the Dashboard and connect to the MySQL Enterprise Dashboard either using the standard HTTP protocol, or using an SSL connection (HTTPS). By default, you can connect to MySQL Enterprise Dashboard using <http://host:18080>, where `host` is the hostname or IP address of the MySQL Enterprise Service Manager. The default SSL URL is <http://host:18443>. These values can be overridden during installation. You can check the configured values by looking at the `configuration_report.txt` file within your installation directory.

### Note

If you are connecting using SSL, the built-in certificate has been self-signed and may be highlighted as 'unsafe' within the browser on initial connection. You should add an exception for the certificate on this server to prevent problems accessing the site.

The Monitoring page provides an instant health check for all of the MySQL servers across the enterprise.

From this page users can:

- View monitoring data and all critical MySQL Advisor Rule violations for all or selected servers.
- Close and annotate MySQL Advisor Rule violations.
- Quickly determine if there is a Monitor Agent that is not communicating with the Service Manager.
- Quickly determine if there is a server that is in trouble or completely down.
- View indicator value graphs for key MySQL and operating system (OS) level metrics. Graph presentation will default to a thumbnail view but will open into a larger image upon being clicked.

The monitored server or servers are displayed in a tab on the left known as the [Server Tree](#). You can navigate to a number of pages that provide more detailed information. These pages include:

- [Monitor](#): The overview page providing you with a quick summary of the servers, their status, events, availability and load. The remainder of this chapter details the contents of this page.
- [Advisors](#): Shows the various advisors configured in your installation and allows you to schedule their execution on different servers, apply and manage rules and manage the advisor installation itself. For more information, see [Section 15.7, “The Advisors Page”](#).
- [EVENTS](#): Provides an interface into the event system that highlights specific issues and problems on your monitored servers. For more information on using Events, see [Section 15.8, “The Events Page”](#).
- [Query Analyzer](#): Interfaces to the query monitoring system that can be used to monitor and track the individual queries that are being executed on a system and help to highlight problem queries that may need optimization or that may be affecting server load. For more information, see [Section 15.10, “The Query Analyzer Page”](#).
- [Graphs](#): Enables you to view and configure a number of individual graphs covering a range of different statistics. For more details on how to view and use these graphs, see [Section 15.9, “The Graphs Page”](#).
- [Replication](#): Provides information on the status and structure of your servers that are using replication. This page is only available if you have a suitable subscription level. For more information, see [Section 15.11, “The Replication Page”](#).

- **Settings**: Controls the settings for the server, including email configuration, passwords, and server and user management. For more information, see [Section 15.5, “The Settings Page”](#).

Graphs are shown in the center of the page beneath the tabs. If applicable, you'll also find a list of critical events.

On the right is the color-coded **Heat Chart**, showing the advisors that are installed by default. The **Heat Chart** shows the most important advisors, allowing a quick overview of the state of your servers. You may open the **Heat Chart** in its own window by clicking the [Standalone Heat Chart](#) link. If applicable, you'll also find a list of critical events.

The [Show/Hide Legend](#) link toggles display of the key to the icons used in the **Heat Chart**.

#### Note

Find colorblind-accessible icons in the [alternate](#) directory. On Linux this directory is immediately below the [/monitor/apache-tomcat/webapps/ROOT/web/resources/images/](#) directory. These images are stored in the same directory on Windows. To use them, backup the originals and then copy and paste the alternate set into the [images](#) directory.

If a specific server is selected in the **Server Tree** details about this server are shown beneath the legend in the **Meta Info** area. The information shown in this area is the host name, the MySQL version number, the number of scheduled rules, the operating system, and the CPU.

The **Meta Info** section also shows how long the agent has been running, when it last contacted the MySQL server it is monitoring, and the last time the agent contacted the dashboard. Mouse over the date shown beside **UP SINCE** and a pop-up box displays the time that has elapsed since the server instance was last started. You can also mouse over the **LAST MySQL CONTACT** and the **LAST AGENT CONTACT** dates.

#### Note

In the case of remote monitoring, the agent runs on a different machine than the MySQL server that it is monitoring. The **Hostname**, **MySQL**, and **Rules** information applies to the system being monitored. The **OS** and **CPU** information applies to the machine on which the agent is running. For more information about remote monitoring see, [Section 15.3.3.6.4, “Configuring an Agent to Monitor a Remote MySQL Server”](#).

The top of the screen shows the refresh cycle and [Help](#) and [Log Out](#) links. Click the [Help](#) link to open the documentation in a separate browser window. Choose [Log Out](#) if you wish to leave the Dashboard or to log in as a different user. Different refresh rates are available from the drop-down listbox.

In the footer are external links to MySQL Enterprise and information about the current user. Users can remain connected to the Dashboard and update their subscription, use the Enterprise Knowledge Base, and contact technical support. Your subscription information is also displayed here, showing the number of days remaining and the number of licenses. The number of licenses indicates to the number of machines that may be monitored; any number of MySQL servers may be running on a specific machine.

The footer also contains a link to the **Settings** page. If your subscription is current it reads **SUBSCRIPTION IS UP-TO-DATE**. **MORE INFO.....** For more information about the **Settings** page see [Section 15.5.7, “The Product Information Screen”](#).

### 15.4.1. The Server Tree

The tab on the left displays the Server tree. By default the first group of servers is selected. This selection determines the information shown on the [Monitor](#) page.

If a server group is selected, the information presented on the [Monitor](#) page is aggregate information for this group; if only one server is selected the information applies to that server only.

Change your server selection and the information shown in the graphs and in the **Heat Chart** changes.

#### Note

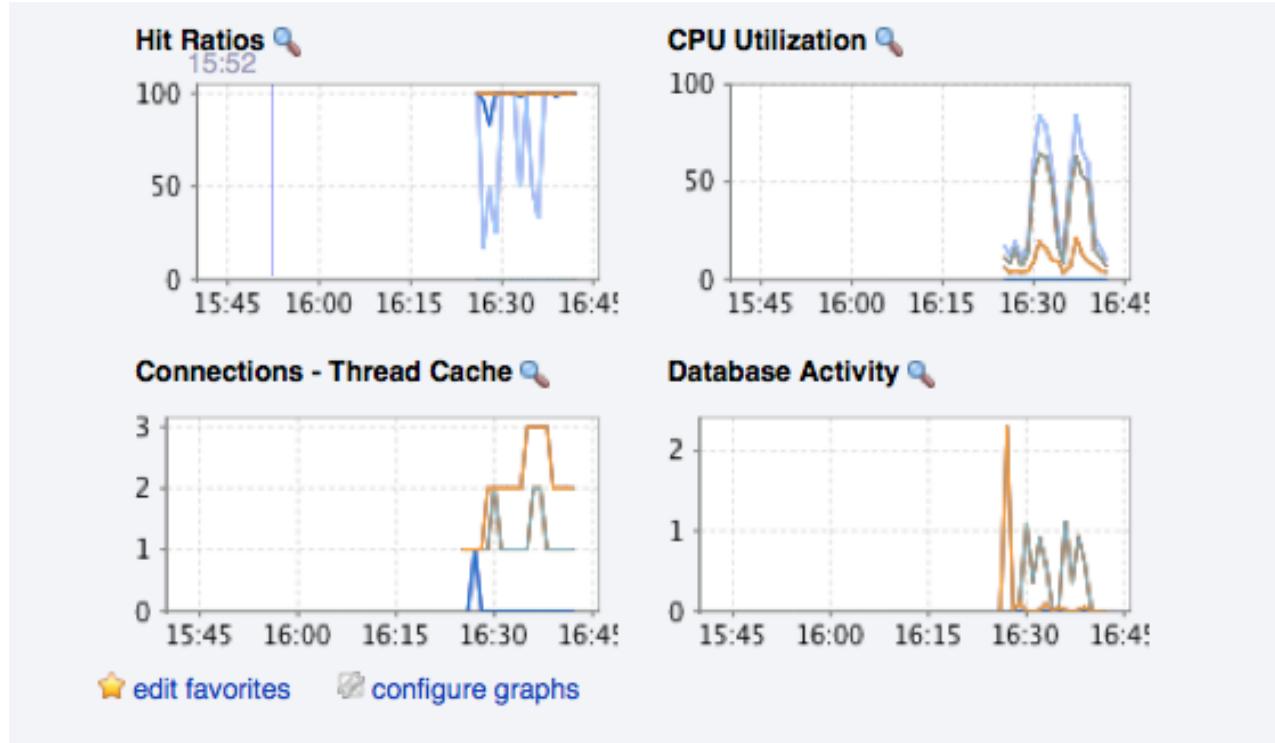

For more information about server groups see, [Section 15.5.3.2, “Grouping Servers”](#).

The individual server, or server group, selected in the Server Tree also determines what information appears when the **Advisors** tab or the **EVENTS** tab is selected.

The Server Tree presents an easy way to navigate to different groups or to specific servers.

### 15.4.2. The Server Graphs and Critical Events

The center of the [Monitor](#) page gives a visual representation of the state of your servers.

**Figure 15.29. MySQL Enterprise Dashboard: The Graphs Screen**

The graphs present information about the currently selected server or server group. The default graphs show the hit ratios, CPU utilization, connections, and database activity for a specific interval.

Graphs also provide an entry point for examining the operations on a server in relation to the queries that were being on the server at the time. The plots of the graph are correlated with the queries that are being executed at that time, enabling you to monitor your server usage more effectively. By clicking and dragging on a graph you can zoom in on the graph content and then view the queries that were being executed during the specified period to gain a better insight into the operation of your servers. This information is only available if you have configured query analysis, and have enabled query analysis for the servers you are monitoring. For more information, see [Section 15.10, “The Query Analyzer Page”](#).

To set the interval click the [configure graphs](#) link immediately below the graphs. This opens a dialog box where you can choose the default interval for the x-axis of the graphs. Defining a shorter or longer interval gives you a shorter or longer term view of server activity. The thumbnail and full-size graph dimensions can also be adjusted from this dialog box. Save any changes that you have made and the values chosen will be the defaults whenever you log in.

You can also choose the default graphs shown on the [Monitor](#) page. To do this click the [edit favorites](#) link and choose the graphs you want from the drop-down list box. To choose contiguous graphs, hold down the **Shift** key and click the desired graphs. For a noncontiguous selection, click the desired graphs while holding down the **Ctrl** key. The maximum number of graphs that can be displayed on the [Monitor](#) page is six. Save your changes and these will be the default graphs whenever you log in.

Color coding helps distinguish different aspects of each graph. With [Database Activity](#) for example, you can readily distinguish [SELECT](#) statements from database insertions.

Clicking a graph opens a detailed view with **GRAPH DISPLAY** and **CONFIGURE** tabs. Choose the [Configure](#) tab to temporarily change the way that a graph displays. Changes made from this tab only apply to the standalone graph while it is open. Persistent changes are made as described above.

Dismiss the enlarged graph by clicking the **HIDE** button.

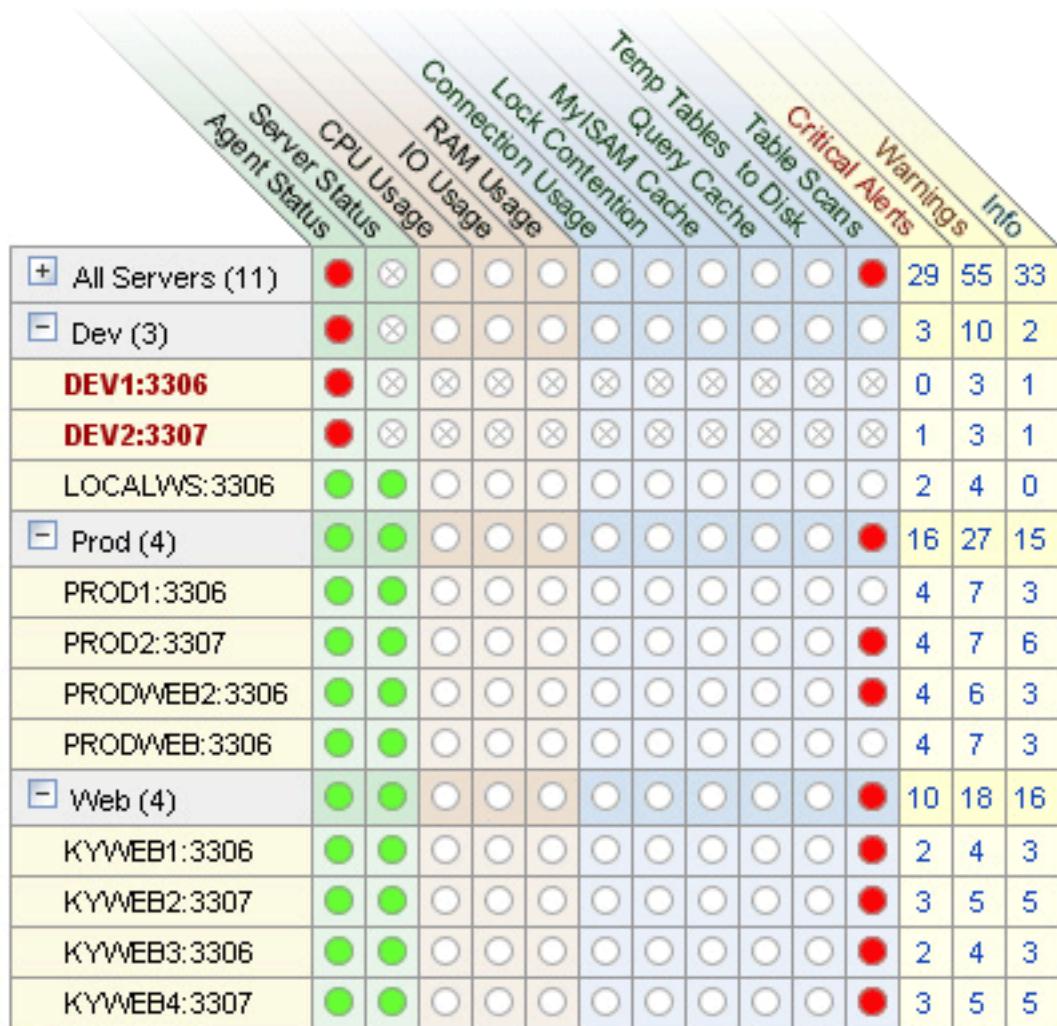

Alerts from the event system will be displayed immediately below the charts. For more information on the events display, see [Section 15.8, “The Events Page”](#).

### 15.4.3. The Heat Chart

The [Heat Chart](#) is found on the right side of the [Monitor](#) page and shows the status of critical rules. Monitored servers are organized by groups. To view the status of a specific server, click the + button next to the appropriate server group.

Whenever a new agent contacts the Service Manager for the first time, all the rules in the Heat Chart Advisor are automatically activated. These Advisors monitor the status of the server and agent, critical operating system indicators, and important events related to your MySQL servers. An example follows.

**Figure 15.30. MySQL Enterprise Dashboard: The Heat Chart**

To interpret the Heat Chart see the following legend.

**Figure 15.31. MySQL Enterprise Dashboard: The Heat Chart Legend**

Server & Agent Status	Monitored Events
● up	○ ok
● down	● info
○ unknown	● warning
	● critical
	○ unknown

The status `unknown` will typically apply when an agent is down and can no longer report the status of the server that it is monitoring. The status `unknown` may also apply if the data collection that should be collected is not available on the server being monitored.

You may open the Heat Chart in its own browser window by clicking the [Standalone Heat Chart](#) link immediately below the [Heat Chart](#) on the left. If you like, the refresh rate can be set to a different rate than the setting on the [Monitor](#) page.

In addition to showing the most important advisors, the [Heat Chart](#) also has columns that display the number of critical, warning, and informational alarms. Clicking the hyperlink in any one of these columns takes you to the [Event](#) screen, which gives more detailed information. For more information about events see, [Section 15.8, “The Events Page”](#).

When the Dashboard is first installed no notification groups are associated with the Advisors shown in the Heat Chart. For more information on this topic see, [Section 15.3.2.7.3, “Installing Advisors After Initial Log-in”](#) and, [Section 15.5.5, “Manage Notification Groups”](#).

## 15.5. The Settings Page

### Note

MySQL Enterprise subscription, MySQL Enterprise Monitor, MySQL Replication Monitor, and MySQL Query Analyzer are only available to commercial customers. To learn more, see: <http://www.mysql.com/products/enterprise/features.html>.

Upon initial installation you may have configured your MySQL Enterprise credentials and also outgoing email settings. This section explores the configuration settings in more detail, and also shows how to manage servers, users, notification groups, Simple Network Management Protocol (SNMP) traps, log files, and the product information screen.

Knowledge of server management is a prerequisite for properly configuring advisors—the subject of [Section 15.7, “The Advisors Page”](#).

To get to the [Settings](#) page open the Dashboard and choose the [Settings](#) tab.

### 15.5.1. Global Settings

The **GLOBAL SETTINGS** control the main configuration parameters for the entire MySQL Enterprise Monitor system, including your email notifications, data purge, and Enterprise website credentials.

**Figure 15.32. MySQL Enterprise Dashboard: Settings**

**Outgoing Email Settings**

Enable Email Notifications  
From Address (ex. "MySQL Dashboard" <name@domain.com>)

**SMTP Server**

**SMTP Server Login**

Disable JavaMail TLS/SSL

Update Password On Save

SMTP Server Password      Confirm Password

**On Save, Send Test Email Message to (optional)**

**Data Purge Behavior**

Remove Historical Data Collection Older Than  
4 weeks

Remove Service Manager Logs Older Than  
never

Remove Query Analyzer Data Older Than  
4 weeks

**Remote Server Inventory Schedule**

Re-inventory Remote Servers Every  
12 hours

This will re-inventory all connected servers. The information collected may be used in custom data collection.

**MySQL Enterprise Credentials**

These credentials are used to login to MySQL Enterprise at mysql.com to enable subscription updates and to login to support.mysql.com to check the status of open Support issues.

Email Address (MySQL Enterprise Login)

Enterprise Password (MySQL Enterprise Password)

Confirm Password

**HTTP Proxy Settings**

Proxy Host:port

Proxy Username

Proxy Password      Confirm Password

**MySQL Enterprise Product Key**

If this server cannot connect to mysql.com to verify subscription information, you can manually import this information from enterprise.mysql.com.

MySQL Enterprise Product Key  
 no file selected

**Advisor Bundle**

Import Advisors and Graphs from file (\*.jar)  
 no file selected

Update Advisors and Graphs  
Click the button below to retrieve the latest Advisor Rules and Graphs from MySQL.

The **GLOBAL SETTINGS** page is divided into a number of different sections:

- **OUTGOING EMAIL SETTINGS**

Configures the settings for email notifications by MySQL Enterprise Service Manager. You must configure the **FROM ADDRESS** **SMTP SERVER** settings. If your server requires authorization, complete the necessary server login details, and whether SSL is required.

You can test your configuration immediately by adding an email address to the **ON SAVE, SEND TEST EMAIL MESSAGE TO** box.

For more information about [Outgoing Email Settings](#) see, [Section 15.3.2.7.5, “Outgoing Email Settings”](#).

- **SNMP TRAPS**

The **SNMP TRAPS** section of the **GLOBAL SETTINGS** tab allows you to enable Simple Network Management Protocol so that your Network Management System (NMS) can handle events created by the MySQL Enterprise Monitor. SNMP notifications are off by default. You can enable them by clicking the **ENABLE SNMP NOTIFICATIONS** checkbox.

MySQL Enterprise Service Manager includes support for both SNMPv1 and SNMPv2. You can select the SNMP version to use

by clicking the corresponding **USE SNMPV1** or **USE SNMPV2** radio button.

In the **TARGET 1** or **TARGET 2** text box enter the IP address or hostnames of your NMS listeners. The port number defaults to the well-known SNMP port, [162](#). If you are not using this port, enter the port that your Network Management System is listening on.

Enter the appropriate community string in the **Community String** text box. The default value for this string is **public**.

For the trap address for Advisor traps, you can optionally elect to use the address of the agent that triggered the alert, rather than the address of the MySQL Enterprise Service Manager. To do this, click the **USE THE REMOTE MYSQL AGENT HOST IP ADDRESS AS THE SNMP TRAP AGENT ADDRESS FOR ADVISOR TRAPS**. For internally generated SNMP traps (i.e. with MySQL Enterprise Service Manager) you can also specify an alternate address by putting the IP address in the **SNMP TRAP AGENT ADDRESS FOR INTERNALLY GENERATED TRAPS** box.

To ensure that the target you have specified is valid, check the **On Save, Send Test Trap** check box. The remaining check boxes help you to configure how your NMS responds to MySQL Enterprise Monitor. Check the **UP/DOWN APPLICATION** check box to configure NMS for starting up or shutting down the MySQL Enterprise Monitor. For configuration of advisor events choose a level of severity and check the **ADVISOR EVENT WITH THE SEVERITY OF CRITICAL** check box. Finally, choose the **APPLICATION ERROR** check box to configure NMS to support application error traps. Be sure to save your settings before exiting.

If you wish to enable SNMP traps globally, check the **Enable SNMP Notifications** checkbox. To enable SNMP traps only for specific rules run against specific servers or server groups leave this checkbox unchecked—enabling specific SNMP traps is done as rules are scheduled. For instructions on doing this see [Section 15.7.2, “Scheduling Rules”](#).

The Management Information Base (MIB) file associated with SNMP trapping is called **MONITOR.MIB**. For the location this file see [The Management Information Base \(MIB\) File](#).

### Note

The MIB file supplied with MySQL Enterprise Service Manager is not directly compatible with OpenNMS. For a sample of the modifications that need to be made, please see the comments for [Bug#41714](#).

- **SERVER LOCALE**

The **Server Locale** setting determines the language of notification for the following items:

- Email notifications
- SNMP traps
- The naming conventions for shared resources such as a replication group name prefix

The initial value in this drop down list box is the locale for the OS on which the Dashboard is running.

- **SERVER HOSTNAME**

You can alter the hostname and port used to identify the MySQL Enterprise Service Manager when reporting notifications. This can be useful if the server hostname, and the hostname you want to use when connecting to your MySQL Enterprise Service Manager

### Note

Only change the **PORT** setting if you have altered or redirected the original port used when installing MySQL Enterprise Service Manager. Entering the incorrect information will not affect the accessibility of your system, except when clicking links within the notification messages.

You can also alter the name for the server displayed in the login page by changing the value in the **LOGIN DISPLAY NAME**. You may want to use this to display an organizational or divisional title, rather than the hostname, of the MySQL Enterprise Service Manager.

- **DATA PURGE BEHAVIOR**

The **Data Purge Behavior** section of the [Global Preferences](#) page lets you remove old log files and also old data from the repository. The default purge interval is **28 days**. If you wish to purge data, change this setting by choosing from the drop-down list. Choosing **52 weeks**, for example, will remove all data that is older than a year.

### Warning

Purging data will permanently remove information from the repository. Since events are derived from data contained

in the repository, they will be purged along with the data.

Ensure that there is adequate disk space for the repository. If you are monitoring numerous servers and running many rules the size of the repository can increase rapidly. Choose purge behavior accordingly.

The default value for purging, `never`, is the safest option. However, please choose a purge setting that makes sense for your environment.

### Note

The purge process is started approximately once every minute. If you change the purge duration from a larger timespan to a smaller one, the data may start to be purged immediately.

You can configure the data purge behavior for a number of different systems individually:

- **Remove Historical Data Collection Older Than** configures the duration that the main data about your servers is retained. This includes all data collections, including CPU, memory and connections and activity statistics.
- **Remove Service Manager Logs Older Than** configures the duration that the main MySQL Enterprise Service Manager logs are retained.
- **Remove Query Analyzer Data Older Than** configures the duration that the query analyzer statistics and information about individual queries is retained.

Notes for setting purge behavior:

- Purging can be carried out manually by enabling the `innodb_file_per_table` for the repository database and then using an `OPTIMIZE TABLE` operation to reclaim space from deleted rows in the table.
- If you set the purge value to a very low timespan value when the previous setting was quite high then the space used for the data that was purged will not be reclaimed from the InnoDB tablespaces. You can do this by running `OPTIMIZE TABLE` on the MySQL tables for MySQL Enterprise Service Manager to reclaim the space from the purged rows.
- You cannot set the Query Analyzer purge period to a value greater than historical data collection purge period. If you attempt to do so you will get a warning: `An invalid Query Analyzer data life span was given. Value may not be larger than data life span..`

- **REMOTE SERVER INVENTORY SCHEDULE**

MySQL Enterprise Monitor keeps track of all the databases and tables in a server, as well as the amount of RAM, disk space, and other items. A re-inventory updates this information in case you have added or dropped databases and tables. Depending upon the configuration of your system, this operation can tax resources. If you are monitoring many remote servers this is an operation you may want to perform in off-peak hours only.

- **MYSQL ENTERPRISE CREDENTIALS**

You can specify the credentials for logging into the MySQL Enterprise Website. These should match the user name and password that you have registered with MySQL for your enterprise subscription.

### Note

Only administrators can change the `MySQL Enterprise Credentials` section or enter a product key; for other users, this section does not show up in the interface. For more information about different users and their rights see [Section 15.5.4, “Managing Users”](#). Specifying incorrect credentials results in the error message, “Your credentials do not appear to be valid.”

- **HTTP PROXY SETTINGS**

You may want to update your HTTP Proxy Settings if your MySQL Enterprise Service Manager is not directly connected to the internet. The proxy settings will be used when updating the information within the What's New page and when accessing the [MySQL Enterprise Website](#) for authentication of your license and product key information. For more information, see [Section 15.6, “The What's New Page”](#).

- **MYSQL ENTERPRISE PRODUCT KEY**

You may update your `MySQL Enterprise Product Key`. If you do not have access to the Internet from the Dashboard, this provides an alternate way to update or activate the MySQL Enterprise Monitor.

To enter your product key first download it from the MySQL Enterprise website. Copy the key to a location accessible from the Dashboard. Use the **BROWSE** button to locate the key and then press the **SAVE** button.

If you wish to switch from using your MySQL Enterprise credentials to using a product key to update MySQL Enterprise Monitor, you must first clear your credentials. Do this by removing the email address from the **MYSQL ENTERPRISE CREDENTIALS** section and then clicking the **SAVE** button. You may then enter and save your MySQL Enterprise product key.

### Note

Only administrators can change the **MySQL Enterprise Credentials** section or enter a product key; for other users, this section does not show up in the interface. For more information about different users and their rights see [Section 15.5.4, “Managing Users”](#). Specifying incorrect credentials results in the error message, “Your credentials do not appear to be valid.”

- **ADVISOR BUNDLE**

You can update your Advisor Bundle and the associated rules and graphs by importing a new Advisor Bundle. To update your Advisor Bundle using a bundle file that you have previously downloaded:

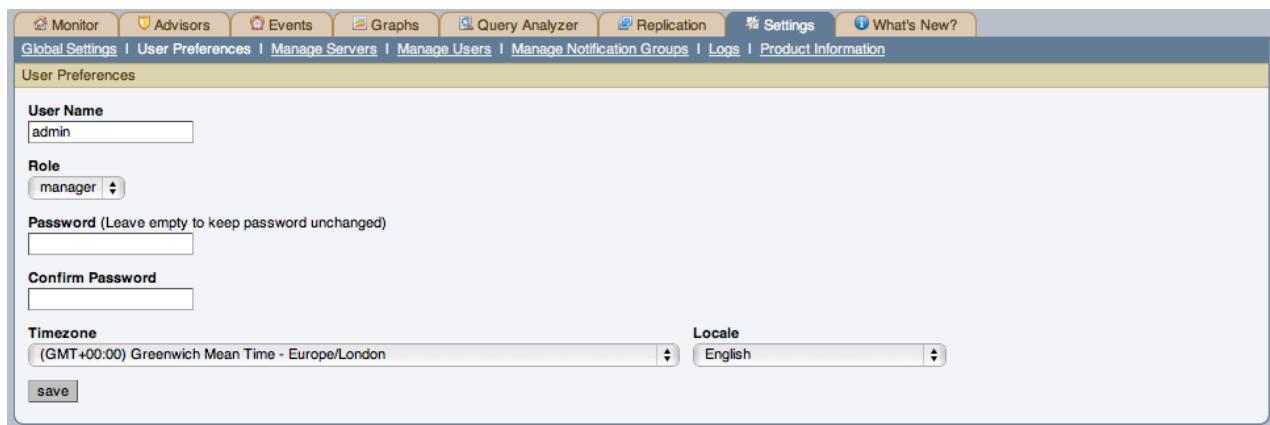

1. Click **CHOOSE FILE** and locate your Advisor Bundle on your computer.
2. Click **SAVE** to upload the updated bundle and validate the contents.

To update the Advisor Bundle automatically from the [MySQL Enterprise Website](#) using your existing MySQL Enterprise Credentials, click the **UPDATE ADVISORS** button.

## 15.5.2. User Preferences

On this page users can change their passwords, user names, and locale information.

**Figure 15.33. MySQL Enterprise Dashboard: User Preferences**

Change your password by entering a new value into the **PASSWORD** text box. To change your user name enter a new value into the **USERNAME** text box. Click the **SAVE USER PROPERTIES** button to commit this change.

You may also adjust your time zone and locale information from this page. The settings on this page apply only to the user who is currently logged in.

The MySQL Enterprise Service Manager determines the default value for the locale by looking at your browser settings. Changing this value, determines the language setting for any future logins to the Dashboard, overriding your browser settings.

### Note

Be sure to set the correct time zone so that alerts are time stamped correctly.

This setting applies only to the specific user.

## 15.5.3. Manage Servers

To help with server management, the Service Manager supports the logical grouping of MySQL servers. This allows you to group servers in any fashion you choose. For example, you can manage servers according to purpose. You can group servers by whether the servers handle Internet or intranet data, by whether they power finance or HR applications, or, if you prefer, you may organize

them by physical location rather than by functionality.

**Figure 15.34. MySQL Enterprise Dashboard: Manage Servers**

Server	Query Analyzer			MySQL	Up Since	Last MySQL	Agent	Last Agent	Port	Data Dir	Reporting Delay
	Enabled	Examples	Explains								
All Servers (2)	Off	Off	Off	5.0.70-log	Aug 29, 2009 6:09:29 PM	Jan 15, 2010 10:59:01 AM	2.2.0.1606	Jan 15, 2010 10:59:13 AM	3306	/mnt/data1/mysql/db/	137 ms ahead
bear:3306 (ungrouped)	Off	Off	Off	5.1.30	Jan 12, 2010 3:56:25 PM	Jan 15, 2010 10:56:02 AM	2.2.0.1580	Jan 15, 2010 10:59:15 AM	3306	/var/mysql/5.1/data/	about 3 m behind
tiger:3306 (ungrouped)	Off	Off	Off								

For a server to appear in the Dashboard there must be an agent monitoring it. If you wish to add a server to the Dashboard follow the procedure for installing an agent found at [Section 15.3.3, “Monitor Agent Installation”](#). Instructions for adding a remote server are found at [Section 15.3.3.6.4, “Configuring an Agent to Monitor a Remote MySQL Server”](#).

The **MANAGE SERVERS** panel also allows you to control the Query Analyzer and Data Migration. For more information, see [Section 15.10.7, “Query Analyzer Settings”](#) and [Section 15.12.9, “Migrating 1.3.x Historical Data to MySQL Enterprise Monitor 2.0”](#).

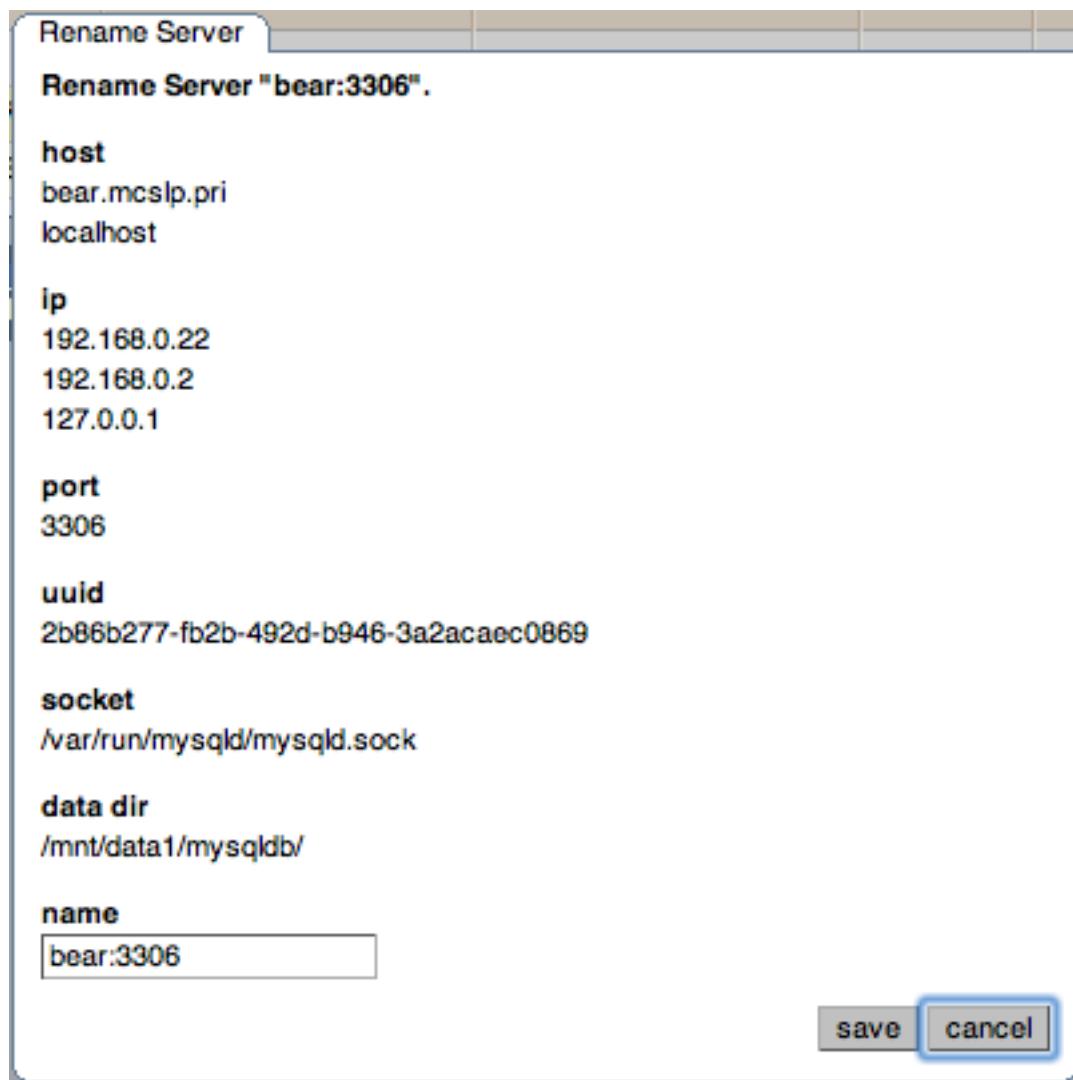

#### Note

The **ALL SERVERS** group is built in and every monitored server is a member of this group.

### 15.5.3.1. Renaming a Server

You can rename an existing server without losing the current historical data or configuration information. Renaming the server also allows you to modify the name of the server to be more descriptive according to the server's role within your organization. For example, you may want to rename a server from the default host name to include the department and application for the MySQL server.

**Figure 15.35. MySQL Enterprise Dashboard: Server Renaming**

#### **Note**

Renaming a server using the **MANAGE SERVERS** tab overrides all other settings, including changes made within the agent configuration.

### 15.5.3.2. Grouping Servers

All monitored servers are automatically included in the top level server grouping, **ALL SERVERS**. Other server groupings are replication groups or user-defined groups.

You can create a user-defined group by clicking the **MANAGE SERVERS** link. Add a group name and then click the **CREATE GROUP** button. The new group will be displayed immediately.

Replication groups are automatically discovered by MySQL Enterprise Monitor and in this respect differ from user-defined groups. For more information about replication groups see [Section 15.11, “The Replication Page”](#). However, like user-defined groups you can edit the name of a replication group and add other servers to it.

To add to a group, select the [add to group](#) link. Choose the server or servers you wish to add and then complete the operation by choosing the **ADD TO GROUP** button. You can add a server to a group even if the agent is down.

To remove a server from a group expand the server group tree and click the [remove from group](#) link. To delete a server altogether see [Section 15.5.3.3, “Removing a Server From the Dashboard”](#).

#### **Note**

Slaves removed from a replication group will be rediscovered and re-added to that group.

To delete an group, you can use the **DELETE GROUP** link. This will delete the group and remove the servers from being part of the deleted group.

### Warning

You cannot delete automatically created groups, such as those built during replication discovery, unless the group is empty. If the group is not empty, you will get an error.

There are three ways to modify an existing group; by renaming it, adding to it, or removing it. Select the **rename** link to change the name of a group and **add to group** to add servers. Deleting a group simply requires clicking the **remove all from group** link. This removes the server group but has no effect on individual servers.

### 15.5.3.3. Removing a Server From the Dashboard

If you no longer wish to monitor a MySQL server you can remove it from the Dashboard. There is no provision for deleting an active server from the Dashboard—to remove a server you must make it inactive by stopping the agent.

For instructions on stopping an agent see:

- Windows: [Section 15.3.3.5.1, “Starting/Stopping the Agent on Windows”](#)
- Unix: [Section 15.3.3.5.3, “Starting/Stopping the Agent on Unix”](#)
- Mac OS X: [Section 15.3.3.5.2, “Starting/Stopping the Agent on Mac OS X”](#)

Once the agent is stopped you may delete the monitored server. Deleting a server simply means that it will no longer show up in the Dashboard.

Remove a server by choosing the SETTINGS tab and then the **MANAGE SERVERS** link. Find the server you wish to remove and delete it by clicking the **DELETE** link within the pop-up menu. Deleting a server from the **ALL SERVERS** group or from any other group will remove it from the Dashboard entirely.

### Note

A **DELETE** link will not be available for an active server. You must stop the agent before this link will appear.

You may remove a server from any group at any time. Removing the last server from a group also removes that group.

### 15.5.4. Managing Users

The **MANAGE SERVERS** panel allows to create, delete and manage individual users that have access to MySQL Enterprise Service Manager

**Figure 15.36. MySQL Enterprise Dashboard: Manage Users**

To log in to the Dashboard a user account is required. There are three types of users with varying privileges; Administrators, Database Administrators, and Agents. The **Administrator** can create additional users and differs from a **DBA** in this respect. For this reason the **Manage Users** does not display if a DBA user logs in. Additionally, only administrators can change the MySQL Enterprise Credentials section or enter a product key on the **Global Settings** page. These sections do not appear when DBA users log in. For more information on this subject see [Section 15.5.1, “Global Settings”](#). The **Agent** account simply allows the MySQL Enterprise Monitor Agent to communicate with the Dashboard. There is no need for more than one agent account but defining an account for each server that is monitored can be an advantage since this minimizes exposure should any one agent be compromised. You cannot log in to the Dashboard using the agent's credentials.

When the Dashboard is first launched there are two default users, **Administrator** and **Agent**, both created during installation. Their default user names are respectively, **admin** and **agent**. The Administrator defined during installation as having the root role is unique; this user cannot be deleted.

If you are logged in as an **Administrator**, you can add a new user by choosing the **Manage Users** link from the **Settings**

page. To create a user click the CREATE USER button, select a role for the user, and enter a user name and password.

When a new user first logs in, a dialog box opens requesting time zone and locale information. This information may be changed later from the [User Preferences](#) page. For more information, see [Section 15.5.2, “User Preferences”](#).

If you installed the Advisors through the Dashboard you should have already configured the settings for the root role user. (See [Section 15.5.1, “Global Settings”](#) and following for more information about this topic.)

### Warning

To receive MySQL Enterprise and Advisor updates configure the MySQL Enterprise settings for at least one user. The MySQL Enterprise settings were set up on the first login to the Dashboard. For information on changing these settings see, [Section 15.5.1, “Global Settings”](#).

To edit an existing user's information, select the [Manage Users](#) link, then select the user you wish to edit. Make your desired changes in the fields provided and then save your changes.

To delete an existing user, merely select the [delete](#) link.

## 15.5.5. Manage Notification Groups

The **MANAGE NOTIFICATION GROUPS** panels allows you to create and manage the notification groups used when different notifications and warnings are distributed.

**Figure 15.37. MySQL Enterprise Dashboard: Manage Notification Groups**

Group Name	Recipients	SMS	MEM Admin
Admins	admin@example.com	false	true

Notification groups are collections of users who should be notified when advisor alerts occur. These users may have login credentials for the Dashboard but this is not a requirement.

You can create a group by clicking the [create group](#) link. Specify a group name and add recipients. When adding a user an email address must be specified. If you are adding multiple users separate them with commas.

To modify an existing notification group, select the [edit](#) link next to the group name. Deleting a group simply requires clicking the [delete](#) link.

**Figure 15.38. MySQL Enterprise Dashboard: Edit Notification Groups**

If a rule triggers an alarm, an email will be sent to the members of the notification group specified when the rule was scheduled. For more information about scheduling rules see [Section 15.7.2, “Scheduling Rules”](#).

To use this group for notification using the SMS interface, select the checkbox next to **SMS**. This will force the messages to be encoded suitable for sending using SMS. Messages will be sent using the configured SMS service.

You can also optionally select a notification group to be used when sending critical error messages (such as MySQL Enterprise Monitor Agent or MySQL Enterprise Service Manager failures) by selecting the checkbox next to **MEM ADMIN**.

### Note

You should ensure that there is a mail server available for sending out alerts and that there is an account configured for receiving any alerts that are created. For SMS messages, you must ensure that you have configured your SMS service settings.

## 15.5.6. Logs

Use the [Logs](#) link to inspect the various log files associated with the MySQL Enterprise Service Manager. The following image is an example of this screen.

**Figure 15.39. MySQL Enterprise Dashboard: Logs**

Log Name	Threshold	Last Modified	Entries		
All	N/A	Nov 19, 2008 4:07:37 PM	838		
Advisors	Info	Nov 19, 2008 11:44:28 AM	338		
Agent Monitoring	Info	N/A	0		
Agent Tasks	Info	N/A	0		
Data Collection	Info	N/A	0		
Graphs	Info	Nov 19, 2008 11:44:12 AM	4		
Groups	Info	N/A	0		
Inventory	Info	Nov 19, 2008 11:44:24 AM	4		
JDBC	Info	N/A	0		
Misc	Info	Nov 19, 2008 11:44:29 AM	11		
Migration	Info	Nov 19, 2008 1:52:09 PM	340		
Notification	Info	N/A	0		
Preferences	Info	N/A	0		
Replication	Info	N/A	0		
Security	Info	N/A	0		
SQL	Info	N/A	0		
Timing	Info	Nov 19, 2008 4:07:37 PM	140		
Xwork	Warning	N/A	0		
Apache	Warning	Nov 19, 2008 11:26:32 AM	1		
Catalina	Warning	N/A	0		
Hibernate	Warning	N/A	0		
Freemarker	Warning	N/A	0		
Spring	Warning	N/A	0		
EH Cache	Warning	N/A	0		

The various categories of logs are shown in alphabetic order. The most recent changes to each log are shown in the **LAST MODIFIED** column. The number of entries in any specific log is shown under the **ENTRIES** column.

To view detailed information click the [Log Name](#). This will open a separate browser window showing the date, time, alert type, and accompanying message.

On this screen you can filter log information in a couple of ways; by the message type and by time period .

To filter by message type select from the options in the **LEVEL** drop-down box. These are, in order of decreasing severity:

- All
- Error
- Warning
- Information
- Trace
- Debug

You can also adjust the number of items that appear on each page.

Press the [clear all logs](#) link to remove all log entries. To remove entries of a specific kind click the [clear logs](#) link associated with the specific log you would like to remove. A confirmation dialog box allows you to back out of this operation and avoid accidentally removing log information.

To clear log files of a specific age see the [Data Purge Behavior](#) section of the [Global Preferences](#) page. For more information on this topic see [Data Purge Behavior \[1381\]](#).

Use the [edit log level](#) link to change the type of error logged. The value selected from the [Edit Log Level](#) dialog box determines what appears under the **THRESHOLD** column (second from the left in [Data Purge Behavior \[1381\]](#)).

Selecting [Error](#) from the list box will create the least number of log entries and [Debug](#) the most. Choosing [None](#) turns off logging altogether.

It is also possible to download a compressed version of all the log files. For more information, see [Section 15.5.7, “The Product Information Screen”](#).

## 15.5.7. The Product Information Screen

Use the [Product Information](#) link to view detailed information about your subscription level and contract status.

- **Subscription Warnings**

The **SUBSCRIPTION WARNINGS** section contains information unique to your subscription. Information provided here will relate to your subscription settings and the servers currently being monitored. For more information, see [Section 15.5.7.1, “Subscription Warning”](#).

- **Contract Status**

The **CONTRACT STATUS** section displays the subscription level, expiration date, contract number, the number of servers supported, and your MySQL Enterprise user name. The **SUBSCRIPTION LEVEL** section gives more detailed information, including features and any restrictions that may apply. You may update your subscription at any time by clicking the **UPDATE** button.

- **Subscription Information**

The **SUBSCRIPTION INFORMATION** section contains detailed information about your subscription level and the number of hosts currently monitored within your subscription level.

- **Enterprise Dashboard Server Info**

The **ENTERPRISE DASHBOARD SERVER INFO** section provides detailed information about the running of your MySQL Enterprise Service Manager, including information about the Java environment, hostname and version information.

The section also includes detailed information about the current status of your MySQL Enterprise Service Manager, showing information on the agents, rules, and outstanding status of the various components. The information provided in this section is listed below:

- **PENDING HEARTBEATS**
- **PROCESSED HEARTBEATS**
- **PENDING JOBS**
- **NUMBER OF AGENTS**
- **MONITORED MYSQLD INSTANCES**
- **BUILD VERSION**
- **ADVISOR VERSION**
- **NUMBER OF RULES**
- **NUMBER OF GRAPHS**
- **LAST SUCCESSFUL EMAIL**
- **LAST EMAIL FAILURE**
- **LAST FAILURE MESSAGE**

You can monitor the status of the email messages sent by MySQL Enterprise Service Manager by looking at the values of the **LAST SUCCESSFUL EMAIL** and **LAST EMAIL FAILURE** sections. Any failure by MySQL Enterprise Service Manager to send an email will be reported, with the failure date recorded in **LAST EMAIL FAILURE**. You can examine the **LAST FAILURE MESSAGE** field to determine the precise reason for the failure.

- **Readme**

The **README** section contains a copy of the text [Readme](#) file provided with each release, and provides release specific information about your MySQL Enterprise Service Manager installation.

- **Diagnostic Report**

The page includes a hyperlink, **DOWNLOAD DIAGNOSTIC REPORT**. Click this link to download a compressed version of the MySQL Enterprise Service Manager log files. All the log files found on the [Logs](#) page (for more information about logs see [Section 15.5.6, “Logs”](#)) are contained in this file. It also contains the Java properties file, the monitored MySQL servers property file, information about the status of the JDBC connection and Java threads, and the [subscription.xml](#) file. This report is especially useful for debugging the MySQL Enterprise Service Manager and the MySQL Enterprise Monitor Agent.

### 15.5.7.1. Subscription Warning

The [Subscriptions Warning](#) section on the product information page displays any warnings relative to your subscription. For example, if your subscription has expired you may receive a message such as the following:

```
Your Subscription Needs to be Updated
* Your Platinum subscription expired 3 days ago on Feb 14, 2008 11:59:59 PM.
If the subscription information on this page is not current, you can
update it by going to the Enterprise Monitor Global Settings page and
providing MySQL Enterprise credentials or by importing a new product
key that you downloaded from http://www.mysql.com/enterprise/download.php .
To update or renew your subscription, please contact your MySQL
Account Representative at sales@mysql.com or visit
http://www.mysql.com/about/contact/renew.html. After the update or
renewal is complete you can then follow the above instructions for
updating your subscription.
```

Follow these instructions to update your subscription. If you see this message and your subscription has already been updated, simply click the **UPDATE** button in the **CONTRACT STATUS** section of this page. This should update your subscription and remove the warning.

#### Note

After updating your subscription remember to also update your advisors. For instructions on doing this see [Section 15.7.1, “Installing and Updating Advisors”](#).

## 15.6. The What's New Page

The What's New Page provides a simplified interface for providing updates and news related to your MySQL Enterprise Subscription. By default, the information is automatically updated every hour. To disable the updates, or force an update, see [Section 15.6.1, “Setting What's New Configuration”](#).

**Figure 15.40. The What's New Tab**

**Improved MySQL Query Analyzer!**

Visually Correlate System Performance with Query Activity!

1. Pick your favorite graph: Database Activity, Load Average – any graph
2. Use your mouse to select a spike or any region on the graph
3. View exactly which queries were running at the selected time

[Click here for help configuring Query Analyzer](#)

"We tripled our database performance in three days rather than taking weeks."

Keith Souhrada, Software Development Engineer, Big Fish Games

"We learned more about query usage in two minutes than we could in two years."

Jeff Freund, CTO, Clickability (InformationWeek, Nov, 2008)

[Enterprise Software](#) | [Update Service](#) | [Knowledge Base](#) | [Technical Support](#) | [About](#)

Logged in as "admin" - 2.1.1.1138 - Jan 14, 2010 5:21:35 PM  
Monitoring 0 instances on 0 hosts (unlimited hosts available). Subscription is up-to-date. More info....

The **WHAT'S NEW** page is divided into three main sections:

- The area on the left-hand side of the page is used to provide information about the major new features and functionality in MySQL Enterprise Monitor.
- **OPEN SUPPORT ISSUES** provides a quick interface to the list of currently open issues with MySQL Support as identified through the MySQL Enterprise and Support websites. Issues that are currently marked in the system as *Waiting On Customer* are also added to the main MySQL Enterprise Dashboard above the Heat Chart.
- To use the Open Support Issues functionality, you must have set your MySQL Enterprise credentials within MySQL Enterprise Dashboard. For more information, see [Section 15.5.1, “Global Settings”](#).
- **IMPORTANT PRODUCT RELEASE ANNOUNCEMENTS** provides a list of news items from the news feed provided on the MySQL Enterprise website. The news feed will contain important information, including, but not limited to:
  - New releases of MySQL Products, including MySQL Server and MySQL Enterprise Monitor.
  - End-of-life and support changes.
  - Urgent errors and notifications.

When items are new (unread), they will be indicated with a star icon. Unread items on the What's New page will also be notified with a number in the tab title within the main Dashboard. Items are automatically marked as read when you visit the What's New page.

The announcements information is made available in two ways, using either a connection to the MySQL Enterprise website, when the information will be updated at a set interval, or through information included with the MySQL Enterprise Advisor bundles.

### Note

To use poll the MySQL Enterprise site directly your MySQL Enterprise Service Manager must have access to the MySQL Enterprise website. If your MySQL Enterprise Service Manager is not directly connected to the Internet, you

**Note** You can set an HTTP Proxy to be used to access the information. For more information on configuring an HTTP Proxy, see [Section 15.5.1, “Global Settings”](#).

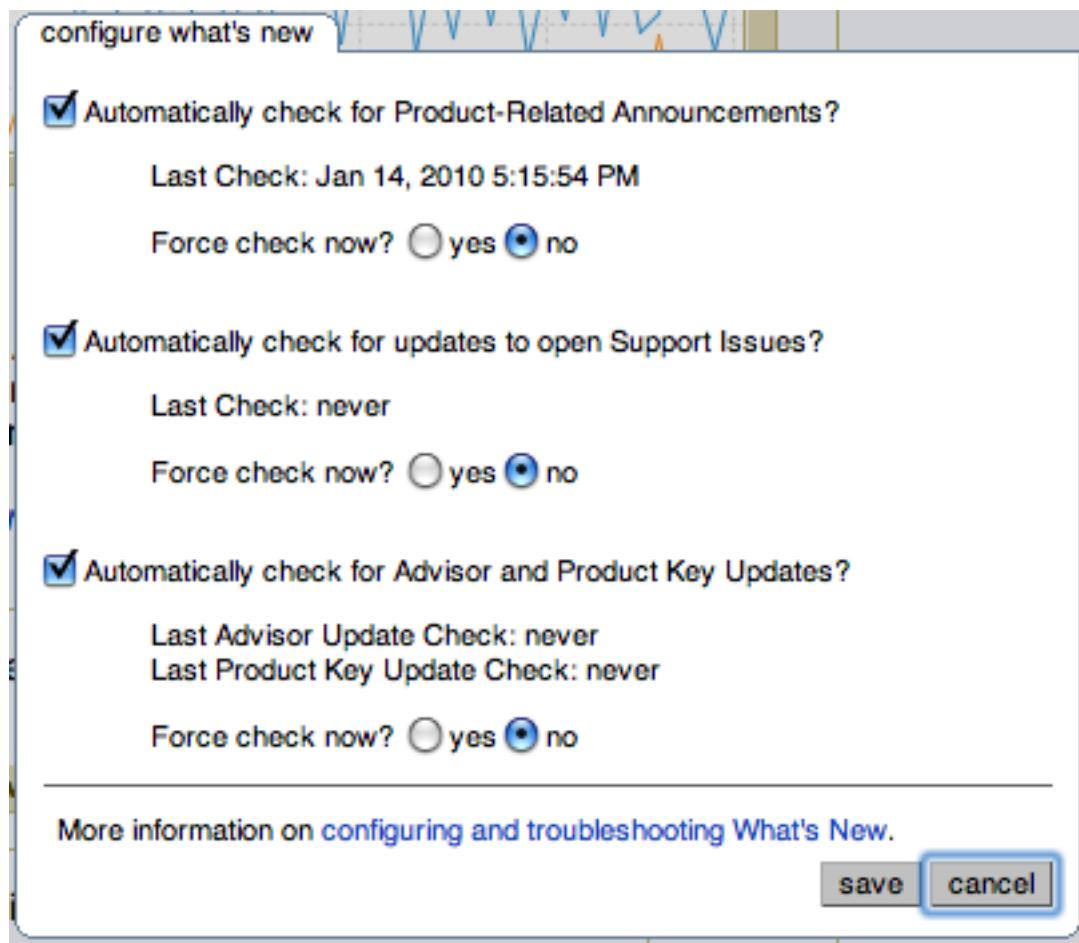

### Note

You can disable the display of your open Support issues and product notifications by using the CONFIGURE WHAT'S NEW link on the **WHAT'S NEW** page. For more information, see [Section 15.6.1, “Setting What's New Configuration”](#).

## 15.6.1. Setting What's New Configuration

You can configure the operation and forcibly update the information on the What's New page by clicking the CONFIGURE WHAT'S NEW button at the top-right of the What's New page.

**Figure 15.41. What's New Configuration**

The configurable options are:

- **AUTOMATICALLY CHECK FOR NEW ANNOUNCEMENTS?**

To disable the New Announcements updates, deselect the checkbox. Updates are enabled by default.

The last time an update of the New Announcements information was successfully executed is displayed below the title.

You can force an update of the New Announcements information by selecting the YES radio button next to **FORCE CHECK NOW?**. A check will be executed when you click the **SAVE** button to close the configuration dialog.

- **AUTOMATICALLY CHECK TO SUPPORT ISSUES?**

To disable the Support Issues updates, deselect the checkbox. Updates are enabled by default.

The last time an update of the Support Issues information was successfully executed is displayed below the title.

You can force an update of the Support Issues information by selecting the YES radio button next to **FORCE CHECK NOW?**. A check will be executed when you click the SAVE button to close the configuration dialog.

- Automatically check for Advisor and Product Key Updates?

The MySQL Enterprise Service Manager can automatically look for changes to your MySQL Enterprise Advisor and product key information by polling the MySQL Enterprise website.

To disable the Advisor and Product key updates, deselect the checkbox. Updates are enabled by default.

You can force a check for updates to the Advisor and Product key information by selecting the YES radio button next to **FORCE CHECK NOW?**. A check will be executed when you click the SAVE button to close the configuration dialog.

Click **SAVE** to save your settings. If you selected any system to force an update, the update will take place in the background. To cancel your changes, click **CANCEL**.

## 15.7. The Advisors Page

### Note

MySQL Enterprise subscription, MySQL Enterprise Monitor, MySQL Replication Monitor, and MySQL Query Analyzer are only available to commercial customers. To learn more, see: <http://www.mysql.com/products/enterprise/features.html>.

MySQL Enterprise Advisors are a series of scripts that gather information from your MySQL servers using the Service Manager and the Monitor Agents, analyze that information based on custom rules developed by MySQL AB, and then offer alerts and advice when necessary. As new rules are introduced, the MySQL Enterprise Advisors can be updated through the MySQL Enterprise website.

The MySQL Enterprise Advisors fall into the following categories:

- Administration
  - Better manage databases
  - Suggest improvements for smoother operation
- Heat Chart
  - Drive the status indicators in the Heat Chart
  - Identify up/down status and performance issues
- Performance
  - Identify potential performance bottlenecks
  - Make suggestions for improved database speed
- Replication
  - Identify replication bottlenecks
  - Improve replication design
- Schema
  - Identify schema changes
  - Find security loopholes
- Security
  - Protect MySQL servers
  - Find security loopholes

An advisor category provides a set of rules designed to enforce MySQL best practices for that specific category. Rules can be targeted to run at the individual server or group level and, upon rule violation, provide alerts and expert advice on how to address and correct a problem before it becomes a costly outage.

Individual rules are defined in the `items-mysql-monitor.xml` file. On Windows this file is found in the `C:\Program Files\MySQL\Enterprise\Agent\share\mysql-monitor-agent` directory and on Unix in the `/opt/mysql/enterprise/agent/share/mysql-monitor-agent` directory. Find below the rule for discovering a `root` account with no password.

```
<ITEM>
 <NAME>no_root_password</NAME>
 <FIELD>no_password</FIELD>
 <SCOPE>table</SCOPE>
 <CODE>
 <![CDATA[SELECT COUNT(*) AS no_password FROM mysql.user WHERE user='root' AND password='']]>
 </CODE>
 <NAMESPACE>mysql</NAMESPACE>
 <RETURNS>INTEGER</RETURNS>
 <SOURCE>table</SOURCE>
 <INSTANCE>mysql.user</INSTANCE>
</ITEM>
```

Your MySQL Enterprise subscription level determines which rules are available to you. Subscription levels are cumulative, meaning that higher MySQL Enterprise levels have access to all the rules of the lower levels.

When the Dashboard is first installed, the only rules that are scheduled are those that belong to the `Heat Chart` group.

Go to the Advisors screen by logging in to the Dashboard and choosing the `Advisors` tab.

## 15.7.1. Installing and Updating Advisors

Instructions for installing Advisors are given in [Section 15.3.2.7.3, “Installing Advisors After Initial Log-in”](#), and following. Principally, you need to configure your MySQL Enterprise login or enter your product key before you can update your Advisors.

If your MySQL Enterprise login is configured, you can download the latest Advisors by navigating to the `Advisors` page and finding the `Check for Updates` link. You can periodically update advisors in this way.

### Note

If you do not have Internet access and cannot use the online update option you can manually import advisors. This process is described in [Section 15.3.2.7.3, “Installing Advisors After Initial Log-in”](#).

## 15.7.2. Scheduling Rules

Once the MySQL Enterprise Advisors have been installed, you can configure which advisors you would like to run on a scheduled basis.

You can schedule rules by individual server or by group. This is done by first selecting the desired server or server group from the `Server` tree found on the left side of the screen. Next select the `Advisors` tab.

Opening the `Advisors` tab takes you to the `Current Schedule` page. If you have only just installed the MySQL Enterprise Monitor then you will only see the `Heat Chart` group of advisors. Clicking the `+` button will show all the rules in the `Heat Chart` group.

Clicking the `+` button beside any specific rule will show the servers that this rule is running on, its frequency, and its status. Initially, all the `Heat Chart` rules are enabled.

For a more complete description of a rule, click the rule's name. This opens a dialog box that gives detailed information about the rule.

To view the advisors other than the `Heat Chart` group, select the `Add to Schedule` link. This will show all the advisors available for your subscription level.

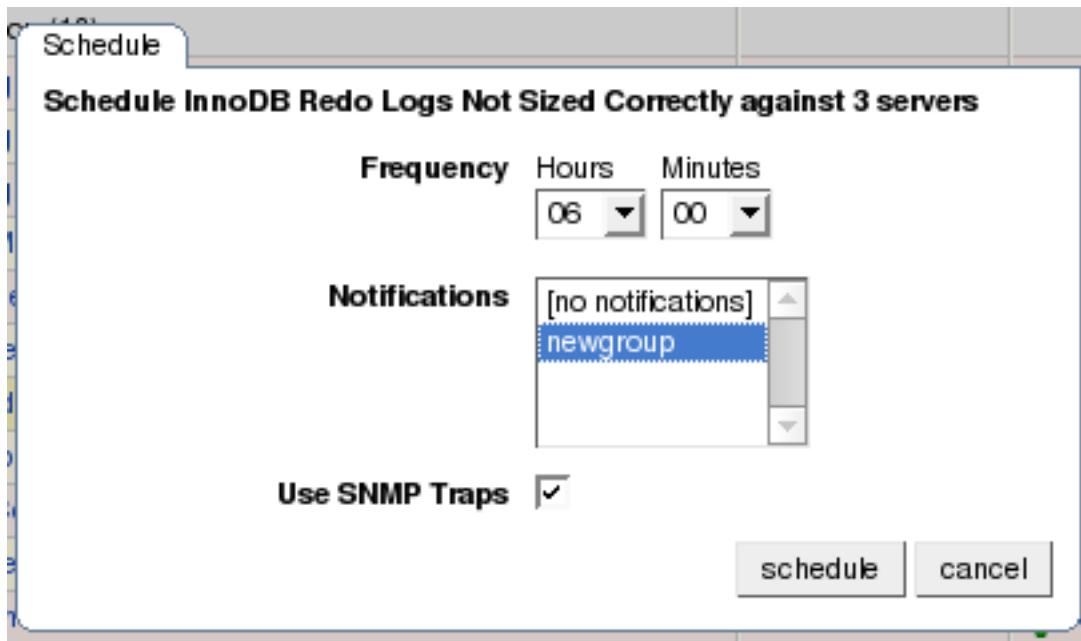

Rules are grouped by functionality and displayed in alphabetic order. To expand a group click the `+` button to the left of the advisor name.

You may activate all the rules in a group by selecting the checkbox beside the group name. Once selected you may apply rules against a specific server or a group of servers. A message showing the group of servers or the specific server you have selected will display immediately below the `SCHEDULE` button. For example, if the `All Servers` group is selected in the server tree, then the message will read, “Schedule Advisors Against All Servers”.

To select a specific rule, expand the group tree by clicking the `+` button. Select the checkbox to the left of the rule you wish to

schedule. Click SCHEDULE to display the following dialog box:

**Figure 15.42. MySQL Enterprise Dashboard: Scheduling Dialog**

The Schedule dialog box allows you to configure the following fields:

- **Frequency**: Dictates how often the rule will run. The default value for different rules varies but a rule can be set to run at any interval desired.

### Warning

Setting the frequency of a rule involves tradeoffs. Rule evaluation consumes system resources—CPU, memory, and disk space. While the amount consumed is small, if you run all the rules against dozens of servers on a very frequent basis, you may put a significant load on the Service Manager. So select an appropriate frequency. For example, unless you are stopping and restarting your servers frequently, rules that check server configuration variables probably don't need to run very often.

Another consideration is that certain status variables increase monotonically until a server is restarted. Examples of these are `Key_reads`, `Qcache_hits`, `Questions`, `Table_locks_waited`, and similar variables. The value returned by `SHOW STATUS` for these variables is the value since the server was started (or since the last `FLUSH STATUS` command), which is not very useful for performance tuning, especially if the server has been running for an extended period of time. For performance tuning it is much better to know the change in state (for example, delta) of these values over the last 10 minutes, 1 hour, or whatever time frame is appropriate for your application. The frequency at which you schedule a rule is the time frame used to calculate the delta values of these variables, and it is the delta that is used in expression evaluation, not the absolute value. Consequently, select a frequency that is appropriate for the metrics being used in the expression.

- **Notifications**: A listbox of users, notification groups, or both who will be emailed when an advisor reaches an alert level. Single or multiple selections are allowed. For instructions on setting up notification groups see, [Section 15.5.5, “Manage Notification Groups”](#).

Set the frequency, identify whomever you wish to notify, and click SCHEDULE to schedule the advisor. Upon completion, you should see the message, `Successfully scheduled`.

If you haven't set up global SNMP traps and would like your Network Management System (NMS) to handle events related to a specific rule then check the `Use SNMP Traps` checkbox. For more information about Simple Network Management Protocol (SNMP) see [Simple Network Management Protocol \(SNMP\) Traps](#).

Scheduling rules using the checkbox and the SCHEDULE button is an effective way to schedule multiple rules. To schedule a single rule you may also use the `schedule` link.

When scheduling more than one rule, you have the option of selecting a checkbox to use the default frequency of each rule or you

may choose a frequency that will apply to all selected rules. When customizing the frequency, take care that you choose a value that is appropriate to all the rules selected.

**Note**

If the agent does not have the `SUPER` privilege and InnoDB-related rules are scheduled, a warning will appear in the `DataCollection` log. This also occurs if `mysqld` is started with the `skip-innodb` option. For more information about agent rights see [Section 15.3.3.1, “Creating a MySQL User Account for the Monitor Agent”](#).

### 15.7.2.1. Heat Chart Notifications

It is particularly important that `Notifications` be set for the `Heat Chart` group of rules. This is easily done from the `Current Schedule` page by clicking the + button beside a rule and then clicking a server.

Doing this opens a window with three tabs—`Overview`, `Settings`, and `Advanced`.

The `Overview` tab shows which advisor group a rule belongs to, a description of its purpose, and a link to the history of this alert.

In the `Settings` tab you can adjust the frequency of this rule and also specify a notification group. To select more than one contiguous group press the `Shift` key and click the desired groups. (Some web browsers may require that you drag your selection.) Noncontiguous selections are made by holding down the `Control` key and clicking the desired groups.

If you haven't set up global SNMP traps and would like your Network Management System (NMS) to handle events related to a specific rule then check the `Use SNMP Traps` checkbox. For more information about Simple Network Management Protocol (SNMP) see [Simple Network Management Protocol \(SNMP\) Traps](#).

The `Advanced` tab gives detailed information about how this rule is implemented.

### 15.7.3. Editing Built-in Rules

The frequency and thresholds defined for a rule are default recommendations. To edit these properties choose the `Create/Edit Rule` link.

The following image shows the screen used to edit rules:

**Figure 15.43. MySQL Enterprise Dashboard: Editing Rules**

<b>Rule Name</b>	<input type="text" value="Temporary Tables To Disk Ratio Excessive - copy"/>	<b>Advisor</b>	<input type="button" value="Heat Chart"/>	<b>Version</b>	<input type="text" value="1.0"/>
<b>Expression</b>					
<pre>(%Uptime% &gt; 10800) &amp;&amp; (((%Created_tmp_disk_tables% / (%Created_tmp_tables%)) * 100) &gt; THRESHOLD)</pre>					
<b>Thresholds</b>					
Critical Alert	<input type="text" value="90"/>	Warning Alert	<input type="text" value="75"/>	Info Alert	<input type="text" value="50"/>
<b>Variable Assignment</b>					
Variable	Data Item	Instance			
%Uptime%	mysql:server:Uptime	<input type="button" value="local"/>	<input type="button" value="delete"/>		
%Created_tmp_disk_table	mysql:server:Created_tmp_disk_tables	<input type="button" value="local"/>	<input type="button" value="delete"/>		
%Created_tmp_tables%	mysql:server:Created_tmp_tables	<input type="button" value="local"/>	<input type="button" value="delete"/>		
%tmp_table_size%	mysql:server:tmp_table_size	<input type="button" value="local"/>	<input type="button" value="delete"/>		
%max_heap_table_size%	mysql:server:max_heap_table_size	<input type="button" value="local"/>	<input type="button" value="delete"/>		
<input type="button" value="add row"/>					
<b>Default Frequency</b>					
Hours	<input type="text" value="00"/>	Minutes	<input type="text" value="05"/>		

Beside the rule name is the **Advisor** drop-down list box, used for setting the advisor group. This list box shows existing groupings and any you may have added. The **Expression** textarea shows the advisor rule, **Variable Assignment** the data item associated with variable(s) used in the rule and **Thresholds** determines when to trigger each alert type.

The three levels of **Thresholds** are **Info Alert**, **Warning Alert**, and **Critical Alert** indicating increasing levels of severity. Levels can be triggered by the expression result being equal to a certain value, greater than a certain value, or less than a certain value.

The data items that variables are associated with are operating system (OS) properties such as available RAM or MySQL characteristics such as the InnoDB buffer pool. To see all available data items drop down the **Data Item** list box. For a listing of these data items see [Data Collection Items](#).

In [Figure 15.43, “MySQL Enterprise Dashboard: Editing Rules”](#) the drop-down **Data Item** list box within the **Variable Assignment** frame shows the various MySQL server status or operating system specific variables that may be used in expressions. The text boxes below **Thresholds** define the levels at which informational, warning, or critical alerts are issued.

To lower the threshold for an informational alert, simply increase the number given in the **Info Alert** text box.

When a data item can apply to multiple objects, you need to specify which instance to use for that item, hence the **Instance** text box. In almost all cases this should be set to **local**. The exceptions are as follows:

- For CPU-related items set **INSTANCE** to **cpu0**. Additional CPUs on a system are referred to as **cpu1**, **cpu2** and so on.
- There can be multiple disks mounted on a system. To refer to a specific drive set **INSTANCE** to the name of the mounted drive. On Windows this would be **C:**, **D:**, and so on. On Unix systems, use whatever is valid for the **df** command.
- For RAM-related items set **INSTANCE** to **mem**.

- Where there are table-specific variables, the database name and table name must be specified in the INSTANCE text box. This topic is discussed in detail in what follows.

**Note**

It is not possible to have a data item that is unrelated to an instance. This raises the error, `You must map "<variable>" to an instance`, and you will be unable to save the rule.

An agent can only collect data from one MySQL server, so the `instance` entry for a variable in a rule does not need to specify which MySQL server to use; no matter how many servers are being monitored there is always a one-to-one relationship between an agent and its monitored server.

However, on one server there may be multiple occurrences of a variable. For example, there are multiple possible occurrences of table-specific variables such as `Avg_row_length` because there can be multiple databases and tables defined in a MySQL server. In this case, the “instance” refers to the database and table that a data item should be associated with, specified in the form `databasename.tablename`. So, for example, if you want to reference the `Avg_row_length` of the `mysql` database `user` table in an expression, select the `mysql:tablestatus:Avg_row_length` from the DATA ITEM list box and specify `mysql.user` in the INSTANCE text box.

On the other hand, in the case of a global server variable, there is only one possible target. For example, there can only be one instance of `delay_key_write` because this variable is global and applies to the server as a whole. In this case specify `local` in the INSTANCE text box.

To save your changes click the SAVE button at the bottom of the page.

**Note**

You can change only the thresholds and the frequency of built-in rules. So that rules function properly when updated, other changes are prohibited.

Should you wish to make other changes to a built-in rule, copy it and modify it as desired.

You can edit a rule even if it is currently scheduled. Your changes will not be overwritten when new rules are imported using the [Check for Updates](#) link.

## 15.7.4. Creating Advisors and Rules

In addition to using and editing the advisors and rules provided by MySQL Enterprise, users can create their own advisors and rules to meet their own unique needs. To do this go to the [Advisors](#) page and choose the [Create/Edit Rule](#) link.

### 15.7.4.1. Creating Advisors

Similar existing rules are grouped together in advisor groups.

The built-in advisors are:

- Administration
- Heat Chart
- Performance
- Replication
- Schema
- Security

The ability to create your own advisor group allows you to create groupings suitable to your circumstances.

You can create your own grouping by simply clicking the CREATE ADVISOR button. Enter an appropriate name and click the ADD button. The newly created group will appear in the Advisor column.

The newly created advisor is added to the list box of advisors shown in [Figure 15.43, “MySQL Enterprise Dashboard: Editing Rules”](#). You can now use this category of advisors when you create a new rule.

### 15.7.4.2. Overview of Rule Creation

---

Rules are created using the same screen seen in [Figure 15.43, “MySQL Enterprise Dashboard: Editing Rules”](#). To begin creating a rule from scratch, click the CREATE RULE button. However, the simplest way to create a new rule is to copy an existing one. Unlike editing an existing rule, when you copy a rule, every element of that rule is editable.

You can change the rule name, the advisor group that a rule belongs to and you can set your own version number. In [Figure 15.43, “MySQL Enterprise Dashboard: Editing Rules”](#), you have already seen how the threshold and frequency of a rule may be altered.

Most importantly you can alter a rule's expression. Expressions are the core of a MySQL Enterprise Advisor and are used to define the scenario being monitored. An expression can be as simple as a single server parameter or can be quite complex, combining multiple parameters with various mathematical operations.

An expression has two main characteristics:

- An expression defines a situation where a best practice is not being followed
- The result of an expression must always be 1 or 0 (that is, true or false)

If an expression evaluates to true for a specific server, an alarm is raised, indicating that a best practice is not being followed. If an expression evaluates to false no alarm is raised because the best practice is indeed being followed.

For example, if having binary logging enabled is considered a best practice for a production server (which we believe it is), then this best practice is being violated if `log_bin` is OFF. Consequently, the expression for the “Binary Logging Not Enabled” rule is “`%log_bin% == OFF`”. If this evaluates to 1, an alarm is raised because the best practice is not being followed.

An expression is made up of one or more variables and zero or more mathematical operators. The MySQL Enterprise Monitor uses the MySQL database server's expression parser and evaluator. For a complete list of operators and functions see [Chapter 11, “Functions and Operators”](#). For a complete list of the built-in variables used when creating rules see [Section 5.1.1, “Server Option and Variable Reference”](#).

Creating an expression is dependent on variables defined in the **VARIABLE ASSIGNMENT** frame. This frame links variables used in the expression field with data gathered from the target MySQL server instance—server status variables, operating system status information, and table information. Variable names are associated with elements in the **DATA ITEM** drop-down list. If you need to define more than one variable simply click the ADD ROW button. For a complete listing of the data collection items used in creating rules see [Data Collection Items](#).

The remaining fields determine the information that displays in a notification email or the informational pop-up window associated with each advisor.

#### Note

When saving a new rule ensure that you do not duplicate the name of an existing rule.

### 15.7.4.3. Variables

When an expression is evaluated variables get replaced by values. For example, part of the expression for the “MyISAM Key Cache Has Sub-Optimal Hit Rate” rule calculates the hit rate as follows:

```
100 - (%Key_reads% / %Key_read_requests%)*100
```

If the current value of `%Key_reads%` is 4522 and the current value of `%Key_read_requests%` is 125989, the hit ratio assesses to 96.4%:

```
100 - ((4522 / 125989) * 100)
```

By convention, the Advisors supplied by MySQL use ‘%’ as the delimiter, for example, `%Key_reads%`. This makes variables more readily identifiable.

In addition to being used in an expression, variables may also be used in the **Description**, **Advice**, **Action**, and **Links** attributes of a rule. This allows you to report the current value of an expression.

For instance, you can add the message, “The current value of Key\_reads is `%Key_reads%`. ” to the **Advice** text box. When this is displayed on the screen, the value of `%Key_reads%` is substituted into the text. Supposing `%Key_reads%` has a value of 4522, the message becomes “The current value of Key\_reads is 4522.”

### 15.7.4.4. Thresholds

Each expression has a threshold value that triggers an alert. The **THRESHOLD** keyword is used to associate that value with an alert level—either an **Info**, **Warning**, or **Critical** alert.

For example, the expression for the performance advisor, “Thread Cache Size May Not Be Optimal”, is:

```
100-((%Threads_created% / %Connections%) * 100) < THRESHOLD
```

The `THRESHOLD` is set at 95% for an Info level alert, 85% for a Warning alert, and 75% for a Critical alert; producing alerts of three different levels.

Expressions can be quite simple. The expression for “Binary Logging Not Enabled” (one of the Administration alerts) is:

```
%log_bin% == THRESHOLD
```

When the result is `OFF`, only one alert is triggered—a Warning level alert. In this situation you might think we could just use the expression `%log_bin% == "OFF"`. However, doing this would not test binary logging against a threshold so would not result in an alert.

When you create an expression, think carefully about the conditions under which it should be evaluated and the conditions under which it should not. For example, the expression for the “MyISAM Key Cache Has Sub-Optimal Hit Rate” rule is:

```
(%Uptime% > 10800) && (%Key_read_requests% > 10000) »
&& (100-((%Key_reads% / %Key_read_requests%) * 100) < THRESHOLD)
```

The essence of the rule is really: `(100-((%Key_reads% / %Key_read_requests%) * 100) < THRESHOLD)`. However, when a server is first starting up, it may take a while to reach a state that is representative of normal operations. For example, the key cache and the query cache may need some period of time before they have cached typical application data as opposed to start-up and initialization data. In this case, the first part of the expression, `(%Uptime% > 10800)`, holds off evaluating this expression until the system has been running for 10800 seconds (3 hours).

In addition, if some part of the system is not heavily used an alert may be triggered based on limited data. For example, if your application does not use the MyISAM storage engine, the “MyISAM Key Cache Has Sub-Optimal Hit Rate” rule may be triggered based on very limited use of other MyISAM tables such as the `mysql.user` table. For this reason, this advisor has a second part—`(%Key_read_requests% > 10000)`—meaning the rule won’t be evaluated unless there is plenty of activity associated with the key cache.

In other circumstances, there may be periods of time during which you don’t want a rule to be evaluated—a blackout period. For example, the expression for the “Slave Too Far Behind Master” rule is: `%Seconds_Behind_Master% > THRESHOLD`. However, suppose you run a backup process between 6 and 7 pm on a replication slave, and it’s normal for that slave to get behind the master by an amount more than the `THRESHOLD` during that time. In that case you don’t want to receive an alert because the rule violation is expected. You can achieve this by adding the following to the expression: `&& CURTIME() NOT BETWEEN '18:00:00' AND '19:00:00'` In essence, this means “don’t trigger an alert between 18:00:00 and 19:00:00 (6 pm and 7 pm)”.

#### 15.7.4.5. Using Strings

String values may appear in the `Expression` or the `Thresholds` text boxes. In both cases, they must be enclosed within quotation marks. For example, the expression for the “Slave I/O Thread Not Running” rule is:

```
(%Slave_running% == "ON") && (%Slave_IO_Running% != THRESHOLD)
```

In similar fashion the `Critical Alerts` threshold text box is set to a value of `"Yes"`.

When the expression is evaluated, either `"OFF"` or `"ON"` will be substituted for `%Slave_running%`, and `"Yes"` or `"No"` for `%Slave_IO_Running%`, depending on the state of your system. If the slave is running but the I/O thread is not, the expression then becomes:

```
("ON" == "ON") && ("No" != "Yes")
```

Without quotation marks this expression would not evaluate to `TRUE` as it should.

##### Note

So that it is interpreted properly, the `==` operator is converted to `=` before being passed to the MySQL expression parser.

#### 15.7.4.6. Wiki Format

When editing or defining a rule, the text entered in the `Problem Description`, `Advice`, `Recommended Action`, and `Links and Further Reading` text boxes may be formatted in Wiki format. This allows you to format text and add hyperlinks when creating or editing your own rules.

Find a brief introduction to using Wiki formatting in the following table.

**Table 15.1. MySQL Enterprise Monitor: Wiki Formatting**

Example	Description
<u><b>bold</b></u>	boldface text
~~ <i>italic</i> ~~	italicize text
\\	create a line break
\\\	create a double line break
\\\\\G	create a backslash
* <i>item 1</i>	create a bulleted list item
# <i>item 1</i>	create a numbered list item
\_	use the '\_' to escape special characters
{moreInfo:name url}	create a hyperlink

So the following Wiki text:

```
Replication is a __very nice feature__ of MySQL. Replication can be very useful for solving problems in the following areas:
* Data Distribution
* Load Balancing
* Backup and Recovery
You can check replication status and start a slave using the following commands: SHOW SLAVE STATUS \\G\\START SLAVE;
{moreInfo:MySQL Manual: Replication FAQ|http://dev.mysql.com/doc/refman/5.0/en/replication-faq.html}
```

Would be translated into the following HTML markup:

```
Replication is a very nice feature of MySQL. Replication can be very useful for solving problems in the following areas:

Data distribution
Load Balancing
Backup and recovery
You can check replication status and start a slave with the following commands: SHOW SLAVE STATUS \G;
START SLAVE;
MySQL Manual: Replication FAQ
```

To find out more about this format go to the [wikipedia.org](https://en.wikipedia.org) web site.

#### 15.7.4.7. Creating a New Rule: An Example

This section documents the steps required to create a rule. Before attempting to create a rule, please review the preceding sections of this chapter.

This example creates a rule that checks the number of rows in a table. Having 50,000 rows in this table is deemed to warrant a critical alert. Lesser numbers are assigned to informational and warning level alerts.

Begin by navigating to the [Advisors](#) tab and clicking the [manage rules](#) link. Then choose the CREATE RULE button.

Create your custom rule by following these steps:

1. Using the [Rule Name](#) text box, give the rule an appropriate name. Something such as "Excessive number of records in [table\\_name](#) table", may be appropriate.
2. From the [Advisor](#) drop down list box choose an advisor group for your rule. The [Administration](#) group of rules might be suitable but if you wish, create your own group of advisors. For instructions on doing this see [Section 15.7.4.1, “Creating Advisors”](#).
3. Enter the following expression in the [EXPRESSION](#) text area: '%[table\\_name](#)\_num\_rows% > THRESHOLD'. Replace [table\\_name](#) with the name of the table you wish to monitor. Note that the variable [%table\\_name\\_num\\_rows%](#) has not yet been defined.
4. Set the Thresholds.

- a. Set the [Critical Alert](#) level to 50000.
  - b. Set the [Warning Alert](#) level to 10000.
  - c. Set the [Info Alert](#) level to 5000.
5. Define your variable in the [Variable Assignment](#) frame.
    - a. In the [Variable](#) text box enter '[%table\\_name\\_num\\_rows%](#)', the variable used in the [Expression](#) text box
    - b. In the [Data Item](#) drop down list box find and select the [mysql:table:numrows](#) entry. (For a description of all the data items available see [Data Collection Items](#).)
    - c. In the [Instance](#) text box enter [database\\_name.table\\_name](#).
  6. Add appropriate entries for the [Problem Description](#), the [Advice](#), and the [Links](#) text areas. If you wish, use Wiki markup for these text areas. See [Section 15.7.4.6, “Wiki Format”](#) for more information. Note that you can also reference the '[%table\\_name\\_num\\_rows%](#)' variable in these text areas. For example, you can display the current number of rows with a message such as '[table\\_name](#) currently has [%table\\_name\\_num\\_rows%](#) rows.'
  7. Save the rule.

Once the rule is created it needs to be scheduled against the server that contains the database table you wish to monitor. For instructions on scheduling rules see [Section 15.7.2, “Scheduling Rules”](#).

## 15.7.5. Creating a Custom Data Collection Item

[Section 15.7.4.7, “Creating a New Rule: An Example”](#) shows how to create a custom rule and [Data Collection Items](#) shows the data items that can be used in rule creation. However, in some circumstances you may want to create a rule that uses a custom data collection item.

You can create additional custom data collection items by editing the [share/mysql-proxy/items/custom.xml](#) custom rule file added during installation. The [custom.xml](#) is installed automatically, but is not affected when running an upgrade installation. The rules file is listed last in the [agent-item-files](#) configuration parameter, which means that any rules and data collection items added to this file will supercede the standard data collection definitions.

Once you have made changes to the [custom.xml](#), you must restart the agent to load the custom definitions.

### 15.7.5.1. Modifying the Custom Data Item XML File

As an example, this section shows how to create a data item for monitoring the amount of free InnoDB tablespace. You can have multiple items in your [custom.xml](#) file, just specify additional [class](#) entries. A sample entry is provided in the [custom.xml](#) file that is included during installation. You can replace, or add the following definition to the file:

```
<?xml version="1.0" encoding="utf-8"?>
<classes>
 <class>
 <classname>innodb_min_free</classname>
 <namespace>mysql</namespace>
 <query><![CDATA[SELECT MIN(substring_index(substring_index(table_comment, " ", 3), " ", -1))/1024/1024
 as Free FROM INFORMATION_SCHEMA.TABLES WHERE engine = 'InnoDB']]></query>
 </class>
</classes>
```

After saving the file, ensure that the [agent-item-files](#) parameter within the configuration includes the [custom.xml](#) file. For example:

```
[mysql-proxy]
...
agent-item-files = share/mysql-proxy/items/quan.lua,share/mysql-proxy/items/items-mysql-monitor.xml,»
 share/mysql-proxy/items/agent-allocation-stats.lua,share/mysql-proxy/items/custom.xml
...
```

For this change to take effect you must restart the agent. To do this see:

- Windows: [Section 15.3.3.5.1, “Starting/Stopping the Agent on Windows”](#)
- Unix: [Section 15.3.3.5.3, “Starting/Stopping the Agent on Unix”](#)
- Mac OS X: [Section 15.3.3.5.2, “Starting/Stopping the Agent on Mac OS X”](#)

Once the agent has restarted, you will find the new data item in the [Data Item](#) drop down list box on the [Rule Definition](#) page. Its fully qualified name is [mysql:table:innodb\\_min\\_free](#).

## 15.7.6. Disabling and Unscheduling Rules

In some circumstances you may no longer wish to apply a rule against a specific server or group of servers and in other circumstances you may want to suspend a rule for a short length of time. With this in mind, it is possible to disable or unschedule a rule.

To disable or unschedule an advisor choose the [Current Schedule](#) screen of the [Advisors](#) tab.

Rules may be disabled or unscheduled using the buttons on the upper or lower left of the screen. You may also change a rule by clicking the [enabled](#) or [unschedule](#) hyperlink to the right of a rule. The buttons are particularly useful when you are altering more than one rule.

To no longer run a rule against a specific server, expand the advisor group and the specific rule by clicking the + button. You may then click the UNSCHEDULE button. When the dialog window opens, choose the UNSCHEDULE button and that rule will no longer be applied. If you wish to back out of the operation choose CANCEL. If, at a later date, you wish to institute this rule again, you may do so from the [Add to Schedule](#) page.

If you want to suspend a rule temporarily, use the DISABLE button and follow the same process you would for unscheduling. Once a rule is disabled the link under the status column changes to red and reads [disabled](#). When a rule is disabled, data is no longer collected for that rule. A disabled rule is easily re-enabled by clicking the [disabled](#) link or by using the ENABLE button.

Multiple rules may be altered for one or more servers by selecting the appropriate checkbox and then clicking the UNSCHEDULE, ENABLE, or DISABLE button.

### Note

Rules associated with the heat chart cannot be disabled or unscheduled as they are required by MySQL Enterprise Monitor.

## 15.7.7. Advisor Blackout Periods

Database servers require regular maintenance and during these periods you may wish to stop Monitor Agents from reporting their findings. During a blackout period rules are not evaluated and notifications are put on hold but Monitor Agents continue to collect data. In this respect blacked-out rules differ from disabled rules; data continues to be collected and stored in the repository.

Blackout periods are enabled by entering the following URL into the address bar of your browser, substituting the appropriate host name, port and server name:

```
http://localhost:18080/rest?command=blackout >
&server_name=SuSE:3306&blackout_state=true
```

If you are unsure of the host name and port to use, check the [configuration\\_report.txt](#) file. Be sure to specify the correct port for the Tomcat server. Specify the server you wish to blackout using the name that appears in the Server Tree, being sure to include a colon and port number as shown in the preceding example.

An HTTP authentication dialog box requesting your Dashboard user name and password will open. Specify the administrator's credentials. The default user name is [admin](#); use the password you specified when you initially logged in to the Dashboard.

You can also blackout a server group by entering the following URL into the address bar of your browser, substituting the appropriate host name, and server group name:

```
http://localhost:18080/rest?command=blackout >
&group_name=Finance&blackout_state=true
```

When the HTTP authentication dialog box opens, enter the administrator's credentials.

You can confirm that a server is blacked out by looking at the server name in the Dashboard; the name of a blacked out server is greyed.

To reactivate the blacked-out server or server group, use the appropriate URL and query string, changing the [blackout\\_state=true](#) name/value pair to [blackout\\_state=false](#). Again, this must be done by a user with administrative privileges.

### Note

Restarting MySQL Enterprise Monitor will **not** reactivate a blacked out server.

### 15.7.7.1. Scripting Blackouts

Rather than opening your web browser and blacking out a server by typing entries into the address bar, you can write a script to achieve the same effect. This section documents a sample blackout script that can be run from the command line.

Create the following file and save it as `blackout.pl`.

```
#!/usr/bin/perl
use LWP 5.64;
USAGE: blackout.pl servicemanager:18080 admin password servername:3306 true
$ARGV[0] = management server hostname:port
$ARGV[1] = management server username
$ARGV[2] = management server password
$ARGV[3] = mysqld managed instance server name and port
$ARGV[4] = blackout state (true/false)
my $browser = LWP::UserAgent->new();
$browser->credentials(
 $ARGV[0],
 '',
 $ARGV[1],
 $ARGV[2]
);
my $url = URI->new('http://'.$ARGV[0].'/rest');
$url->query_form(# And here the form data pairs:
 'command' => 'blackout',
 'server_name' => $ARGV[3],
 'blackout_state' => $ARGV[4]
);
my $response = $browser->post($url);
if (!$response->is_success) {
 die $response->status_line . "\n";
}
```

#### Note

Windows users can omit the shebang line.

On Unix systems use the `chmod +x blackout.pl` command to make the file executable.

At the command line enter `blackout.pl servicemanager:18080 admin password servername:3306 true`.

If you are unsure of the host name and port to use, check the `configuration_report.txt` file. Be sure to specify the correct port for the Tomcat server. Specify the server you wish to blackout using the name that appears in the Server Tree, being sure to include a colon and port number as shown in the preceding example. Make sure that the user you specify is a "manager". Specifying a user with "dba" rights only will not black out a server and no error will be displayed.

You can confirm that a server is blacked out by looking at the server name in the Dashboard; the name of a blacked out server is greyed. To end the blackout, run the same script, changing the final argument to `false`.

#### Note

Restarting MySQL Enterprise Monitor will **not** reactivate a blacked out server.

## 15.8. The Events Page

#### Note

MySQL Enterprise subscription, MySQL Enterprise Monitor, MySQL Replication Monitor, and MySQL Query Analyzer are only available to commercial customers. To learn more, see: <http://www.mysql.com/products/enterprise/features.html>.

Once an advisor has been scheduled, it will run at set intervals. If it finds nothing of interest no alerts or emails will be created.

Events are defined using a number of different levels according to the severity of the alert. The seven levels are

- **Failure:** Indicates a failure for the given rule or event. Usually this indicates that the rule on which the event is based has failed, probably due to a typo or other error. Occasionally it can indicate a failure to retrieve the required information for a given rule.
- **Critical:** The event is critical and requires immediate attention. Critical events normally indicate that a serious problem has, or is about, to occur. You should examine the event and determine the cause and fix it as soon as possible.
- **Warning:** The event is a warning of something that you should be aware of, but which is not affecting the operation of your server.
- **Info:** The event is for informational purposes. Info events are used to indicate issues that do not affect the operation of your

server, but which may highlight a minor configuration or other issue.

- **Success:** The rule has executed successfully with no issues. This is used to indicate that the result of the rule is OK and is used to indicate when an event that was previously in a Critical or Failure state has returned to normal.
- **Unknown:** Indicates when the current state of the event/rule is currently unknown. This state can be issued when the current status of the event cannot be determined.
- **Closed:** The issue has been corrected and marked closed.

For convenience, the event states are also represented by icons, as defined in the table below. The table also shows the relative level of the alert from the highest (Critical) to the lowest (unknown). The order represented here is used when identifying when an event has transitioned between levels (for example, from Success to Critical), hence triggering a notification, and when sorting events based on their current state.

Icon	Description
	An octagonal red icon indicates a critical alert.
	A triangular yellow icon a warning.
	A conversation bubble an informational alert.
	A green tick beside an event indicates that the rule has run successfully and no alert created.
	A question mark icon indicates that the status of the rule is unknown.

When alerts are triggered, they appear on the **EVENTS** screen. Alerts also appear on the [Monitor](#) screen in order of severity. The notification group or groups associated with a specific rule receive email notification when an alert is triggered. For more information about creating notification groups see [Section 15.5.5, “Manage Notification Groups”](#).

To view open events, click the **EVENTS** tab. The tree-view on the left determines which server or server group these events belong to. Open events are shown in tabular format.

**Figure 15.44. MySQL Enterprise Dashboard: Events Screen**

Current	Worst	Server	Category	Rule	Time	Status
		bear:3306	Heat Chart	CPU I/O Usage Excessive	Jun 24, 2009 4:02:04 PM	
		bear:3306	Heat Chart	Table Scans Excessive	Jun 24, 2009 3:56:01 PM	
		bear:3306	Heat Chart	CPU Usage Excessive	Jun 24, 2009 3:47:07 PM	

The event table has the following columns:

- **CURRENT:** An icon indicating the current severity of the alert
- **WORST:** An icon indicating the worst severity recorded for this alert
- **SERVER:** The name of the server the alert applies to
- **ADVISOR:** The category of the advisor
- **RULE:** A short description of the rule that has been violated
- **TIME:** The approximate time the event occurred
- **STATUS:** The status of the event

- **UNNAMED COLUMN:** Provides a link to the [Close](#) dialog box

By default, all events are shown but the list of events can be filtered using the form displayed above the event list. The options include filtering by:

- Severity
- Date (using a range with From/To)
- Advisor group
- Specific rule
- Status

Choose the options you are interested in and click the FILTER button to refresh the display. You may limit the number of items that appear on a page by choosing a different value from the **LIMIT** drop down listbox.

The drop down list box showing severity has the options: [All](#), [Alerts](#), [Critical](#), [Warning](#), [Info](#), [Success](#), and [Unknown](#). Selecting the option [All](#) shows all alerts and also those rules that have run successfully.

A successful rule is one that has not been violated and is indicated by a green tick icon.

The [Alerts](#) shows only those rules that have been violated.

Columns can be sorted by clicking the individual column headings. The alerts shown in [Figure 15.44, “MySQL Enterprise Dashboard: Events Screen”](#).

The server shown in [Figure 15.44, “MySQL Enterprise Dashboard: Events Screen”](#), is filtered for [All](#). Typically, when filtering by severity you would choose [Alerts](#) and, if you see a [Critical](#), [Warning](#), or [Info](#) alert, use the [All](#) filter to see when the rule last ran successfully. This may assist in determining the cause of the alert.

Besides filtering for severity, you can also choose to filter for a specific time period using the [From](#) and [To](#) text boxes. You also have the choice of filtering by specific rules or categories of rules. The [Status](#) drop-down list box let's you choose [All](#), [Open](#), or [Closed](#) events. To avoid excessive scrolling, you can also limit the number of events that show on a specific page.

For more information about an alert, click the rule name. A pop-up window will appear showing a description of the alert and the exact time of occurrence. This pop-up windows provides links to useful resources and advice for resolution. You can also view the exact expression that generated the event.

## 15.8.1. Closing an Event

After determining what action to take, events should be closed.

To resolve an individual alert click the [close](#) link in the **OPERATIONS/NOTES** column. Document the resolution using the [Notes](#) text area and choose the [CLOSE EVENT\(S\)](#) button.

To close a number of alerts simultaneously, select the checkbox beside the alerts you wish to close and then click the [CLOSE](#) button to the lower or upper left side of the screen.

Once an event has been closed it appears on the **EVENTS** screen showing a [resolution notes](#) link. Click this link to review the notes. Events that have been closed are saved in the Repository. If you wish to view closed events filter the display by choosing [Closed](#) from the **STATUS** drop-down box.

## 15.8.2. Notification of Events

If you have created notification groups and then configured individual rules to send their notification to one or more groups then the notification works as follows:

- Notification of an event takes place when a rule is executed and the severity level for a given rule changes. For example, if during execution of a rule, the result of the rule goes from severity level [Success](#) to [Critical](#), the configured notification groups will get one email with the detail of the event and current status.
- If the status of the event has not changed when the rule is next executed, no new email is sent.

This is true whether the rule is executed as part of its normal schedule or execution of the rule has been explicitly requested.

SNMP notifications are sent each time a given rule is executed, irrespective of the current or returned state.

## 15.9. The Graphs Page

### Note

MySQL Enterprise subscription, MySQL Enterprise Monitor, MySQL Replication Monitor, and MySQL Query Analyzer are only available to commercial customers. To learn more, see: <http://www.mysql.com/products/enterprise/features.html>.

Navigate to the [Graphs](#) page by choosing the **GRAPHS** tab.

By default four graphs are displayed on the [Monitor page](#). These graphs present information about the currently selected server or server group, showing the hit ratios, CPU utilization, connections, and database activity. Color coding helps distinguish different aspects of each graph.

From the [Monitor](#) page you can make permanent or temporary changes to the way a graph is displayed. For example, you can choose to display the last hour's activity or you can choose to view a specific period of time.

Persistent changes to the way the graphs display are only made from the [Monitor](#) page. You can set the size of the thumbnails and the full-sized graphs and you can also set their refresh interval. For more information, see [Section 15.4.2, “The Server Graphs and Critical Events”](#). As with the [Monitor](#) page, the data shown in the graphs is determined by the server or group of servers selected in the server tree.

The [Graphs](#) page shows all the available graphs and provides the capability of adjusting the scale of the graphs, allowing a more or less detailed view as the situation requires. To ensure that you have the latest versions of the various graphs click on the **CHECK FOR UPDATES** link on the top left of this page.

All graphs support the ability to drag and select a specific area of the graph. When you select an area of the graph, the display changes to the **QUERY ANALYZER** tab and displays the queries that were being executed during the selected time period. You can also zoom into the graph by selecting specific time periods. For more information on using the graphs to monitor the execution of specific queries, see [Section 15.10.3, “Using Graphs to Identify Queries”](#).

### 15.9.1. Displaying Graphs

The total number of graphs varies depending upon your subscription level. The four graphs that appear by default on the [Monitor](#) page are:

- Hit Ratios
- Database Activity
- Connections
- CPU Utilization

When the [Graphs](#) page is first opened, no graphs are visible. To view a graph click the + button on the left or, to view all graphs, use the EXPAND ALL button.

The larger size of graphs is the primary reason for viewing graphs on the [Graphs](#) page rather than on the [Monitor](#) page. Additionally, you can only show a maximum of six graphs on the [Monitor](#) page; the remaining graphs can only be viewed from the [Graphs](#) page.

### 15.9.2. Setting an Interval

Change the interval for a graph by choosing values from the **HOURS** and **MINUTES** drop-down list boxes. If necessary adjust the width and height of the graph and then click the UPDATE button. The changes to the time span apply to all the graphs on the [Graphs](#) page but have *no* effect on the graphs on the [Monitor](#) page.

To change the graphs both here and on the [Monitor](#) page use the [configure graphs](#) link on the top right. This opens a dialog box for setting the default interval for the x-axis. Save any changes that you have made and the values chosen will be the defaults whenever you log in. You can also change the defaults from the [Monitor](#) page as described in [Section 15.4.2, “The Server Graphs and Critical Events”](#); defaults for other users will be unchanged.

Use the RESET button to restore the default value for the interval. Doing this will also reset the default size of the graphs.

### 15.9.3. Setting a Time Span

Setting a graph to display a time span gives you a historical perspective on server activity. You may want to know what was happening at a specific point in time or you may wish to look at an extended period to determine patterns or trends. Changing the time span gives you the flexibility to do this.

In the **TIME DISPLAY** drop-down list box select the **From/To** option. Choosing this option updates the display to include **TO** and **FROM** text boxes.

Set the date you wish to start viewing from by manually entering the date in year, month, and day format (2007-03-14). However, it is much easier to click the calendar icon and choose a date from the drop-down calendar. Enter a terminating date in the same way. If you wish, you may also choose the specific time of day by selecting the hour and minute.

If necessary adjust the width and height of the graph and then click the **UPDATE** button. The changes to the time span apply to all the graphs on the [Graphs](#) page but have *no* effect on the graphs on the [Monitor](#) page. You cannot change the time span of the graphs that appear on the [Monitor](#) page. Changes apply only to the current user; defaults for other users will be unchanged.

Use the **RESET** button to cancel your changes.

## 15.10. The Query Analyzer Page

### Note

MySQL Enterprise subscription, MySQL Enterprise Monitor, MySQL Replication Monitor, and MySQL Query Analyzer are only available to commercial customers. To learn more, see: <http://www.mysql.com/products/enterprise/features.html>.

Query Analyzer enables you to monitor the statements being executed on a monitored server and retrieve information about the query, number of executions and the execution times of each query. Queries are normalized, so that the unique data defined within each query has been removed. By removing the data specific elements of the queries, the generic queries can be counted and identified more easily.

### Important

MySQL Query Analyzer is designed to gather query performance information from a variety of sources. Query Analyzer uses a new agent plug-in to proxy your queries and collect performance data that is then transmitted to the Enterprise Monitor. This is a new role for the Agent: it is no longer just monitoring, it is now *optionally* between your MySQL client application and the mysql server.

Depending upon your system load, it is possible to overload the proxy or have the proxy/agent consume system resources needed by mysql itself. In particular, the memory needed by the MySQL Agent for basic monitoring is fairly small and consistent and depends on the number of rules you have enabled. However, when the Query Analyzer is enabled, the Agent can use significantly more memory to monitor and analyze whatever queries you direct through it. In this case, the amount of memory used depends on the number of unique normalized queries, example queries and example `EXPLAINS` being processed plus the network bandwidth required to send this query performance data to the Service Manager. In general, the amount of memory used for the Query Analyzer is well-bounded, but under heavy load or, in some cases under older versions of linux, RAM usage by Query Analyzer may be too high for your environment and load.

Therefore we advise you to use this release of Query Analyzer extensively in development, test and stage environments under load for an extended period of time before considering usage in a production environment. For all deployments:

1. Carefully monitor the Agent's resource consumption using the new graph **MEMORY USAGE - AGENT** graphs available on the **GRAPH** tab. You can also add an SMTP or SNMP notification to the new Heat Chart rule **MYSQL AGENT MEMORY USAGE EXCESSIVE**.
2. If the amount of memory consumed is too high, consider sampling queries during nonpeak hours or monitoring only a subset of queries on this system.

If you experience any problems with Query Analyzer, we're interested in working with you closely and quickly to resolve them. Please open a Support issue right away. We're already working hard on optimizing Agent/proxy RAM usage and are planning a series of rapid releases to quickly distribute these and other improvements to you.

Query Analyzer works by intercepting the SQL statements that your MySQL client application sends to the MySQL server. Instead of connecting direct to the MySQL Server, queries are routed through the MySQL Enterprise Monitor Agent, the agent/proxy forwards the queries on to the server and sends the replies back to the client application as normal. In addition to forwarding the queries, the agent/proxy will also normalize the queries and then supply the execution information about each query to the monitor. The

forwarding functionality is provided by the same module that supports the MySQL Proxy application. For information on MySQL Proxy, see [Section 14.6, “MySQL Proxy”](#).

## Important

The MySQL Proxy component, and Query Analyzer, require that clients connecting through MySQL Enterprise Monitor Agent are using MySQL 5.0 or later. Clients that use the library provided with MySQL 4.1 or earlier will not work with MySQL Enterprise Monitor Agent.

Once your MySQL client application has been configured to communicate using the MySQL Enterprise Monitor Agent, queries will be monitored and the simplified queries, without the query specific data, will be sent to the MySQL Enterprise Monitor Agent.

There are a number of different ways that you can enable Query Analysis. For more information on the different options, see [Section 15.10.1, “Enabling Query Analyzer”](#).

To analyse the queries captured by the agent/proxy, change to the [Query Analyzer](#) page. You can see an example of the table on that page in the figure below.

**Figure 15.45. MySQL Enterprise Dashboard: Query Analyzer**

Query	Database	Exec Count	Exec Time (hh:mm:ss.ms)			Rows			Bytes			First Seen

The main Query Analyzer table provides the summary information for all of the queries executed using the agent/proxy. The table will track all the queries submitted to the server using the agent/proxy. The table will show a maximum of 20 rows, and you can page through the list of queries by using the page numbers, or the NEXT, PREVIOUS, FIRST, and LAST buttons. To filter the list of queries that are displayed, or to change the number of queries, see [Section 15.10.4, “Filtering Query Analyzer Data”](#).

Each row within the table provides the statistical information for one normalized query statement. If you have configured multiple agent/proxies to accept and forward queries to different servers, then you can expand the server view. The summary information displayed is different depending on whether you have selected a server group or an individual server.

If you have selected a server group, then the information displayed is aggregated from across the entire group. The same query executed on multiple servers will show average, total and minimum/maximum information for that query across all the servers. If you select an individual server, then only queries executed on that server are included within the table.

For each row, the following columns are populated according to the selected filtering options. For example, if the filter have been configured to show queries within the last 30 minutes (INTERVAL), then only queries executed during that time will be displayed, and the corresponding statistics, such as execution times, rows returned and bytes returned will be according to that 30 minute timespan.

- **QUERY:** The normalized version of the query. Normalization removes the query-specific data so that different queries with different data parameters are identified as the same basic query.

The information is shown as one query per row. Each query row is expandable, and can be expanded to show the execution

times for individual servers for that query.

- **DATABASE:** The default database in use at the time of the query. The database name may not match the database used within the query if you have explicitly stated the database name in the query.
- **EXEC COUNT:** The number of times that the query has been executed.
- **EXEC TIME:** The execution time for all the matching queries. This is the time, for every invocation of the corresponding query, as calculated by comparing the time when the query was submitted and when the results were returned by the server. Times are expressed in HH:MM:SS.MS (hours, minutes, seconds, and milliseconds).

The **EXECUTION** column is further subdivided into the following columns:

- **COUNT:** The total number of executions.
- **TOTAL:** The cumulative execution time for all the executions of this query.
- **MAX:** The maximum execution time for an execution of this query.
- **AVG:** The average execution time for the execution of this query.

When looking at the information provided in this query, you should consider comparing the average and maximum execution times to see if there was a problem on a specific server or during a specific time period when the query took place, as this may indicate an issue that needs to be investigated. For more information, see [Section 15.10.5, “Using Query Analyzer Data”](#).

#### Note

Due to limitations in the counters used for monitor queries on Windows, the time reported for short queries may be reported 0.000. This will be fixed in a future release.

- **ROWS:** The rows returned by the query. The column is sub-divided into the following columns:
  - **TOTAL:** The sum total number of rows returned by all executions of the query.
  - **MAX:** The maximum number of rows returned by a single execution of the query.
  - **AVG:** The average number of rows returned by all executions of the query.
- **BYTES:** The number of bytes returned by each query. The column is sub-divided into the following columns:
  - **TOTAL:** The sum total bytes returned by all executions of the query.
  - **MAX:** The maximum number of bytes returned by a single execution of the query.
  - **AVG:** The average number of bytes returned by all executions of the query.
- **FIRST SEEN:** The first time the query was seen within the given filter conditions.

You can sort the list of queries by clicking the column name. The direction of the sort (highest to lowest, or lowest to highest) is indicated by a triangle next to the currently selected column. The default is to sort the list of queries by the Total Execution time.

## 15.10.1. Enabling Query Analyzer

There are three different ways of enabling query analyzer:

- Change your MySQL client application to talk to the Proxy port you configured during installation. This requires changing your MySQL client application code, and may require that you stop and restart your MySQL client application , but does not require any changes to your MySQL server. For more information, see [Section 15.10.1.1, “Enabling Query Analyzer by Changing the MySQL Client Application”](#).
- Change your MySQL server to listen on a different port, and configure the Agent/proxy to listen on the original MySQL server port. This does not require any changes to your MySQL client application , but will require shutting down and restarting your MySQL server, which may affect your cache and performance. For more information, see [Section 15.10.1.2, “Enabling Query Analyzer by Changing MySQL Server”](#).
- Use IP tables to redirect the network packets to the agent/proxy.

## Important

MySQL Query Analyzer is designed to gather query performance information from a variety of sources. Query Analyzer uses a new agent plug-in to proxy your queries and collect performance data that is then transmitted to the Enterprise Monitor. This is a new role for the Agent: it is no longer just monitoring, it is now *optionally* between your MySQL client application and the mysql server.

Depending upon your system load, it is possible to overload the proxy or have the proxy/agent consume system resources needed by mysql itself. In particular, the memory needed by the MySQL Agent for basic monitoring is fairly small and consistent and depends on the number of rules you have enabled. However, when the Query Analyzer is enabled, the Agent can use significantly more memory to monitor and analyze whatever queries you direct through it. In this case, the amount of memory used depends on the number of unique normalized queries, example queries and example `EXPLAINS` being processed plus the network bandwidth required to send this query performance data to the Service Manager. In general, the amount of memory used for the Query Analyzer is well-bounded, but under heavy load or, in some cases under older versions of linux, RAM usage by Query Analyzer may be too high for your environment and load.

Therefore we advise you to use this release of Query Analyzer extensively in development, test and stage environments under load for an extended period of time before considering usage in a production environment. For all deployments:

1. Carefully monitor the Agent's resource consumption using the new graph **MEMORY USAGE - AGENT** graphs available on the **GRAPH** tab. You can also add an SMTP or SNMP notification to the new Heat Chart rule **MYSQL AGENT MEMORY USAGE EXCESSIVE**.
2. If the amount of memory consumed is too high, consider sampling queries during nonpeak hours or monitoring only a subset of queries on this system.

If you experience any problems with Query Analyzer, we're interested in working with you closely and quickly to resolve them. Please open a Support issue right away. We're already working hard on optimizing Agent/proxy RAM usage and are planning a series of rapid releases to quickly distribute these and other improvements to you.

Note that you must have enabled Query Analyzer within the agent/proxy during installation. If you did not enable Query Analyzer during the installation of the agent/proxy, check the following elements within the main `mysql-monitor-agent.ini` configuration file:

- Add the `proxy` plugin to the `plugins` parameter:

```
plugins=proxy,agent
```

- Ensure that the `quan.lua` items file is enabled in the `agent-item-files` configuration property:

```
agent-item-files = share/mysql-proxy/items/quan.lua,share/mysql-proxy/items/items-mysql-monitor.xml
```

- Check and set the `proxy-address`, `proxy-backend-addresses`, and `proxy-lua-script` settings are configured:

```
proxy-address=:6446
proxy-backend-addresses = 127.0.0.1:3306
proxy-lua-script = share/mysql-proxy/quan.lua
```

For more information on these configuration options, see [Section 15.3.3.6.1, “MySQL Enterprise Monitor Agent \(`mysql-monitor-agent.ini`\) Configuration”](#).

## Note

The Query Analyzer functionality may show as being enabled on a server, even though the modules within MySQL Enterprise Monitor Agent may not have been enabled.

You may also need to make some additional changes to the security configuration on your server to ensure that queries are correctly reported to MySQL Enterprise Service Manager:

- You must ensure that each user configured within your MySQL client application that connects through the agent/proxy and is required to report query analyzer information is allowed to connect to the server from the host on which the agent/proxy is running. When the user connects to the agent/proxy, and the agent/proxy connects to the server the host of the agent/proxy will be used as the identifying client host name during the connection.

### Warning

Because the proxy is providing the immediate connectivity to the MySQL server, authentication must use the proxy hostname, not the client hostname.

To update your user credentials, you need to use the `GRANT` statement. For example:

```
mysql> GRANT SELECT,UPDATE,INSERT on database.* to 'user'@'localhost' IDENTIFIED BY 'password';
```

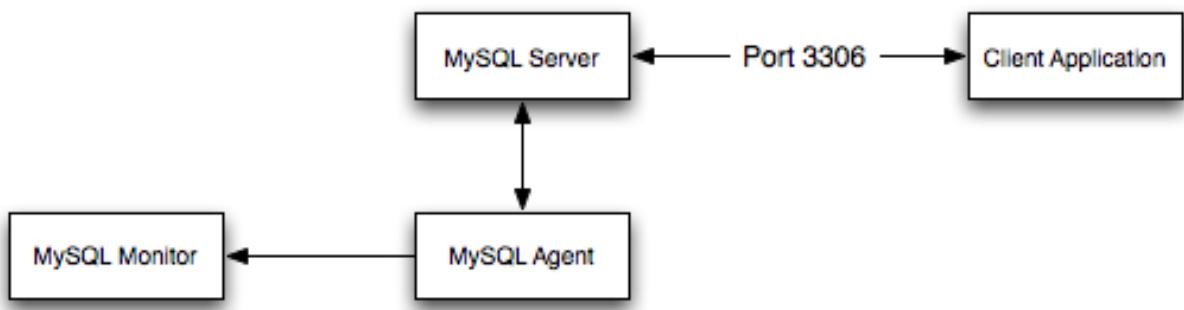

- The MySQL client application user must have `SELECT` privileges on the `mysql.inventory` table. This table contains the server UUID and is required to report the query analyzer data to the MySQL Enterprise Service Manager. To enable this, use the `GRANT` option:

```
mysql> GRANT SELECT on mysql.inventory to 'user'@'localhost' IDENTIFIED BY 'password';
```

#### 15.10.1.1. Enabling Query Analyzer by Changing the MySQL Client Application

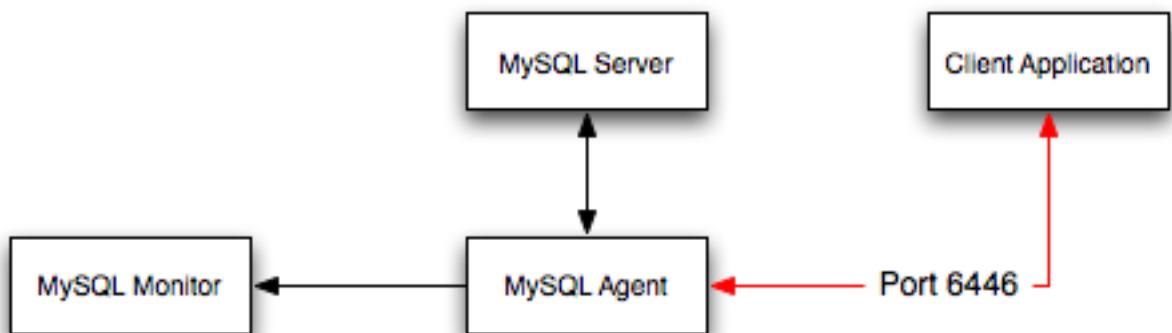

Generally, changing your MySQL client application is the easiest and recommended method. For example, given a typical structure like the one shown in the figure below, the client application would need to be modified so that it no longer communicated directly with the MySQL server, but to the agent/proxy.

**Figure 15.46. MySQL Enterprise Dashboard: Standard Agent/Monitor Topology**

You can see an example of the structure when communicating using the agent/proxy below.

**Figure 15.47. MySQL Enterprise Dashboard: Query Analyzer Agent/Monitor Topology**

To enable query analyzer within your MySQL client application:

1. Make sure that the MySQL Enterprise Service Manager and your MySQL Enterprise Monitor Agent are configured and running.

2. Confirm the configuration of your agent by examining the contents of the `etc/mysql-monitor-agent.ini` file within your installed Agent directory.

Queries will be sent to the host specified in the `proxy-backend-addresses` parameter, and the agent will listen for connections to be redirected to the server on the host name and port configured in the `proxy-address` parameter.

3. Now modify your MySQL client application to communicate with the address specified in the `proxy-address` parameter.

Alternatively, if you do not want to modify your application directly, you can use iptables or firewall rules to redirect queries from the original host/port combination to the agent's port.

Because connections to the MySQL server will be coming from the agent/proxy, not the original host, the user credentials used must be have a suitable `GRANT` statement for connections from `localhost`, or the host on which the agent/proxy is executing. The user name and password information will be passed on directly through the agent/proxy from the client to the server.

4. Confirm that your MySQL client application still operates normally. There should be no difference between communicating directly with the MySQL server and communicating using the agent/proxy.

#### Note

If you are using the `mysql` client to connect to the agent/proxy and your backend servers, make sure that you are communicating with the proxy over the right port. By default, if you specify `localhost` as the host name, then `mysql` will connect using the local Unix domain socket, rather than the TCP/IP socket.

You can enforce `mysql` to use the right port either by explicitly requesting the protocol type, or by using the IP address rather than `localhost`. For example, both of these command lines will start the client using the right protocol:

```
shell> mysql --port=6446 --protocol=tcp
shell> mysql --port=6446 --host=127.0.0.1
```

#### Note

It is recommended that you use one agent/proxy per MySQL server instance. The agent/proxy is not able to forward queries to multiple MySQL server backends.

### 15.10.1.2. Enabling Query Analyzer by Changing MySQL Server

When enabling Query Analyzer by changing the MySQL Server, you need to shutdown your server, edit the MySQL configuration file, and then restart MySQL. You will also need to change your Agent/proxy configuration so that the Agent/proxy is listening on the original MySQL TCP/IP port. To use this method:

1. Edit the `/etc/my.cnf` or other MySQL configuration file and change or add the `port` setting from it's current value (default 3306), to another value. For example:

```
port = 3307
```

2. Shutdown your MySQL Server.
3. Startup your MySQL Server and confirm that is running.
4. Edit your MySQL Enterprise Monitor Agent configuration so that the agent/proxy is listening for connections on the original MySQL port:

```
proxy-address=:3306
proxy-backend-addresses = 127.0.0.1:3307
```

5. Stop and restart MySQL Enterprise Monitor Agent.

You should now be able to connect to your MySQL server through the MySQL Enterprise Monitor Agent by connecting on the original port:

```
shell> mysql --host=127.0.0.1
```

### 15.10.2. Getting Detailed Query Information

---

If you click an individual query, a pop-up window will provide more detailed information about the individual query. You can see an example of this in the figure below. The available tabs within this window will depend on whether you have configured the more detailed query information. By default, you will always be provided the Summary Details page. If enabled, you may also view Example Details, which provide more detailed data about a specific query, including the data and parameters submitted. In addition, you may also enable Example Explain, which provides you with the ability to remotely execute an `EXPLAIN` statement with the specified query and view the resulting information.

- The Canonical Query tab:

**Figure 15.48. MySQL Enterprise Dashboard: Canonical Query Tab for a Query**

Canonical Query    Example Query    Explain Query    908 B    165 B    1

Overview of information collected and aggregated for queries of this form.

**Alias**  
None specified.

**Canonical Form**  
[truncated](#) | [full](#) | [formatted](#)

---

```

SELECT
 COUNT(message_id) AS cnt,
 DATE_FORMAT(FROM_UNIXTIME(datetime), ?) AS
 fmtdate
 , process_mode, process_type
FROM
 logs_amavis
WHERE
 datetime >= ? AND datetime <= ?
GROUP BY
 process_mode ASC, process_type ASC, fmtdate
 ASC

```

---

**Execution Time Statistics**

Max Time	Min Time	Avg Time	Total Time	Standard Deviation
11.123	0.274	2.140	12.838	

**Row Statistics**

Max Rows	Min Rows	Avg Rows	Total Rows	Standard Deviation	Total Size	Max Size
408	37	129	776	82	24.21 KB	12.8 KB

**Number of Executions**  
6

**Time Span**  
From Oct 27, 2008 10:16:07 AM to Oct 27, 2008 10:46:07 AM.

hide
expand »

In addition to the summary information given in the table, you will get detailed execution statistics, including the minimum time, maximum time, average time, total time and the standard deviation. The standard deviation will enable you to determine whether a particular invocation of a query is outside the normal distribution of times for the given query.

Row statistics provide more detailed contents on the maximum, minimum, average, total, and standard deviation for the number of rows returned by the query, and the total size and maximum size of the data returned. The time period for the total and average figures is shown under the Summary Time Span.

The detailed view for a query also provides three different views of the query. The [truncated](#) version is a shortened version of the query. The [full](#) version of the query is the entire query statement. Normalization removes the constants from the individual queries so that queries following the same logical structure are identified as the same basic query.

To close the query detail window, click the HIDE button.

To simplify the identification of a given query, you can create a query alias. The alias will be used in place of the normalized query text within the Query Analyzer table. To create an alias for a query, click the CREATE ALIAS link against the query. The maximum length for a query alias is 255 characters.

- The **Example Query** tab:

**Figure 15.49. MySQL Enterprise Dashboard: Example Query Tab for a Query**

Canonical Query   Example Query   Explain Query 908 B | 165 B | 134.

The query with the longest execution time during the Time Span (usually the slowest but not always).

**Sampled Query**

The Example Details tab provides detailed information about the most expensive query executed, as determined by the execution time.

In addition to the full query, with data, that was executed, the tab shows the execution time, data, user, thread ID, client host and execution host for the given query.

- The Explain Query tab:

**Figure 15.50. MySQL Enterprise Dashboard: Explain Query Tab for a Query**

The Example Explain tab enables you to view the output from running the query with the `EXPLAIN` prefix. For more information, see [Section 12.8.2, “`EXPLAIN` Syntax”](#).

### 15.10.3. Using Graphs to Identify Queries

The MySQL Enterprise Dashboard supports correlated graphs so that you can compare the graphed execution parameters, such as the server load, thread statistics, or RAM usage, against the queries that were being executed by the server or servers being monitored at that time.

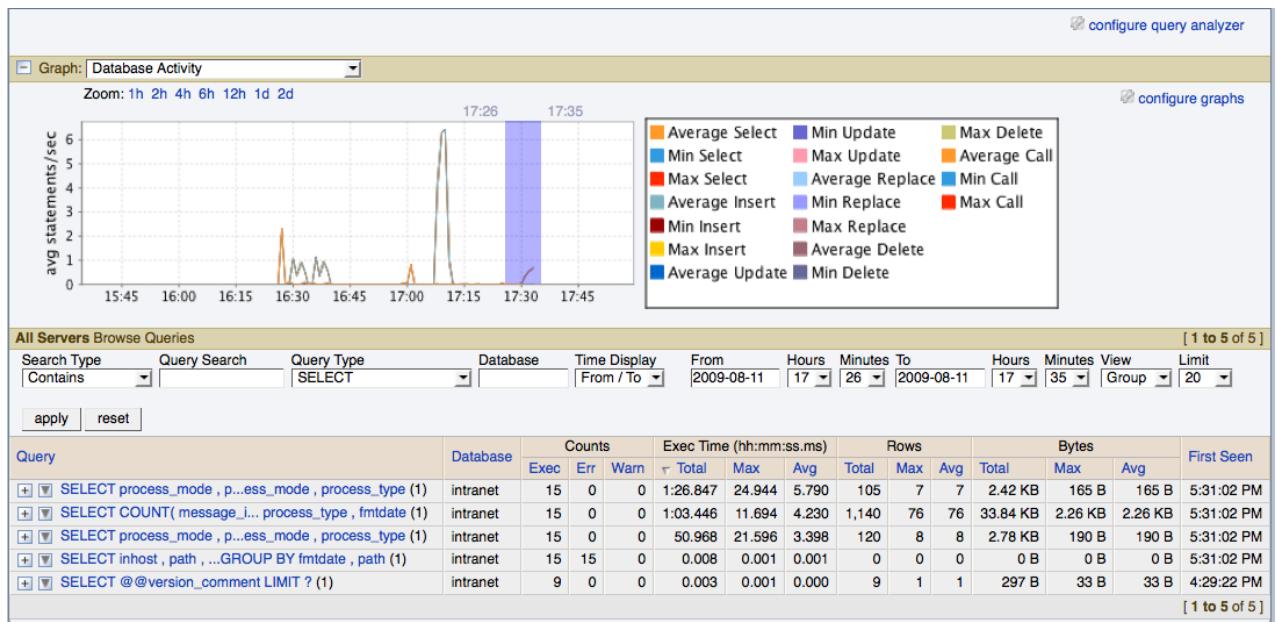

You can use the correlated graphs in two different ways:

- By dragging and selecting an area on a graph as displayed within the **MONITOR** over view tab, or the **GRAPHS** tab of the MySQL Enterprise Dashboard. When using either of these two tabs, you can drag and select any region on a displayed graph, and the display will change to the **QUERY ANALYZER** tab, displaying the corresponding zoomed graph, and the associated queries being executed during the selected period.
- You can select a graph to be displayed within the **QUERY ANALYZER** tab. Open the **GRAPH** section, and use the pop-up list to select the graph to be displayed. You can see an example of this in [Figure 15.51, “MySQL Enterprise Dashboard: Correlated Graphs”](#).

When using the correlated graphs, selecting an area within the graph will set the start and end time within the query filtering selection. You can combine with other filtering options, such as the **QUERY TYPE**, to zero-in on the queries that you want to examine.

To use the graphs in this manner, select a starting point and click, while holding down the button, drag a selection area to set the time-range for the query display. The time range that you have selected will be displayed above the graph as you select the area.

**Figure 15.51. MySQL Enterprise Dashboard: Correlated Graphs**

You can also explicitly zoom in and out of the displayed graph by using the links next to the **ZOOM** label. You can select to show

just an hour of the graph material, or larger ranges up to two days. At all times, the area on the graph highlighted in blue is the actual date/time range selected within the list of analyzed queries.

For more information on filtering your queries, see [Section 15.10.4, “Filtering Query Analyzer Data”](#).

## 15.10.4. Filtering Query Analyzer Data

You can filter the queries shown within the Query Analyzer table by using the form at the top of the table. The different fields of the form are used to specify the parameters for the filter process. Once you have specified a filter, all the queries and related statistics shown within the Query Analyzer table are displayed in relation to the filter settings. For example, by default, the filter settings show the queries for the last 30 minutes. All the statistics shown are relative to the last 30 minutes, including average, maximum and execution counts.

The filter fields are:

- **SEARCH TYPE** and **QUERY SEARCH** support text searching of the normalized query. For the search type you can specify either a basic text match, or a regular expression match. In addition to the basic text match, you can also search for a query that does not contain a particular string. For regular expression searches, you can specify whether the regular expression should match, or not match (negative regexp) the queries. Regular expressions are parsed using the standard MySQL `REGEXP( )` function. For more information, see [Section 11.5.2, “Regular Expressions”](#).

### Note

The search is performed against the canonical version of the query. You cannot search against specific text or values within the parameters of the query itself.

- **DATABASE**: Limit the queries to those executed within a specific database. The database match is performed using the `LIKE` match from the MySQL database, hence you can use the `%` and `_` characters to multiple and single character matches. For more information, see [Section 3.3.4.7, “Pattern Matching”](#).
- The **TIME DISPLAY** menu selects whether the time selection for filtering should be based on the time **INTERVAL** (only queries recorded within the displayed time period are shown, using the **HOURS** and **MINUTES** pop-up), or whether the selection should be based on a time period (**FROM/TO**), where you can select the time range to be displayed.

Using the **INTERVAL** mode shows queries within the given time period from the point the graph was updated. For example, if you select 30 minutes, then the queries shown were captured within the last 30 minutes. If you updated the display at 14:00, then the queries displayed would have been captured between 13:30 and 14:00. Using interval mode limits the timespan for the filter selection to a maximum of 23 hours and 59 minutes.

Using the **FROM/TO** mode enables you to show queries between specific dates and times. Using this mode you can show only the queries received during a specific time span, and you can display the query history for a much longer time period, for as long as you have been recording query analysis information.

- The **VIEW** selection determines whether the information should be returned on a group basis, where an aggregate of the same query executed on all monitored servers is shown, or on a **SERVER** basis, where queries are summarized by individual server. If the latter option has been selected, the table includes an additional column showing the server.
- **QUERY TYPE** lets you select the type of query on which to filter queries. Selecting **ALL** will show all queries. Additional query types you can select include `SELECT`, `INSERT`, `UPDATE` and other main SQL query types.
- **LIMIT** specifies the number of queries to be displayed within each page.

When you have set your filter parameters, you can update the Query Analysis display by clicking the **FILTER** button. To reset the fields to the default settings click the **RESET** button.

## 15.10.5. Using Query Analyzer Data

The information provided by Query Analyzer can be complex to understand and resolve into simple targets and resolutions for your MySQL client application. The information can be used in different ways to find problems in your queries or your servers, or both. Provided below are some tips on how to get the best out of the Query Analyzer interface, and how to identify different queries and problems based on the information shown by the Query Analyzer system.

First, consider the information provided by individual columns by your queries. In particular, the following columns can highlight specific problems with your queries or database server:

- **Execution Count**: High execution counts, especially for a query that you expect to be executed very rarely, may indicate that your MySQL client application is either running a simple query too frequently, or may be running a query multiple times that could otherwise be cached. You should pay particular attention to queries where the execution count increases significantly in a

short period of time compared to the normal execution rate.

**How to find:** Use the sort feature to sort the queries by execution count.

- **New queries:** New queries appearing in the Query Analyzer tab, especially if they appear after other queries have been in the display for a number of hours or days may indicate a number of issues:
- **Execution times:** Long execution times, and a long max execution time compared to the average execution time may indicate a problem with a specific query and specific parameters.

**How to find:** Use the sort feature to sort the queries by execution count.

You can also use the filtering and sort options to get specific information about potential problem queries.

## 15.10.6. Troubleshooting Query Analyzer

If you are having trouble with Query Analyzer, either because the information is not being shown or the full range of queries that you expect are not appearing in the Query Analyzer page then there are a number of systems you can check.

To confirm that your system is correctly configured for Query Analysis, check the following:

- Confirm that the agent is running by checking the Agent log and the status of the server within MySQL Enterprise Service Manager
- Check the configuration of the agent. You must confirm the following:
  - The `plugins` parameter within the main configuration file, `mysql-monitor-agent.ini`, must contain the `proxy` plugin:

```
plugins=proxy,agent
```

- The `agent-item-files` parameter within the main configuration file, `mysql-monitor-agent.ini`, must specify the `share/mysql-proxy/items/quant.lua` script:

```
agent-item-files = share/mysql-proxy/items/quant.lua, »
share/mysql-proxy/items/items-mysql-monitor.xml
```

- The proxy configuration parameters must point to the MySQL server where you want your queries to be sent. For example, if you are running your agent on the same host as your MySQL server then you might have the following lines in your `mysql-monitor-agent.ini` file:

```
proxy-address=:6446
proxy-backend-addresses = 127.0.0.1:3306
proxy-lua-script = share/mysql-proxy/quant.lua
```

The above configuration can means:

- The agent/proxy will listen on the current machine, using port 6446 (`proxy-address`).
- The agent/proxy will send all queries received on to the host `127.0.0.1` on port `3306` (the standard MySQL port), as per the `proxy-backend-addresses` parameter.

You can see a sample complete configuration file (`mysql-monitor-agent.ini`), using the `127.0.0.1` as the MySQL backend server, and reporting to a MySQL Enterprise Service Manager called `monitor`:

```
[mysql-proxy]
plugins=proxy,agent
agent-mgmt-hostname = http://agent:password@monitor:18080/heartbeat
mysqld-instance-dir= etc/instances
agent-item-files = share/mysql-proxy/items/quant.lua,share/mysql-proxy/items/items-mysql-monitor.xml
proxy-address=:6446
proxy-backend-addresses = 127.0.0.1:3306
proxy-lua-script = share/mysql-proxy/quant.lua
agent-uuid = a3113263-4993-4890-8235-cadef9617c4b
log-file = mysql-monitor-agent.log
pid-file=/opt/mysql/enterprise/agent/mysql-monitor-agent.pid
```

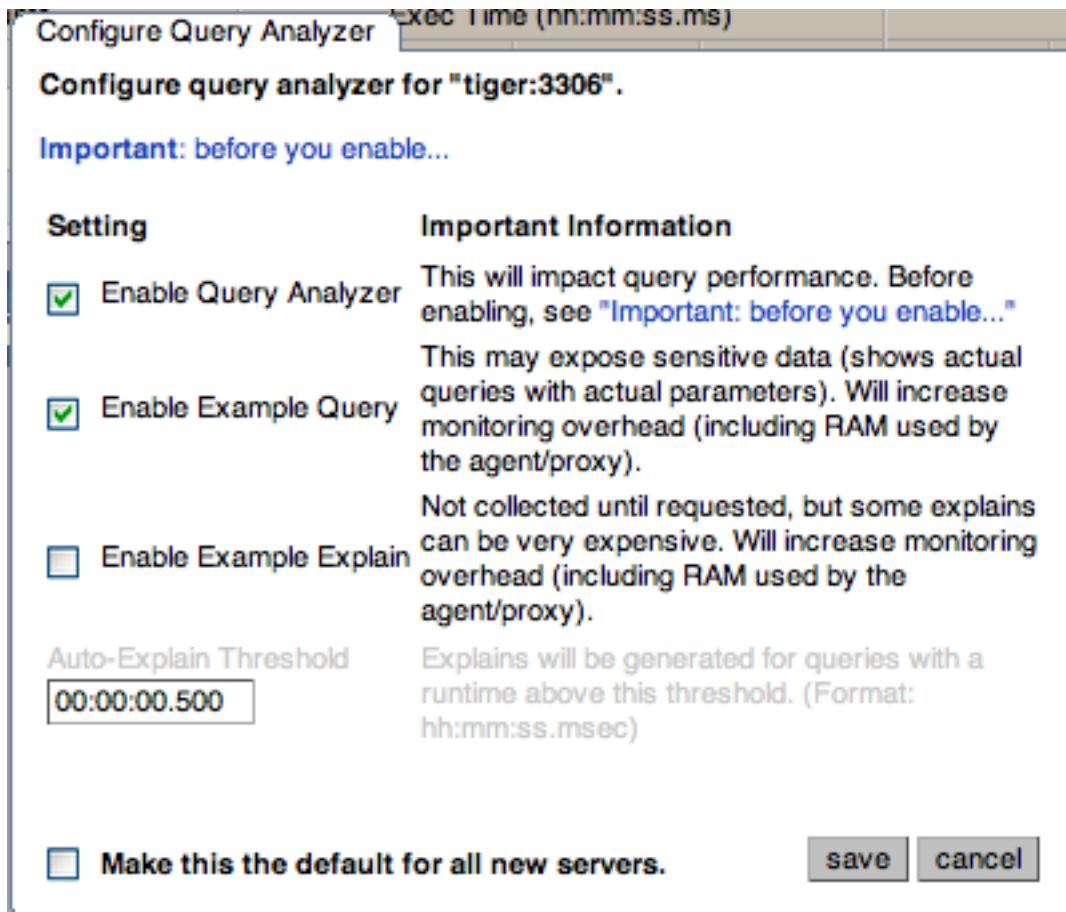

- Confirm that you can connect through the agent proxy to your backend MySQL server. You can do this by checking with the MySQL client. You must specify the same options as you would if you were connecting to the original server, including specifying the same user and password information:

- Check that your MySQL client application is configured to use the configured proxy port, instead of the real MySQL port when sending queries.
- Confirm that Query Analyzer enabled for your host. For more information, see [Section 15.10.7, “Query Analyzer Settings”](#).

## 15.10.7. Query Analyzer Settings

There are a number of settings related to the Query Analyzer data. You can configure the query analyzer operation by using the **CONFIGURE QUERY ANALYZER** link within the **QUERY ANALYZER** tab, or through the **CONFIGURE QUERY ANALYZER** button within the **MANAGE SERVERS** tab within the **SETTINGS** tab. Both methods provide you with the same dialog:

**Figure 15.52. MySQL Enterprise Dashboard: Query Analyzer Configuration**

Through either solution, the configuration options that you select are applied to the individual server or server group selected within the **SERVERS** navigation panel.

There are three configuration options available through either method:

- **ENABLE QUERY ANALYZER** configures whether query analyzer should be enabled for this server or server group. If selected, query analyzer will be enabled. To disable, delect the check box.

If Query Analyzer has been enabled, then you can additional configure the Example Query function by selecting the **ENABLE EXAMPLE QUERY** checkbox. Enabling this option provides an additional tab when you open the **CANONICAL QUERY** window when clicking a query.

- **ENABLE EXAMPLE QUERY** allows the Query Analyzer to display more information about individual queries. When enabled, queries and their data items (rather than the canonical form shown by default) will be provided. Enabling this option may expose the full query statements and therefore may present a security issue.

With the **EXAMPLE QUERY** option enabled, an additional tab within the query summary details is made available. For more information, see [Section 15.10.2, “Getting Detailed Query Information”](#).

If you have enabled **EXAMPLE QUERY**, then you can additional enable **EXAMPLE EXPLAIN**. To enable this tab, select the **ENABLE EXAMPLE EXPLAIN** checkbox.

- **ENABLE EXAMPLE EXPLAIN** provides another tab when viewing a query where you can view the output from **EXPLAIN** output from MySQL for the selected query. This will show the full query and how the query was executed within the servers.

When the **EXPLAIN** functionality has been enabled, the **AUTO-EXPLAIN THRESHOLD** controls when the **EXPLAIN** output for a query is triggered. Queries that take longer than the **AUTO-EXPLAIN THRESHOLD** will have the **EXPLAIN** output generated and stored in the database to be display in the **EXAMPLE EXPLAIN** tab.

Enabling this option may add overhead to the execution of your server, as the server will run an **EXPLAIN** statement each time it identifies a long running query. For more information, [Section 15.13, “MySQL Enterprise Monitor Frequently Asked Questions”](#).

To enable or disable query analyzer for an individual server, go to the **SETTINGS** page and click the **MANAGE SERVERS** link. To configure all the properties, click the **CONFIGURE QUERY ANALYZER** link next to server you want modify.

Alternatively, for each server, the **QUERY ANALYZER** column shows the current setting, On or Off, and whether the **EXAMPLE** and **EXPLAIN** functionality is enabled. To change any setting, click the current status to toggle between the On/Off position.

To disable or enable Query Analyzer for the selected servers, use the **DISABLE QUERY ANALYZER** or **enable query analyzer** buttons within the **SETTINGS** page. You must have selected one or more servers from the list of available servers before selecting these buttons.

You can use the options that you have just selected as the default for all new servers that register with MySQL Enterprise Service Manager by using select the **MAKE THIS THE DEFAULT FOR ALL NEW SERVERS** checkbox. By default, when a new server registers with MySQL Monitor, the server is automatically configured to supply Query Analyzer data. This can have impact on the performance of your monitor and agent as it increases the amount of information supplied to the MySQL Monitor.

Configuration of Query Analyzer occurs through the **CONFIGURE DEFAULTS** button from within the **QUERY ANALYZER** page.

## 15.11. The Replication Page

### Note

MySQL Enterprise subscription, MySQL Enterprise Monitor, MySQL Replication Monitor, and MySQL Query Analyzer are only available to commercial customers. To learn more, see: <http://www.mysql.com/products/enterprise/features.html>.

Navigate to the **Replication** page by choosing the **REPLICATION** tab. This page provides a quick summary view of the state of your replication servers or, if you wish, you can drill down and determine specifics about any master or slave.

### Note

Servers, whether masters or slaves, must be monitored for them to appear on this page.

### Note

There will be no **Replication** page if your subscription level does not support this feature.

The **Replication** page groups all master servers with their slaves. Masters and their slaves are autodiscovered and a grouping is created. This grouping shows up on the replication page and also in the **Heat Chart** on the **Monitor** page. Scans run on a five minute interval, so depending upon the order of discovery, it can take as long as 2 polling intervals to create a complete group.

**Figure 15.53. MySQL Enterprise Dashboard: Replication Groups**

Servers	Type	Slave IO	Slave SQL	Time Behind	Binlog
Replication 1 (5)	TREE	Running	Stopped		
local-tree-master:10001	master				master-bin.000035
local-tree-master-slave:10002	master/slave	Running	Running	00:00:00	master-slave-bin.000035
local-tree-slave3:10008	slave	Running	Running	00:00:00	
local-tree-slave2:10007	slave	Running	Running	00:00:00	
local-tree-slave:10003	slave	Running	Stopped		
Replication 4 (4)	MIXED	Running	Running		
ring1:10004	master/slave	Running	Running	00:00:00	master-bin.000030
ring2:10005	master/slave	Running	Running	00:00:00	master-bin.000030
ring2-slave:10009	slave	Running	Running	00:00:00	
ring3:10006	master/slave	Running	Running	00:00:00	master-bin.000030

Discovery events are logged to the [Replication](#) log. To view this log navigate to the [Settings](#) page and choose the **LOGS** link. View all replication-related events by clicking the **REPLICATION** link. This log can be a useful tool should you need to debug the replication topology discovery process.

### Warning

The agent must be installed on the same machine as the server you are monitoring for discovery to work properly. Do **not** use remote monitoring.

Replication groups can be managed from the [Manage Servers](#) page in the same way as other groups. However, any slaves removed from a server group will automatically be restored to that group. It is also possible to add nonslaves to a replication grouping. For more information about server groupings see [Section 15.5.3.2, “Grouping Servers”](#).

## 15.11.1. Replication Page Details

Choose a value from the **REFRESH** drop-down list box to set the rate at which information is updated. This refresh rate applies only to the information presented on this page: It is independent of the rate set for the [Monitor](#) page.

The following columns describe replication servers and their slaves:

- Servers: Displays the group name and any master servers and slaves
- Type: Indicates the topology of a server group or in the case of individual servers, whether a server is a master, a master/slave, or a slave
- Slave IO: Reports the status of the slave I/O thread
- Slave SQL: Reports the status of the slave SQL thread
- Seconds Behind: The number of seconds the slave is behind the master. This column is blank if a server is a master.
- Binlog: The binary log file name
- Binlog Pos: The current position in the binary log file
- Master Binlog: The master binary log file name
- Master Binlog Pos: The current position in the master binary log file
- Last Error: The most recent error
- Unlabeled Column: Use the **RENAME GROUP** link on the server group line to edit the server group name

Levels of indentation in the [Servers](#) column show the relationship between master servers and their slaves. Most column headings are active links that allow you to change the order of display by clicking the header. Sorting works differently for different column groupings. Click the [Seconds Behind](#) header to order servers by the number of seconds they are behind their master. However, in all cases, the server topology is respected. For example, in a [TREE](#) topology, ordering occurs within branches only.

If the agent is down, servers show in bold red in the [Servers](#) column. The [Slave IO](#) and the [Slave SQL](#) columns display [stopped](#) in red text if these threads are not running. If an agent is down, italics is used to display the last known status of the I/O or SQL threads.

Clicking a master server opens a dialog box that displays information about the server. The information shown includes:

- The number of slave servers
- The binary log file name
- The binary log position
- Which databases are replicated and which not

The dialog box also includes a link that allows the user to hide or show the slave servers.

Clicking a slave server opens a dialog window showing extensive information about the slave.

## 15.12. MySQL Enterprise Monitor Reference

This appendix contains reference information for MySQL Enterprise Monitor.

### 15.12.1. MySQL Enterprise Monitor Limitations

The following list provides information on known limitations within MySQL Enterprise Monitor

- The maximum size for data stored within the [mysql.inventory](#) table is 64 bytes.
- The MySQL Enterprise Monitor Agent when operating for Query Analyzer as a proxy cannot handle queries greater than 16MB.
- The MySQL Enterprise Monitor Agent when operating for Query Analyzer as a proxy does not support clients using the MySQL protocol older than MySQL 5.0.
- The MySQL Enterprise Monitor Agent when operating for Query Analyzer as a proxy does not support clients affects the authentication of clients. As the proxy is the real client connecting to the backend MySQL server, authentication should use the hostname of the proxy, not the original client.
- When viewing the graphs generated by MySQL Enterprise Service Manager, the fonts used for the graphs may not be displayed properly if the required font is missing.

You can specify a custom font by setting a custom property within the embedded MySQL Server to a known working font. To do this, connect to your embedded MySQL sever using the information provided by the [configuration\\_report.txt](#) file. Once connected, execute the following statement:

```
mysql> INSERT INTO map_entries VALUES (1,'Helvetica','graph.font');
```

Replacing [Helvetica](#) with the font you want to use.

The font used for graph rendering will be selected as follows, in this order:

1. The user override value.
  2. The MySQL Enterprise Service Manager default of Arial.
  3. The graph engine default of SansSerif.
- It is not possible to monitor more than one MySQL Enterprise Dashboard instance hosted on the same machine simultaneously within the same browser, even if each MySQL Enterprise Dashboard uses a different port for access. The effect of this limitation may be more significant on certain browsers.
  - When monitoring multiple MySQL instances with one MySQL Enterprise Monitor Agent, if any of the MySQL instances are down at the point when the agent is started, the agent will not attempt to reconnect to the servers. This could lead to indications

that MySQL instances were down when in fact they were running and available. To avoid this problem, ensure all of the monitored instances are available before starting the agent.

## 15.12.2. Supported Browsers

The MySQL Enterprise Dashboard is known to work within the following browser environments:

- Microsoft Internet Explorer 7.x, 8.x

### Note

MySQL Enterprise Dashboard is not compatible with the **COMPATIBILITY VIEW** option within Internet Explorer 8.x. Please make sure this option is disabled before using MySQL Enterprise Dashboard

- Safari 3.2, 4.x
- Firefox 3.0, 3.5

The MySQL Enterprise Dashboard is known *not* to work within the following browser environments:

- Microsoft Internet Explorer 6.x
- Opera
- Google Chrome

## 15.12.3. Installation Requirements

The Service Manager is available for Windows, Mac OS X, and a variety of Unix and Linux operating systems. In most cases, the standard operating system and packages are supported without further libraries and modules. All the required components are installed automatically.

- **Mac OS X Notes**

- The Mac OS X Service Manager is only supported on Intel architecture. However, the Mac OS X agent is supported for both Intel and the PowerPC.
- Installation requires approximately 450MB of disk space for MySQL Enterprise Service Manager

- **Windows Notes**

- Installation requires approximately 260MB of disk space for MySQL Enterprise Service Manager

- **Unix/Linux Notes**

- Installation requires approximately 450MB of disk space for MySQL Enterprise Service Manager
- On FreeBSD, you must have `bind8` installed.

### Note

Disk-space usage requirements are approximate for the base application. During usage, the service manager records detailed information about your MySQL servers and environment, and disk space usage will increase with time to record this historical data. You can control how long information is stored once the service manager has been installed.

The minimum recommended requirements for the service manager are at least a 2GHz CPU, with two or more CPU cores, and at least 2GB of RAM. If you are monitoring a large number of services, then there will be an increased load on the server manager. Running the service manager on a machine that is already running other tasks is only recommended if you are monitoring a small number of agents. For monitoring five or more agents simultaneously, you should dedicate a machine to the process. For more information, see [Section 15.12.5, “Choosing Suitable MySQL Enterprise Service Manager Hardware Configurations”](#).

The Monitor Agent is available for a wide range of operating systems. For an up-to-date list please see the <http://www.mysql.com/products/enterprise/>. The agent can be used to monitor any MySQL server from version 4.0.x through 6.0.x.

Production support is not currently available for MySQL Enterprise Monitor (Service Manager component) in virtualized environments.

### 15.12.4. Creating a new SSL KeyStore

The SSL certificate that is provided with the server during installation is a sample certificate only. If you want to use SSL for communicating with your MySQL Enterprise Service Manager and MySQL Enterprise Dashboard you should replace the supplied certificate with your own certificate.

The certificate keystore is located in the `apache-tomcat/conf/myKeyStore` file within your MySQL Enterprise Service Manager installation.

To create a new, self-signed, certificate, use the `keytool` command (provided with Java SE Security) to create a new certificate file:

```
shell> keytool -genkey -alias tomcat -keyalg RSA -validity 1825 -keystore newKeystore
```

You will be prompted to fill in the certificate information and to provide a unique password for the certificate.

The `-validity` specifies the length of the certificate created, specified in days. The `-alias` is required to ensure that the certificate is associated with `tomcat`.

Once you have created the new keystore, you should shutdown MySQL Enterprise Service Manager, copy the new keystore file to `apache-tomcat/conf/myKeyStore` and restart MySQL Enterprise Service Manager.

If you have an existing certificate that you would like to import into your keystore, you need to import the certificate using the following command:

```
shell> keytool -import -alias tomcat -keystore newKeystore -file public.pem
```

For more information on using SSL certificates in Tomcat see [Apache Tomcat 6.0: SSL Configuration HOW-TO](#).

### 15.12.5. Choosing Suitable MySQL Enterprise Service Manager Hardware Configurations

Running MySQL Enterprise Service Manager places a reasonable load on your system, and this load increases linearly as you add more agents monitoring more servers. Ideally, you should use a dedicated machine for MySQL Enterprise Service Manager, rather than running it alongside other applications and services.

#### Minimum System Requirements

- 2 or more CPU cores
- 2 or more GB of RAM
- Disk I/O subsystem applicable for a write-intensive database

#### Recommended System Requirements (if monitoring 100 or more MySQL servers)

- 4 or more CPU cores
- 8 or more GB of RAM
- Disk I/O subsystem applicable for a write-intensive database (RAID10, RAID 0+1)

### 15.12.6. MySQL Enterprise Monitor Agent Reference

The MySQL Enterprise Monitor Agent supports the following configurable options:

**Table 15.2. `mysql-monitor-agent` Help Options**

Format	Config File	Description	Introduction	Deprecated	Removed
<code>--help</code>		Show help options			

Format	Config File	Description	Introduction	Deprecated	Removed
--help-admin		Show options for the admin-module			
--help-agent		Show agent options			
--help-all		Show all help options			
--help-monitor		Show monitor options			
--help-proxy		Show options for the proxy-module			

**Table 15.3. mysql-monitor-agent Admin Options**

Format	Config File	Description	Introduction	Deprecated	Removed
--admin-address	admin-address	Defines the listening address and port for the admin module			
--admin-lua-script	admin-lua-script	Script to execute by the admin module			
--admin-password	admin-password	Password for authentication for admin module			
--admin-username	admin-username	Username for authentication for admin module			
--proxy-address	proxy-address	Listening address:port of the proxy server			

**Table 15.4. mysql-monitor-agent Agent Options**

Format	Config File	Description	Introduction	Deprecated	Removed
- - - agent-collector-plugins	agent-collector-plugins	Load the specified collector plugins			
- - - agent-force-uncorking	agent-force-uncorking	Forcibly turn off corking (randomization of data collection intervals)	2.1.0		
- - - agent-generate-uuid	agent-generate-uuid	Generate a UUID for use with the agent-uuid			
- - - agent-heartbeat-interval	agent-heartbeat-interval	The interval for generating heartbeat operations			
--agent-host-id	agent-host-id	The host ID for the agent			
- - - agent-host-id-commandline	agent-host-id-commandline	The command to use to generate the agent host id			
--agent-hostname	agent-hostname	Hostname of the agent host			
--agent-item-files	agent-item-files	List of data items for additional collections			
- - - agent-max-response-size	agent-max-response-size	Maximum response size for agent data	2.1.0		
- - - agent-mgmt-hostname	agent-mgmt-hostname	URL of the management server			
- - - agent-run-os-tests	agent-run-os-tests	Run the operating system tests and shutdown			

Format	Config File	Description	Introduction	Deprecated	Removed
- - agent-sync-attempts	agent-sync-attempts	Synchronize the attempts to connect at resync			
--agent-track-alloc	agent-track-alloc	Enable the tracking of the allocation sizes			
--agent-uuid	agent-uuid	UUID of this agent			

**Table 15.5. mysql-monitor-agent Monitor Options**

Format	Config File	Description	Introduction	Deprecated	Removed
--monitor-interval	monitor-interval	Interval for executing queries against the backend			
- - monitor-lua-script	monitor-lua-script	Script filename for the monitor			
- - monitor-password	monitor-password	Set the password for the monitored MySQL Server			
- - monitor-username	monitor-username	Set the username for the monitored MySQL Server			

**Table 15.6. mysql-monitor-agent Proxy Options**

Format	Config File	Description	Introduction	Deprecated	Removed
--no-proxy	no-proxy	Don't start the proxy module			
- - proxy-backend-addresses	proxy-backend-addresses	Address:port of the remote MySQL server			
- - proxy-fix-bug-25371	proxy-fix-bug-25371	Enable the fix for Bug#25371 (for mysqld > 2.0.0.12) for older libmysql versions			
--proxy-lua-script	proxy-lua-script	Filename for Lua script for proxy operations			
- - proxy-pool-no-change-user	proxy-pool-no-change-user	Don't use the protocol CHANGE_USER to reset the connection when coming from the connection pool			
- - proxy-read-only-backend-addresses	proxy-read-only-backend-addresses	Address:port of the remote MySQL server (read only)			
- - proxy-skip-profiling	proxy-skip-profiling	Disabled profiling of queries			

**Table 15.7. mysql-monitor-agent Application Options**

Format	Config File	Description	Introduction	Deprecated	Removed
--basedir	basedir	Specify the base directory to prepend to paths in the config			
--daemon	daemon	Start in daemon-mode			
--defaults-file	defaults-file	Specify the configuration file			
--keepalive	keepalive	Try to restart the proxy if a crash occurs			
- - log-back-trace-on-crash	log-back-trace-on-crash	Try to invoke the debug and generate a backtrace on crash			
--log-file	log-file	Specify the file for logging error messages			
--log-level	log-level	Logging level			
--log-use-syslog	log-use-syslog	Log errors to syslog			
--lua-cpath	lua-cpath	Set the LUA_CPATH			
--lua-path	lua-path	Set the LUA_PATH			
--max-open-files	max-open-files	Specify the maximum number of open files to support			
--pid-file	pid-file	PID file to store the process ID (when in daemon mode)			
--plugin-dir	plugin-dir	Path to the plugin files			
--plugins	plugins	List of plugins to load			
--user	user	Specify the user to use when running mysql-monitor-agent			
--version	version	Show the version information			

- [--help](#)

Command-Line Format	<a href="#">--help</a>

Command-Line Format	<a href="#">--help-monitor</a>
---------------------	--------------------------------

Show options for the monitor module.

- `--help-agent`

<b>Command-Line Format</b>	<code>--help-agent</code>
----------------------------	---------------------------

Show options for the agent module.

- `--admin-address=host:port`

<b>Command-Line Format</b>	<code>--admin-address</code>
<b>Config-File Format</b>	<code>admin-address</code>
<b>Permitted Values</b>	
<b>Type</b>	<code>string</code>
<b>Default</b>	<code>:4041</code>

Specify the host name (or IP address) and port for the administration port. The default is `localhost:4041`.

- `--admin-lua-script=script`

<b>Command-Line Format</b>	<code>--admin-lua-script</code>
<b>Config-File Format</b>	<code>admin-lua-script</code>
<b>Permitted Values</b>	
<b>Type</b>	<code>filename</code>
<b>Default</b>	

Specify the script to use for the administration module for the proxy.

- `--admin-password=pass`

<b>Command-Line Format</b>	<code>--admin-password</code>
<b>Config-File Format</b>	<code>admin-password</code>
<b>Permitted Values</b>	
<b>Type</b>	<code>string</code>
<b>Default</b>	

Define the password to use to authenticate users wanting to connect to the administration module of `mysql-monit-or-agent`. The administration module uses the MySQL protocol to request a username and password for connections.

- `--admin-username=user`

<b>Command-Line Format</b>	<code>--admin-username</code>
<b>Config-File Format</b>	<code>admin-username</code>
<b>Permitted Values</b>	
<b>Type</b>	<code>string</code>
<b>Default</b>	<code>root</code>

Define the username to use to authenticate users wanting to connect to the administration module of `mysql-monit-or-agent`. The default username is `root`. The administration module uses the MySQL protocol to request a username and password for connections.

- `--agent-collector-plugins=user`

<b>Command-Line Format</b>	<code>--agent-collector-plugins</code>
<b>Config-File Format</b>	<code>agent-collector-plugins</code>

<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	collect_lua

A comma-separated list of the plugins to be used and loaded by the agent and used to provide collector items.

- `--agent-force-uncorking`

<b>Version Introduced</b>	2.1.0
<b>Command-Line Format</b>	<code>--agent-force-uncorking</code>
<b>Config-File Format</b>	<code>agent-force-uncorking</code>

Forcibly turn off the corking of responses sent to MySQL Enterprise Service Manager. The corking mechanism tries to randomize the collection intervals of data sent up to the server to prevent flooding the server with information.

The frequency of collecting the data is not modified by this setting.

- `--agent-generate-uuid`

<b>Command-Line Format</b>	<code>--agent-generate-uuid</code>
<b>Config-File Format</b>	<code>agent-generate-uuid</code>

Regenerates a UUID for the agent. You can use this to generate a new UUID if you have copied configuration information for an agent from one machine to another. To use:

```
shell> /opt/mysql/enterprise/agent/bin/mysql-monitor-agent --agent-generate-uuid
ee9296d7-f7cd-4fee-8b26-ead884ebf398
2009-03-05 11:49:37: (critical) shutting down normally
```

For more information, see [Section 15.3.3.6.3, “Monitoring Multiple MySQL Servers”](#).

- `--agent-heartbeat-interval=#`

<b>Command-Line Format</b>	<code>--agent-heartbeat-interval</code>
<b>Config-File Format</b>	<code>agent-heartbeat-interval</code>
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	3

Specify the heartbeat interval. The agent sends heartbeat messages to MySQL Enterprise Service Manager to indicate that it is available and still running and monitoring servers. The MySQL Enterprise Service Manager uses this information to help identify when an agent is available or not.

- `--agent-host-id=HOSTID`

<b>Command-Line Format</b>	<code>--agent-host-id</code>
<b>Config-File Format</b>	<code>agent-host-id</code>

Define the agent host id. The host id should be a unique identifier for the host on which the agent is running, and is different to the agent UUID. You can override the host ID for use within HA environments where you have two identical agent configurations, one on a live server, and one on a backup server to be brought into use if the primary server fails. The host ID is used to identify the host by the server, and during failover you want the host ID to remain constant as you monitor either the original or failover (replacement) server.

- `--host-id-commandline`

<b>Command-Line Format</b>	<code>--agent-host-id-commandline</code>
<b>Config-File Format</b>	<code>agent-host-id-commandline</code>

Specify the command line to generate the host ID. By default, the host ID is generated by using a variety of methods configured for a specific platform, including using SSH keys and embedded host ID information. You can replace this with an alternative command-line

- `--basedir`

<b>Command-Line Format</b>	<code>--agent-hostname</code>
<b>Config-File Format</b>	<code>agent-hostname</code>

Override the automatically determined hostname. You can use this to specify an alternate hostname for the agent. This can be useful if your host has multiple hostnames and you want the machine identified by a specific hostname.

- `--agent-item-files`

<b>Command-Line Format</b>	<code>--agent-item-files</code>
<b>Config-File Format</b>	<code>agent-item-files</code>

A comma separated list of the item files used to load data items that are then collected and sent to MySQL Enterprise Service Manager. For more information, see [Section 15.7.5, “Creating a Custom Data Collection Item”](#).

- `--agent-max-response-size`

<b>Version Introduced</b>	2.1.0
<b>Command-Line Format</b>	<code>--agent-max-response-size</code>
<b>Config-File Format</b>	<code>agent-max-response-size</code>
	<b>Permitted Values</b>
	Type <code>numeric</code>
	Default <code>65536</code>

Specify the maximum size of the response packet sent to MySQL Enterprise Service Manager

- `--agent-mgmt-hostname`

<b>Command-Line Format</b>	<code>--agent-mgmt-hostname</code>
<b>Config-File Format</b>	<code>agent-mgmt-hostname</code>

Set the URL of the MySQL Enterprise Service Manager where collected data is sent. The URL should include the username and password for the agents, for example: `http://agent:password@memserver:18080/heartbeat`.

### Note

If you have the `http_proxy` environment variable configured within your environment, you should add the value of `agent-mgmt-hostname` to the `no_proxy` variable to ensure that data is correctly transmitted to MySQL Enterprise Service Manager and not redirected through the configured proxy address.

- `--agent-run-os-tests`

<b>Command-Line Format</b>	<code>--agent-run-os-tests</code>
<b>Config-File Format</b>	<code>agent-run-os-tests</code>

Runs the internal operating system tests, and then exits. Using this option will generate a large body of information about the various operating system information that can be collected about the host. You can use this to determine whether the agent is collecting the right amount, quantity and quality of information to the server.

A truncated sample of the output is provided below:

```
2010-01-22 16:15:45: (critical) MySQL Monitor Agent 2.1.1.1138 started.
sigar-test-all.c.128 ():
 pid = 1353
sigar-test-all.c.110 ():
```

```

mem.ram = 6080,
mem.total = 6374154240,
mem.used = 3356090368,

 cpu.wait = 0,
 cpu.total = 349022960
[1]
 cpu.user = 6130420,
 cpu.sys = 12671090,
 cpu.nice = 0,
...

```

- `--agent-sync-attempts`

<b>Command-Line Format</b>	<code>--agent-sync-attempts</code>
<b>Config-File Format</b>	<code>agent-sync-attempts</code>

Attempt to synchronise with the server during the resynchronization.

- `--basedir`

<b>Command-Line Format</b>	<code>--agent-track-alloc</code>
<b>Config-File Format</b>	<code>agent-track-alloc</code>

Track the memory allocation in the various modules of the agent to help monitor the memory usage.

- `--basedir`

<b>Command-Line Format</b>	<code>--agent-uuid</code>
<b>Config-File Format</b>	<code>agent-uuid</code>
	<b>Permitted Values</b>
	<b>Type</b> <code>string</code>

Specify the agent UUID. A UUID is automatically generated for each agent during installation, with the UUID automatically added to the configuration. You can generate a new UUID using the `agent-generate-uuid` command line option.

- `--basedir`

<b>Command-Line Format</b>	<code>--basedir</code>
<b>Config-File Format</b>	<code>basedir</code>
	<b>Permitted Values</b>
	<b>Type</b> <code>filename</code>

Specify a base directory that will be prepended to all other filename configuration options. The base name should be an absolute (not relative) directory. If you specify a relative directory, `mysql-monitor-agent` will generate an error during startup.

- `--defaults-file`

<b>Command-Line Format</b>	--defaults-file
<b>Config-File Format</b>	defaults-file

Specify a file to use as the file with configuration information. If not specified, configuration options are only taken from the command line.

- --event-threads=#

<b>Command-Line Format</b>	--event-threads
<b>Config-File Format</b>	event-threads
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	1

Specify the number of event threads reserved to handle incoming requests.

- --keepalive

<b>Command-Line Format</b>	--keepalive
<b>Config-File Format</b>	keepalive

Creates a process surrounding the main `mysql-monitor-agent` which will attempt to restart the true `mysql-monitor-agent` process in the event of a crash or other failure.

- --log-backtrace-on-crash

<b>Command-Line Format</b>	--log-backtrace-on-crash
<b>Config-File Format</b>	log-backtrace-on-crash

Logs the backtrace to the error log and tries to initialize the debugger in the event of a failure.

- --log-file=filename

<b>Command-Line Format</b>	--log-file
<b>Config-File Format</b>	log-file
<b>Permitted Values</b>	
<b>Type</b>	filename

Specify the name of a file to be used to record log information.

- --log-file=filename

<b>Command-Line Format</b>	--log-level
<b>Config-File Format</b>	log-level
<b>Permitted Values</b>	
<b>Type</b>	enumeration
<b>Valid Values</b>	error, warning, info, message, debug

The log level to be used when outputting error messages. The specification will output that level (or lower) of a given error message. For example, `message` will also output `info`, `warning`, and `error` messages.

- --log-use-syslog

<b>Command-Line Format</b>	--log-use-syslog
----------------------------	------------------

<b>Config-File Format</b>	<code>log-use-syslog</code>
---------------------------	-----------------------------

Causes errors to be sent to the syslog (Unix/Linux only).

- `--lua-cpath=path`

<b>Command-Line Format</b>	<code>--lua-cpath</code>
<b>Config-File Format</b>	<code>lua-cpath</code>
	<b>Permitted Values</b>
<b>Type</b>	<code>filename</code>

Specify the `LUA_CPATH` to be used when loading compiled modules or libraries for Lua scripts.

- `--lua-path=path`

<b>Command-Line Format</b>	<code>--lua-path</code>
<b>Config-File Format</b>	<code>lua-path</code>
	<b>Permitted Values</b>
<b>Type</b>	<code>filename</code>

Specify the `LUA_CPATH` to be used when loading modules for Lua.

- `--max-open-files=#`

<b>Command-Line Format</b>	<code>--max-open-files</code>
<b>Config-File Format</b>	<code>max-open-files</code>
	<b>Permitted Values</b>
<b>Type</b>	<code>numeric</code>

The maximum number of open files and sockets supported by the `mysql-monitor-agent` process. You may need to increase this with certain scripts.

- `--monitor-interval#=`

<b>Command-Line Format</b>	<code>--monitor-interval</code>
<b>Config-File Format</b>	<code>monitor-interval</code>
	<b>Permitted Values</b>
<b>Type</b>	<code>numeric</code>
<b>Default</b>	<code>1</code>
<b>Min Value</b>	<code>1</code>

Execute queries against the backends at this interval. The default is 1.

- `--monitor-lua-script=SCRIPT`

<b>Command-Line Format</b>	<code>--monitor-lua-script</code>
<b>Config-File Format</b>	<code>monitor-lua-script</code>
	<b>Permitted Values</b>
<b>Type</b>	<code>string</code>

Filename of the Lua script to use for the monitor module.

- `--monitor-password=PASS`

---

<b>Command-Line Format</b>	--monitor-password
<b>Config-File Format</b>	monitor-password
	<b>Permitted Values</b>
<b>Type</b>	string

The password for the monitoring user account.

- --monitor-username=USER

<b>Command-Line Format</b>	--monitor-username
<b>Config-File Format</b>	monitor-username
	<b>Permitted Values</b>
<b>Type</b>	string

**Default** monitor

The username for the monitoring user account.

- --no-proxy

<b>Command-Line Format</b>	--no-proxy
<b>Config-File Format</b>	no-proxy

Disable the proxy module.

- --plugin-dir=path

<b>Command-Line Format</b>	--plugin-dir
<b>Config-File Format</b>	plugin-dir
	<b>Permitted Values</b>
<b>Type</b>	filename

The directory to use when loading plugins for mysql-monitor-agent.

- --plugins=plugin,...

<b>Command-Line Format</b>	--plugins
<b>Config-File Format</b>	plugins
	<b>Permitted Values</b>
<b>Type</b>	string

A comma-separated list of the plugins to be loaded.

- --proxy-address=host:port

<b>Command-Line Format</b>	--proxy-address
	-P
<b>Config-File Format</b>	proxy-address
	<b>Permitted Values (&gt;= 2.1.0)</b>
<b>Type</b>	string

**Default** :6446

The listening host name (or IP address) and port of the proxy server. The default is :6446 (all IPs on port 6446).

- `--proxy-read-only-backend-addresses=host:port`

<b>Command-Line Format</b>	<code>--proxy-read-only-backend-addresses</code>
	<code>-r</code>
<b>Config-File Format</b>	<code>proxy-read-only-backend-addresses</code>
	<b>Permitted Values</b>
<b>Type</b>	<code>string</code>

The listening host name (or IP address) and port of the proxy server for read-only connections. The default is for this information not to be set.

- `--proxy-backend-addresses=host:port`

The host name (or IP address) and port of the MySQL server to connect to. You can specify multiple backend servers by supplying multiple options. Clients are connected to each backend server in round-robin fashion. For example, if you specify two servers A and B, the first client connection will go to server A; the second client connection to server B and the third client connection to server A.

- `--proxy-pool-no-change-user`

<b>Command-Line Format</b>	<code>--proxy-pool-no-change-user</code>
<b>Config-File Format</b>	<code>proxy-pool-no-change-user</code>

Disables the use of the MySQL protocol `CHANGE_USER` when reusing a connection from the pool of connections specified by the `backend-addresses` list.

- `--proxy-skip-profiling`

disables profiling of queries (tracking time statistics). The default is for tracking to be enabled.

- `--proxy-fix-bug-25371`

<b>Command-Line Format</b>	<code>--proxy-fix-bug-25371</code>
<b>Config-File Format</b>	<code>proxy-fix-bug-25371</code>

Gets round an issue when connecting to a MySQL server later than 5.1.12 when using a MySQL client library of any earlier version.

- `--proxy-lua-script=file`

<b>Command-Line Format</b>	<code>--proxy-lua-script</code>
	<code>-s</code>
<b>Config-File Format</b>	<code>proxy-lua-script</code>
	<b>Permitted Values</b>
<b>Type</b>	<code>filename</code>

specify the Lua script file to be loaded. Note that the script file is not physically loaded and parsed until a connection is made. Also note that the specified Lua script is reloaded for each connection; if the content of the Lua script changes while `mysql-monitor-agent` is running then the updated content will automatically be used when a new connection is made.

- `--daemon`

<b>Command-Line Format</b>	<code>--daemon</code>
<b>Config-File Format</b>	<code>daemon</code>

Starts the proxy in daemon mode.

- `--pid-file=file`

<b>Command-Line Format</b>	--pid-file
<b>Config-File Format</b>	pid-file
	<b>Permitted Values</b>
	Type    filename

Sets the name of the file to be used to store the process ID.

- --user=user

<b>Command-Line Format</b>	--user
<b>Config-File Format</b>	user
	<b>Permitted Values</b>
	Type    string

Run `mysql-monitor-agent` as the specified `user`.

- --version

<b>Command-Line Format</b>	--version
	-V
<b>Config-File Format</b>	version

Show the version number.

### 15.12.7. Configuring Tomcat Parameters

The parameters for the Tomcat hosting system used to support MySQL Enterprise Service Manager and MySQL Enterprise Dashboard can have an affect on the performance of the system.

The default settings for Java for Tomcat are as follows:

Initial heap size	-Xms	768MB
Maximum heap size	-Xmx	768MB
Java stack size	-Xss	128MB

You can change these parameters to higher values, by editing the `JAVA_OPTS` setting within the corresponding platform script.

- On Unix/Linux and Mac OS X

Edit the values within `apache-tomcat/bin/setenv.sh` file within your MySQL Enterprise Service Manager directory. You should avoid setting maximum figures higher than the physical memory of your system as this may reduce, rather than increase the performance.

If you change these parameters, you will need to shutdown and restart MySQL Enterprise Service Manager for the changes to take effect.

- Windows

Edit the `JAVA_OPTS` settings within the `apache-tomcat/bin/setenv.bat` file.

To enable the changes, you must re-install your service. To do this, shutdown your MySQL Enterprise Service Manager service and then reinstall the service by running:

```
shell> mysqlmonitorctl.bat uninstall
shell> mysqlmonitorctl.bat install
```

On all platforms, changes to the `JAVA_OPTS` using the above methods should be retained over an upgrade of the MySQL Enterprise Service Manager service.

If you change these parameters, you must restart MySQL Enterprise Service Manager for the changes to take effect.

## 15.12.8. Backing up MySQL Enterprise Service Manager

If you want to backup the data stored within your MySQL Enterprise Service Manager, you can use any of the typical backup solutions, such as `mysqldump`, to save your data. All you need to backup the information is host name, user name and password details that were set during the installation of the MySQL Enterprise Service Manager

You can locate this information by examining the contents of the `configuration_report.txt` file that was generated when MySQL Enterprise Service Manager was installed. A sample of the file is provided below:

```
MySQL Enterprise Monitor (Version 2.0.0.7088 : 20081031_152749_r7088)
Here are the settings you specified:
Application hostname and port: http://127.0.0.1:18080
Tomcat Ports: 18080 - 18443 (SSL)
MySQL Port : 13306
Repository Credentials (bundled MySQL):

service_manager/Password
Use the following command to login to the MySQL Enterprise Monitor database:
mysql -bservice_manager -pPassword -P13306 -h127.0.0.1
```

The last line provides the information about how to connect to the server using the standard `mysql` command line client.

All the MySQL Enterprise Monitor repository information, including your configuration, rule and historical data is stored within the `mem` database.

To backup this information using `mysqldump` you might use the following command:

```
shell> mysqldump --single-transaction >
-bservice_manager -pPassword -P13306 -h127.0.0.1 mem >mem.dump
```

The above command would create a file, `mem.dump`, containing all of the MySQL Enterprise Monitor data.

To ensure consistency in a recovery situation, you may also want to backup the agent configuration and metadata stored on each monitored MySQL server. To do this:

- Backup the configuration files of each agent. You should keep a copy of the `etc` directory for each agent. This directory contains the main configuration file, `mysql-monitor-agent.ini`, and the configuration information for each server being monitored, which is stored within the `etc/instances` directory.
- On each server being monitored, retain a copy of the `mysql.inventory` table, which contains the unique ID of the MySQL server.

## 15.12.9. Migrating 1.3.x Historical Data to MySQL Enterprise Monitor 2.0

You can migrate the data generated during a MySQL Enterprise Monitor 1.3.x installation using the Data Migration functionality of the **SERVER CONFIGURATION** panel.

To use the data migration feature, you must have installed MySQL Enterprise Service Manager using an *update* installer. The update installer performs the initial migration of your configuration, rules, schedule, and events data. The historical data is not migrated until you explicitly request the migration of information within the **MANAGE SERVERS** section of the **SETTINGS** panel.

Data migration works on a single server, allowing you to select on which servers you want to migrate information. The migration is subject to the following:

- You must elect to migrate the data from each server individually.
- Migration takes approximately 5-6 hours, for each month, for each server. Therefore, if you have six months of data on 10 servers it could take between 300 and 360 hours (15 days) to migrate all of your historical data one server at a time.
- To limit the data migration, set the **DATA PURGE BEHAVIOR** within the **SETTINGS** page. Only data more recent than the specified purge period will be migrated. Data older than the purge period will be ignored.
- To prevent performance issues, migrate only one or a small number of servers concurrently.

- You can start and stop the migration of the data at any time. As a general guide, you should avoid stopping the data migration process and allow it to complete unless:
  - Run out of disk space.
  - MySQL Enterprise Service Manager becomes too slow and unresponsive.
  - Migration never completes.

With the last item, where the migration never completes, occasionally there are some aspects of the data that cannot be migrated successfully. This will prevent the migration process completing, but does not affect the conversion of any data that could be migrated.

### Starting Historical Data Migration

To start data migration:

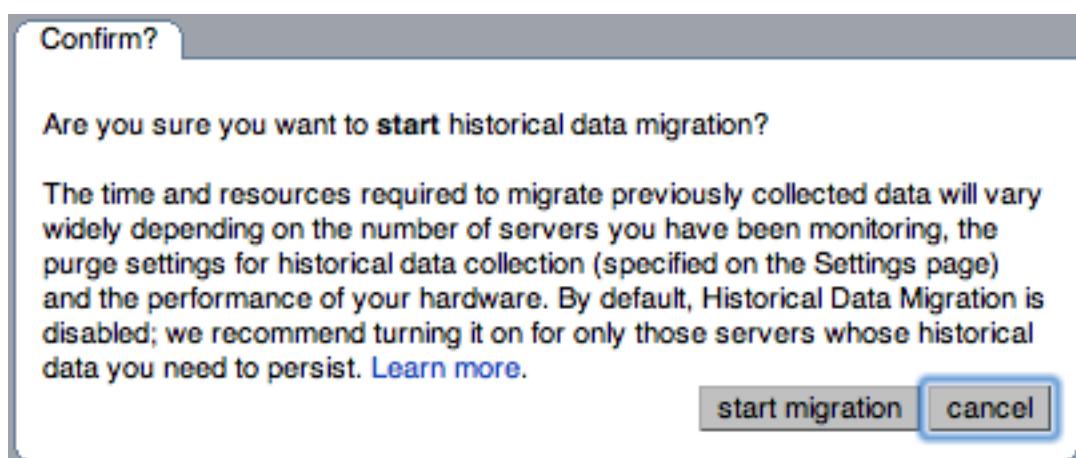

- Switch to the **MANAGE SERVERS** display of the **SETTINGS** panel within MySQL Enterprise Dashboard.
- Ensure that the data migration functionality has been enabled. The START and STOP buttons next to **HISTORICAL DATA MIGRATION** will be visible.

**Figure 15.54. MySQL Enterprise Monitor: Historical Data Migration Availability**

Server	Enabled	MySQL	Up Since	Last MySQL	Agent	Last Agent	Port	Data Dir	Reporting Delay	Migration Status	
All Servers (1)	Off	Off	5.0.70-log	Aug 29, 2009 6:09:29 PM	Jan 15, 2010 12:07:42 PM	2.2.0.1606	Jan 15, 2010 12:08:01 PM	3306	/mnt/data1/mysql/db/	138 ms ahead	N/A
bear:3306 (ungrouped)	Off	Off	Off								

- Select the servers you want to migrate by using the checkbox next to each server name. You can select one or more servers to migrate. Servers that are suitable for migration will show their migration status within the **MIGRATION STATUS** column. If the server is not able to be migrated, **N/A** will be shown.
- Click START next to **HISTORICAL DATA MIGRATION**.
- You will be presented with a confirmation dialog box. To start the migration, click **START MIGRATION**. To cancel migration, click **CANCEL**.
- The servers that have been selected for migration will show **Queued for Migration** in the **MIGRATION STATUS** column.

**Figure 15.55. MySQL Enterprise Monitor: Confirming Historical Data Migration**

### Monitoring Historical Data Migration

You can check the migration status of any individual server by examining the **MIGRATION STATUS** column for each server. You can see an example of the migration status below.

**Figure 15.56. MySQL Enterprise Monitor: Historical Data Migration Progress**

Migration Status	
	N/A
Migrating : 41 variables (50%)	Start: Nov 19, 2008 1:51:28 PM
Migrating : 8 variables (9%)	Start: Nov 19, 2008 1:51:27 PM

Note that the migration status is shown according to the state of migration at the time the page was loaded. The actual migration continues in the background, and the current state may not match the state of the migration at the time it is viewed.

Servers showing **Done** in the **MIGRATION STATUS** column have already completed their migration.

You can check the overall migration status by examining the **UPGRADE STATUS** display.

#### Stopping Historical Data Migration

You can stop the migration process for any server that is still migrating data. The migration can be restarted at any time without causing any problems.

To stop the historical data migration:

1. Select the servers you want to stop migrating by using the checkbox next to each server name. You can select one or more servers to stop migrating.
2. Click **STOP** next to **HISTORICAL DATA MIGRATION**.

Confirmation that the migration has been stopped will be provided. If migration has already completed, you will be notified.

#### Removing Old Data

Once data migration has been completed for all the servers you want to migrate, you may want to delete or remove access to the old data within your MySQL Enterprise Monitor repository. Data for MySQL Enterprise Monitor 1.3 was stored in a database called **merlin** within the MySQL repository. Data for MySQL Enterprise Monitor 2.0 is stored within a database called **mem**.

To create a backup of the old information, use **mysqldump**:

```
shell> mysqldump -usevice_manager -pPassword -P13306 -h127.0.0.1 merlin >data-1.3.sql
```

The above will create a file, **data-1.3.sql** containing all of the MySQL Enterprise Monitor 1.3 information.

If you remove access to the old data, then the data migration options for old servers will be removed from the **MANAGE SERVERS** panel within MySQL Enterprise Service Manager. To remove access, you need to **REVOKE** access to the **merlin** database:

```
mysql& REVOKE ALL on merlin.* FROM 'service_manager';
```

Note that revoking access to the old data will not reclaim any of the disk space used by the old data.

To delete the data from the database and free up the space being used by the historical information, **DROP** the **merlin** database:

```
mysql& DROP DATABASE merlin;
```

Once all the data has been migrated you can hide the migration user interface by clicking the **HIDE MIGRATION INTERFACE** button.

## 15.12.10. Regular MySQL Enterprise Monitor Maintenance

MySQL Enterprise Monitor is generally self managing and does not need excessive maintenance. You should, however, be aware of certain maintenance tasks that you can automate or will need to manually perform to keep your MySQL Enterprise Monitor running efficiently.

- Make sure you have set the purge interval for your data to an appropriate value according to duration and history of data that you want to keep. For more information, see [Data Purge Behavior](#).
- Check, and delete, the contents of the temporary directory with your MySQL Enterprise Service Manager installation directory.

## 15.12.11. Advisor/Graph Reference

### Basic

- **Advisors**
  - [Agent Host Time Out of Sync Relative to Dashboard](#)
  - [Connection Usage Excessive](#)
  - [CPU I/O Usage Excessive](#)

## 15.12.11.1. Advisors

Individual Advisor information is show below.

- **32-Bit Binary Running on 64-Bit AMD Or Intel System**

The chip architecture and operating system installed on a machine both impact the performance of software running on the system. While it is possible to run 32-bit software on many 64-bit systems, in general, software built to run on a 64-bit system will run better on such a system than software built to run on a 32-bit system.

**Default frequency** 06:00:00

- **Account Has An Overly Broad Host Specifier**

The MySQL server has user accounts with overly broad host specifiers. A MySQL account is identified by both a username and a hostname, which are found in the User and Host columns of the mysql.user table. The User value is the name that a client must supply when connecting to the server. The Host value indicates the host or hosts from which the user is allowed to connect. If this is a literal hostname, the account is limited to connections only from that host. If the hostname contains the '%' wildcard character, the user can connect from any host that matches the wildcard character and potentially from any host at all.

From a security standpoint, literal host values are best and % is worst. Accounts that have Host values containing wildcards are more susceptible to attack than accounts with literal host values, because attackers can attempt to connect from a broader range of machines.

For example, if an account has user and host values of `root` and %, it means that you can connect as the root user from `any` machine if you know the password. By contrast, if the host name is `localhost` or `127.0.0.1`, the attacker can only attempt to connect as the root user from the server host.

**Default frequency** 00:05:00

- **Account Has Global Privileges**

A MySQL server may have user accounts with privileges on all databases and tables (\*.\*). In most cases global privileges should be allowed only for the MySQL root user, and possibly for users that you trust or use for backup purposes. Global privileges such as `DROP`, `ALTER`, `DELETE`, `UPDATE`, `INSERT`, and `LOCK TABLES` may be dangerous as they may cause other users to be affected adversely.

**Default frequency** 00:05:00

- **Account Has Old Insecure Password Hash**

Prior to MySQL 4.1, password hashes computed by the `PASSWORD()` function were 16 bytes long. As of MySQL 4.1 (and later), `PASSWORD()` was modified to produce a longer 41-byte hash value to provide enhanced security.

**Default frequency** 06:00:00

- **Account Has Strong MySQL Privileges**

Certain account privileges can be dangerous and should only be granted to trusted users when necessary. For example, the `FILE` privilege allows a user to read and write files on the database server (which includes sensitive operating system files), the `PROCESS` privilege allows currently executing statements to be monitored, and the `SHUTDOWN` privilege allows a user to shut down the server. In addition, the `GRANT` privilege allows a user to grant privileges to others.

**Default frequency** 00:05:00

- **Agent Host Time Out of Sync Relative to Dashboard**

To maintain data consistency and to facilitate day-to-day system management operations, which often require comparing logs, files, and timestamps across servers, it is important that the server clocks across all your systems and data centers be synchronized with respect to each other relative to UTC time (which takes timezones into account). When the clock on one server is minutes or hours behind another server, any timestamps created in the databases or on the file systems of those two servers will differ by that amount. Thus if you depend on timestamps to test the freshness of some data item, or if you are trying to diagnose a problem and need to compare timestamps across systems, your task will be more complicated due to this time difference.

In addition, the data and graphs shown in the MySQL Enterprise Monitor Dashboard will be skewed by the difference in time between the machine hosting the Service Manager and the machines running the Agents. For example, if the time on an Agent machine is one hour behind the time on the Service Manager machine, the MySQL server that Agent is monitoring will appear to be down (see [Bug#45937](#)) and no data will appear in the graphs for that server for the first hour after the Agent is started.

**Default frequency** 00:05:00

- **Attempted Connections To The Server Have Failed**

Aborted connection attempts to MySQL may indicate an issue with respect to the server or network, or could be indicative of DoS or password-cracking attempts against the MySQL Server. The `aborted-connects` count is incremented when:

- A client does not have privileges to access a database
- A client uses the wrong password
- A malformed packet is received
- The `connect_timeout` variable is exceeded

**Default frequency** 00:05:00

- **AUTO\_INCREMENT Field Limit Nearly Reached**

Many applications need to generate unique numbers and sequences for identification purposes (e.g. customer IDs, bug or trouble ticket tags, membership or order numbers, etc). MySQL's mechanism for doing this is the `AUTO_INCREMENT` column attribute, which enables you to generate sequential numbers automatically.

However, the range of numbers that can be generated is limited by the underlying data type. For example, the maximum value possible for a `TINYINT UNSIGNED` column is 255. If you try to generate a number that exceeds the maximum allowed by the underlying data type (e.g. by inserting a `NULL` value into the `AUTO_INCREMENT` column), you will trigger database errors and your application may not behave properly.

Note that the primary purpose of `AUTO_INCREMENT` in MySQL is to generate a sequence of `positive` integers. The use of non-positive numbers in an `AUTO_INCREMENT` column is unsupported, so you may as well define those columns to be `UNSIGNED`, which effectively doubles their allowable range.

**Default frequency** 06:00:00

- **Binary Log File Count Exceeds Specified Limit**

The binary log captures DML, DDL, and security changes that occur and stores these changes in a binary format. The binary log enables replication as well as point-in-time recovery, preventing data loss during a disaster recovery situation. It also enables you to review all alterations made to your database. However, binary logs consume disk space and file system resources, and can be removed from a production server after they are no longer needed by the slaves connecting to this master server, and after they have been backed up.

**Default frequency** 06:00:00

- **Binary Log Space Exceeds Specified Limit**

The binary log captures DML, DDL, and security changes that occur and stores these changes in a binary format. The binary log enables replication as well as point-in-time recovery, preventing data loss during a disaster recovery situation. It also enables you to review all alterations made to your database. However, binary logs consume disk space and can be removed from a production server after they are no longer needed by the slaves connecting to this master server, and after they have been backed up.

**Default frequency** 06:00:00

- **Binary Log Usage Exceeding Disk Cache Memory Limits**

When binary log usage exceeds the binary log cache memory limits, it is performing excessive disk operations. For optimal performance, transactions that move through the binary log should be contained within the binary log cache.

**Default frequency** 00:05:00

- **Binary Logging Is Limited**

The binary log captures DML, DDL, and security changes that occur and stores these changes in a binary format. The binary log enables point-in-time recovery, preventing data loss during a disaster recovery situation. It also enables you to review all alterations made to your database.

Binary logging can be limited to specific databases with the `--binlog-do-db` and the `--binlog-ignore-db` options. However, if these options are used, your point-in-time recovery options are limited accordingly, along with your ability to review alterations made to your system.

**Default frequency** 06:00:00

- **Binary Logging Not Enabled**

The binary log captures DML, DDL, and security changes that occur and stores these changes in a binary format. The binary log enables point-in-time recovery, preventing data loss during a disaster recovery situation. It also enables you to review all alterations made to your database.

**Default frequency** 06:00:00

- **Binary Logging Not Synchronized To Disk At Each Write**

By default, the binary log is not synchronized to disk at each write. If the server host, operating system, or MySQL server crash, there is a chance that the latest statements in the binary log are not written to disk. To prevent this, you can cause the binary log to be synchronized to disk after every Nth binary log entry using the `sync_binlog` global variable. 1 is the safest value, but also the slowest.

**Default frequency** 06:00:00

- **Connection Usage Excessive**

Once the maximum connection limit for the MySQL server has been reached, no other user connections can be established and errors occur on the client side of the application.

**Default frequency** 00:01:00

- **CPU I/O Usage Excessive**

CPU I/O usage should be low on a properly configured and well-tuned system. Excessive CPU I/O usage is often indicative of poor disk or network performance.

**Default frequency** 00:01:00

- **CPU Usage Excessive**

CPU usage should be low-to-moderate on a properly configured and well-tuned system. Excessive CPU usage can be indicative of many problems: insufficient RAM, fragmented disks, poorly-tuned queries, etc.

**Default frequency** 00:01:00

- **CREATE TABLE LIKE Does Not Require Any Privileges On Source Table**

Due to [Bug#25578](#), a user who does not have any access to a database can still clone the structure of tables in that database. Knowing the structure of tables in a database may give a determined hacker insight that allows him or her to proceed with other exploits.

This bug has been fixed in later versions of the MySQL server.

**Default frequency** 06:00:00

- **DataFlushed To Disk After Each SQL Statement**

MySQL updates its data files on disk with the write() system call after every SQL statement and lets the operating system handle the synchronizing to disk. You can force MySQL to flush everything to disk after every SQL statement with the `-flush` option, however, this will have an adverse effect on performance.

**Default frequency** 06:00:00

- **Database May Not Be Portable Due To Identifier Case Sensitivity**

The case sensitivity of the underlying operating system determines the case sensitivity of database and table names. If you are using MySQL on only one platform, you don't normally have to worry about this. However, depending on how you have configured your server you may encounter difficulties if you want to transfer tables between platforms that differ in filesystem case sensitivity.

**Default frequency** 06:00:00

- **Date-Handling Bugs Can Crash The Server**

Two bugs related to date-handling operations can crash the server leading to potential Denial of Service (DoS) attacks:

- `STR_TO_DATE(1,NULL)` caused a server crash ([Bug#15828](#));
- Invalid arguments to `DATE_FORMAT()` caused a server crash ([Bug#20729](#)).

These bugs have been fixed in later versions of the MySQL server.

**Default frequency** 06:00:00

- **Default Value Being Used For max\_prepared\_stmt\_count**

Prepared statements may increase performance in applications that execute similar statements more than once, primarily because the query is parsed only once. Prepared statements can also reduce network traffic because it is only necessary to send the data for the parameters for each execution rather than the whole statement.

However, prepared statements consume memory in the MySQL server until they are closed, so it is important to use them properly and to limit the number of statements that can be open at any one time. The default value for `max_prepared_stmt_count` may not be appropriate for your application and environment.

**Default frequency** 06:00:00

- **Disabling Next-Key Locking In InnoDB Can Crash The Server**

Due to several bugs, the server could crash if next-key locking in InnoDB was disabled.

These bugs have been fixed in later versions of the MySQL server.

**Default frequency** 06:00:00

- **Event Scheduler Disabled**

The Event Scheduler is a very useful feature when enabled. It is a framework for executing SQL commands at specific times or at regular intervals. Conceptually, it is similar to the idea of the Unix crontab (also known as a "cron job") or the Windows Task Scheduler.

The basics of its architecture are simple. An event is a stored routine with a starting date and time, and a recurring tag. Once defined and activated, it will run when requested. Unlike triggers, events are not linked to specific table operations, but to dates and times. Using the event scheduler, the database administrator can perform recurring events with minimal hassle. Common uses are the cleanup of obsolete data, the creation of summary tables for statistics, and monitoring of server performance and usage.

**Default frequency** 00:05:00

---

- **Excessive Disk Temporary Table Usage Detected**

If the space required to build a temporary table exceeds either `tmp_table_size` or `max_heap_table_size`, MySQL creates a disk-based table in the server's tmpdir directory. Also, tables that have TEXT or BLOB columns are automatically placed on disk.

For performance reasons it is ideal to have most temporary tables created in memory, leaving exceedingly large temporary tables to be created on disk.

**Default frequency** 00:05:00

- **Excessive Number of Locked Processes**

Depending on the circumstances, storage engines, and other factors, one process may be using or accessing a resource (e.g. a table or row) required by another process in such a way that the second process cannot proceed until the first process releases the resource. In this case the second process is in a "locked" state until the resource is released. If many processes are in a locked state it may be a sign of serious trouble related to resource contention, or a long running session that is not releasing currently held locks when it should have.

**Default frequency** 00:01:00

- **Excessive Number of Long Running Processes**

Most applications and databases are designed to execute queries very quickly. If many queries are taking a long time to execute (e.g. more than a few seconds) it can be a sign of trouble. In such cases queries may need to be tuned or rewritten, or indexes added to improve performance. In other cases the database schema may have to be redesigned.

**Default frequency** 00:01:00

- **Excessive Number of Long Running Processes Locked**

Most applications and databases are designed to execute queries very quickly, and to avoid resource contention where one query is waiting for another to release a lock on some shared resource. If many queries are locked and taking a long time to execute (e.g. more than a few seconds), it can be a sign of performance trouble and resource contention. In such cases queries may need to be tuned or rewritten, or indexes added to improve performance. In other cases the database schema may have to be redesigned.

**Default frequency** 00:01:00

- **Excessive Percentage Of Attempted Connections To The Server Have Failed**

Excess aborted connection attempts to MySQL may indicate an issue with respect to the server or network, or could be indicative of DoS or password-cracking attempts against the MySQL Server. The aborted-connects count is incremented when:

- A client does not have privileges to access a database
- A client uses the wrong password
- A malformed packet is received
- The connect\_timeout variable is exceeded

**Default frequency** 00:05:00

- **Flush Time Set To Non-Zero Value**

If `flush_time` is set to a non-zero value, all tables are closed every flush\_time seconds to free up resources and synchronize unflushed data to disk. If your system is unreliable and tends to lock up or restart often, forcing out table changes this way degrades performance but can reduce the chance of table corruption or data loss. We recommend that this option be used only on Windows, or on systems with minimal resources.

**Default frequency** 06:00:00

- **General Query Log Enabled**

The general query log is a general record of what mysqld is doing. The server writes information to this log when clients connect or disconnect, and it logs each SQL statement received from clients. The general query log can be very useful when you suspect an error in a client and want to know exactly what the client sent to mysqld.

However, the general query log should not be enabled in production environments because:

- It adds overhead to the server;
- It logs statements in the order they were received, not the order they were executed, so it is not reliable for backup/recovery;
- It grows fast and can use a lot of disk space;
- You cannot stop logging to the general query log without stopping the server (for versions previous to 5.1).  
You should use the binary log instead.

**Default frequency** 06:00:00

- **Improper key\_cache\_block\_size Setting Can Corrupt MyISAM Tables**

The server deducts some bytes from the `key_cache_block_size` option value and reduces it to the next lower 512 byte boundary. The resulting block size is not a power of two. Setting the `key_cache_block_size` system variable to a value that is not a power of two results in MyISAM table corruption.

This bug has been fixed in later versions of the MySQL server.

**Default frequency** 06:00:00

- **In-Memory Temporary Table Size Limited By Maximum Heap Table Size**

If the space required to build a temporary table exceeds either `tmp_table_size` or `max_heap_table_size`, MySQL creates a disk-based table in the server's tmpdir directory. For performance reasons it is ideal to have most temporary tables created in memory, leaving exceedingly large temporary tables to be created on disk. Many DBAs configure `tmp_table_size` appropriately, but forget that `max_heap_table_size` also plays a role.

**Default frequency** 06:00:00

- **Incorrect InnoDB Flush Method On Windows Using MySQL Version 4.1.9**

If `innodb_file_per_table` is enabled and `innodb_flush_method` is not set to `unbuffered` on Windows when using MySQL Server version 4.1.9, MySQL may not start and you may see operating system error code 87.

**Default frequency** 06:00:00

- **Indexes Not Being Used Efficiently**

The target server does not appear to be using indexes efficiently. The values of `Handler_read_rnd_next` and `Handler_read_rnd` together - which reflect the number of rows read via full table scans - are high compared to the Handler variables which denote index accesses - such as `Handler_read_key`, `Handler_read_next` etc. You should examine your tables and queries for proper use of indexes.

**Default frequency** 00:05:00

- **InnoDB Buffer Cache Has Sub-Optimal Hit Rate**

Logical I/O is many times faster than physical I/O, and therefore a DBA should strive to keep physical I/O to a minimum. It is true that logical I/O is not free, and that the DBA should work to keep `all` I/O to a minimum, but it is best if most data access is performed in memory. When using InnoDB, most data access should occur in RAM, and therefore the InnoDB buffer cache hit rate should be high.

**Default frequency** 00:05:00

- **InnoDB Buffer Pool Writes May Be Performance Bottleneck**

For optimal performance, InnoDB should not have to wait before writing pages into the InnoDB buffer pool.

**Default frequency** 00:05:00

- **InnoDB Doublewrite Buffer Enabled**

InnoDB uses a novel file flush technique called *doublewrite*. It adds safety to recovery following an operating system crash or a power outage, and improves performance on most varieties of Unix by reducing the need for `fsync()` operations.

Doublewrite means that before writing pages to a data file, InnoDB first writes them to a contiguous tablespace area called the doublewrite buffer. Only after the write and the flush to the doublewrite buffer has completed does InnoDB write the pages to their proper positions in the data file. If the operating system crashes in the middle of a page write, during recovery InnoDB can find a good copy of the page from the doublewrite buffer.

**Default frequency** 06:00:00

- **InnoDB Flush Method May Not Be Optimal**

Different values for `innodb_flush_method` can have a marked effect on InnoDB performance. In some versions of GNU/Linux and Unix, flushing files to disk by invoking `fsync()` (which InnoDB uses by default) or other similar methods, can be surprisingly slow. If you are dissatisfied with database write performance, you might try setting the `innodb_flush_method` parameter to `O_DIRECT` or `O_DSYNC`.

**Default frequency** 06:00:00

- **InnoDB Log BufferFlushed To Disk After Each Transaction**

By default, InnoDB's log buffer is written out to the log file at each transaction commit and a flush-to-disk operation is performed on the log file, which enforces ACID compliance. In the event of a crash, if you can afford to lose a second's worth of transactions, you can achieve better performance by setting `innodb_flush_log_at_trx_commit` to either 0 or 2. If you set the value to 2, then only an operating system crash or a power outage can erase the last second of transactions. This can be very useful on slave servers, where the loss of a second's worth of data can be recovered from the master server if needed.

**Default frequency** 06:00:00

- **InnoDB Log Waits May Be Performance Bottleneck**

For optimal performance, InnoDB should not have to wait before writing DML activity to the InnoDB log buffer.

**Default frequency** 00:05:00

- **InnoDB Tablespace Cannot Automatically Expand**

If the InnoDB tablespace is not allowed to automatically grow to meet incoming data demands and your application generates more data than there is room for, out-of-space errors will occur and your application may experience problems.

**Default frequency** 06:00:00

- **InnoDB Transaction Logs Not Sized Correctly**

To avoid frequent checkpoint activity and reduce overall physical I/O, which can slow down write-heavy systems, the InnoDB transaction logs should be approximately 50-100% of the size of the InnoDB buffer pool, depending on the size of the buffer pool.

**Default frequency** 06:00:00

- **Insecure Password Authentication Option Is Enabled**

Prior to MySQL 4.1, password hashes computed by the `PASSWORD()` function were 16 bytes long. As of MySQL 4.1 (and later), `PASSWORD()` was modified to produce a longer 41-byte hash value to provide enhanced security. However, in order to allow backward-compatibility with user tables that have been migrated from pre-4.1 systems, you can configure MySQL to accept logins for accounts that have password hashes created using the old, less-secure `PASSWORD()` function, but this is not recommended.

**Default frequency** 06:00:00

- **Insecure Password Generation Option Is Enabled**

Prior to MySQL 4.1, password hashes computed by the `PASSWORD()` function were 16 bytes long. As of MySQL 4.1 (and later), `PASSWORD()` was modified to produce a longer 41-byte hash value to provide enhanced security. In order to allow backward-compatibility with older client programs, you can configure MySQL to generate short (pre-4.1) password hashes for new passwords, however, this is not recommended.

**Default frequency** 06:00:00

- **INSERT ON DUPLICATE KEY UPDATE Bug May Break Replication**

For `INSERT ... ON DUPLICATE KEY UPDATE` statements where some `AUTO_INCREMENT` values were generated automatically for inserts and some rows were updated, one auto-generated value was lost per updated row, leading to faster exhaustion of the range of the `AUTO_INCREMENT` column. Affected versions of MySQL include 5.0.24 to 5.0.34, and 5.1.12 to 5.1.17 (inclusive).

Because the original problem can affect replication (different values on master and slave), it is recommended that the master and its slaves be upgraded to the current version.

**Default frequency** 06:00:00

- **Key Buffer Size Greater Than 4 GB**

To minimize disk I/O, the MyISAM storage engine employs a key cache (or key buffer) to keep the most frequently accessed index blocks in memory. However, prior to MySQL version 5.0.52 this key buffer is limited in size to 4 GB, [even on 64-bit operating systems](#). If set to a larger value, mysqld may crash when it tries to increase the actual buffer beyond 4 GB. Note that key\_buffer\_size is limited to 4GB on both 32-bit and 64-bit Windows systems, even in MySQL version 5.0.52 and later.

**Default frequency** 06:00:00

- **Key Buffer Size May Not Be Optimal For Key Cache**

The key cache hit ratio represents the proportion of keys that are being read from the key cache in memory instead of from disk. This should normally be greater than 99% for optimum efficiency.

**Default frequency** 00:05:00

- **Key Buffer Size May Not Be Optimal For System RAM**

The target server does not appear to have sufficient memory devoted to the key cache. On a dedicated server, this cache is commonly about 25%-50% of total RAM.

**Default frequency** 06:00:00

- **LOCAL Option Of LOAD DATA Statement Is Enabled**

The LOAD DATA statement can load a file that is located on the server host, or it can load a file that is located on the client host when the LOCAL keyword is specified.

There are two potential security issues with supporting the LOCAL version of LOAD DATA statements:

- The transfer of the file from the client host to the server host is initiated by the MySQL server. In theory, a patched server could be built that would tell the client program to transfer a file of the server's choosing rather than the file named by the client in the LOAD DATA statement. Such a server could access any file on the client host to which the client user has read access.
- In a Web environment where the clients are connecting from a separate web server, a user could use LOAD DATA LOCAL to read any files that the web server process has read access to (assuming that a user could run any statement against the SQL server). In this environment, the client with respect to the MySQL server actually is the web server, not the remote program being run by the user who connects to the web server.

**Default frequency** 00:05:00

- **Lock Contention Excessive**

Performance can be degraded if the percentage of table operations that have to wait for a lock is high compared to the overall number of lock requests. This can happen when using a table-level locking storage engine, such as MyISAM, instead of a row-level locking storage engine.

**Default frequency** 00:05:00

- **Malformed Password Packet In Connection Protocol Can Crash Server**

Due to [Bug#28984](#), a malformed password packet in the connection protocol could cause the server to crash. This can lead to denial of service (DoS) attacks.

This bug has been fixed in later versions of the MySQL server.

**Default frequency** 06:00:00

- **Maximum Connection Limit Nearing Or Reached**

Once the maximum connection limit for the MySQL server has been reached, no other user connections can be established and errors occur on the client side of the application.

**Default frequency** 00:05:00

- **Missing Security Improvements In GRANT Options**

The GRANT statement is used to create MySQL user accounts and to grant rights to accounts. Due to bugs 15756 and 14385, rights may be granted erroneously in certain circumstances:

- In grant table comparisons, improper use of a latin1 collation caused some hostname matches to be true that should have been false ([Bug#15756](#)).
- GRANTS to users with wildcards in their host information could be erroneously applied to similar users with the same user-name and similar wildcards. For example, a privilege granted to foo@% is also applied to user foo@192.% ([Bug#14385](#)).

These bugs have been fixed in later versions of the MySQL server.

**Default frequency** 06:00:00

- **Multi-Byte Encoding Processing Can Lead To SQL Injection**

Due to bug 8378, the server incorrectly parsed strings escaped with the mysql\_real\_escape\_string() C API function. As a result, even when the character set-aware mysql\_real\_escape\_string() function was used, SQL injection was possible.

This bug has been fixed in later versions of the MySQL server.

**Default frequency** 06:00:00

- **Multiple Threads Used When Repairing MyISAM Tables**

Using multiple threads when repairing MyISAM tables can improve performance, but it can also lead to table and index corruption as reported by several bugs ([#11527](#), [#11684](#), [#18874](#)). Even though these bugs have been fixed, this feature is still considered beta-quality, as noted in the manual.

**Default frequency** 06:00:00

- **MyISAM Concurrent Insert Setting May Not Be Optimal**

MyISAM uses table-level locking, which can adversely affect performance when there are many concurrent INSERT and SELECT statements because INSERTs will block all SELECTs until the INSERT is completed. However, MyISAM can be configured to allow INSERT and SELECT statements to run concurrently in certain situations.

- If `concurrent_insert is set to 1` (the default), MySQL allows INSERT and SELECT statements to run concurrently `for MyISAM tables that have no free blocks in the middle` of the data file.
- If `concurrent_insert is set to 2` (available in MySQL 5.0.6 and later), MySQL allows concurrent inserts `for all MyISAM tables`, even those that have holes. For a table with a hole, new rows are inserted at the end of the table if it is in use by another thread. Otherwise, MySQL acquires a normal write lock and inserts the row into the hole.

Note that setting concurrent\_insert to 2 allows tables to grow even when there are holes in the middle. This can be bad for applications that delete large chunks of data but continue to issue many SELECTs, thus effectively preventing INSERTs from filling the holes.

**Default frequency** 06:00:00

- **MyISAM Indexes Found with No Statistics**

The MySQL optimizer needs index statistics to help make choices about whether to use indexes to satisfy SQL queries. Having no statistics or outdated statistics limits the optimizer's ability to make smart and informed access plan choices.

**Default frequency** 12:00:00

- **MyISAM Key Cache Has Sub-Optimal Hit Rate**

The key cache hit ratio represents the proportion of index values that are being read from the key cache in memory instead of from disk. This should normally be greater than 99% for optimum efficiency.

**Default frequency** 00:05:00

- **MySQL Agent Memory Usage Excessive**

The memory needed by the MySQL Agent for basic monitoring is fairly small and consistent, and depends on the number of rules you have enabled. However, when the Query Analyzer is enabled, the Agent can use significantly more memory to monitor and analyze whatever queries you direct through it. In this case, the amount of memory used depends on the number of unique normalized queries, example queries and example explains being processed, plus the network bandwidth required to send query data to the Service Manager. In general, the amount of memory used for the Query Analyzer is small and well-

bounded, but under some circumstances it can become excessive, especially on older versions of Linux.

**Default frequency** 00:01:00

- **MySQL Agent Not Communicating With Database Server**

The MySQL Enterprise Service Agent must be able to communicate with the local MySQL database server in order to monitor the server and provide advice on enforcement of best practices.

**Default frequency** 00:01:00

- **MySQL Agent Not Reachable**

In order to monitor a MySQL server, a Service Agent must be running and communicating with the Service Manager. If the Agent cannot communicate with the Service Manager, the Service Manager has no way of knowing if the MySQL database server being monitored is running, and it cannot collect current statistics to properly evaluate the rules scheduled against that server.

**Default frequency** 00:00:01

- **MySQL Server Has Been Restarted**

To perform useful work, a database server must be up-and-running continuously. It is normal for a production server to run continuously for weeks, months, or longer. If a server has been restarted recently, it may be the result of planned maintenance, but it may also be due to an unplanned event that should be investigated.

**Default frequency** 00:05:00

- **MySQL Server Not Reachable**

To perform useful work, it must be possible to connect to the local MySQL database server. If the MySQL Enterprise Service Agent cannot communicate with the server, it is likely the server is not running.

**Default frequency** 00:01:00

- **Next-Key Locking Disabled For InnoDB But Binary Logging Enabled**

Next-key locking in InnoDB can be disabled, which may improve performance in some situations. However, this may result in inconsistent data when recovering from the binary logs in replication or recovery situations. Starting from MySQL 5.0.2, this option is even more unsafe than it was in version 4.1.x.

**Default frequency** 06:00:00

- **No Limit On Total Number Of Prepared Statements**

Due to [Bug#16365](#), there is no limit to the number of prepared statements that can be open per connection. This can lead to a Denial Of Service (DoS) attack, as the server will crash with out-of-memory (OOM) errors when the amount of statements becomes very large.

This bug has been fixed in later versions of the MySQL server.

**Default frequency** 06:00:00

- **No Value Set For myisam-recover**

The `myisam-recover` option enables automatic MyISAM crash recovery should a MyISAM table become corrupt for some reason. If this option is not set, then a table will be "Marked as crashed" if it becomes corrupt, and no sessions will be able to SELECT from it, or perform any sort of DML against it.

**Default frequency** 06:00:00

- **Non-Authorized User Has DB, Table, Or Index Privileges On All Databases**

Privileges such as SELECT, INSERT, ALTER, and so forth allow a user to view and change data, as well as impact system performance. Such operations should be limited to only those databases to which a user truly needs such access so the user cannot inadvertently affect other people's applications and data stores.

**Default frequency** 01:00:00

- **Non-Authorized User Has GRANT Privileges On All Databases**

The **GRANT** privilege, when given on all databases as opposed to being limited to a few specific databases, enables a user to give to other users those privileges that the grantor possesses on all databases. It can be used for databases, tables, and stored routines. Such a privilege should be limited to as few users as possible. Users who do indeed need the GRANT privilege should have that privilege limited to only those databases they are responsible for, and not for all databases.

**Default frequency** 01:00:00

- **Non-Authorized User Has Server Admin Privileges**

Certain privileges, such as SHUTDOWN and SUPER, are primarily used for server administration. Some of these privileges can have a dramatic effect on a system because they allow someone to shutdown the server or kill running processes. Such operations should be limited to a small set of users.

**Default frequency** 01:00:00

- **Object Changed: Database Has Been Altered**

For development environments, changes to databases and objects may be a normal occurrence, but not for production environments. It is wise to know when any changes occur in a production environment with respect to any database structures and investigate the reasons for the changes.

**Default frequency** 00:10:00

- **Object Changed: Database Has Been Created**

For development environments, changes to databases and objects may be a normal occurrence, but not for production environments. It is wise to know when any changes occur in a production environment with respect to any database structures and investigate the reasons for the changes.

**Default frequency** 00:10:00

- **Object Changed: Database Has Been Dropped**

For development environments, changes to databases and objects may be a normal occurrence, but not for production environments. It is wise to know when any changes occur in a production environment with respect to any database structures and investigate the reasons for the changes.

**Default frequency** 00:10:00

- **Object Changed: Function Has Been Created**

For development environments, changes to databases and objects may be a normal occurrence, but not for production environments. It is wise to know when any changes occur in a production environment with respect to any database structures and investigate the reasons for the changes.

**Default frequency** 00:10:00

- **Object Changed: Function Has Been Dropped**

For development environments, changes to databases and objects may be a normal occurrence, but not for production environments. It is wise to know when any changes occur in a production environment with respect to any database structures or functions and investigate the reasons for the changes.

**Default frequency** 00:10:00

- **Object Changed: Index Has Been Created**

For development environments, changes to databases and objects may be a normal occurrence, but not for production environments. It is wise to know when any changes occur in a production environment with respect to any database structures and investigate the reasons for the changes.

**Default frequency** 00:10:00

- **Object Changed: Index Has Been Dropped**

For development environments, changes to databases and objects may be a normal occurrence, but not for production environments. It is wise to know when any changes occur in a production environment with respect to any database structures and investigate the reasons for the changes.

**Default frequency** 00:10:00

- **Object Changed: Table Has Been Altered**

For development environments, changes to databases and objects may be a normal occurrence, but not for production environments. It is wise to know when any changes occur in a production environment with respect to database structures and investigate the reasons for the changes.

**Default frequency** 00:10:00

- **Object Changed: Table Has Been Created**

For development environments, changes to databases and objects may be a normal occurrence, but not for production environments. It is wise to know when any changes occur in a production environment with respect to database structures and investigate the reasons for the changes.

**Default frequency** 00:10:00

- **Object Changed: Table Has Been Dropped**

For development environments, changes to databases and objects may be a normal occurrence, but not for production environments. It is wise to know when changes occur in a production environment with respect to database structures and investigate the reasons for the changes.

**Default frequency** 00:10:00

- **Object Changed: User Has Been Dropped**

For development environments, changes to databases and objects may be a normal occurrence, but not for production environments. It is wise to know when changes occur in a production environment with respect to database structures and investigate the reasons for the changes.

**Default frequency** 00:10:00

- **Object Changes Detected**

For development environments, changes to databases and objects may be a normal occurrence, but not for production environments. It is wise to know when any changes occur in a production environment with respect to any database structures and investigate the reasons for the changes.

**Default frequency** 00:10:00

- **Prepared Statements Not Being Closed**

Prepared statements may increase performance in applications that execute similar statements more than once, primarily because the query is parsed only once. Prepared statements can also reduce network traffic because it is only necessary to send the data for the parameters for each execution rather than the whole statement.

However, prepared statements take time to prepare and consume memory in the MySQL server until they are closed, so it is important to use them properly. If you are not closing prepared statements when you are done with them, you are needlessly tying up memory that could be put to use in other ways.

**Default frequency** 00:05:00

- **Prepared Statements Not Being Used Effectively**

Prepared statements may increase performance in applications that execute similar statements more than once, primarily because the query is parsed only once. Prepared statements can also reduce network traffic because it is only necessary to send the data for the parameters for each execution rather than the whole statement.

However, prepared statements take time to prepare and consume memory in the MySQL server until they are closed, so it is important to use them properly. If you are only executing a statement a few times, the overhead of creating a prepared statement may not be worthwhile.

**Default frequency** 00:05:00

- **Query Cache Has Sub-Optimal Hit Rate**

When enabled, the query cache should experience a high degree of "hits", meaning that queries in the cache are being reused by other user connections. A low hit rate may mean that not enough memory is allocated to the cache, identical queries are not being issued repeatedly to the server, or that the statements in the query cache are invalidated too frequently by INSERT, UPDATE or DELETE statements.

**Default frequency** 00:05:00

- **Query Cache Not Available**

MySQL can cache the results of SELECT statements in memory so that they do not have to constantly be parsed and executed. If your application often runs the same queries over and over, caching the results can increase performance significantly. It's important to use a version or binary of MySQL that supports the query cache.

**Default frequency** 06:00:00

- **Query Cache Not Enabled**

Enabling the query cache can increase performance by 200% for queries that are executed often and have large result sets.

**Default frequency** 00:05:00

- **Query Cache Potentially Undersized**

When the Query Cache is full, and needs to add more queries to the cache, it will make more room in the cache by freeing the least recently used queries from the cache, and then inserting the new queries. If this is happening often then you should increase the size of the cache to avoid this constant "swapping".

**Default frequency** 00:05:00

- **RAM Usage Excessive**

A reasonable amount of free memory is required for a system to perform well. Without free memory, new processes and threads cannot start, and the operating system may do excessive paging (swapping blocks of memory to and from disk).

**Default frequency** 00:01:00

- **Root Account Can Login Remotely**

By default, MySQL includes a root account with unlimited privileges that is typically used to administer the MySQL server. If possible, accounts with this much power should not allow remote logins in order to limit access to only those users able to login to the machine on which MySQL is running. This helps prevent unauthorized users from accessing and changing the system.

**Default frequency** 00:05:00

- **Root Account Without Password**

The root user account has unlimited privileges and is intended for administrative tasks. Privileged accounts should have strong passwords to prevent unauthorized users from accessing and changing the system.

**Default frequency** 00:05:00

- **Row-based Replication Broken For UTF8 CHAR Columns Longer Than 85 Characters**

Due to [Bug#37426](#), row-based replication breaks when CHAR() UTF8 fields with a length greater than 85 characters are used.

This bug has been fixed in later versions of the MySQL server.

**Default frequency** 06:00:00

- **Security Alterations Detected: User Privileges Granted**

For development environments, changes to database security privileges may be a normal occurrence, but for production environments it is wise to know when any security changes occur with respect to database privileges, and to ensure that those changes are authorized and required.

**Default frequency** 00:05:00

- **Security Alterations Detected: User Privileges Revoked**

For development environments, changes to database security privileges may be a normal occurrence, but for production environments it is wise to know when any security changes occur with respect to database privileges, and to ensure that those changes are authorized and required.

**Default frequency** 00:05:00

- **Security Alterations Have Been Detected**

For development environments, changes to database security privileges may be a normal occurrence, but for production environments it is wise to know when any security changes occur with respect to database privileges, and to ensure that those changes are authorized and required.

**Default frequency** 00:05:00

- **Security Risk with BINLOG statement**

Due to [Bug#31611](#), any user can execute BINLOG statements, which effectively gives them the ability to execute any SQL statement regardless of the privileges associated with their user account (i.e. as given by the GRANT statement). This allows any connected user to get any privileges they want, edit any data they want, add and drop tables, etc.

This bug has been fixed in later versions of the MySQL server.

**Default frequency** 06:00:00

- **Server Contains Default "test" Database**

By default, MySQL comes with a database named `test` that anyone can access. This database is intended only for testing and should be removed before moving into a production environment. Because the default `test` database can be accessed by any user and has permissive privileges, it should be dropped immediately as part of the installation process.

**Default frequency** 00:05:00

- **Server Has Accounts Without A Password**

Accounts without passwords are particularly dangerous because an attacker needs to guess only a username. Assigning passwords to all accounts helps prevent unauthorized users from accessing the system.

**Default frequency** 00:05:00

- **Server Has Anonymous Accounts**

Anonymous MySQL accounts allow clients to connect to the server without specifying a username. Since anonymous accounts are well known in MySQL, removing them helps prevent unauthorized users from accessing the system.

**Default frequency** 00:05:00

- **Server Includes A Root User Account**

By default, MySQL includes a root account with unlimited privileges that is typically used to administer the MySQL server. There is no reason this account must be named 'root'. Accounts with this much power should not be easily discovered. Since the root account is well known in MySQL, changing its name helps prevent unauthorized users from accessing and changing the system.

**Default frequency** 00:05:00

- **Server-Enforced Data Integrity Checking Disabled**

SQL Modes define what SQL syntax MySQL should support and what kind of data validation checks it should perform. If no SQL modes are enabled this means there is no form of server-enforced data integrity, which means incoming data that is invalid will not be rejected by the server, but instead will be changed to conform to the target column's default datatype. Note, however, that beginning with MySQL 4.1, any client can change its own session SQL mode value at any time.

**Default frequency** 06:00:00

- **Server-Enforced Data Integrity Checking Not Strict**

SQL Modes define what SQL syntax MySQL should support and what kind of data validation checks it should perform. There are many possible options that can be used in conjunction with each other to specify varying degrees of syntax and data validation checks the MySQL server will perform. However, to ensure the highest level of confidence for data integrity, at least one of the following should be included in the list: [TRADITIONAL](#), [STRICT\\_TRANS\\_TABLES](#), or [STRICT\\_ALL\\_TABLES](#).

Note, however, that beginning with MySQL 4.1, any client can change its own session SQL mode value at any time.

**Default frequency** 06:00:00

- **Slave Detection Of Network Outages Too High**

Slaves must deal with network connectivity outages that affect the ability of the slave to get the latest data from the master, and

hence cause replication to fall behind. However, the slave notices the network outage only after receiving no data from the master for `slave_net_timeout seconds`. You may want to decrease `slave_net_timeout` so the outages -- and associated connection retries -- are detected and resolved faster. The default for this parameter is 3600 seconds (1 hour), which is too high for many environments.

**Default frequency** 06:00:00

- **Slave Error: Unknown or Incorrect Time Zone**

In order to use time zone names in conjunction with certain statements, functions, and data types, you must configure the server to understand those names by loading information from the operating system's time zone files into a set of tables in the `mysql` database. However, while the MySQL installation procedure creates those time zone tables, it does not load them; they must be loaded manually after installation.

**Default frequency** 00:05:00

- **Slave Execution Position Too Far Behind Read Position**

When a slave receives updates from its master, the I/O thread stores the data in local files known as relay logs. The slave's SQL thread reads the relay logs and executes the updates they contain. If the position from which the SQL thread is reading is way behind the position to which the I/O thread is currently writing, it is a sign that replication is getting behind and results of queries directed to the slave may not reflect the latest changes made on the master.

**Default frequency** 00:05:00

- **Slave Has Been Stopped**

If replication on a slave has been stopped, it means the slave is not retrieving the latest statements from the master and it is not executing those statements on the slave.

**Default frequency** 00:01:00

- **Slave Has Experienced A Replication Error**

When a slave receives updates from its master it must apply those updates locally so the data on the slave matches that on the server. If an error occurs while applying an update on a slave, the data on the slave may not match that on the master and it is an indication that replication may be broken.

**Default frequency** 00:05:00

- **Slave Has Login Accounts With Inappropriate Privileges**

Altering and dropping tables on a slave can break replication. Unless the slave also hosts non-replicated tables, there is no need for accounts with these privileges. As an alternative, you should set the `read_only` flag `ON` so the server allows no updates except from users that have the SUPER privilege or from updates performed by slave threads.

**Default frequency** 06:00:00

- **Slave Has Problem Communicating With Master**

Slaves must connect to a master to get the latest data from the master. If they cannot connect, or periodically have trouble connecting, replication may fall behind (i.e. the slave may not have the lastest data that was written to the master).

**Default frequency** 00:05:00

- **Slave Has Stopped Replicating**

If neither the slave I/O thread nor the slave SQL threads are running, it means the slave is not getting the latest statements from the master and it is not executing those statements on the slave, and thus replication has stopped entirely.

**Default frequency** 00:01:00

- **Slave I/O Thread Not Running**

The slave I/O thread is the thread that retrieves statements from the master's binary log and records them into the slave's relay log. If this thread isn't running, it means the slave is not able to retrieve the latest data from the master.

**Default frequency** 00:01:00

- **Slave Not Configured As Read Only**

Arbitrary or unintended updates to a slave may break replication or cause a slave to be inconsistent with respect to its master. Making a slave [read\\_only](#) can be useful to ensure that a slave accepts updates only from its master server and not from clients; it minimizes the possibility of unintended updates.

**Default frequency** 06:00:00

- **Slave Relay Log Space Is Very Large**

When a slave receives updates from its master, the I/O thread stores the data in local files known as relay logs. The slave's SQL thread reads the relay logs and executes the updates they contain. After the SQL thread has executed all the updates in a relay log, the file is no longer needed and can be deleted to conserve disk space.

**Default frequency** 06:00:00

- **Slave Relay Logs Not Automatically Purged**

When a slave receives updates from its master, the I/O thread stores the data in local files known as relay logs. The slave's SQL thread reads the relay logs and executes the updates they contain. After the SQL thread has executed all the updates in a relay log, the file is no longer needed and can be deleted to conserve disk space.

**Default frequency** 06:00:00

- **Slave SQL Thread Not Running**

The slave SQL thread is the thread that reads statements from the slave's relay log and executes them to bring the slave in sync with the master. If this thread isn't running, it means the slave is not able to apply the latest changes it has read from the master, and results of queries directed to the slave may not reflect the latest changes made on the master.

**Default frequency** 00:01:00

- **Slave SQL Thread Reading From Older Relay Log Than I/O Thread**

When a slave receives updates from its master, the I/O thread stores the data in local files known as relay logs. The slave's SQL thread reads the relay logs and executes the updates they contain. If the SQL thread is reading from an older relay log than the one to which the I/O thread is currently writing, it is a sign that replication is getting behind and results of queries directed to the slave may not reflect the latest changes made on the master.

**Default frequency** 00:05:00

- **Slave Too Far Behind Master**

If a slave is too far behind the master, results of queries directed to the slave may not reflect the latest changes made on the master.

**Default frequency** 00:01:00

- **Slave Waiting To Free Relay Log Space**

For slaves with limited disk space you can place a limit on how large the replication relay log can grow. When the limit is reached, the I/O thread stops reading binary log events from the master server until the SQL thread has caught up and deleted some unprocessed relay logs. While this protects MySQL from filling up the disk, it means replication is delayed and the slave will fall behind the master.

**Default frequency** 00:05:00

- **Slave Without REPLICATION SLAVE Accounts**

If the master ever fails, you may want to use one of the slaves as the new master. An account with the REPLICATION SLAVE privilege must exist for a server to act as a replication master (so a slave can connect to it), so it's a good idea to create this account on your slaves to prepare it to take over for a master if needed.

**Default frequency** 06:00:00

- **Slow Query Log Not Enabled**

The slow query log can be used to identify queries that take a long time to complete.

**Default frequency** 00:05:00

- **Stored Procedures Found With SELECT \* Syntax**

Best practices for SQL coding state that no query should be issued with SELECT \*. Reasons include:

- To ensure that only the necessary columns are returned from a SQL statement, the actual column names should be specifically entered. This cuts down on unwanted network traffic as only columns necessary for query satisfaction are present.
- If the underlying table has columns added or removed, the query itself may malfunction if cursors or other such application objects are used.

**Default frequency** 06:00:00

- **Stored Routine Runs In Definer's Rather Than Caller's Security Context**

Due to bug 18630, a stored routine created by one user and then made accessible to a different user using GRANT EXECUTE could be executed by that user with the privileges of the routine's definer.

This bug has been fixed in later versions of the MySQL server.

**Default frequency** 06:00:00

- **Symlinks Are Enabled**

You can move tables and databases from the database directory to other locations and replace them with symbolic links to the new locations. You might want to do this, for example, to move a database to a file system with more free space or to increase the speed of your system by spreading your tables to different disks.

However, symlinks can compromise security. This is especially important if you run mysqld as root, because anyone who has write access to the server's data directory could then delete any file in the system!

**Default frequency** 06:00:00

- **Table Cache Not Optimal**

MySQL is multi-threaded, so there may be many clients issuing queries for a given table simultaneously. To minimize the problem with multiple client threads having different states on the same table, the table is opened independently by each concurrent thread.

The table cache is used to cache file descriptors for open tables and there is a single cache shared by all clients. Increasing the size of the table cache allows mysqld to keep more tables open simultaneously by reducing the number of file open and close operations that must be done. If the value of `Open_tables` is approaching the value of `table_cache`, this may indicate performance problems.

**Default frequency** 00:05:00

- **Table Cache Set Too Low For Startup**

The table cache size controls the number of open tables that can occur at any one time on the server. MySQL will work to open and close tables as needed, however you should avoid having the table cache set too low, causing MySQL to constantly open and close tables to satisfy object access.

If the table cache limit has been exceeded by the number of tables opened in the first three hours of service, then the table cache size is likely set too low.

**Default frequency** 00:30:00

- **Table Lock Contention Excessive**

Performance can be degraded if the percentage of table operations that have to wait for a lock is high compared to the overall number of lock requests. This can happen when using a table-level locking storage engine, such as MyISAM, instead of a row-level locking storage engine.

**Default frequency** 00:05:00

- **Table Scans Excessive**

The target server does not appear to be using indexes efficiently. The values of Handler\_read\_rnd\_next and Handler\_read\_rnd together - which reflect the number of rows read via full table scans - are high compared to the sum of Handler variables which denote all row accesses - such as Handler\_read\_key, Handler\_read\_next etc. You should examine your tables and queries for proper use of indexes.

**Default frequency** 00:05:00

- **Tables Found with No Primary or Unique Keys**

A primary or unique key of a relational table uniquely identifies each record in the table. Except in very unusual circumstances, every database table should have one or more columns designated as the primary key or as a unique key, and it is common practice to declare one.

**Default frequency** 12:00:00

- **Temporary Tables To Disk Ratio Excessive**

If the space required to build a temporary table exceeds either `tmp_table_size` or `max_heap_table_size`, MySQL creates a disk-based table in the server's tmpdir directory. Also, tables that have TEXT or BLOB columns are automatically placed on disk.

For performance reasons it is ideal to have most temporary tables created in memory, leaving exceedingly large temporary tables to be created on disk.

**Default frequency** 00:05:00

- **Thread Cache Not Enabled**

Each connection to the MySQL database server runs in its own thread. Thread creation takes time, so rather than killing the thread when a connection is closed, the server can keep the thread in its thread cache and use it for a new connection later.

**Default frequency** 00:05:00

- **Thread Cache Size May Not Be Optimal**

Each connection to the MySQL database server runs in its own thread. Thread creation takes time, so rather than killing the thread when a connection is closed, the server can keep the thread in its thread cache and use it for a new connection later.

**Default frequency** 00:05:00

- **Too Many Concurrent Queries Running**

Too many active queries indicates there is a severe load on the server, and may be a sign of lock contention or unoptimized SQL queries.

**Default frequency** 00:05:00

- **Use Of View Overrides Column Update Privileges On Underlying Table**

Due to [Bug#27878](#), by using a view, a user who only has privileges to update a given column of a table is able to update any column of that table, even though the view is defined with SQL SECURITY INVOKER. Also, use of a view could allow a user to gain update privileges for tables in other databases.

This bug has been fixed in later versions of the MySQL server.

**Default frequency** 06:00:00

- **User Can Gain Privileges By Running Stored Routine Declared Using SQL SECURITY INVOKER**

Due to [Bug#27337](#), if a stored routine was declared using SQL SECURITY INVOKER, a user who invoked the routine could gain privileges. For example, a user without the CREATE privilege on a certain database could gain that privilege after invoking a stored routine.

This bug has been fixed in later versions of the MySQL server.

**Default frequency** 06:00:00

- **User Has Rights To Database That Does Not Exist**

When a database is dropped, user privileges on the database are not automatically dropped. This has security implications as that user will regain privileges if a database with the same name is created in the future, which may not be the intended result.

**Default frequency** 00:05:00

- **User With Only ALTER Privilege On Partitioned Table Can Obtain SELECT Privilege Information**

Due to [Bug#23675](#), a user with only the ALTER privilege on a partitioned table could obtain information about the table that should require the SELECT privilege.

This bug has been fixed in later versions of the MySQL server.

**Default frequency** 06:00:00

- **Users Can View All Databases On MySQL Server**

The SHOW DATABASES privilege should be granted only to users who need to see all the databases on a MySQL Server. It is recommended that the MySQL Server be started with the `--skip-show-database` option enabled to prevent anyone from using the SHOW DATABASES statement unless they have been specifically granted the SHOW DATABASES privilege.

Note: If a user is granted any global privilege, such as CREATE TEMPORARY TABLES or LOCK TABLES, they are automatically given the ability to show databases unless the server is started with the `--skip-show-database` option enabled. DBAs should be aware of this fact, in the event that any applications make use of temporary tables.

**Default frequency** 00:05:00

- **XA Distributed Transaction Support Enabled For InnoDB**

XA Distributed Transaction support is turned on by default. If you are not using this feature, note that it adds an extra fsync for each transaction and may adversely affect performance.

**Default frequency** 06:00:00

## 15.12.11.2. Graph Definition Reference

Individual graphs are defined below.

### Connections

<b>Name</b>	Connections
<b>Range Label</b>	# connections
<b>Series</b>	<b>Expression</b>
<b>Cached</b>	<code>cached</code>
<b>Running</b>	<code>running</code>
<b>Total</b>	<code>connected</code>
<b>Variables</b>	<b>Data Item</b>
<b>connected</b>	<code>mysql:status:Threads_connected</code>
<b>running</b>	<code>mysql:status:Threads_running</code>
<b>cached</b>	<code>mysql:status:Threads_cached</code>

### Connections - Aborted

<b>Name</b>	Connections - Aborted
<b>Range Label</b>	total/min
<b>Series</b>	<b>Expression</b>
<b>Clients</b>	<code>clients</code>
<b>Connections</b>	<code>connections</code>
<b>Variables</b>	<b>Data Item</b>
<b>clients</b>	<code>mysql:status:Aborted_clients</code>
<b>connections</b>	<code>mysql:status:Aborted_connects</code>

### Connections - Cache

<b>Name</b>	Connections - Cache
<b>Range Label</b>	total/min
<b>Series</b>	<b>Expression</b>
<b>Connections</b>	<code>connections</code>

---

<b>Threads Created</b>	<code>tcreated</code>
<b>Variables</b>	<b>Data Item</b>
<b>tcreated</b>	<code>mysql:status:Threads_created</code>
<b>connections</b>	<code>mysql:status:Connections</code>

**Connections - Maximum**

<b>Name</b>	Connections - Maximum
<b>Range Label</b>	total
<b>Series</b>	<b>Expression</b>
<b>Allowed</b>	<code>max_connections_allowed</code>
<b>Used</b>	<code>max_connections_used</code>
<b>Variables</b>	<b>Data Item</b>
<b>max_connections_allowed</b>	<code>mysql:variables:max_connections</code>
<b>max_connections_used</b>	<code>mysql:status:Max_used_connections</code>

**CPU Utilization**

<b>Name</b>	CPU Utilization
<b>Range Label</b>	%
<b>Series</b>	<b>Expression</b>
<b>Kernel</b>	<code>sys/(sys+user+wait+idle)*100</code>
<b>Total</b>	<code>(sys+user+wait)/(sys+user+wait+idle)*100</code>
<b>User</b>	<code>user/(sys+user+wait+idle)*100</code>
<b>Wait I/O</b>	<code>wait/(sys+user+wait+idle)*100</code>
<b>Variables</b>	<b>Data Item</b>
<b>sys</b>	<code>os:cpu:cpu_sys</code>
<b>user</b>	<code>os:cpu:cpu_user</code>
<b>wait</b>	<code>os:cpu:cpu_wait</code>
<b>idle</b>	<code>os:cpu:cpu_idle</code>

**Database Activity**

<b>Name</b>	Database Activity
<b>Range Label</b>	avg statements/sec
<b>Series</b>	<b>Expression</b>
<b>Call</b>	<code>((call_proc)/60)</code>
<b>Delete</b>	<code>((deletes+delete_multi)/60)</code>
<b>Insert</b>	<code>((inserts+insert_selects)/60)</code>
<b>Replace</b>	<code>((replaces+replace_selects)/60)</code>
<b>Select</b>	<code>(selects/60)</code>
<b>Update</b>	<code>((updates+update_multi)/60)</code>
<b>Variables</b>	<b>Data Item</b>
<b>selects</b>	<code>mysql:status:Com_select</code>
<b>inserts</b>	<code>mysql:status:Com_insert</code>
<b>insert_selects</b>	<code>mysql:status:Com_insert_select</code>
<b>updates</b>	<code>mysql:status:Com_update</code>
<b>update_multi</b>	<code>mysql:status:Com_update_multi</code>
<b>replaces</b>	<code>mysql:status:Com_replace</code>

<code>replace_selects</code>	<code>mysql:status:Com_replace_select</code>
<code>deletes</code>	<code>mysql:status:Com_delete</code>
<code>delete_multi</code>	<code>mysql:status:Com_delete_multi</code>
<code>call_proc</code>	<code>mysql:status:Com_call_procedure</code>

**Hit Ratios**

<b>Name</b>	Hit Ratios
<b>Range Label</b>	%
<b>Series</b>	<b>Expression</b>
<b>InnoDB Buffer</b>	<code>100-((iReads / (iReadRequests+1))*100)</code>
<b>Key Cache</b>	<code>(100-((keyReads / (keyReadRequests+1))*100)) * (keyReadRequests &gt;= keyReads)</code>
<b>Query Cache</b>	<code>(qHits/(qHits+qInserts+1))*100</code>
<b>Thread Cache</b>	<code>100-((tcreated / (connections+1))*100)</code>
<b>Variables</b>	<b>Data Item</b>
<code>keyReads</code>	<code>mysql:status:Key_reads</code>
<code>keyReadRequests</code>	<code>mysql:status:Key_read_requests</code>
<code>iReads</code>	<code>mysql:status:Innodb_buffer_pool_reads</code>
<code>iReadRequests</code>	<code>mysql:status:Innodb_buffer_pool_read_requests</code>
<code>tcreated</code>	<code>mysql:status:Threads_created</code>
<code>connections</code>	<code>mysql:status:Connections</code>
<code>qHits</code>	<code>mysql:status:Qcache_hits</code>
<code>qInserts</code>	<code>mysql:status:Qcache_inserts</code>

**InnoDB Adaptive Hash Index Memory**

<b>Name</b>	InnoDB Adaptive Hash Index Memory
<b>Range Label</b>	MB
<b>Series</b>	<b>Expression</b>
<b>Hash Node Size</b>	<code>( hash_size * 16384 ) / 1024 / 1024</code>
<b>Variables</b>	<b>Data Item</b>
<code>hash_size</code>	<code>mysql:innodbstatus:innodb_hash_node_heap</code>

**InnoDB Adaptive Hash Index Searches**

<b>Name</b>	InnoDB Adaptive Hash Index Searches
<b>Range Label</b>	searches/sec
<b>Series</b>	<b>Expression</b>
<code>hash searches</code>	<code>hash</code>
<code>non-hash searches</code>	<code>nonhash</code>
<b>Variables</b>	<b>Data Item</b>
<code>hash</code>	<code>mysql:innodbstatus:innodb_hash_searches_per_sec</code>
<code>nonhash</code>	<code>mysql:innodbstatus:innodb_non_hash_searches_per_sec</code>

**InnoDB Adaptive Hash Index Usage**

<b>Name</b>	InnoDB Adaptive Hash Index Usage
<b>Range Label</b>	cells
<b>Series</b>	<b>Expression</b>

<b>total cells</b>	<code>size</code>
<b>used cells</b>	<code>used</code>
<b>Variables</b>	<b>Data Item</b>
<b>size</b>	<code>mysql:innodbstatus:innodb_hash_table_size</code>
<b>used</b>	<code>mysql:innodbstatus:innodb_hash_used_cells</code>

**InnoDB Buffer Pool**

<b>Name</b>	InnoDB Buffer Pool
<b>Range Label</b>	MB
<b>Series</b>	<b>Expression</b>
<b>Modified</b>	<code>(modified*16384)/(1024*1024)</code>
<b>Total Size</b>	<code>(size*16384)/(1024*1024)</code>
<b>Used</b>	<code>(used*16384)/(1024*1024)</code>
<b>Variables</b>	<b>Data Item</b>
<b>size</b>	<code>mysql:innodbstatus:innodb_bp_size</code>
<b>used</b>	<code>mysql:innodbstatus:innodb_bp_db_pages</code>
<b>modified</b>	<code>mysql:innodbstatus:innodb_bp_modified_pages</code>

**InnoDB OS File Access**

<b>Name</b>	InnoDB OS File Access
<b>Range Label</b>	avg operations/sec
<b>Series</b>	<b>Expression</b>
<b>File fsync()</b>	<code>(fsync/60)</code>
<b>File Reads</b>	<code>(read/60)</code>
<b>File Writes</b>	<code>(write/60)</code>
<b>Variables</b>	<b>Data Item</b>
<b>read</b>	<code>mysql:innodbstatus:innodb_io_os_file_reads</code>
<b>write</b>	<code>mysql:innodbstatus:innodb_io_os_file_writes</code>
<b>fsync</b>	<code>mysql:innodbstatus:innodb_io_os_file_fsyncs</code>

**InnoDB Row Details**

<b>Name</b>	InnoDB Row Details
<b>Range Label</b>	avg rows/sec
<b>Series</b>	<b>Expression</b>
<b>Rows Deleted</b>	<code>(deleted/60)</code>
<b>Rows Inserted</b>	<code>(inserted/60)</code>
<b>Rows Read</b>	<code>(read/60)</code>
<b>Rows Updated</b>	<code>(updated/60)</code>
<b>Variables</b>	<b>Data Item</b>
<b>read</b>	<code>mysql:innodbstatus:innodb_rows_read</code>
<b>inserted</b>	<code>mysql:innodbstatus:innodb_rows_inserted</code>
<b>updated</b>	<code>mysql:innodbstatus:innodb_rows_updated</code>
<b>deleted</b>	<code>mysql:innodbstatus:innodb_rows_deleted</code>

**InnoDB Semaphores**

<b>Name</b>	InnoDB Semaphores
-------------	-------------------

<b>Range Label</b>	avg waits/sec
<b>Series</b>	<b>Expression</b>
<b>OS Waits</b>	(oswaits/60)
<b>Spin Rounds</b>	(srounds/60)
<b>Spin Waits</b>	(swaits/60)
<b>Variables</b>	<b>Data Item</b>
<b>swaits</b>	mysql:innodbstatus:innodb_sem_mutex_spin_waits
<b>srounds</b>	mysql:innodbstatus:innodb_sem_mutex_rounds
<b>oswaits</b>	mysql:innodbstatus:innodb_sem_mutex_os_waits

**KBytes In/Out**

<b>Name</b>	KBytes In/Out
<b>Range Label</b>	avg kbytes/sec
<b>Series</b>	<b>Expression</b>
<b>Received</b>	((bytesIn/1024)/60)
<b>Sent</b>	((bytesOut/1024)/60)
<b>Total</b>	((bytesIn+bytesOut)/1024)/60)
<b>Variables</b>	<b>Data Item</b>
<b>bytesIn</b>	mysql:status:Bytes_received
<b>bytesOut</b>	mysql:status:Bytes_sent

**Load Average**

<b>Name</b>	Load Average
<b>Range Label</b>	Load Average
<b>Series</b>	<b>Expression</b>
<b>1</b>	zero
<b>15</b>	two
<b>5</b>	one
<b>Variables</b>	<b>Data Item</b>
<b>zero</b>	os:loadavg:0
<b>one</b>	os:loadavg:1
<b>two</b>	os:loadavg:2

**Memory Usage - Agent**

<b>Name</b>	Memory Usage - Agent
<b>Range Label</b>	MB
<b>Series</b>	<b>Expression</b>
<b>Agent</b>	agent_mem_size / 1024 / 1024
<b>Lua</b>	lua_mem_size / 1024 / 1024
<b>Variables</b>	<b>Data Item</b>
<b>lua_mem_size</b>	agent:lua:mem_size
<b>agent_mem_size</b>	agent:proc:mem_resident

**Memory Usage - OS Resident**

<b>Name</b>	Memory Usage - OS Resident
<b>Range Label</b>	MB

---

Series	Expression
<b>Total</b>	<code>ram_total/(1024*1024)</code>
<b>Used</b>	<code>(ram_total-ram_unused)/(1024*1024)</code>
<b>Variables</b>	<b>Data Item</b>
<b>ram_total</b>	<code>os:mem:ram_total</code>
<b>ram_unused</b>	<code>os:mem:ram_unused</code>

**Memory Usage - OS Virtual**

<b>Name</b>	Memory Usage - OS Virtual
<b>Range Label</b>	MB
<b>Series</b>	<b>Expression</b>
<b>Total</b>	<code>swap_total/(1024*1024)</code>
<b>Used</b>	<code>(swap_total-swap_unused)/(1024*1024)</code>
<b>Variables</b>	<b>Data Item</b>
<b>swap_total</b>	<code>os:mem:swap_total</code>
<b>swap_unused</b>	<code>os:mem:swap_unused</code>

**MyISAM Key Buffer Usage**

<b>Name</b>	MyISAM Key Buffer Usage
<b>Range Label</b>	MB
<b>Series</b>	<b>Expression</b>
<b>Allocated</b>	<code>((blk_size)*(used+unused))/1024/1024</code>
<b>Total Size</b>	<code>key_buffer/1024/1024</code>
<b>Unused</b>	<code>(blk_size*unused)/1024/1024</code>
<b>Used</b>	<code>(blk_size*used)/1024/1024</code>
<b>Variables</b>	<b>Data Item</b>
<b>key_buffer</b>	<code>mysql:variables:key_buffer_size</code>
<b>blk_size</b>	<code>mysql:variables:key_cache_block_size</code>
<b>unused</b>	<code>mysql:status:Key_blocks_unused</code>
<b>used</b>	<code>mysql:status:Key_blocks_used</code>

**Opened Tables**

<b>Name</b>	Opened Tables
<b>Range Label</b>	total/min
<b>Series</b>	<b>Expression</b>
<b>Opened Tables</b>	<code>openedTables</code>
<b>Variables</b>	<b>Data Item</b>
<b>openedTables</b>	<code>mysql:status:Opened_tables</code>

**Query Cache Blocks**

<b>Name</b>	Query Cache Blocks
<b>Range Label</b>	num blocks
<b>Series</b>	<b>Expression</b>
<b>Free</b>	<code>free_blocks</code>
<b>Size</b>	<code>size_blocks</code>
<b>Variables</b>	<b>Data Item</b>

---

<code>size_blocks</code>	<code>mysql:status:Qcache_total_blocks</code>
<code>free_blocks</code>	<code>mysql:status:Qcache_free_blocks</code>

**Query Cache Efficiency**

<b>Name</b>	Query Cache Efficiency
<b>Range Label</b>	avg cache ops/sec
<b>Series</b>	<b>Expression</b>
<b>Hits</b>	<code>(hits/60)</code>
<b>Inserts</b>	<code>(inserts/60)</code>
<b>Not Cached</b>	<code>(not_cached/60)</code>
<b>Variables</b>	<b>Data Item</b>
<b>hits</b>	<code>mysql:status:Qcache_hits</code>
<b>inserts</b>	<code>mysql:status:Qcache_inserts</code>
<b>not_cached</b>	<code>mysql:status:Qcache_not_cached</code>

**Query Cache Lowmem Prunes**

<b>Name</b>	Query Cache Lowmem Prunes
<b>Range Label</b>	avg cache ops/sec
<b>Series</b>	<b>Expression</b>
<b>Lowmem Prunes</b>	<code>(deletes/60)</code>
<b>Variables</b>	<b>Data Item</b>
<b>deletes</b>	<code>mysql:status:Qcache_lowmem_prunes</code>

**Query Cache Memory**

<b>Name</b>	Query Cache Memory
<b>Range Label</b>	MB
<b>Series</b>	<b>Expression</b>
<b>Free MB</b>	<code>free/(1024*1024)</code>
<b>Size MB</b>	<code>size/(1024*1024)</code>
<b>Variables</b>	<b>Data Item</b>
<b>size</b>	<code>mysql:variables:query_cache_size</code>
<b>free</b>	<code>mysql:status:Qcache_free_memory</code>

**Query Cache Queries**

<b>Name</b>	Query Cache Queries
<b>Range Label</b>	num queries
<b>Series</b>	<b>Expression</b>
<b>Queries in Cache</b>	<code>queries</code>
<b>Variables</b>	<b>Data Item</b>
<b>queries</b>	<code>mysql:status:Qcache_queries_in_cache</code>

**Replication Delay**

<b>Name</b>	Replication Delay
<b>Range Label</b>	total seconds
<b>Series</b>	<b>Expression</b>

---

<b>Seconds Behind Master</b>	<code>sbehind</code>
<b>Variables</b>	<b>Data Item</b>
<b>sbehind</b>	<code>mysql:slavestatus:Seconds_Behind_Master</code>

**Row Accesses**

<b>Name</b>	Row Accesses
<b>Range Label</b>	avg rows/sec
<b>Series</b>	<b>Expression</b>
<b>Average Rows Per Query</b>	<code>((first+key+next+prev+hread_rnd+hread_rnd_next+sort_rows) / questions)</code>
<b>Rows Read via Full Scan</b>	<code>((hread_rnd+hread_rnd_next)/60)</code>
<b>Rows Read via Indexes</b>	<code>((first+key+next+prev)/60)</code>
<b>Variables</b>	<b>Data Item</b>
<b>first</b>	<code>mysql:status:Handler_read_first</code>
<b>key</b>	<code>mysql:status:Handler_read_key</code>
<b>next</b>	<code>mysql:status:Handler_read_next</code>
<b>prev</b>	<code>mysql:status:Handler_read_prev</code>
<b>hread_rnd</b>	<code>mysql:status:Handler_read_rnd</code>
<b>hread_rnd_next</b>	<code>mysql:status:Handler_read_rnd_next</code>
<b>sort_rows</b>	<code>mysql:status:Sort_rows</code>
<b>questions</b>	<code>mysql:status:Questions</code>

**Row Writes**

<b>Name</b>	Row Writes
<b>Range Label</b>	avg rows/sec
<b>Series</b>	<b>Expression</b>
<b>Rows Deleted</b>	<code>(delete/60)</code>
<b>Rows Inserted</b>	<code>(write/60)</code>
<b>Rows Updated</b>	<code>(update/60)</code>
<b>Variables</b>	<b>Data Item</b>
<b>delete</b>	<code>mysql:status:Handler_delete</code>
<b>update</b>	<code>mysql:status:Handler_update</code>
<b>write</b>	<code>mysql:status:Handler_write</code>

**Sort Activity**

<b>Name</b>	Sort Activity
<b>Range Label</b>	total/min
<b>Series</b>	<b>Expression</b>
<b>Merge Passes</b>	<code>Sort_merge_passes</code>
<b>Range</b>	<code>Sort_range</code>
<b>Scan</b>	<code>Sort_scan</code>
<b>Variables</b>	<b>Data Item</b>
<b>Sort_merge_passes</b>	<code>mysql:status:Sort_merge_passes</code>
<b>Sort_range</b>	<code>mysql:status:Sort_range</code>
<b>Sort_scan</b>	<code>mysql:status:Sort_scan</code>

**Table Lock Wait Ratio**

Name	Table Lock Wait Ratio
Range Label	lock wait %
Series	Expression
<b>Wait Ratio</b>	<code>((lock_waits/lock_immediate)*100)</code>
Variables	Data Item
<code>lock_waits</code>	<code>mysql:status:Table_locks_waited</code>
<code>lock_immediate</code>	<code>mysql:status:Table_locks_immediate</code>

**Table Locks**

Name	Table Locks
Range Label	avg locks/sec
Series	Expression
<b>Immediate</b>	<code>(locks_immediate/60)</code>
<b>Waited</b>	<code>(locks_waited/60)</code>
Variables	Data Item
<code>locks_waited</code>	<code>mysql:status:Table_locks_waited</code>
<code>locks_immediate</code>	<code>mysql:status:Table_locks_immediate</code>

**Temporary Tables**

Name	Temporary Tables
Range Label	total/min
Series	Expression
<b>Disk Temp Tables</b>	<code>diskTempTables</code>
<b>Memory Temp Tables</b>	<code>memoryTempTables</code>
Variables	Data Item
<code>memoryTempTables</code>	<code>mysql:status:Created_tmp_tables</code>
<code>diskTempTables</code>	<code>mysql:status:Created_tmp_disk_tables</code>

## 15.13. MySQL Enterprise Monitor Frequently Asked Questions

**Note**

MySQL Enterprise subscription, MySQL Enterprise Monitor, MySQL Replication Monitor, and MySQL Query Analyzer are only available to commercial customers. To learn more, see: <http://www.mysql.com/products/enterprise/features.html>.

## Questions and Answers

### **16.13.1: Can I run MySQL Enterprise Service Manager on machine with other applications running?**

You can, but ideally you should be running your MySQL Enterprise Service Manager on a dedicated machine, especially if you are monitoring a number of different agents. For more information, see [Section 15.12.5, “Choosing Suitable MySQL Enterprise Service Manager Hardware Configurations”](#).

### **16.13.2: What is the relationship between the advisor JAR file and the key?**

The JAR file contains graph and advisor definitions. The key file contains typical customer validation data such as contract information, number of servers covered, subscription level and dates.

### **16.13.3: During query analysis, I am unable to obtain an `EXAMPLE` or `EXPLAIN` information when examining the detail of the analyzed query within the **QUERY ANALYZER** panel.**

You must explicitly enable the `EXAMPLE` and `EXPLAIN` query functionality. Make sure that you have enabled both panels. See [Section 15.10.7, “Query Analyzer Settings”](#).

### **16.13.4: I have started a Data Migration of my old data for a server to MySQL Enterprise Service Manager 2.0, but I have noticed that the performance of the monitor server has degraded significantly. Can I stop the migration?**

You can stop the migration of your historical data at any time. Go to the **MANAGE SERVERS** display of the **SETTINGS** panel and click **STOP** next to each server that is being migrated. You can restart the migration at any point.

### **16.13.5: Can the Trial-level key work with the Gold-level advisors JAR file?**

The Trial-level key can only be used with the Trial-level advisors JAR file.

### **16.13.6: Does the Gold-level key support Silver-level advisors?**

The Gold-level advisor JAR file will contain Silver-level advisors plus Gold-level advisors. However, you cannot use the Gold-level key with the Silver-level advisors JAR file. The Gold-level key can only be used with the Gold-level advisors JAR file.

### **16.13.7: Does Query Analyzer work with all versions of MySQL and the MySQL Client Libraries?**

The MySQL Proxy component, and Query Analyzer, require that clients connecting through MySQL Enterprise Monitor Agent are using MySQL 5.0 or later. Clients that use the library provided with MySQL 4.1 or earlier will not work with MySQL Enterprise Monitor Agent.

#### **16.13.8: I have enabled EXPLAIN queries for Query Analyzer, but no queries with the EXPLAIN data are showing up in the display.**

Query Analyzer only obtains EXPLAIN information when the MySQL Enterprise Monitor Agent identifies a long running query. If none of your queries exceed the defined threshold, then the EXPLAIN information is not obtained and provided to the Query Analyzer for display.

To change the query duration at which an EXPLAIN is triggered, you must edit the `share/mysql-proxy/quan.lua` file within the MySQL Enterprise Monitor Agent directory on each server. You need to change the value configured in the `auto_explain_min_exec_time_us`. The default is 500ms:

```
--
-- configuration
--
-- SET GLOBAL analyze_query.auto_filter = 0
if not proxy.global.config.quan then
 proxy.global.config.quan = {
 analyze_queries = true, -- track all queries
 query_cutoff = 160, -- only show the first 160 chars of the query
 num_worst_queries = 5,
 auto_explain = true,
 auto_explain_min_exec_time_us = 500 * 1000
 }
end
```

The value is expressed in microseconds, which is why the value must be multiplied by 1000. To reduce this value to 100ms you would modify the line:

```
auto_explain_min_exec_time_us = 100 * 1000
```

You do not need to restart MySQL Enterprise Monitor Agent for the changes to take effect.

#### **16.13.9: While monitoring my network traffic I have noticed that the agents communicate information at irregular intervals to the MySQL Enterprise Service Manager. I cannot see anything in my configuration that would explain this behavior. What is going on?**

Each MySQL Enterprise Monitor Agent periodically sends information to the server about a range of different information, including the core rule and statistical data, Query Analyzer information and other data used to monitor the status of your MySQL server.

One element of this is called the MySQL Enterprise Monitor Agent Heartbeat, which is core information exchange that indicates that the monitored server is still up and running. The heartbeat information is vital because it tells the MySQL Enterprise Service Manager that the agent and server are still communicating. This information is sent regularly to the MySQL Enterprise Service Manager, but to prevent multiple agents from sending the information at the same time, and creating a large network load (or storm), the interval is randomized with each heartbeat. The randomization ensures that the information is still uploaded periodically, but without the potential to overload the network with this data.

#### **16.13.10: How do I change the name of a server?**

Go to the **MANAGE SERVERS** panel within **SETTINGS** and click **RENAME SERVER**.

Renaming the server in this way will override all other server naming, including changes to the agent configuration.

#### **16.13.11: My MySQL Enterprise Service Manager is behind a firewall but it cannot communicate with the MySQL Enterprise website to register and download my license key and advisor bundle. I normally use a proxy service to access external websites. How do I configure the proxy settings for MySQL Enterprise Dashboard?**

To configure a proxy service, you need to edit the `apache-tomcat/conf/catalina.properties` file within the MySQL Enterprise Service Manager installation directory. To make the changes, the proxy configuration information to the end of the file by setting the `http.proxyHost` and `http.proxyPort` properties:

```
http.proxyHost=proxy.example.com
http.proxyPort=8080
```

You will need to restart the MySQL Enterprise Service Manager for the change to take effect:

```
shell> mysqlmonitorctl.sh restart
```

#### **16.13.12: I have set the graphs to update every 5 minutes, and the page refresh to occur every minute. The page is refreshing correctly, but the graphs do not seem to update.**

The graph refresh and page refresh are two different parameters. The graphs will update according to their refresh period, regardless of the refresh period set for the main display page.

#### **16.13.13: Why do some rules appear to have a SEVERITY of UNKNOWN?**

Due to timing issues, certain rules such as “32-Bit Binary Running on 64-Bit AMD Or Intel System” and “Key Buffer Size Greater Than 4 GB” do not evaluate correctly due to timing issues. This is a known issue and will be resolved in future versions of MySQL Enterprise Monitor.

#### **16.13.14: How frequently is the data purge process executed?**

A data purge process is started approximately once a minute. If you have changed the purge period then the data will start to be purged within the next minute.

#### **Questions and Answers**

##### **16.13.1: Do all my MySQL Enterprise subscriptions need to be at the same tier?**

MySQL Enterprise subscriptions must be at the same tier (Basic, Silver, Gold, Platinum) for all database servers that power that specific application.

##### **16.13.2: Are there any MySQL Enterprise White Papers available?**

Yes. Detailed architecture, technology, and business white papers are available. [ht-tp://www.mysql.com/products/enterprise/whitepapers.html](http://www.mysql.com/products/enterprise/whitepapers.html)

#### **16.13.3: Does MySQL Enterprise include Maintenance, Updates, and Upgrades?**

Yes. As long as you have a valid contract for MySQL Enterprise, you will receive all new MySQL Enterprise Server software releases including Software Maintenance, Updates, and Upgrades. The Software Update Service will automatically notify you of the new releases.

#### **16.13.4: What if I plan to add more MySQL servers to my MySQL Enterprise subscription?**

A great option is the MySQL Enterprise Unlimited offering that allows you cover an unlimited number of MySQL servers for a fixed, low price. <http://www.mysql.com/products/enterprise/unlimited.html>

#### **16.13.5: What is the list of Supported Platforms?**

MySQL Enterprise provides broad coverage in its list of Supported Platforms. <http://www.mysql.com/support/supportedplatforms/>

#### **16.13.6: How do I buy MySQL Enterprise?**

For pricing and to buy MySQL Enterprise, visit the [Online Shop](#) For volume discounts or for more information, please [ht-tp://www.mysql.com/about/contact/sales.html?s=corporate](http://www.mysql.com/about/contact/sales.html?s=corporate)

#### **16.13.7: How should I decide between MySQL Enterprise Basic, Silver, Gold and Platinum?**

MySQL Enterprise subscriptions are available in 4 tiers, providing you the flexibility of choosing the capabilities and SLA that best meet your requirements. <http://www.mysql.com/products/enterprise/features.html> If you have questions and what to discuss your specific requirements, please <http://www.mysql.com/about/contact/sales.html?s=corporate>

#### **16.13.8: How do I get a 30-day trial on MySQL Enterprise?**

You can experience the MySQL Enterprise Monitor for 30 days by registering to receive an email with login instructions. [ht-tp://www.mysql.com/trials/enterprise](http://www.mysql.com/trials/enterprise)

#### **16.13.9: Are there any Demo/Tutorials available for MySQL Enterprise?**

Yes. Multiple self-running demos are available. <http://www.mysql.com/products/enterprise/demo.html>

#### **16.13.10: What is MySQL Production Support?**

Production Support consists of 4 components:

- Problem Resolution Support
- Consultative Support
- Knowledge Base
- Technical Account Manager (option)

MySQL Production Support gives you priority access with guaranteed response times to assist you with the development, deployment and management of your MySQL applications. <http://www.mysql.com/products/enterprise/support.html>

#### **16.13.11: Does MySQL Enterprise include 24x7 Technical Support?**

MySQL Enterprise, at the Gold and Platinum tiers, includes 24x7 phone and email access to the MySQL Support Team. [ht-tp://www.mysql.com/products/enterprise/problemresolution.html](http://www.mysql.com/products/enterprise/problemresolution.html)

#### **16.13.12: What is MySQL Enterprise Server?**

MySQL Enterprise Server software is the most reliable, secure and up-to-date version of MySQL for cost-effectively delivering E-commerce, Online Transaction Processing (OLTP), and multi-terabyte Data Warehousing applications. It is a fully integrated transaction-safe, ACID compliant database with full commit, rollback, crash recovery and row level locking capabilities. MySQL delivers the ease of use, scalability, and performance that has made it MySQL the world's most popular open source database. [ht-tp://www.mysql.com/products/enterprise/server.html](http://www.mysql.com/products/enterprise/server.html)

#### **16.13.13: What is the pricing of MySQL Enterprise?**

The pricing model for MySQL Enterprise is based on two key components: per server and per year. MySQL Enterprise does not have artificial restrictions based on CPUs, Memory, Machine Size, or Named Users. MySQL Enterprise is available in 4 tiers (Basic, Silver, Gold and Platinum). Choose the tier that best meets your requirements and budget. [ht-tp://www.mysql.com/about/contact/sales.html?s=corporate](http://www.mysql.com/about/contact/sales.html?s=corporate)

[tp://www.mysql.com/products/enterprise/features.html](http://www.mysql.com/products/enterprise/features.html)

#### **16.13.14: What is MySQL Enterprise Unlimited?**

MySQL Enterprise Unlimited is a unique offering that allows you to deploy an unlimited number of MySQL Enterprise Servers for the price of a single CPU of Oracle Enterprise Edition. <http://www.mysql.com/products/enterprise/unlimited.html>

#### **16.13.15: What is a Technical Account Manager?**

MySQL Enterprise, at the Platinum tier, provides the option for a Technical Account Manager (TAM). The TAM is your advocate within MySQL, who proactively works to maximize your benefits from MySQL Support Services. [ht-tp://www.mysql.com/products/enterprise/tam.html](http://www.mysql.com/products/enterprise/tam.html)

#### **16.13.16: Are there any Webinars available?**

Yes. MySQL provides regularly scheduled Live Webinars. <http://www.mysql.com/news-and-events/web-seminars/index.html> MySQL also provides On-Demand Webinars to fit your schedule. These are recordings of previously held Live Webinars that you can replay at any time. <http://www.mysql.com/news-and-events/web-seminars/index.html>

#### **16.13.17: Can I buy MySQL Enterprise subscriptions for multiple years?**

MySQL Enterprise subscriptions have duration of at least 1 year. Customers have the flexibility of choosing terms with multi-year durations. To purchase multi-year contracts, please <http://www.mysql.com/about/contact/sales.html?s=corporate>

#### **16.13.18: Does MySQL Enterprise include Emergency Hot Fix Builds?**

MySQL Enterprise, at the Gold and Platinum tiers, gives you the ability to request an Emergency Hot Fix Build to fix issues not already fixed in a MySQL Rapid Update or MySQL Quarterly Service Pack.

#### **16.13.19: Does MySQL provide IP (Intellectual Property) Indemnification?**

MySQL Enterprise, at the Gold and Platinum tiers, has the option of IP Indemnification, for qualifying customers at no extra cost. This provides you with legal protection that you expect from enterprise software providers. [ht-tp://www.mysql.com/products/enterprise/indemnification.html](http://www.mysql.com/products/enterprise/indemnification.html)

#### **16.13.20: What is MySQL Enterprise?**

The MySQL Enterprise subscription is the most comprehensive offering of MySQL database software, services and production support to ensure your business achieves the highest levels of reliability, security and uptime.

MySQL Enterprise includes:

- MySQL Enterprise Server software, the most reliable, secure and up-to date version of the world's most popular open source database
- MySQL Enterprise Monitor that continuously monitors your database and proactively advises you on how to implement MySQL best practices
- MySQL 24x7 Production Support with fast response times to assist you in the development, deployment and management of MySQL applications

MySQL Enterprise is available in 4 tiers (Basic, Silver, Gold, Platinum). <http://www.mysql.com/products/enterprise/features.html>

#### **16.13.21: What is MySQL Consultative Support?**

MySQL Enterprise, at the Gold and Platinum tiers, includes Consultative Support. This is a proactive approach to support that is designed to help you avoid critical outages. MySQL Support Engineers advise you on how to properly design and tune your MySQL servers, schema, queries, and replication set-up to maximize performance and availability. Also, by taking the initiative to properly design and tune your MySQL database applications you can avoid having to purchase expensive hardware for your IT infrastructure. <http://www.mysql.com/products/enterprise/consultativesupport.html>

#### **16.13.22: Can I buy MySQL Enterprise subscriptions for only some of my production MySQL database servers?**

When you choose MySQL Enterprise subscriptions, they must cover all database servers that power that specific application. To negotiate volume discounts, please <http://www.mysql.com/about/contact/sales.html?s=corporate>

#### **MySQL Monitor**

## Questions and Answers

### **16.13.1: What MySQL Enterprise subscription levels include the MySQL Enterprise Monitor?**

The Enterprise Monitor is available under MySQL Enterprise subscription levels Silver, Gold and Platinum. <http://www.mysql.com/products/enterprise/features.html>

### **16.13.2: How is the Enterprise Monitor web application architected?**

The Enterprise Monitor web application is comprised of 3 components:

- Monitor Agent: A lightweight C program that is installed on each of the monitored MySQL servers. Its purpose is to collect MySQL SQL and operating system metrics that allow the DBA to monitor the overall health, availability and performance of the MySQL server. The Monitor Agent is the only component within the application that touches or connects to the MySQL Server. It reports the data it collects using XML over HTTP to the centralized Service Manager.
- Service Manager: The main server of the application. The Service Manager manages and stores the data collections that come in from each monitor agent. It analyzes these collections using MySQL provided best practice Advisor rules to determine the health, security, availability and performance of each of the monitored MySQL Servers. The Service Manager also provides the content for the Enterprise Dashboard which serves as the client user interface for the distributed web application.
- Repository: A MySQL database that is used to stored data collections and application-level configuration data.

### **16.13.3: What makes MySQL Enterprise unique?**

Of the products on the market that monitor MySQL, SQL code and OS specific metrics, the MySQL Enterprise Monitor is the only solution that is built and supported by the engineers at MySQL. Unlike other solutions that report on raw MySQL and OS level metrics, the MySQL Enterprise Monitor is designed to optimize the use of MySQL by proactively monitoring MySQL instances and providing notifications and “MySQL DBA expertise in a box” advice on corrective measures DBAs can take before problems occur.

### **16.13.4: How do I get the MySQL Enterprise Monitor?**

The MySQL Enterprise Monitor is available for download to MySQL Enterprise customers at the Silver, Gold and Platinum subscription levels.

- To experience the MySQL Enterprise Monitor for 30 days, visit the <http://www.mysql.com/trials/enterprise>

- To buy MySQL Enterprise, visit the [Online Shop](#)

#### **16.13.5: How is the MySQL Enterprise Monitor installed and deployed?**

The Enterprise Monitor is powered by a distributed web application that is installed and deployed within the confines of the corporate firewall.

#### **16.13.6: What versions of MySQL are supported by the MySQL Enterprise Monitor?**

The MySQL Enterprise Monitor can be used to monitor MySQL versions 4.0 – 5.x.

#### **16.13.7: What operating system platforms are supported by the MySQL Enterprise Monitor?**

The Enterprise Monitor Service Manager is fully supported on most current versions of Linux, Windows XP and Server Editions, Solaris and Mac OSX. The Monitor Agent supports any platform supported by the MySQL Enterprise server. For the complete list of MySQL Enterprise supported operating systems and CPUs, visit the <http://www.mysql.com/support/supportedplatforms/enterprise.html>.

#### **16.13.8: What are the long-term benefits of the MySQL Enterprise Monitor?**

Over time, the task of managing even medium-scale MySQL server farms becomes exponentially more complicated, especially as the load of users, connections, application queries, and objects on each MySQL server increases. The Enterprise Monitor continually monitors the dynamic security, performance, replication and schema relevant metrics of all MySQL servers, so as the number of MySQL continues to grow, DBAs are kept up to date on potential problems and proactive measures that can be implemented to ensure each server continues to operate at the highest levels of security, performance and reliability.

#### **16.13.9: What is MySQL Enterprise Monitor?**

Included as part of a MySQL Enterprise subscription, the MySQL Enterprise Monitor is a distributed, web-based application that helps customers reduce downtime, tighten security and increase throughput of their MySQL servers by telling them about problems in their database applications before they occur. It is downloadable from the Enterprise Customer web site and is deployed within the safety of the customer datacenter.<http://www.mysql.com/products/enterprise/monitor.html>

#### **16.13.10: What are the immediate benefits of implementing the MySQL Enterprise Monitor?**

Often MySQL installations are implemented with default settings that may not be best suited for specific applications or usage patterns. The MySQL Advisors go to work immediately in these environments to identify potential problems and proactively notify and advise DBAs on key MySQL settings that can be tuned to improve availability, tighten security, and increase the throughput of their existing MySQL servers

#### **16.13.11: Which set of Enterprise Advisors, Advisor Rules and features are best for my use of MySQL?**

The Enterprise Monitor Advisors and Advisor Rules are available at 3 MySQL Enterprise subscription tiers: Choose MySQL Enterprise Silver if you need:

- Assurance you are running the most current, bug-free version of MySQL across all of your servers.
- Recoverability of your MySQL servers.
- The highest level of security for your MySQL servers.
- Monitoring of maximum or disallowed MySQL connections.
- Optimized startup configuration settings.

Choose MySQL Enterprise Gold, when you need everything in Silver, PLUS:

- Easy collection and detection of problematic SQL code running on your production or development systems.
- Insight and corrective advice on MySQL replication status, sync, and performance related issues.
- Auto detection and documenting of your Replication topologies.
- Advanced monitoring of your Replication and Scale-out environment.

Choose MySQL Enterprise Platinum, when you need everything in Gold, PLUS:

- Identification and advice on unplanned database and object level schema changes (Create, Alter, and Drop) across your MySQL servers.
- Proactive monitoring and advice on tuning the performance of your MySQL servers.

**16.13.12: How are subscribers notified about the availability of new or updated MySQL Enterprise Monitor, MySQL Enterprise Advisors and Advisor Rules?**

Customers will receive notifications of new and updated MySQL Enterprise Monitor and Advisors as they become available through the MySQL Enterprise Software Update Service. Notifications will be generated and sent based on the customer profile and the MySQL Enterprise subscription level.

**16.13.13: What are the features and related benefits of the MySQL Enterprise Monitor?**

The MySQL Enterprise Monitor is like having a "Virtual DBA Assistant" at your side to recommend best practices to eliminate security vulnerabilities, improve replication, and optimize performance. For the complete features and benefits, visit the <http://www.mysql.com/products/enterprise/monitor-features.html>.

**16.13.14: Which Advisors and features are included under different MySQL Enterprise subscription levels?**

For the complete list of the MySQL Enterprise Advisors that are available under each MySQL Enterprise subscription level, visit the <http://www.mysql.com/products/enterprise/features.html>.

**16.13.15: What are the MySQL Enterprise Advisors and Advisor Rules?**

The MySQL Enterprise Advisors are a set of best practice guidelines for the optimal use of MySQL. Advisors are spread across database specific disciplines and are comprised of a set of MySQL Advisor Rules that proactively monitor all MySQL servers and report on database application problems before they occur. Each Advisor Rule provides a detailed overview of the problem it is designed to identify, advices on how to correct the problem, specifies commands to implement the recommended fix and links to resources for additional research into the issue at hand. <http://www.mysql.com/products/enterprise/advisors.html>

## MySQL Query Analyzer

### Questions

- [16.13.1: Can I leave the MySQL Query Analyzer enabled at all times?](#)

- [16.13.12: Does Query Analyzer work with MySQL Cluster?](#)
- [16.13.13: Does Query Analyzer handle prepared statements?](#)
- [16.13.14: How can I get the MySQL Query Analyzer?](#)
- [16.13.15: How much degradation in performance does mysql-proxy introduce?](#)
- [16.13.16: What are the main features and benefits of the MySQL Query Analyzer?](#)
- [16.13.17: What overhead can I expect when the MySQL Query Analyzer is installed and enabled?](#)

## Questions and Answers

### **16.13.1: Can I leave the MySQL Query Analyzer enabled at all times?**

We have customers who have the Query Analyzer enabled and collecting queries on their development and QA servers so they can tune their code and monitor the fixes as part of the development process. For production systems, Query collection and analysis can easily be toggled on when a slowdown occurs. To avoid collection mode overhead many users are using simple scripts to enable the Query Analyzer to sample queries during nonpeak hours, typically during 30 minute windows. They can then view the collected queries using the date/time or interval filter options.

### **16.13.2: How are subscribers notified about updates to the MySQL Query Analyzer application components?**

Customers will receive notifications of the MySQL Query Analyzer updates as they become available through the MySQL Enterprise Software Update and Alert Service. Notifications will be generated and sent based on the customer profile and the MySQL Enterprise subscription level.

### **16.13.3: What are the typical use cases of the MySQL Query Analyzer?**

The typical use cases for developers, DBAs and system administrators are:

- Developers – Monitor and tune application queries during development before they are promoted to production.
- DBAs and System Administrators – Identify problem SQL code as it runs in production and advise development teams on how to tune. This use case benefits the most from regular sampling of queries as they are running, most often during nonpeak hours.

### **16.13.4: What is the MySQL Query Analyzer?**

The MySQL Query Analyzer allows DBAs, developers and system administrators to improve application performance by collecting, monitoring, and analyzing queries as they run on their MySQL servers. <http://www.mysql.com/products/enterprise/query.html>

### **16.13.5: Does the query analyzer look at all queries? or only queries which would show up in the slow-queries log?**

The Query Analyzer sees all queries that you route through the agent/proxy that performs the query analysis and aggregate them directly.

### **16.13.6: Do the MySQL clients have to connect to the port of the mysql proxy to enable the QA?**

Yes, or you can re-direct them in various ways, by reconfiguring mysqld to listen to some other port, and the proxy to 3306, use iptables redirection, etc. We have some examples in the manual for the product on how to do it (semi)-transparently.

### **16.13.7: How is the MySQL Query Analyzer installed and enabled?**

The Query Analyzer feature is installed with the Monitor Agent. It is enabled during agent installation and can be toggled between collection and pass-thru modes from the Query Analysis page of the Enterprise Monitor.

### **16.13.8: Does Query Analyzer capture queries by the root user?**

Yes, Query Analyzer captures all queries by all users providing that the queries are sent through the proxy port configured by the MySQL Enterprise Monitor Agent.

### **16.13.9: What makes the MySQL Query Analyzer unique?**

Other products (free, open source and commercial) that provide MySQL query monitoring are dependent on the MySQL Slow Query Log being enabled and available for sampling. While this provides some time savings over the DBA collecting and parsing the Log, the Slow Query Log comes with overhead and does not capture sub millisecond executions. The log data also grows very large very quickly.

The MySQL Query Analyzer collects queries and execution statistics with no dependence on the SQL Query Log, it captures all SQL statements sent to the MySQL server and provides an aggregated view into the most expensive queries in number of executions and total execution time. It is also fully supported as part of the MySQL Enterprise subscription.

### **16.13.10: Does the "Rows" area show the rows returned/updated or the rows visited by the query?**

Returned/updated. We don't have visibility into how many rows were touched. at an instance level. Some of the graphs we provide will show you when your queries are touching a lot of rows.

### **16.13.11: Does Query Analyzer enable me to monitor the disk reads and writes during a query?**

No, that information is not available to be shown at this time.

**16.13.12: Does Query Analyzer work with MySQL Cluster?**

Yes, providing that each node is monitored with an agent and query analyzer has been enabled for that node. Note that you must be accessing your cluster data through a standard MySQL node for this to work.

**16.13.13: Does Query Analyzer handle prepared statements?**

At this time, the query analyzer does not track server-side prepared statements. However the default configurations for most client-side libraries for MySQL don't use them, they emulate them client-side, and those will be tracked by the query analyzer.

**16.13.14: How can I get the MySQL Query Analyzer?**

The MySQL Query Analyzer is available for download to MySQL Enterprise customers at the Gold and Platinum subscription levels.

- To experience the MySQL Enterprise Monitor for 30 days, visit the <http://www.mysql.com/trials/enterprise>
- To buy MySQL Enterprise, visit the [Online Shop](#)

**16.13.15: How much degradation in performance does mysql-proxy introduce?**

At the very least it's equivalent to a network hop in latency. The degradation is directly related to your average query execution time. If your queries execute in microseconds (which can happen if served from query cache) then the degradation will be higher, and noticeable. We've seen some applications that actually do work when they execute queries, the degradation is much less, and in some limited cases because of scheduling, the application actually has better throughput.

**16.13.16: What are the main features and benefits of the MySQL Query Analyzer?**

For the complete features and benefits, visit the <http://www.mysql.com/products/enterprise/monitor-features.html>

**16.13.17: What overhead can I expect when the MySQL Query Analyzer is installed and enabled?**

The average overhead when in active collection mode is in the 15-20% range. In pass-thru mode the overhead is minimal, weighing in at 1-5% on most MySQL systems of average load.

---

# Chapter 16. Replication

Replication enables data from one MySQL database server (the master) to be replicated to one or more MySQL database servers (the slaves). Replication is asynchronous - slaves need not be connected permanently to receive updates from the master. This means that updates can occur over long-distance connections and even over temporary or intermittent connections such as a dial-up service. Depending on the configuration, you can replicate all databases, selected databases, or even selected tables within a database.

The target uses for replication in MySQL include:

- Scale-out solutions - spreading the load among multiple slaves to improve performance. In this environment, all writes and updates must take place on the master server. Reads, however, may take place on one or more slaves. This model can improve the performance of writes (since the master is dedicated to updates), while dramatically increasing read speed across an increasing number of slaves.
- Data security - because data is replicated to the slave, and the slave can pause the replication process, it is possible to run backup services on the slave without corrupting the corresponding master data.
- Analytics - live data can be created on the master, while the analysis of the information can take place on the slave without affecting the performance of the master.
- Long-distance data distribution - if a branch office would like to work with a copy of your main data, you can use replication to create a local copy of the data for their use without requiring permanent access to the master.

Replication in MySQL features support for one-way, asynchronous replication, in which one server acts as the master, while one or more other servers act as slaves. This is in contrast to the *synchronous* replication which is a characteristic of MySQL Cluster (see [Chapter 17, MySQL Cluster NDB 6.X/7.X](#)).

There are a number of solutions available for setting up replication between two servers, but the best method to use depends on the presence of data and the engine types you are using. For more information on the available options, see [Section 16.1.1, “How to Set Up Replication”](#).

There are two core types of replication format, Statement Based Replication (SBR), which replicates entire SQL statements, and Row Based Replication (RBR), which replicates only the changed rows. You may also use a third variety, Mixed Based Replication (MBR). For more information on the different replication formats, see [Section 16.1.2, “Replication Formats”](#). From MySQL 5.1.12 to MySQL 5.1.28, mixed format is the default. Beginning with MySQL 5.1.29, statement-based format is the default.

Replication is controlled through a number of different options and variables. These control the core operation of the replication, timeouts, and the databases and filters that can be applied on databases and tables. For more information on the available options, see [Section 16.1.3, “Replication and Binary Logging Options and Variables”](#).

You can use replication to solve a number of different problems, including problems with performance, supporting the backup of different databases, and as part of a larger solution to alleviate system failures. For information on how to address these issues, see [Section 16.3, “Replication Solutions”](#).

For notes and tips on how different data types and statements are treated during replication, including details of replication features, version compatibility, upgrades, and problems and their resolution, including an FAQ, see [Section 16.4, “Replication Notes and Tips”](#).

For detailed information on the implementation of replication, how replication works, the process and contents of the binary log, background threads and the rules used to decide how statements are recorded and replicated, see [Section 16.2, “Replication Implementation”](#).

## 16.1. Replication Configuration

Replication between servers in MySQL is based on the binary logging mechanism. The MySQL instance operating as the master (the source of the database changes) writes updates and changes as “events” to the binary log. The information in the binary log is stored in different logging formats according to the database changes being recorded. Slaves are configured to read the binary log from the master and to execute the events in the binary log on the slave’s local database.

The master is “dumb” in this scenario. Once binary logging has been enabled, all statements are recorded in the binary log. Each slave receives a copy of the entire contents of the binary log. It is the responsibility of the slave to decide which statements in the binary log should be executed; you cannot configure the master to log only certain events. If you do not specify otherwise, all events in the master binary log are executed on the slave. If required, you can configure the slave to process only events that apply to particular databases or tables.

Each slave keeps a record of the binary log coordinates: The file name and position within the file that it has read and processed

from the master. This means that multiple slaves can be connected to the master and executing different parts of the same binary log. Because the slaves control this process, individual slaves can be connected and disconnected from the server without affecting the master's operation. Also, because each slave remembers the position within the binary log, it is possible for slaves to be disconnected, reconnect and then "catch up" by continuing from the recorded position.

Both the master and each slave must be configured with a unique ID (using the `server-id` option). In addition, each slave must be configured with information about the master host name, log file name, and position within that file. These details can be controlled from within a MySQL session using the `CHANGE MASTER TO` statement on the slave. The details are stored within the slave's `master.info` file.

This section describes the setup and configuration required for a replication environment, including step-by-step instructions for creating a new replication environment. The major components of this section are:

- For a guide to setting up two or more servers for replication, [Section 16.1.1, “How to Set Up Replication”](#), deals with the configuration of the systems and provides methods for copying data between the master and slaves.
- Events in the binary log are recorded using a number of formats. These are referred to as statement-based replication (SBR) or row-based replication (RBR). A third type, mixed-format replication (MIXED), uses SBR or RBR replication automatically to take advantage of the benefits of both SBR and RBR formats when appropriate. The different formats are discussed in [Section 16.1.2, “Replication Formats”](#).
- Detailed information on the different configuration options and variables that apply to replication is provided in [Section 16.1.3, “Replication and Binary Logging Options and Variables”](#).
- Once started, the replication process should require little administration or monitoring. However, for advice on common tasks that you may want to execute, see [Section 16.1.4, “Common Replication Administration Tasks”](#).

## 16.1.1. How to Set Up Replication

This section describes how to set up complete replication of a MySQL server. There are a number of different methods for setting up replication, and the exact method to use depends on how you are setting up replication, and whether you already have data within your master database.

There are some generic tasks that are common to all replication setups:

- On the master, you must enable binary logging and configure a unique server ID. This might require a server restart. See [Section 16.1.1.1, “Setting the Replication Master Configuration”](#).
- On each slave that you want to connect to the master, you must configure a unique server ID. This might require a server restart. See [Section 16.1.1.2, “Setting the Replication Slave Configuration”](#).
- You may want to create a separate user that will be used by your slaves to authenticate with the master to read the binary log for replication. The step is optional. See [Section 16.1.1.3, “Creating a User for Replication”](#).
- Before creating a data snapshot or starting the replication process, you should record the position of the binary log on the master. You will need this information when configuring the slave so that the slave knows where within the binary log to start executing events. See [Section 16.1.1.4, “Obtaining the Replication Master Binary Log Coordinates”](#).
- If you already have data on your master and you want to use it to synchronize your slave, you will need to create a data snapshot. You can create a snapshot using `mysqldump` (see [Section 16.1.1.5, “Creating a Data Snapshot Using mysqldump”](#)) or by copying the data files directly (see [Section 16.1.1.6, “Creating a Data Snapshot Using Raw Data Files”](#)).
- You will need to configure the slave with settings for connecting to the master, such as the host name, login credentials, and binary log file name and position. See [Section 16.1.1.10, “Setting the Master Configuration on the Slave”](#).

Once you have configured the basic options, you will need to follow the instructions for your replication setup. A number of alternatives are provided:

- If you are establishing a new MySQL master and one or more slaves, you need only set up the configuration, as you have no data to exchange. For guidance on setting up replication in this situation, see [Section 16.1.1.7, “Setting Up Replication with New Master and Slaves”](#).
- If you are already running a MySQL server, and therefore already have data that must be transferred to your slaves before replication starts, have not previously configured the binary log and are able to shut down your MySQL server for a short period during the process, see [Section 16.1.1.8, “Setting Up Replication with Existing Data”](#).

- If you are adding slaves to an existing replication environment, you can set up the slaves without affecting the master. See [Section 16.1.1.9, “Introducing Additional Slaves to an Existing Replication Environment”](#).

If you will be administering MySQL replication servers, we suggest that you read this entire chapter through and try all statements mentioned in [Section 12.5.1, “SQL Statements for Controlling Master Servers”](#), and [Section 12.5.2, “SQL Statements for Controlling Slave Servers”](#). You should also familiarize yourself with the replication startup options described in [Section 16.1.3, “Replication and Binary Logging Options and Variables”](#).

#### Note

Note that certain steps within the setup process require the `SUPER` privilege. If you do not have this privilege, it might not be possible to enable replication.

### 16.1.1.1. Setting the Replication Master Configuration

On a replication master, you must enable binary logging and establish a unique server ID. If this has not already been done, this part of master setup requires a server restart.

Binary logging *must* be enabled on the master because the binary log is the basis for sending data changes from the master to its slaves. If binary logging is not enabled, replication will not be possible.

Each server within a replication group must be configured with a unique server ID. This ID is used to identify individual servers within the group, and must be a positive integer between 1 and  $(2^{32})-1$ . How you organize and select the numbers is entirely up to you.

To configure the binary log and server ID options, you will need to shut down your MySQL server and edit the `my.cnf` or `my.ini` file. Add the following options to the configuration file within the `[mysqld]` section. If these options already exist, but are commented out, uncomment the options and alter them according to your needs. For example, to enable binary logging using a log file name prefix of `mysql-bin`, and configure a server ID of 1, use these lines:

```
[mysqld]
log-bin=mysql-bin
server-id=1
```

After making the changes, restart the server.

#### Note

If you omit `server-id` (or set it explicitly to its default value of 0), a master refuses connections from all slaves.

#### Note

For the greatest possible durability and consistency in a replication setup using `InnoDB` with transactions, you should use `innodb_flush_log_at_trx_commit=1` and `sync_binlog=1` in the master `my.cnf` file.

#### Note

Ensure that the `skip-networking` option is not enabled on your replication master. If networking has been disabled, your slave will not be able to communicate with the master and replication will fail.

### 16.1.1.2. Setting the Replication Slave Configuration

On a replication slave, you must establish a unique server ID. If this has not already been done, this part of slave setup requires a server restart.

If the slave server ID is not already set, or the current value conflicts with the value that you have chosen for the master server, you should shut down your slave server and edit the configuration to specify a unique server ID. For example:

```
[mysqld]
server-id=2
```

After making the changes, restart the server.

If you are setting up multiple slaves, each one must have a unique `server-id` value that differs from that of the master and from each of the other slaves. Think of `server-id` values as something similar to IP addresses: These IDs uniquely identify each server instance in the community of replication partners.

#### Note

If you omit `server-id` (or set it explicitly to its default value of 0), a slave refuses to connect to a master.

You do not have to enable binary logging on the slave for replication to be enabled. However, if you enable binary logging on the slave, you can use the binary log for data backups and crash recovery on the slave, and also use the slave as part of a more complex replication topology (for example, where the slave acts as a master to other slaves).

### 16.1.1.3. Creating a User for Replication

Each slave must connect to the master using a MySQL user name and password, so there must be a user account on the master that the slave can use to connect. Any account can be used for this operation, providing it has been granted the `REPLICATION SLAVE` privilege. You may wish to create a different account for each slave, or connect to the master using the same account for each slave.

You need not create an account specifically for replication. However, you should be aware that the user name and password will be stored in plain text within the `master.info` file (see [Section 16.2.2.2, “The Slave Status Files”](#)). Therefore, you may want to create a separate account that has privileges only for the replication process, to minimize the possibility of compromise to other accounts.

To create a new account, use `CREATE USER`. To grant this account the privileges required for replication, use the `GRANT` statement. If you create an account solely for the purposes of replication, that account needs only the `REPLICATION SLAVE` privilege. For example, to set up a new user, `repl`, that can connect for replication from any host within the `mydomain.com` domain, issue these statements on the master:

```
mysql> CREATE USER 'repl'@'%mydomain.com' IDENTIFIED BY 'slavepass';
mysql> GRANT REPLICATION SLAVE ON *.* TO 'repl'@'%mydomain.com';
```

See [Section 12.4.1, “Account Management Statements”](#), for more information on statements for manipulation of user accounts.

### 16.1.1.4. Obtaining the Replication Master Binary Log Coordinates

To configure replication on the slave you must determine the master's current coordinates within its binary log. You will need this information so that when the slave starts the replication process, it is able to start processing events from the binary log at the correct point.

If you have existing data on your master that you want to synchronize on your slaves before starting the replication process, you must stop processing statements on the master, and then obtain its current binary log coordinates and dump its data, before permitting the master to continue executing statements. If you do not stop the execution of statements, the data dump and the master status information that you use will not match and you will end up with inconsistent or corrupted databases on the slaves.

To obtain the master binary log coordinates, follow these steps:

1. Start a session on the master by connecting to it with the command-line client, and flush all tables and block write statements by executing the `FLUSH TABLES WITH READ LOCK` statement:

```
mysql> FLUSH TABLES WITH READ LOCK;
```

For `InnoDB` tables, note that `FLUSH TABLES WITH READ LOCK` also blocks `COMMIT` operations.

#### Warning

Leave the client from which you issued the `FLUSH TABLES` statement running so that the read lock remains in effect. If you exit the client, the lock is released.

2. In a different session on the master, use the `SHOW MASTER STATUS` statement to determine the current binary log file name and position:

```
mysql > SHOW MASTER STATUS;
+-----+-----+-----+-----+
| File | Position | Binlog_Do_DB | Binlog_Ignore_DB |
+-----+-----+-----+-----+
| mysql-bin.000003 | 73 | test | manual,mysql |
```

The `File` column shows the name of the log file and `Position` shows the position within the file. In this example, the binary log file is `mysql-bin.000003` and the position is 73. Record these values. You need them later when you are setting up the slave. They represent the replication coordinates at which the slave should begin processing new updates from the master.

If the master has been running previously without binary logging enabled, the log file name and position values displayed by

`SHOW MASTER STATUS` or `mysqldump --master-data` will be empty. In that case, the values that you need to use later when specifying the slave's log file and position are the empty string ('') and 4.

You now have the information you need to enable the slave to start reading from the binary log in the correct place to start replication.

If you have existing data that needs to be synchronized with the slave before you start replication, leave the client running so that the lock remains in place and then proceed to [Section 16.1.1.5, “Creating a Data Snapshot Using mysqldump”](#), or [Section 16.1.1.6, “Creating a Data Snapshot Using Raw Data Files”](#). The idea here is to prevent any further changes so that the data copied to the slaves is in synchrony with the master.

If you are setting up a brand new master and slave replication group, you can exit the first session to release the read lock.

### 16.1.1.5. Creating a Data Snapshot Using `mysqldump`

One way to create a snapshot of the data in an existing master database is to use the `mysqldump` tool. Once the data dump has been completed, you then import this data into the slave before starting the replication process.

To obtain a snapshot of the data using `mysqldump`:

1. If you have not already locked the tables on the server to prevent statements that update data from executing:

Start a session on the server by connecting to it with the command-line client, and flush all tables and block write statements by executing the `FLUSH TABLES WITH READ LOCK` statement:

```
mysql> FLUSH TABLES WITH READ LOCK;
```

Remember to use `SHOW MASTER STATUS` and record the binary log details for use when starting up the slave. The point in time of your snapshot and the binary log position must match. See [Section 16.1.1.4, “Obtaining the Replication Master Binary Log Coordinates”](#).

2. In another session, use `mysqldump` to create a dump either of all the databases you want to replicate, or of selected individual databases. For example:

```
shell> mysqldump --all-databases --lock-all-tables >dbdump.db
```

An alternative to using a bare dump, is to use the `--master-data` option, which automatically appends the `CHANGE MASTER TO` statement required on the slave to start the replication process.

```
shell> mysqldump --all-databases --master-data >dbdump.db
```

3. In the client where you acquired the read lock, release the lock:

```
mysql> UNLOCK TABLES;
```

Alternatively, exit the first session to release the read lock.

When choosing databases to include in the dump, remember that you will need to filter out databases on each slave that you do not want to include in the replication process.

You will need either to copy the dump file to the slave, or to use the file from the master when connecting remotely to the slave to import the data.

### 16.1.1.6. Creating a Data Snapshot Using Raw Data Files

If your database is particularly large, copying the raw data files may be more efficient than using `mysqldump` and importing the file on each slave.

However, using this method with tables in storage engines with complex caching or logging algorithms may not give you a perfect “in time” snapshot as cache information and logging updates may not have been applied, even if you have acquired a global read lock. How the storage engine responds to this depends on its crash recovery abilities.

In addition, this method does not work reliably if the master and slave have different values for `ft_stopword_file`, `ft_min_word_len`, or `ft_max_word_len` and you are copying tables having full-text indexes.

If you are using `InnoDB` tables, you can use the `InnoDB Hot Backup` tool to obtain a consistent snapshot. This tool records

the log name and offset corresponding to the snapshot to be later used on the slave. [Hot Backup](#) is a nonfree (commercial) tool that is not included in the standard MySQL distribution. See the [InnoDB Hot Backup](#) home page at <http://www.innodb.com/wp/products/hot-backup/> for detailed information.

Otherwise, you can obtain a reliable binary snapshot of [InnoDB](#) tables only after shutting down the MySQL Server.

To create a raw data snapshot of [MyISAM](#) tables you can use standard copy tools such as [cp](#) or [copy](#), a remote copy tool such as [scp](#) or [rsync](#), an archiving tool such as [zip](#) or [tar](#), or a file system snapshot tool such as [dump](#), providing that your MySQL data files exist on a single file system. If you are replicating only certain databases then make sure you copy only those files that relate to those tables. (For [InnoDB](#), all tables in all databases are stored in the shared tablespace files, unless you have the [innodb\\_file\\_per\\_table](#) option enabled.)

You may want to specifically exclude the following files from your archive:

- Files relating to the [mysql](#) database.
- The [master.info](#) file.
- The master's binary log files.
- Any relay log files.

To get the most consistent results with a raw data snapshot you should shut down the master server during the process, as follows:

1. Acquire a read lock and get the master's status. See [Section 16.1.1.4, “Obtaining the Replication Master Binary Log Coordinates”](#).
2. In a separate session, shut down the master server:

```
shell> mysqladmin shutdown
```

3. Make a copy of the MySQL data files. The following examples show common ways to do this. You need to choose only one of them:

```
shell> tar cf /tmp/db.tar ./data
shell> zip -r /tmp/db.zip ./data
shell> rsync --recursive ./data /tmp/dbdata
```

4. Restart the master server.

If you are not using [InnoDB](#) tables, you can get a snapshot of the system from a master without shutting down the server as described in the following steps:

1. Acquire a read lock and get the master's status. See [Section 16.1.1.4, “Obtaining the Replication Master Binary Log Coordinates”](#).
2. Make a copy of the MySQL data files. The following examples show common ways to do this. You need to choose only one of them:

```
shell> tar cf /tmp/db.tar ./data
shell> zip -r /tmp/db.zip ./data
shell> rsync --recursive ./data /tmp/dbdata
```

3. In the client where you acquired the read lock, release the lock:

```
mysql> UNLOCK TABLES;
```

Once you have created the archive or copy of the database, you will need to copy the files to each slave before starting the slave replication process.

### 16.1.1.7. Setting Up Replication with New Master and Slaves

The easiest and most straightforward method for setting up replication is to use new master and slave servers.

You can also use this method if you are setting up new servers but have an existing dump of the databases from a different server that you want to load into your replication configuration. By loading the data into a new master, the data will be automatically rep-

licated to the slaves.

To set up replication between a new master and slave:

1. Configure the MySQL master with the necessary configuration properties. See [Section 16.1.1.1, “Setting the Replication Master Configuration”](#).
2. Start up the MySQL master.
3. Set up a user. See [Section 16.1.1.3, “Creating a User for Replication”](#).
4. Obtain the master status information. See [Section 16.1.1.4, “Obtaining the Replication Master Binary Log Coordinates”](#).
5. On the master, release the read lock:

```
mysql> UNLOCK TABLES;
```

6. On the slave, edit the MySQL configuration. See [Section 16.1.1.2, “Setting the Replication Slave Configuration”](#).
7. Start up the MySQL slave.
8. Execute a `CHANGE MASTER TO` statement to set the master replication server configuration. See [Section 16.1.1.10, “Setting the Master Configuration on the Slave”](#).

Perform the slave setup steps on each slave.

Because there is no data to load or exchange on a new server configuration you do not need to copy or import any information.

If you are setting up a new replication environment using the data from a different existing database server, you will now need to run the dump file generated from that server on the new master. The database updates will automatically be propagated to the slaves:

```
shell> mysql -h master < fulldb.dump
```

## 16.1.1.8. Setting Up Replication with Existing Data

When setting up replication with existing data, you will need to decide how best to get the data from the master to the slave before starting the replication service.

The basic process for setting up replication with existing data is as follows:

1. With the MySQL master running, create a user to be used by the slave when connecting to the master during replication. See [Section 16.1.1.3, “Creating a User for Replication”](#).
2. If you have not already configured the `server-id` and enabled binary logging on the master server, you will need to shut it down to configure these options. See [Section 16.1.1.1, “Setting the Replication Master Configuration”](#).

If you have to shut down your master server, this is a good opportunity to take a snapshot of its databases. You should obtain the master status (see [Section 16.1.1.4, “Obtaining the Replication Master Binary Log Coordinates”](#)) before taking down the master, updating the configuration and taking a snapshot. For information on how to create a snapshot using raw data files, see [Section 16.1.1.6, “Creating a Data Snapshot Using Raw Data Files”](#).

3. If your master server is already correctly configured, obtain its status (see [Section 16.1.1.4, “Obtaining the Replication Master Binary Log Coordinates”](#)) and then use `mysqldump` to take a snapshot (see [Section 16.1.1.5, “Creating a Data Snapshot Using mysqldump”](#)) or take a raw snapshot of the live server using the guide in [Section 16.1.1.6, “Creating a Data Snapshot Using Raw Data Files”](#).
4. Update the configuration of the slave. See [Section 16.1.1.2, “Setting the Replication Slave Configuration”](#).
5. The next step depends on how you created the snapshot of data on the master.

If you used `mysqldump`:

- a. Start the slave, using the `--skip-slave-start` option so that replication does not start.
- b. Import the dump file:

```
shell> mysql < fulldb.dump
```

If you created a snapshot using the raw data files:

- a. Extract the data files into your slave data directory. For example:

```
shell> tar xvf dbdump.tar
```

You may need to set permissions and ownership on the files so that the slave server can access and modify them.

- b. Start the slave, using the `--skip-slave-start` option so that replication does not start.
6. Configure the slave with the replication coordinates from the master. This tells the slave the binary log file and position within the file where replication needs to start. Also, configure the slave with the login credentials and host name of the master. For more information on the `CHANGE MASTER TO` statement required, see [Section 16.1.1.10, “Setting the Master Configuration on the Slave”](#).
7. Start the slave threads:

```
mysql> START SLAVE;
```

After you have performed this procedure, the slave should connect to the master and catch up on any updates that have occurred since the snapshot was taken.

If you have forgotten to set the `server-id` option for the master, slaves cannot connect to it.

If you have forgotten to set the `server-id` option for the slave, you get the following error in the slave's error log:

```
Warning: You should set server-id to a non-0 value if master_host
is set; we will force server id to 2, but this MySQL server will
not act as a slave.
```

You also find error messages in the slave's error log if it is not able to replicate for any other reason.

Once a slave is replicating, you can find in its data directory one file named `master.info` and another named `relay-log.info`. The slave uses these two files to keep track of how much of the master's binary log it has processed. Do *not* remove or edit these files unless you know exactly what you are doing and fully understand the implications. Even in that case, it is preferred that you use the `CHANGE MASTER TO` statement to change replication parameters. The slave will use the values specified in the statement to update the status files automatically.

#### Note

The content of `master.info` overrides some of the server options specified on the command line or in `my.cnf`. See [Section 16.1.3, “Replication and Binary Logging Options and Variables”](#), for more details.

A single snapshot of the master suffices for multiple slaves. To set up additional slaves, use the same master snapshot and follow the slave portion of the procedure just described.

### 16.1.1.9. Introducing Additional Slaves to an Existing Replication Environment

To add another slave to an existing replication configuration, you can do so without stopping the master. Instead, set up the new slave by making a copy of an existing slave, except that you configure the new slave with a different `server-id` value.

To duplicate an existing slave:

1. Shut down the existing slave:

```
shell> mysqladmin shutdown
```

2. Copy the data directory from the existing slave to the new slave. You can do this by creating an archive using `tar` or `WinZip`, or by performing a direct copy using a tool such as `cp` or `rsync`. Ensure that you also copy the log files and relay log files.

#### Note

A common problem that is encountered when adding new replication slaves is that the new slave fails with a series of warning and error messages like these:

```

071118 16:44:10 [Warning] Neither --relay-log nor --relay-log-index were used; so
replication may break when this MySQL server acts as a slave and has his hostname
changed!! Please use '--relay-log=new_slave_hostname-relay-bin' to avoid this problem.
071118 16:44:10 [ERROR] FAILED TO OPEN THE RELAY LOG './OLD_SLAVE_HOSTNAME-RELAY-BIN.003525'
(RELAY_LOG_POS 22940879)
071118 16:44:10 [ERROR] COULD NOT FIND TARGET LOG DURING RELAY LOG INITIALIZATION
071118 16:44:10 [ERROR] FAILED TO INITIALIZE THE MASTER INFO STRUCTURE

```

This is due to the fact that, if the `--relay-log` option is not specified, the relay log files contain the host name as part of their file names. (This is also true of the relay log index file if the `--relay-log-index` option is not used. See [Section 16.1.3, “Replication and Binary Logging Options and Variables”](#), for more information about these options.)

To avoid this problem, use the same value for `--relay-log` on the new slave that was used on the existing slave. (If this option was not set explicitly on the existing slave, use `existing_slave_hostname-relay-bin`.) If this is not feasible, copy the existing slave's relay log index file to the new slave and set the `--relay-log-index` option on the new slave to match what was used on the existing slave. (If this option was not set explicitly on the existing slave, use `existing_slave_hostname-relay-bin.index`.) Alternatively—if you have already tried to start the new slave (after following the remaining steps in this section) and have encountered errors like those described previously—then perform the following steps:

- a. If you have not already done so, issue a `STOP SLAVE` on the new slave.  
If you have already started the existing slave again, issue a `STOP SLAVE` on the existing slave as well.
  - b. Copy the contents of the existing slave's relay log index file into the new slave's relay log index file, making sure to overwrite any content already in the file.
  - c. Proceed with the remaining steps in this section.
3. Copy the `master.info` and `relay-log.info` files from the existing slave to the new slave if they were not located in the data directory. These files hold the current log coordinates for the master's binary log and the slave's relay log.
  4. Start the existing slave.
  5. On the new slave, edit the configuration and give the new slave a unique `server-id` not used by the master or any of the existing slaves.
  6. Start the new slave. The slave will use the information in its `master.info` file to start the replication process.

### 16.1.1.10. Setting the Master Configuration on the Slave

To set up the slave to communicate with the master for replication, you must tell the slave the necessary connection information. To do this, execute the following statement on the slave, replacing the option values with the actual values relevant to your system:

```

mysql> CHANGE MASTER TO
-> MASTER_HOST='master_host_name',
-> MASTER_USER='replication_user_name',
-> MASTER_PASSWORD='replication_password',
-> MASTER_LOG_FILE='recorded_log_file_name',
-> MASTER_LOG_POS=recorded_log_position;

```

#### Note

Replication cannot use Unix socket files. You must be able to connect to the master MySQL server using TCP/IP.

The `CHANGE MASTER TO` statement has other options as well. For example, it is possible to set up secure replication using SSL. For a full list of options, and information about the maximum permissible length for the string-valued options, see [Section 12.5.2.1, “`CHANGE MASTER TO` Syntax”](#).

### 16.1.2. Replication Formats

Replication works because events written to the binary log are read from the master and then processed on the slave. The events are recorded within the binary log in different formats according to the type of event. The different replication formats used correspond to the binary logging format used when the events were recorded in the master's binary log. The correlation between binary logging formats and the terms used during replication are:

- Replication capabilities in MySQL originally were based on propagation of SQL statements from master to slave. This is called *statement-based replication* (often abbreviated as *SBR*), which corresponds to the standard statement-based binary logging format. In MySQL 5.1.4 and earlier, binary logging and replication used this format exclusively.

- Row-based binary logging logs changes in individual table rows. When used with MySQL replication, this is known as *row-based replication* (often abbreviated as *RBR*). In row-based replication, the master writes *events* to the binary log that indicate how individual table rows are changed.
- As of MySQL 5.1.8, the server can change the binary logging format in real time according to the type of event using *mixed-format logging*.

When the mixed format is in effect, statement-based logging is used by default, but automatically switches to row-based logging in particular cases as described later. Replication using the mixed format is often referred to as *mixed-based replication* or *mixed-format replication*. For more information, see [Section 5.2.4.3, “Mixed Binary Logging Format”](#).

From MySQL 5.1.12 to MySQL 5.1.28, mixed format is the default. Beginning with MySQL 5.1.29, statement-based format is the default.

### Note

**MySQL Cluster.** The default binary logging format in all MySQL Cluster NDB 6.1, 6.2, 6.3, and later 6.x releases is `ROW`. MySQL Cluster Replication always uses row-based replication, and the `NDBCLUSTER` storage engine is incompatible with statement-based replication. Using `NDBCLUSTER` sets row-based logging format automatically.

See [Section 17.6.2, “MySQL Cluster Replication: Assumptions and General Requirements”](#), for more information.

Starting with MySQL 5.1.20, when using `MIXED` format, the binary logging format is determined in part by the storage engine being used and the statement being executed. For more information on mixed-format logging and the rules governing the support of different logging formats, see [Section 5.2.4.3, “Mixed Binary Logging Format”](#).

The logging format in a running MySQL server is controlled by setting the `binlog_format` server system variable. This variable can be set with session or global scope. The rules governing when and how the new setting takes effect are the same as for other MySQL server system variables—setting the variable for the current session lasts only until the end of that session, and the change is not visible to other sessions; setting the variable globally requires a restart of the server to take effect. For more information, see [Section 12.4.4, “SET Syntax”](#).

You must have the `SUPER` privilege to set the global `binlog_format` value. Starting with MySQL 5.1.29, you must have the `SUPER` privilege to set either the global or session `binlog_format` value. ([Bug#39106](#))

The statement-based and row-based replication formats have different issues and limitations. For a comparison of their relative advantages and disadvantages, see [Section 16.1.2.1, “Comparison of Statement-Based and Row-Based Replication”](#).

With statement-based replication, you may encounter issues with replicating stored routines or triggers. You can avoid these issues by using row-based replication instead. For more information, see [Section 19.7, “Binary Logging of Stored Programs”](#).

## 16.1.2.1. Comparison of Statement-Based and Row-Based Replication

Each binary logging format has advantages and disadvantages. For most users, the mixed replication format should provide the best combination of data integrity and performance. If, however, you want to take advantage of the features specific to the statement-based or row-based replication format when performing certain tasks, you can use the information in this section, which provides a summary of their relative advantages and disadvantages, to determine which is best for your needs.

### Advantages of statement-based replication:

- Proven technology that has existed in MySQL since 3.23.
- Less data written to log files. When updates or deletes affect many rows, this results in *much* less storage space required for log files. This also means that taking and restoring from backups can be accomplished more quickly.
- Log files contain all statements that made any changes, so they can be used to audit the database.

### Disadvantages of statement-based replication:

- **Statements that are unsafe for SBR.** Not all statements which modify data (such as `INSERT` `DELETE`, `UPDATE`, and `REPLACE` statements) can be replicated using statement-based replication. Any nondeterministic behavior is difficult to replicate when using statement-based replication. Examples of such DML (Data Modification Language) statements include the following:
  - A statement that depends on a UDF or stored program that is nondeterministic, since the value returned by such a UDF or stored program or depends on factors other than the parameters supplied to it. (Row-based replication, however, simply replicates the value returned by the UDF or stored program, so its effect on table rows and data is the same on both the master

and slave.) See [Section 16.4.1.9, “Replication of Invoked Features”](#), for more information.

- `DELETE` and `UPDATE` statements that use a `LIMIT` clause without an `ORDER BY` are nondeterministic. See [Section 16.4.1.13, “Replication and LIMIT”](#).
- Statements using any of the following functions cannot be replicated properly using statement-based replication:
  - `LOAD_FILE()`
  - `UUID()`, `UUID_SHORT()`
  - `USER()`
  - `FOUND_ROWS()`
  - `SYSDATE()` (unless both the master and the slave are started with the `--sysdate-is-now` option)
  - `GET_LOCK()`
  - `IS_FREE_LOCK()`
  - `IS_USED_LOCK()`
  - `MASTER_POS_WAIT()`
  - `RELEASE_LOCK()`
  - `SLEEP()`
  - `VERSION()`

However, all other functions are replicated correctly using statement-based replication, including `RAND()`, `NOW()`, and so forth.

For more information, see [Section 16.4.1.12, “Replication and System Functions”](#).

Statements that cannot be replicated correctly using statement-based replication are logged with a warning like the one shown here:

```
090213 16:58:54 [Warning] Statement is not safe to log in statement format.
```

A similar warning is also issued to the client in such cases. The client can display it using `SHOW WARNINGS`.

- `INSERT ... SELECT` requires a greater number of row-level locks than with row-based replication.
- `UPDATE` statements that require a table scan (because no index is used in the `WHERE` clause) must lock a greater number of rows than with row-based replication.
- For `InnoDB`: An `INSERT` statement that uses `AUTO_INCREMENT` blocks other nonconflicting `INSERT` statements.
- For complex statements, the statement must be evaluated and executed on the slave before the rows are updated or inserted. With row-based replication, the slave only has to modify the affected rows, not execute the full statement.
- If there is an error in evaluation on the slave, particularly when executing complex statements, statement-based replication may slowly increase the margin of error across the affected rows over time. See [Section 16.4.1.24, “Slave Errors During Replication”](#).
- Stored functions execute with the same `NOW()` value as the calling statement. However, this is not true of stored procedures.
- Deterministic UDFs must be applied on the slaves.
- Table definitions must be (nearly) identical on master and slave. See [Section 16.4.1.7, “Replication with Differing Table Definitions on Master and Slave”](#), for more information.

#### Advantages of row-based replication:

- All changes can be replicated. This is the safest form of replication.

For MySQL versions earlier than 5.1.14, DDL (Data Definition Language) statements such as `CREATE TABLE` are replicated

using statement-based replication, while DML statements, as well as `GRANT` and `REVOKE` statements, are replicated using row-based replication.

In MySQL 5.1.14 and later, the `mysql` database is not replicated. The `mysql` database is instead seen as a node-specific database. Row-based replication is not supported on tables in this database. Instead, statements that would normally update this information—such as `GRANT`, `REVOKE` and the manipulation of triggers, stored routines (including stored procedures), and views—are all replicated to slaves using statement-based replication.

For statements such as `CREATE TABLE ... SELECT`, a `CREATE` statement is generated from the table definition and replicated using statement-based format, while the row insertions are replicated using row-based format.

- The technology is the same as in most other database management systems; knowledge about other systems transfers to MySQL.
- Fewer locks are required on the master, which thus achieves higher concurrency, for the following types of statements:
  - `INSERT ... SELECT`
  - `INSERT` statements with `AUTO_INCREMENT`
  - `UPDATE` or `DELETE` statements with `WHERE` clauses that do not use keys or do not change most of the examined rows.
- Fewer locks are required on the slave for any `INSERT`, `UPDATE`, or `DELETE` statement.

#### Disadvantages of row-based replication:

- RBR tends to generate more data that must be logged. To replicate a DML statement (such as an `UPDATE` or `DELETE` statement), statement-based replication writes only the statement to the binary log. By contrast, row-based replication writes each changed row to the binary log. If the statement changes many rows, row-based replication may write significantly more data to the binary log; this is true even for statements that are rolled back. This also means that taking and restoring from backup can require more time. In addition, the binary log is locked for a longer time to write the data, which may cause concurrency problems.
- Deterministic UDFs that generate large `BLOB` values take longer to replicate with row-based replication than with statement-based replication. This is because the `BLOB` column value is logged, rather than the statement generating the data.
- You cannot examine the logs to see what statements were executed, nor can you see on the slave what statements were received from the master and executed.

However, beginning with MySQL 5.1.29, you can see what data was changed using `mysqlbinlog` with the options `--base64-output=DECODE-ROWS` and `--verbose`.

- Formerly, when performing a bulk operation that includes nontransactional storage engines, changes were applied as the statement executed. With row-based logging, this meant that the binary log was written while the statement was running. On the master, this does not cause problems with concurrency, because tables are locked until the bulk operation terminates. On the slave server, tables were not locked while the slave applied changes, because the slave did not know that those changes were part of a bulk operation.

In such cases, if you retrieved data from a table on the master (for example, using `SELECT * FROM table_name`), the server waited for the bulk operation to complete before executing the `SELECT` statement, because the table was read-locked. On the slave, the server did not wait (because there was no lock). This meant that, until the bulk operation on the slave completed, different results were obtained for the same `SELECT` query on the master and on the slave.

This issue was resolved in MySQL 5.1.24. ([Bug#29020](#))

### 16.1.2.2. Usage of Row-Based Logging and Replication

Major changes in the replication environment and in the behavior of applications can result from using row-based logging (RBL) or row-based replication (RBR) rather than statement-based logging or replication. This section describes a number of issues known to exist when using row-based logging or replication, and discusses some best practices for taking advantage of row-based logging and replication.

For additional information, see [Section 16.1.2, “Replication Formats”](#), and [Section 16.1.2.1, “Comparison of Statement-Based and Row-Based Replication”](#).

For information about issues specific to MySQL Cluster Replication (which depends on row-based replication), see [Section 17.6.3, “Known Issues in MySQL Cluster Replication”](#).

- **RBL, RBR, and temporary tables.** As noted in [Section 16.4.1.20, “Replication and Temporary Tables”](#), temporary tables are not replicated when using row-based format. When mixed format is in effect, “safe” statements involving temporary tables are logged using statement-based format. For more information, see [Section 16.1.2.1, “Comparison of Statement-Based and Row-Based Replication”](#).

### Note

Temporary tables are not replicated when using row-based format because there is no need. In addition, because temporary tables can be read only from the thread which created them, there is seldom if ever any benefit obtained from replicating them, even when using statement-based format.

- **RBL and the `BLACKHOLE` storage engine.** Prior to MySQL 5.1.29, `DELETE` and `UPDATE` statements for `BLACKHOLE` tables did not work with RBL. ([Bug#38360](#))
- **RBL and synchronization of nontransactional tables.** When many rows are affected, the set of changes is split into several events; when the statement commits, all of these events are written to the binary log if the statement is an initial nontransactional statement (occurring in the transaction before any transactional statements). When executing on the slave, a table lock is taken on all tables involved, and then the rows are applied in batch mode. (This may or may not be effective, depending on the engine used for the slave’s copy of the table.)
- **Latency and binary log size.** Because RBL writes changes for each row to the binary log, its size can increase quite rapidly. In a replication environment, this can significantly increase the time required to make changes on the slave that match those on the master. You should be aware of the potential for this delay in your applications.
- **Reading the binary log.** `mysqlbinlog` displays row-based events in the binary log using the `BINLOG` statement (see [Section 12.4.6.1, “BINLOG Syntax”](#)). This statement displays an event in printable form, but as a base 64-encoded string the meaning of which is not evident. As of MySQL 5.1.28, when invoked with the `--base64-output=DECODE-ROWS` and `--verbose` options, `mysqlbinlog` formats the contents of the binary log in a manner that is easily human readable. This is helpful when binary log events were written in row-based format if you want to read or recover from a replication or database failure using the contents of the binary log. For more information, see [Section 4.6.7.2, “mysqlbinlog Row Event Display”](#).
- **Binary log execution errors and `slave_exec_mode`.** If `slave_exec_mode` is `IDEMPOTENT`, a failure to apply changes from RBL because the original row cannot be found does not trigger an error or cause replication to fail. This means that it is possible that updates are not applied on the slave, so that the master and slave are no longer synchronized. Latency issues and use of nontransactional tables with RBR when `slave_exec_mode` is `IDEMPOTENT` can cause the master and slave to diverge even further. For more information about `slave_exec_mode`, see [Section 5.1.4, “Server System Variables”](#).

### Note

`slave_exec_mode=IDEMPOTENT` is generally useful only for circular replication or multi-master replication with MySQL Cluster, for which `IDEMPOTENT` is the default value (see [Section 17.6, “MySQL Cluster Replication”](#)).

For other scenarios, setting `slave_exec_mode` to `STRICT` is normally sufficient; this is the default value for storage engines other than `NDB`.

- **Lack of binary log checksums.** RBL uses no checksums. This means that network, disk, and other errors may not be identified when processing the binary log. To ensure that data is transmitted without network corruption, you may want to consider using SSL, which adds another layer of checksumming, for replication connections. The `CHANGE MASTER TO` statement has options to enable replication over SSL. See also [Section 12.5.2.1, “CHANGE MASTER TO Syntax”](#), for general information about setting up MySQL with SSL.
- **Filtering based on server ID not supported.** A common practice is to filter out changes on some slaves by using a `WHERE` clause that includes the relation `@@server_id <> id_value` clause with `UPDATE` and `DELETE` statements, a simple example of such a clause being `WHERE @@server_id <> 1`. However, this does not work correctly with row-based logging. If you must use the `server_id` system variable for statement filtering, you must also use `-binlog_format=STATEMENT`.
- **Database-level replication options.** The effects of the `--replicate-do-db`, `--replicate-ignore-db`, and `--replicate-rewrite-db` options differ considerably depending on whether row-based or statement-based logging is used. Because of this, it is recommended to avoid database-level options and instead use table-level options such as `--replicate-do-table` and `--replicate-ignore-table`. For more information about these options and the impact that your choice of replication format has on how they operate, see [Section 16.1.3, “Replication and Binary Logging Options and Variables”](#).

## 16.1.2.3. Safe and Unsafe Statements in Logging and Replication

When speaking of the “safeness” of a statement in MySQL Replication, we are referring to whether a statement and its effects can be replicated correctly using statement-based format. If this is true of the statement, we refer to the statement as *safe*; otherwise, we refer to it as *unsafe*.

In general, a statement is safe if it deterministic, and unsafe if it is not. However, certain nondeterministic functions are *not* considered unsafe (see [Nondeterministic functions not considered unsafe](#), later in this section). In addition, statements using results from floating-point math functions—which are hardware-dependent—are always considered safe (see [Section 16.4.1.10, “Replication and Floating-Point Values”](#)).

**Handling of safe and unsafe statements.** A statement is treated differently depending on whether the statement is considered safe, and with respect to the binary logging format (that is, the current value of `binlog_format`).

- No distinction is made in the treatment of safe and unsafe statements when the binary logging mode is `ROW`.
- If the binary logging format is `MIXED`, statements flagged as unsafe are logged using the row-based format; statements regarded as safe are logged using the statement-based format.
- If the binary logging format is `STATEMENT`, statements flagged as being unsafe generate a warning to this effect. (Safe statements are logged normally.)

For more information, see [Section 16.1.2, “Replication Formats”](#).

**Statements considered unsafe.** Statements having the following characteristics are considered unsafe:

- **Statements containing system functions that may return a different value on slave.** These functions include `FOUND_ROWS()`, `GET_LOCK()`, `IS_FREE_LOCK()`, `IS_USED_LOCK()`, `LOAD_FILE()`, `MASTER_POS_WAIT()`, `RELEASE_LOCK()`, `ROW_COUNT()`, `SESSION_USER()`, `SLEEP()`, `SYSDATE()`, `SYSTEM_USER()`, `USER()`, `UUID()`, and `UUID_SHORT()`.

**Nondeterministic functions not considered unsafe.** Although these functions are not deterministic, they are treated as safe for purposes of logging and replication: `CONNECTION_ID()`, `CURDATE()`, `CURRENT_DATE()`, `CURRENT_TIME()`, `CURRENT_TIMESTAMP()`, `CURTIME()`, `LOCALTIME()`, `LOCALTIMESTAMP()`, `NOW()`, `UNIX_TIMESTAMP()`, `UTC_DATE()`, `UTC_TIME()`, `UTC_TIMESTAMP()`, and `LAST_INSERT_ID()`

For more information, see [Section 16.4.1.12, “Replication and System Functions”](#).

- **References to system variables.** Most system variables are not replicated correctly using the statement-based format. For exceptions, see [Section 5.2.4.3, “Mixed Binary Logging Format”](#).

See [Section 16.4.1.32, “Replication and Variables”](#).

- **UDFs.** Since we have no control over what a UDF does, we must assume that it is executing unsafe statements.
- **Updates a table having an `AUTO_INCREMENT` column.** This is unsafe because the order in which the rows are updated may differ on the master and the slave.

For more information, see [Section 16.4.1.1, “Replication and `AUTO\_INCREMENT`”](#).

- **`INSERT DELAYED` statement.** This statement is considered unsafe because the insertion of the rows may interleave with concurrently executing statements.
- **Updates using `LIMIT`.** The order in which rows are retrieved is not specified.

See [Section 16.4.1.13, “Replication and `LIMIT`”](#).

- **Accesses or references log tables.** The contents of the system log table may differ between master and slave.
- **Nontransactional operations after transactional operations.** Within a transaction, allowing any nontransactional reads or writes to execute after any transactional reads or writes is considered unsafe.

For more information, see [Section 16.4.1.28, “Replication and Transactions”](#).

- **Accesses or references self-logging tables.** All reads and writes to self-logging tables are considered unsafe. Within a transaction, any statement following a read or write to self-logging tables is also considered unsafe.
- **`LOAD DATA INFILE` statements.** Beginning with MySQL 5.1.50, `LOAD DATA INFILE` is considered unsafe, it causes a warning in statement-based mode, and a switch to row-based format when using mixed-format logging. See [Section 16.4.1.14, “Replication and `LOAD DATA INFILE`”](#).

For additional information, see [Section 16.4.1, “Replication Features and Issues”](#).

### 16.1.3. Replication and Binary Logging Options and Variables

The next few sections contain information about `mysqld` options and server variables that are used in replication and for controlling the binary log. Options and variables for use on replication masters and replication slaves are covered separately, as are options and variables relating to binary logging. A set of quick-reference tables providing basic information about these options and variables is also included (in the next section following this one).

Of particular importance is the `--server-id` option.

<b>Command-Line Format</b>	<code>--server-id=#</code>
<b>Config-File Format</b>	<code>server_id</code>
<b>Option Sets Variable</b>	Yes, <code>server_id</code>
<b>Variable Name</b>	<code>server_id</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	
<b>Type</b>	<code>numeric</code>
<b>Default</b>	<code>0</code>
<b>Range</b>	<code>0-4294967295</code>

This option is common to both master and slave replication servers, and is used in replication to enable master and slave servers to identify themselves uniquely. For additional information, see [Section 16.1.3.2, “Replication Master Options and Variables”](#), and [Section 16.1.3.3, “Replication Slave Options and Variables”](#).

On the master and each slave, you *must* use the `--server-id` option to establish a unique replication ID in the range from 1 to 232 – 1. “Unique”, means that each ID must be different from every other ID in use by any other replication master or slave. Example: `server_id=3`.

If you omit `--server-id`, the default ID is 0, in which case a master refuses connections from all slaves, and a slave refuses to connect to a master. For more information, see [Section 16.1.1.2, “Setting the Replication Slave Configuration”](#).

#### 16.1.3.1. Replication and Binary Logging Option and Variable Reference

The following tables list basic information about the MySQL command-line options and system variables applicable to replication and the binary log.

**Table 16.1. Replication Option/Variable Summary**

Name	Cmd-Line	Option file	System Var	Status Var	Var Scope	Dynamic
<code>abort-slave-event-count</code>	Yes	Yes				
<code>Com_change_master</code>				Yes	Both	No
<code>Com_show_master_status</code>				Yes	Both	No
<code>Com_show_new_master</code>				Yes	Both	No
<code>Com_show_slave_hosts</code>				Yes	Both	No
<code>Com_show_slave_status</code>				Yes	Both	No
<code>Com_slave_start</code>				Yes	Both	No
<code>Com_slave_stop</code>				Yes	Both	No
<code>disconnect-slave-event-count</code>	Yes	Yes				
<code>have_row_based_replication</code>			Yes		Global	No
<code>init_slave</code>	Yes	Yes	Yes		Global	Yes
<code>log-slave-updates</code>	Yes	Yes			Global	No
<code>- Variable:</code>			Yes		Global	No

Name	Cmd-Line	Option file	System Var	Status Var	Var Scope	Dynamic
log_slave_updates						
master-bind	Yes	Yes	Yes			No
master-connect-retry	Yes	Yes				
master-host	Yes	Yes				
master-info-file	Yes	Yes				
master-password	Yes	Yes				
master-port	Yes	Yes				
master-retry-count	Yes	Yes				
master-ssl	Yes	Yes				
master-ssl-ca	Yes	Yes				
master-ssl-capath	Yes	Yes				
master-ssl-cert	Yes	Yes				
master-ssl-cipher	Yes	Yes				
master-ssl-key	Yes	Yes				
master-user	Yes	Yes				
relay-log	Yes	Yes				
relay-log-index	Yes	Yes			Both	No
- Variable: relay_log_index			Yes		Both	No
relay-log-info-file	Yes	Yes				
- Variable: relay_log_info_file						
relay_log_purge	Yes	Yes	Yes		Global	Yes
relay_log_space_limit	Yes	Yes	Yes		Global	No
replicate-do-db	Yes	Yes				
replicate-do-table	Yes	Yes				
replicate-ignore-db	Yes	Yes				
replicate-ignore-table	Yes	Yes				
replicate-rewrite-db	Yes	Yes				
replicate-same-server-id	Yes	Yes				
replicate-wild-do-table	Yes	Yes				
replicate-wild-ignore-table	Yes	Yes				
report-host	Yes	Yes			Global	No
- Variable: report_host			Yes		Global	No
report-password	Yes	Yes			Global	No
- Variable: report_password			Yes		Global	No
report-port	Yes	Yes			Global	No
- Variable: report_port			Yes		Global	No
report-user	Yes	Yes			Global	No
- Variable: report_user			Yes		Global	No
rpl_recovery_rank			Yes		Global	Yes
Rpl_status				Yes	Global	No
show-slave-auth-info	Yes	Yes				
skip-slave-start	Yes	Yes				

Name	Cmd-Line	Option file	System Var	Status Var	Var Scope	Dynamic
slave_compressed_protocol	Yes	Yes	Yes		Global	Yes
slave_exec_mode			Yes		Global	Yes
Slave_heartbeat_period				Yes	Global	No
slave-load-tmpdir - Variable: slave_load_tmpdir	Yes	Yes			Global	No
			Yes		Global	No
slave-net-timeout - Variable: slave_net_timeout	Yes	Yes			Global	Yes
			Yes		Global	Yes
Slave_open_temp_tables				Yes	Global	No
Slave_received_heartbeats				Yes	Global	No
Slave_retried_transactions				Yes	Global	No
Slave_running				Yes	Global	No
slave-skip-errors - Variable: slave_skip_errors	Yes	Yes			Global	No
			Yes		Global	No
slave_transaction_retries	Yes	Yes	Yes		Global	Yes
slave_type_conversions	Yes	Yes	Yes		Global	No
sql_slave_skip_counter			Yes		Global	Yes

Section 16.1.3.2, “Replication Master Options and Variables”, provides more detailed information about options and variables relating to replication master servers. For more information about options and variables relating to replication slaves, see Section 16.1.3.3, “Replication Slave Options and Variables”.

**Table 16.2. Binary Logging Option/Variable Summary**

Name	Cmd-Line	Option file	System Var	Status Var	Var Scope	Dynamic
Bin-log_cache_disk_use				Yes	Global	No
binlog_cache_size	Yes	Yes	Yes		Global	Yes
Binlog_cache_use				Yes	Global	No
bin-log_direct_non_transa ctional_updates	Yes	Yes	Yes		Both	Yes
binlog-do-db	Yes	Yes				
binlog-format - Variable: bin- log_format	Yes	Yes			Both	Yes
			Yes		Both	Yes
binlog-ignore-db	Yes	Yes

Name	Cmd-Line	Option file	System Var	Status Var	Var Scope	Dynamic
log-dump-events						
max_binlog_size	Yes	Yes	Yes		Global	Yes
sporadic-bin-log-dump-fail	Yes	Yes				

Section 16.1.3.4, “Binary Log Options and Variables”, provides more detailed information about options and variables relating to binary logging. For additional general information about the binary log, see Section 5.2.4, “The Binary Log”.

For a table showing *all* command-line options, system and status variables used with `mysqld`, see Section 5.1.1, “Server Option and Variable Reference”.

### 16.1.3.2. Replication Master Options and Variables

This section describes the server options and system variables that you can use on replication master servers. You can specify the options either on the [command line](#) or in an [option file](#). You can specify system variable values using [SET](#).

On the master and each slave, you must use the `server-id` option to establish a unique replication ID. For each server, you should pick a unique positive integer in the range from 1 to  $2^{32} - 1$ , and each ID must be different from every other ID in use by any other replication master or slave. Example: `server-id=3`.

For options used on the master for controlling binary logging, see Section 16.1.3.4, “Binary Log Options and Variables”.

- `auto_increment_increment`

<b>Command-Line Format</b>	<code>--auto_increment_increment[=#]</code>	
<b>Config-File Format</b>	<code>auto_increment_increment</code>	
<b>Option Sets Variable</b>	Yes, <code>auto_increment_increment</code>	
<b>Variable Name</b>	<code>auto_increment_increment</code>	
<b>Variable Scope</b>	Both	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	<code>1</code>
	<b>Range</b>	<code>1-65535</code>

`auto_increment_increment` and `auto_increment_offset` are intended for use with master-to-master replication, and can be used to control the operation of `AUTO_INCREMENT` columns. Both variables have global and session values, and each can assume an integer value between 1 and 65,535 inclusive. Setting the value of either of these two variables to 0 causes its value to be set to 1 instead. Attempting to set the value of either of these two variables to an integer greater than 65,535 or less than 0 causes its value to be set to 65,535 instead. Attempting to set the value of `auto_increment_increment` or `auto_increment_offset` to a noninteger value gives rise to an error, and the actual value of the variable remains unchanged.

#### Note

`auto_increment_increment` is supported for use with `NDB` tables beginning with MySQL 5.1.20, MySQL Cluster NDB 6.2.5, and MySQL Cluster NDB 6.3.2. Previously, setting it when using MySQL Cluster tables or MySQL Cluster Replication produced unpredictable results.

These two variables affect `AUTO_INCREMENT` column behavior as follows:

- `auto_increment_increment` controls the interval between successive column values. For example:

```
mysql> SHOW VARIABLES LIKE 'auto_inc%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| auto_increment_increment | 1 |
| auto_increment_offset | 1 |
+-----+-----+
2 rows in set (0.00 sec)

mysql> CREATE TABLE autoinc1
 -> (col INT NOT NULL AUTO_INCREMENT PRIMARY KEY);
```

```

Query OK, 0 rows affected (0.04 sec)

mysql> SET @@auto_increment_increment=10;
Query OK, 0 rows affected (0.00 sec)

mysql> SHOW VARIABLES LIKE 'auto_inc%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| auto_increment_increment | 10 |
| auto_increment_offset | 1 |
+-----+-----+
2 rows in set (0.01 sec)

mysql> INSERT INTO autoinc1 VALUES (NULL), (NULL), (NULL), (NULL);
Query OK, 4 rows affected (0.00 sec)
Records: 4 Duplicates: 0 Warnings: 0

mysql> SELECT col FROM autoinc1;
+----+
| col |
+----+
| 1 |
| 11 |
| 21 |
| 31 |
+----+
4 rows in set (0.00 sec)

```

- `auto_increment_offset` determines the starting point for the `AUTO_INCREMENT` column value. Consider the following, assuming that these statements are executed during the same session as the example given in the description for `auto_increment_increment`:

```

mysql> SET @@auto_increment_offset=5;
Query OK, 0 rows affected (0.00 sec)

mysql> SHOW VARIABLES LIKE 'auto_inc%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| auto_increment_increment | 10 |
| auto_increment_offset | 5 |
+-----+-----+
2 rows in set (0.00 sec)

mysql> CREATE TABLE autoinc2
 -> (col INT NOT NULL AUTO_INCREMENT PRIMARY KEY);
Query OK, 0 rows affected (0.06 sec)

mysql> INSERT INTO autoinc2 VALUES (NULL), (NULL), (NULL), (NULL);
Query OK, 4 rows affected (0.00 sec)
Records: 4 Duplicates: 0 Warnings: 0

mysql> SELECT col FROM autoinc2;
+----+
| col |
+----+
| 5 |
| 15 |
| 25 |
| 35 |
+----+
4 rows in set (0.02 sec)

```

If the value of `auto_increment_offset` is greater than that of `auto_increment_increment`, the value of `auto_increment_offset` is ignored.

Should one or both of these variables be changed and then new rows inserted into a table containing an `AUTO_INCREMENT` column, the results may seem counterintuitive because the series of `AUTO_INCREMENT` values is calculated without regard to any values already present in the column, and the next value inserted is the least value in the series that is greater than the maximum existing value in the `AUTO_INCREMENT` column. In other words, the series is calculated like so:

$$\text{auto\_increment\_offset} + N \times \text{auto\_increment\_increment}$$

where  $N$  is a positive integer value in the series  $[1, 2, 3, \dots]$ . For example:

```

mysql> SHOW VARIABLES LIKE 'auto_inc%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| auto_increment_increment | 10 |
| auto_increment_offset | 5 |
+-----+-----+
2 rows in set (0.00 sec)

mysql> SELECT col FROM autoinc1;
+----+
| col |
+----+

```

```

+-----+
| col |
+-----+
| 1 |
| 11 |
| 21 |
| 31 |
+-----+
4 rows in set (0.00 sec)

mysql> INSERT INTO autoinc1 VALUES (NULL), (NULL), (NULL), (NULL);
Query OK, 4 rows affected (0.00 sec)
Records: 4 Duplicates: 0 Warnings: 0

mysql> SELECT col FROM autoinc1;
+-----+
| col |
+-----+
| 1 |
| 11 |
| 21 |
| 31 |
| 35 |
| 45 |
| 55 |
| 65 |
+-----+
8 rows in set (0.00 sec)

```

The values shown for `auto_increment_increment` and `auto_increment_offset` generate the series  $5 + N \times 10$ , that is, [5, 15, 25, 35, 45, ...]. The greatest value present in the `col` column prior to the `INSERT` is 31, and the next available value in the `AUTO_INCREMENT` series is 35, so the inserted values for `col` begin at that point and the results are as shown for the `SELECT` query.

It is not possible to confine the effects of these two variables to a single table, and thus they do not take the place of the sequences offered by some other database management systems; these variables control the behavior of all `AUTO_INCREMENT` columns in *all* tables on the MySQL server. If the global value of either variable is set, its effects persist until the global value is changed or overridden by setting the session value, or until `mysqld` is restarted. If the local value is set, the new value affects `AUTO_INCREMENT` columns for all tables into which new rows are inserted by the current user for the duration of the session, unless the values are changed during that session.

The default value of `auto_increment_increment` is 1. See [Section 16.4.1.1, “Replication and AUTO\\_INCREMENT”](#).

- `auto_increment_offset`

<b>Command-Line Format</b>	<code>--auto_increment_offset[=#]</code>
<b>Config-File Format</b>	<code>auto_increment_offset</code>
<b>Option Sets Variable</b>	Yes, <code>auto_increment_offset</code>
<b>Variable Name</b>	<code>auto_increment_offset</code>
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	
<b>Type</b>	<code>numeric</code>
<b>Default</b>	1
<b>Range</b>	1–65535

This variable has a default value of 1. For particulars, see the description for `auto_increment_increment`.

### Note

`auto_increment_offset` is supported for use with `NDB` tables beginning with MySQL 5.1.20, MySQL Cluster `NDB` 6.2.5, and MySQL Cluster `NDB` 6.3.2. Previously, setting it when using MySQL Cluster tables or MySQL Cluster Replication produced unpredictable results.

### 16.1.3.3. Replication Slave Options and Variables

This section describes the server options and system variables that apply to slave replication servers. You can specify the options either on the `command line` or in an `option file`. Many of the options can be set while the server is running by using the `CHANGE MASTER TO` statement. You can specify system variable values using `SET`.

**Server ID.** On the master and each slave, you must use the `server-id` option to establish a unique replication ID in the range

from 1 to  $2^{32} - 1$ . “Unique” means that each ID must be different from every other ID in use by any other replication master or slave. Example `my.cnf` file:

```
[mysqld]
server-id=3
```

## Important

Certain `--master-xxx` options are handled in a special way to ensure that the active replication configuration is not inadvertently altered or affected:

- `--master-host`
- `--master-user`
- `--master-password`
- `--master-port`
- `--master-connect-retry`
- `--master-ssl`
- `--master-ssl-ca`
- `--master-ssl-capath`
- `--master-ssl-cert`
- `--master-ssl-cipher`
- `--master-ssl-key`

Before MySQL 5.1.17, these options are silently ignored if given unless there is no `master.info` file. If that file exists, the MySQL server has already previously been configured for replication, so the information in the file is used instead. Because the server gives an existing `master.info` file precedence over the startup options just described, you might elect not to use startup options for these values at all, and instead to specify the replication parameters associated with them by using the `CHANGE MASTER TO` statement. See [Section 12.5.2.1, “`CHANGE MASTER TO` Syntax”](#).

Beginning with MySQL 5.1.17, these options are deprecated and have no effect when `mysqld` is started. If they are used, an appropriate warning is written to the error log. Instead, you *must* use `CHANGE MASTER TO` to set the values corresponding to the deprecated options. These options are removed in MySQL 5.5.

The `master.info` file format in MySQL 5.1 includes as its first line the number of lines in the file. (See [Section 16.2.2, “Replication Relay and Status Files”](#).) If you upgrade an older server (before MySQL 4.1.1) to a newer version, the new server upgrades the `master.info` file to the new format automatically when it starts. However, if you downgrade a newer server to an older version, you should remove the first line manually before starting the older server for the first time.

If no `master.info` file exists when the slave server starts, it uses the values for those options that are specified in option files or on the command line. This occurs when you start the server as a replication slave for the very first time, when you use `CHANGE MASTER TO`, or when you have run `RESET SLAVE` and then have shut down and restarted the slave.

Because the server uses `master.info` file contents and ignores any startup options that correspond to the values listed in the file, if you start the slave server with different values of the startup options that correspond to values in the file, the different values have no effect. To use different values, the preferred method is to use the `CHANGE MASTER TO` statement to reset the values while the slave is running. Alternatively, you can stop the server, remove the `master.info` file, and restart the server with different option values.

Suppose that you specify this option in your `my.cnf` file to configure a pre-5.1.17 slave server:

```
[mysqld]
master-host=some_host
```

The first time you start the server as a replication slave, it reads and uses that option from the `my.cnf` file. The server then records the value in the `master.info` file. The next time you start the server, it reads the master host value from the `master.info` file only and ignores the value in the option file. If you modify the `my.cnf` file to specify a different master host value of `some_other_host`, the change has no effect. Instead, use `CHANGE MASTER TO` to change the value.

This example shows a more extensive use of startup options to configure a pre-5.1.17 slave server:

```
[mysqld]
server-id=2
master-host=db-master.mycompany.com
master-port=3306
master-user=pertinax
master-password=freitag
master-connect-retry=60
report-host=db-slave.mycompany.com
```

As of 5.1.17, the `master-xxx` options are ignored and result in warnings in the error log.

**Startup options for replication slaves.** The following list describes startup options for controlling replication slave servers. Many of these options can be set while the server is running by using the `CHANGE MASTER TO` statement. Others, such as the `-replicate-*` options, can be set only when the slave server starts. Replication-related system variables are discussed later in this section.

- `--abort-slave-event-count`

<b>Command-Line Format</b>	<code>--abort-slave-event-count=#</code>
<b>Config-File Format</b>	<code>abort-slave-event-count</code>
<b>Permitted Values</b>	
<b>Type</b>	<code>numeric</code>
<b>Default</b>	<code>0</code>
<b>Min Value</b>	<code>0</code>

When this option is set to some positive integer `value` other than 0 (the default) it affects replication behavior as follows: After the slave SQL thread has started, `value` log events are permitted to be executed; after that, the slave SQL thread does not receive any more events, just as if the network connection from the master were cut. The slave thread continues to run, and the output from `SHOW SLAVE STATUS` displays `Yes` in both the `Slave_IO_Running` and the `Slave_SQL_Running` columns, but no further events are read from the relay log.

This option is used internally by the MySQL test suite for replication testing and debugging. It is not intended for use in a production setting.

- `--disconnect-slave-event-count`

<b>Command-Line Format</b>	<code>--disconnect-slave-event-count=#</code>
<b>Config-File Format</b>	<code>disconnect-slave-event-count</code>
<b>Permitted Values</b>	
<b>Type</b>	<code>numeric</code>
<b>Default</b>	<code>0</code>

This option is used internally by the MySQL test suite for replication testing and debugging.

- `--log-slave-updates`

<b>Command-Line Format</b>	<code>--log-slave-updates</code>
<b>Config-File Format</b>	<code>log-slave-updates</code>
<b>Option Sets Variable</b>	Yes, <code>log_slave_updates</code>
<b>Variable Name</b>	<code>log_slave_updates</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	
<b>Type</b>	<code>boolean</code>
<b>Default</b>	<code>FALSE</code>

Normally, a slave does not log to its own binary log any updates that are received from a master server. This option tells the slave to log the updates performed by its SQL thread to its own binary log. For this option to have any effect, the slave must

also be started with the `--log-bin` option to enable binary logging. `--log-slave-updates` is used when you want to chain replication servers. For example, you might want to set up replication servers using this arrangement:

```
A -> B -> C
```

Here, A serves as the master for the slave B, and B serves as the master for the slave C. For this to work, B must be both a master *and* a slave. You must start both A and B with `--log-bin` to enable binary logging, and B with the `-log-slave-updates` option so that updates received from A are logged by B to its binary log.

When using MySQL Cluster Replication prior to MySQL Cluster NDB 6.2.16 and MySQL Cluster NDB 6.3.13, records for “empty” epochs—that is, epochs in which no changes to `NDBCLUSTER` data or tables took place—were inserted into the `ndb_apply_status` and `ndb_binlog_index` tables on the slave even when `--log-slave-updates` was disabled ([Bug#37472](#)). Beginning with MySQL Cluster NDB 6.3.33, MySQL Cluster NDB 7.0.14, and MySQL Cluster NDB 7.1.3, it is possible to re-enable the older behavior by using the `--ndb-log-empty-epochs` option.

### Note

The `--ndb-log-empty-epochs` option was first implemented in MySQL Cluster NDB 6.3.21 and MySQL Cluster NDB 6.4.1, but did not work correctly before the versions cited previously.

- `--log-slow-slave-statements`

<b>Version Introduced</b>	5.1.21
<b>Command-Line Format</b>	<code>--log-slow-slave-statements</code>
<b>Config-File Format</b>	<code>log-slow-slave-statements</code>
	<b>Permitted Values</b>
	<b>Type</b> boolean
	<b>Default</b> off

When the slow query log is enabled, this option enables logging for queries that have taken more than `long_query_time` seconds to execute on the slave.

This option was added in MySQL 5.1.21.

- `--log-warnings[=level]`

<b>Command-Line Format</b>	<code>--log-warnings[=#]</code>
	<code>-W [#]</code>
<b>Config-File Format</b>	<code>log-warnings</code>
<b>Option Sets Variable</b>	Yes, <code>log_warnings</code>
<b>Variable Name</b>	<code>log_warnings</code>
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes
<b>Disabled by</b>	<code>skip-log-warnings</code>
	<b>Permitted Values</b>
	<b>Platform Bit Size</b> 64
	<b>Type</b> numeric
	<b>Default</b> 1
	<b>Range</b> 0-18446744073709547520

This option causes a server to print more messages to the error log about what it is doing. With respect to replication, the server generates warnings that it succeeded in reconnecting after a network/connection failure, and informs you as to how each slave thread started. This option is enabled by default; to disable it, use `--skip-log-warnings`. Aborted connections are not logged to the error log unless the value is greater than 1.

Note that the effects of this option are not limited to replication. It produces warnings across a spectrum of server activities.

- `--master-connect-retry=seconds`

The number of seconds that the slave thread sleeps before trying to reconnect to the master in case the master goes down or the connection is lost. The value in the `master.info` file takes precedence if it can be read. If not set, the default is 60. Connection retries are not invoked until the slave times out reading data from the master according to the value of `--slave-net-timeout`. The number of reconnection attempts is limited by the `--master-retry-count` option.

This option is deprecated as of MySQL 5.1.17 and is removed in MySQL 5.5.

- `--master-host=host_name`

The host name or IP number of the master replication server. The value in `master.info` takes precedence if it can be read. If no master host is specified, the slave thread does not start.

This option is deprecated as of MySQL 5.1.17 and is removed in MySQL 5.5.

- `--master-info-file=file_name`

<b>Command-Line Format</b>	<code>--master-info-file=name</code>
<b>Config-File Format</b>	<code>master-info-file</code>
<b>Permitted Values</b>	
<b>Type</b>	<code>filename</code>
<b>Default</b>	<code>master.info</code>

The name to use for the file in which the slave records information about the master. The default name is `master.info` in the data directory. For information about the format of this file, see [Section 16.2.2.2, “The Slave Status Files”](#).

- `--master-password=password`

The password of the account that the slave thread uses for authentication when it connects to the master. The value in the `master.info` file takes precedence if it can be read. If not set, an empty password is assumed.

This option is deprecated as of MySQL 5.1.17 and is removed in MySQL 5.5.

- `--master-port=port_number`

The TCP/IP port number that the master is listening on. The value in the `master.info` file takes precedence if it can be read. If not set, the compiled-in setting is assumed (normally 3306).

This option is deprecated as of MySQL 5.1.17 and is removed in MySQL 5.5.

- `--master-retry-count=count`

<b>Command-Line Format</b>	<code>--master-retry-count=#</code>
<b>Config-File Format</b>	<code>master-retry-count</code>
<b>Permitted Values</b>	
<b>Platform Bit Size</b>	<code>32</code>
<b>Type</b>	<code>numeric</code>
<b>Default</b>	<code>86400</code>
<b>Range</b>	<code>0-4294967295</code>
<b>Permitted Values</b>	
<b>Platform Bit Size</b>	<code>64</code>
<b>Type</b>	<code>numeric</code>
<b>Default</b>	<code>86400</code>
<b>Range</b>	<code>0-18446744073709551615</code>

The number of times that the slave tries to connect to the master before giving up. Reconnects are attempted at intervals set by the `--master-connect-retry` option (or the `MASTER_CONNECT_RETRY` option of the `CHANGE MASTER TO` statement) and reconnects are triggered when data reads by the slave time out according to the `--slave-net-timeout` option. The default value is 86400. A value of 0 means “infinite”; the slave attempts to connect forever.

- `--master-ssl`, `--master-ssl-ca=file_name`, `--master-ssl-capath=directory_name`, `--master-ssl-cert=file_name`, `--master-ssl-cipher=cipher_list`, `--master-ssl-key=file_name`

These options are used for setting up a secure replication connection to the master server using SSL. Their meanings are the same as the corresponding `--ssl`, `--ssl-ca`, `--ssl-capath`, `--ssl-cert`, `--ssl-cipher`, `--ssl-key` options that are described in [Section 5.5.6.3, “SSL Command Options”](#). The values in the `master.info` file take precedence if they can be read.

These options are deprecated as of MySQL 5.1.17 and are removed in MySQL 5.5.

- `--master-user=user_name`

The user name of the account that the slave thread uses for authentication when it connects to the master. This account must have the `REPLICATION SLAVE` privilege. The value in the `master.info` file takes precedence if it can be read. If the master user name is not set, the name `test` is assumed.

This option is deprecated as of MySQL 5.1.17 and is removed in MySQL 5.5.

- `--max-relay-log-size=size`

The size at which the server rotates relay log files automatically. For more information, see [Section 16.2.2, “Replication Relay and Status Files”](#). The default size is 1GB.

- `--read-only`

Cause the slave to permit no updates except from slave threads or from users having the `SUPER` privilege. On a slave server, this can be useful to ensure that the slave accepts updates only from its master server and not from clients. This variable does not apply to `TEMPORARY` tables.

- `--relay-log=file_name`

The basename for the relay log. The default basename is `host_name-relay-bin`. The server writes the file in the data directory unless the basename is given with a leading absolute path name to specify a different directory. The server creates relay log files in sequence by adding a numeric suffix to the basename.

Due to the manner in which MySQL parses server options, if you specify this option, you must supply a value; *the default basename is used only if the option is not actually specified*. If you use the `--relay-log` option without specifying a value, unexpected behavior is likely to result; this behavior depends on the other options used, the order in which they are specified, and whether they are specified on the command line or in an option file. For more information about how MySQL handles server options, see [Section 4.2.3, “Specifying Program Options”](#).

If you specify this option, the value specified is also used as the basename for the relay log index file. You can override this behavior by specifying a different relay log index file basename using the `--relay-log-index` option.

You may find the `--relay-log` option useful in performing the following tasks:

- Creating relay logs whose names are independent of host names.
  - If you need to put the relay logs in some area other than the data directory because your relay logs tend to be very large and you do not want to decrease `max_relay_log_size`.
  - To increase speed by using load-balancing between disks.
- `--relay-log-index=file_name`

The name to use for the relay log index file. The default name is `host_name-relay-bin.index` in the data directory, where `host_name` is the name of the slave server.

Due to the manner in which MySQL parses server options, if you specify this option, you must supply a value; *the default basename is used only if the option is not actually specified*. If you use the `--relay-log-index` option without specifying a value, unexpected behavior is likely to result; this behavior depends on the other options used, the order in which they are specified, and whether they are specified on the command line or in an option file. For more information about how MySQL handles server options, see [Section 4.2.3, “Specifying Program Options”](#).

If you specify this option, the value specified is also used as the basename for the relay logs. You can override this behavior by specifying a different relay log file basename using the `--relay-log` option.

- `--relay-log-info-file=file_name`

The name to use for the file in which the slave records information about the relay logs. The default name is `relay-log.info` in the data directory. For information about the format of this file, see [Section 16.2.2.2, “The Slave Status Files”](#).

- `--relay-log-purge={0|1}`

Disable or enable automatic purging of relay logs as soon as they are no longer needed. The default value is 1 (enabled). This is a global variable that can be changed dynamically with `SET GLOBAL relay_log_purge = N`.

- `--relay-log-space-limit=size`

This option places an upper limit on the total size in bytes of all relay logs on the slave. A value of 0 means “no limit.” This is useful for a slave server host that has limited disk space. When the limit is reached, the I/O thread stops reading binary log events from the master server until the SQL thread has caught up and deleted some unused relay logs. Note that this limit is not absolute: There are cases where the SQL thread needs more events before it can delete relay logs. In that case, the I/O thread exceeds the limit until it becomes possible for the SQL thread to delete some relay logs because not doing so would cause a deadlock. You should not set `--relay-log-space-limit` to less than twice the value of `--max-relay-log-size` (or `--max-binlog-size` if `--max-relay-log-size` is 0). In that case, there is a chance that the I/O thread waits for free space because `--relay-log-space-limit` is exceeded, but the SQL thread has no relay log to purge and is unable to satisfy the I/O thread. This forces the I/O thread to ignore `--relay-log-space-limit` temporarily.

- `--replicate-do-db=db_name`

The effects of this option depend on whether statement-based or row-based replication is in use.

**Statement-based replication.** Tell the slave SQL thread to restrict replication to statements where the default database (that is, the one selected by `USE`) is `db_name`. To specify more than one database, use this option multiple times, once for each database; however, doing so does *not* replicate cross-database statements such as `UPDATE some_db.some_table SET foo='bar'` while a different database (or no database) is selected.

### Warning

To specify multiple databases you *must* use multiple instances of this option. Because database names can contain commas, if you supply a comma separated list then the list will be treated as the name of a single database.

An example of what does not work as you might expect when using statement-based replication: If the slave is started with `--replicate-do-db=sales` and you issue the following statements on the master, the `UPDATE` statement is *not* replicated:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

The main reason for this “check just the default database” behavior is that it is difficult from the statement alone to know whether it should be replicated (for example, if you are using multiple-table `DELETE` statements or multiple-table `UPDATE` statements that act across multiple databases). It is also faster to check only the default database rather than all databases if there is no need.

**Row-based replication.** Tells the slave SQL thread to restrict replication to database `db_name`. Only tables belonging to `db_name` are changed; the current database has no effect on this. Suppose that the slave is started with `--replicate-do-db=sales` and row-based replication is in effect, and then the following statements are run on the master:

```
USE prices;
UPDATE sales.february SET amount=amount+100;
```

The `february` table in the `sales` database on the slave is changed in accordance with the `UPDATE` statement; this occurs whether or not the `USE` statement was issued. However, issuing the following statements on the master has no effect on the slave when using row-based replication and `--replicate-do-db=sales`:

```
USE prices;
UPDATE prices.march SET amount=amount-25;
```

Even if the statement `USE prices` were changed to `USE sales`, the `UPDATE` statement's effects would still not be replicated.

Another important difference in how `--replicate-do-db` is handled in statement-based replication as opposed to row-based replication occurs with regard to statements that refer to multiple databases. Suppose the slave is started with `--replicate-do-db=db1`, and the following statements are executed on the master:

```
USE db1;
UPDATE db1.table1 SET col1 = 10, db2.table2 SET col2 = 20;
```

If you are using statement-based replication, then both tables are updated on the slave. However, when using row-based replication, only `table1` is affected on the slave; since `table2` is in a different database, `table2` on the slave is not changed by the `UPDATE`. Now suppose that, instead of the `USE db1` statement, a `USE db4` statement had been used:

```
USE db4;
UPDATE db1.table1 SET col1 = 10, db2.table2 SET col2 = 20;
```

In this case, the `UPDATE` statement would have no effect on the slave when using statement-based replication. However, if you

are using row-based replication, the `UPDATE` would change `table1` on the slave, but not `table2`—in other words, only tables in the database named by `--replicate-do-db` are changed, and the choice of default database has no effect on this behavior.

If you need cross-database updates to work, use `--replicate-wild-do-table=db_name.%` instead. See [Section 16.2.3, “How Servers Evaluate Replication Filtering Rules”](#).

### Note

This option affects replication in the same manner that `--binlog-do-db` affects binary logging, and the effects of the replication format on how `--replicate-do-db` affects replication behavior are the same as those of the logging format on the behavior of `--binlog-do-db`.

Beginning with MySQL 5.1.35, this option has no effect on `BEGIN`, `COMMIT`, or `ROLLBACK` statements. ([Bug#43263](#))

- `--replicate-ignore-db=db_name`

As with `--replicate-do-db`, the effects of this option depend on whether statement-based or row-based replication is in use.

**Statement-based replication.** Tells the slave SQL thread not to replicate any statement where the default database (that is, the one selected by `USE`) is `db_name`.

**Row-based replication.** Tells the slave SQL thread not to update any tables in the database `db_name`. The default database has no effect.

When using statement-based replication, the following example does not work as you might expect. Suppose that the slave is started with `--replicate-ignore-db=sales` and you issue the following statements on the master:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

The `UPDATE` statement is replicated in such a case because `--replicate-ignore-db` applies only to the default database (determined by the `USE` statement). Because the `sales` database was specified explicitly in the statement, the statement has not been filtered. However, when using row-based replication, the `UPDATE` statement's effects are *not* propagated to the slave, and the slave's copy of the `sales.january` table is unchanged; in this instance, `--replicate-ignore-db=sales` causes *all* changes made to tables in the master's copy of the `sales` database to be ignored by the slave.

To specify more than one database to ignore, use this option multiple times, once for each database. Because database names can contain commas, if you supply a comma separated list then the list will be treated as the name of a single database.

You should not use this option if you are using cross-database updates and you do not want these updates to be replicated. See [Section 16.2.3, “How Servers Evaluate Replication Filtering Rules”](#).

If you need cross-database updates to work, use `--replicate-wild-ignore-table=db_name.%` instead. See [Section 16.2.3, “How Servers Evaluate Replication Filtering Rules”](#).

### Note

This option affects replication in the same manner that `--binlog-ignore-db` affects binary logging, and the effects of the replication format on how `--replicate-ignore-db` affects replication behavior are the same as those of the logging format on the behavior of `--binlog-ignore-db`.

Beginning with MySQL 5.1.35, this option has no effect on `BEGIN`, `COMMIT`, or `ROLLBACK` statements. ([Bug#43263](#))

- `--replicate-do-table=db_name.tbl_name`

Tells the slave SQL thread to restrict replication to the specified table. To specify more than one table, use this option multiple times, once for each table. This works for both cross-database updates and default database updates, in contrast to `--replicate-do-db`. See [Section 16.2.3, “How Servers Evaluate Replication Filtering Rules”](#).

This option affects only statements that apply to tables. It does not affect statements that apply only to other database objects, such as stored routines. To filter statements operating on stored routines, use one or more of the `--replicate-*--db` options.

- `--replicate-ignore-table=db_name.tbl_name`

Tells the slave SQL thread not to replicate any statement that updates the specified table, even if any other tables might be updated by the same statement. To specify more than one table to ignore, use this option multiple times, once for each table. This

works for cross-database updates, in contrast to `--replicate-ignore-db`. See [Section 16.2.3, “How Servers Evaluate Replication Filtering Rules”](#).

This option affects only statements that apply to tables. It does not affect statements that apply only to other database objects, such as stored routines. To filter statements operating on stored routines, use one or more of the `--replicate-*-db` options.

- `--replicate-rewrite-db=from_name->to_name`

Tells the slave to translate the default database (that is, the one selected by `USE`) to `to_name` if it was `from_name` on the master. Only statements involving tables are affected (not statements such as `CREATE DATABASE`, `DROP DATABASE`, and `ALTER DATABASE`), and only if `from_name` is the default database on the master. This does not work for cross-database updates. To specify multiple rewrites, use this option multiple times. The server uses the first one with a `from_name` value that matches. The database name translation is done *before* the `--replicate-*` rules are tested.

If you use this option on the command line and the “`>`” character is special to your command interpreter, quote the option value. For example:

```
shell> mysqld --replicate-rewrite-db="olddb->newdb"
```

- `--replicate-same-server-id`

To be used on slave servers. Usually you should use the default setting of 0, to prevent infinite loops caused by circular replication. If set to 1, the slave does not skip events having its own server ID. Normally, this is useful only in rare configurations. Cannot be set to 1 if `--log-slave-updates` is used. By default, the slave I/O thread does not write binary log events to the relay log if they have the slave's server ID (this optimization helps save disk usage). If you want to use `--replicate-same-server-id`, be sure to start the slave with this option before you make the slave read its own events that you want the slave SQL thread to execute.

- `--replicate-wild-do-table=db_name.tbl_name`

Tells the slave thread to restrict replication to statements where any of the updated tables match the specified database and table name patterns. Patterns can contain the “`%`” and “`_`” wildcard characters, which have the same meaning as for the `LIKE` pattern-matching operator. To specify more than one table, use this option multiple times, once for each table. This works for cross-database updates. See [Section 16.2.3, “How Servers Evaluate Replication Filtering Rules”](#).

This option applies to tables, views, and triggers. It does not apply to stored procedures and functions, or events. To filter statements operating on the latter objects, use one or more of the `--replicate-*-db` options.

Example: `--replicate-wild-do-table=foo%.bar%` replicates only updates that use a table where the database name starts with `foo` and the table name starts with `bar`.

If the table name pattern is `%`, it matches any table name and the option also applies to database-level statements (`CREATE DATABASE`, `DROP DATABASE`, and `ALTER DATABASE`). For example, if you use `--replicate-wild-do-table=foo%.%`, database-level statements are replicated if the database name matches the pattern `foo%`.

To include literal wildcard characters in the database or table name patterns, escape them with a backslash. For example, to replicate all tables of a database that is named `my_own%db`, but not replicate tables from the `my1ownAABCdb` database, you should escape the “`_`” and “`%`” characters like this: `--replicate-wild-do-table=my\_own\%db`. If you use the option on the command line, you might need to double the backslashes or quote the option value, depending on your command interpreter. For example, with the `bash` shell, you would need to type `--replicate-wild-do-table=my\\_own\\\\%db`.

- `--replicate-wild-ignore-table=db_name.tbl_name`

Tells the slave thread not to replicate a statement where any table matches the given wildcard pattern. To specify more than one table to ignore, use this option multiple times, once for each table. This works for cross-database updates. See [Section 16.2.3, “How Servers Evaluate Replication Filtering Rules”](#).

Example: `--replicate-wild-ignore-table=foo%.bar%` does not replicate updates that use a table where the database name starts with `foo` and the table name starts with `bar`.

For information about how matching works, see the description of the `--replicate-wild-do-table` option. The rules for including literal wildcard characters in the option value are the same as for `--replicate-wild-ignore-table` as well.

- `--report-host=host_name`

The host name or IP number of the slave to be reported to the master during slave registration. This value appears in the output

of `SHOW SLAVE HOSTS` on the master server. Leave the value unset if you do not want the slave to register itself with the master. Note that it is not sufficient for the master to simply read the IP number of the slave from the TCP/IP socket after the slave connects. Due to NAT and other routing issues, that IP may not be valid for connecting to the slave from the master or other hosts.

- `--report-password=password`

The account password of the slave to be reported to the master during slave registration. This value appears in the output of `SHOW SLAVE HOSTS` on the master server if the `--show-slave-auth-info` option is given.

- `--report-port=slave_port_num`

The TCP/IP port number for connecting to the slave, to be reported to the master during slave registration. Set this only if the slave is listening on a nondefault port or if you have a special tunnel from the master or other clients to the slave. If you are not sure, do not use this option.

- `--report-user=user_name`

The account user name of the slave to be reported to the master during slave registration. This value appears in the output of `SHOW SLAVE HOSTS` on the master server if the `--show-slave-auth-info` option is given.

- `--show-slave-auth-info`

Display slave user names and passwords in the output of `SHOW SLAVE HOSTS` on the master server for slaves started with the `--report-user` and `--report-password` options.

- `--skip-slave-start`

Tells the slave server not to start the slave threads when the server starts. To start the threads later, use a `START SLAVE` statement.

- `--slave_compressed_protocol={0|1}`

If this option is set to 1, use compression for the slave/master protocol if both the slave and the master support it. The default is 0 (no compression).

- `--slave-load-tmpdir=file_name`

The name of the directory where the slave creates temporary files. This option is by default equal to the value of the `tmpdir` system variable. When the slave SQL thread replicates a `LOAD DATA INFILE` statement, it extracts the file to be loaded from the relay log into temporary files, and then loads these into the table. If the file loaded on the master is huge, the temporary files on the slave are huge, too. Therefore, it might be advisable to use this option to tell the slave to put temporary files in a directory located in some file system that has a lot of available space. In that case, the relay logs are huge as well, so you might also want to use the `--relay-log` option to place the relay logs in that file system.

The directory specified by this option should be located in a disk-based file system (not a memory-based file system) because the temporary files used to replicate `LOAD DATA INFILE` must survive machine restarts. The directory also should not be one that is cleared by the operating system during the system startup process.

- `--slave-net-timeout=seconds`

The number of seconds to wait for more data from the master before the slave considers the connection broken, aborts the read, and tries to reconnect. The first retry occurs immediately after the timeout. The interval between retries is controlled by the `MASTER_CONNECT_RETRY` option for the `CHANGE MASTER TO` statement or `--master-connect-retry` option, and the number of reconnection attempts is limited by the `--master-retry-count` option. The default is 3600 seconds (one hour).

- `--slave-skip-errors=[err_code1,err_code2,...|all]`

Normally, replication stops when an error occurs on the slave. This gives you the opportunity to resolve the inconsistency in the data manually. This option tells the slave SQL thread to continue replication when a statement returns any of the errors listed in the option value.

Do not use this option unless you fully understand why you are getting errors. If there are no bugs in your replication setup and client programs, and no bugs in MySQL itself, an error that stops replication should never occur. Indiscriminate use of this option results in slaves becoming hopelessly out of synchrony with the master, with you having no idea why this has occurred.

### Note

Prior to MySQL 5.1.35, this option had no effect with row-based logging. ([Bug#39393](#))

For error codes, you should use the numbers provided by the error message in your slave error log and in the output of `SHOW SLAVE STATUS`. Appendix B, *Errors, Error Codes, and Common Problems*, lists server error codes.

You can also (but should not) use the very nonrecommended value of `all` to cause the slave to ignore all error messages and keeps going regardless of what happens. Needless to say, if you use `all`, there are no guarantees regarding the integrity of your data. Please do not complain (or file bug reports) in this case if the slave's data is not anywhere close to what it is on the master. *You have been warned.*

Examples:

```
--slave-skip-errors=1062,1053
--slave-skip-errors=all
```

**System variables used on replication slaves.** The following list describes system variables for controlling replication slave servers. They can be set at server startup and some of them can be changed at runtime using `SET`. Server options used with replication slaves are listed earlier in this section.

- `init_slave`

<b>Command-Line Format</b>	<code>--init-slave=name</code>	
<b>Config-File Format</b>	<code>init_slave</code>	
<b>Option Sets Variable</b>	Yes, <code>init_slave</code>	
<b>Variable Name</b>	<code>init_slave</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>string</code>

This variable is similar to `init_connect`, but is a string to be executed by a slave server each time the SQL thread starts. The format of the string is the same as for the `init_connect` variable.

### Note

The SQL thread sends an acknowledgment to the client before it executes `init_slave`. Therefore, it is not guaranteed that `init_slave` has been executed when `START SLAVE` returns. See Section 12.5.2.7, “`START SLAVE Syntax`”, for more information.

- `rpl_recovery_rank`

This variable is unused, and is removed in MySQL 5.6.

- `slave_compressed_protocol`

<b>Command-Line Format</b>	<code>--slave_compressed_protocol</code>	
<b>Config-File Format</b>	<code>slave_compressed_protocol</code>	
<b>Option Sets Variable</b>	Yes, <code>slave_compressed_protocol</code>	
<b>Variable Name</b>	<code>slave_compressed_protocol</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>OFF</code>

Whether to use compression of the slave/master protocol if both the slave and the master support it.

- `slave_exec_mode`

<b>Version Introduced</b>	5.1.24
---------------------------	--------

<b>Variable Name</b>	<code>slave_exec_mode</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
<b>Type</b>	<code>enumeration</code>
<b>Default</b>	<code>STRICT</code> (ALL)
<b>Default</b>	<code>IDEMPOTENT</code> (NDB)
<b>Valid Values</b>	<code>IDEMPOTENT, STRICT</code>

Controls whether `IDEMPOTENT` or `STRICT` mode is used in replication conflict resolution and error checking. `IDEMPOTENT` mode causes suppression of duplicate-key and no-key-found errors. Beginning with MySQL 5.1.23-ndb-6.2.14 and MySQL 5.1.24, this mode should be employed in multi-master replication, circular replication, and some other special replication scenarios. `STRICT` mode is the default, and is suitable for most other cases.

### Note

MySQL Cluster ignores any value explicitly set for `slave_exec_mode`, and always treats it as `IDEMPOTENT`.

- `slave_load_tmpdir`

<b>Command-Line Format</b>	<code>--slave-load-tmpdir=name</code>
<b>Config-File Format</b>	<code>slave-load-tmpdir</code>
<b>Option Sets Variable</b>	Yes, <code>slave_load_tmpdir</code>
<b>Variable Name</b>	<code>slave_load_tmpdir</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No
	<b>Permitted Values</b>
<b>Type</b>	<code>filename</code>
<b>Default</b>	<code>/tmp</code>

The name of the directory where the slave creates temporary files for replicating `LOAD DATA INFILE` statements.

- `slave_net_timeout`

<b>Command-Line Format</b>	<code>--slave-net-timeout=#</code>
<b>Config-File Format</b>	<code>slave-net-timeout</code>
<b>Option Sets Variable</b>	Yes, <code>slave_net_timeout</code>
<b>Variable Name</b>	<code>slave_net_timeout</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
<b>Type</b>	<code>numeric</code>
<b>Default</b>	<code>3600</code>
<b>Min Value</b>	<code>1</code>

The number of seconds to wait for more data from a master/slave connection before aborting the read. This timeout applies only to TCP/IP connections, not to connections made using Unix socket files, named pipes, or shared memory.

- `slave_skip_errors`

<b>Command-Line Format</b>	<code>--slave-skip-errors=name</code>
<b>Config-File Format</b>	<code>slave-skip-errors</code>

<b>Option Sets Variable</b>	Yes, <code>slave_skip_errors</code>
<b>Variable Name</b>	<code>slave_skip_errors</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No

Normally, replication stops when an error occurs on the slave. This gives you the opportunity to resolve the inconsistency in the data manually. This variable tells the slave SQL thread to continue replication when a statement returns any of the errors listed in the variable value.

- `slave_transaction_retries`

<b>Command-Line Format</b>	<code>--slave_transaction_retries=#</code>
<b>Config-File Format</b>	<code>slave_transaction_retries</code>
<b>Option Sets Variable</b>	Yes, <code>slave_transaction_retries</code>
<b>Variable Name</b>	<code>slave_transaction_retries</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
<b>Platform Bit Size</b>	32
<b>Type</b>	numeric
<b>Default</b>	10
<b>Range</b>	0-4294967295
	<b>Permitted Values</b>
<b>Platform Bit Size</b>	64
<b>Type</b>	numeric
<b>Default</b>	10
<b>Range</b>	0-18446744073709547520

If a replication slave SQL thread fails to execute a transaction because of an `InnoDB` deadlock or because the transaction's execution time exceeded `InnoDB`'s `innodb_lock_wait_timeout` or `NDBCLUSTER`'s `TransactionDeadlockDetectionTimeout` or `TransactionInactiveTimeout`, it automatically retries `slave_transaction_retries` times before stopping with an error. The default value is 10.

- `slave_type_conversions`

<b>Version Introduced</b>	5.1.44-ndb-7.1.3
<b>Command-Line Format</b>	<code>--slave_type_conversions=set</code>
<b>Config-File Format</b>	<code>slave_type_conversions</code>
<b>Option Sets Variable</b>	Yes, <code>slave_type_conversions</code>
<b>Variable Name</b>	<code>slave_type_conversions</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No
	<b>Permitted Values</b>
<b>Type</b>	string
<b>Default</b>	
<b>Valid Values</b>	<code>ALL_LOSSY, ALL_NON_LOSSY, ALL_LOSSY , ALL_NON_LOSSY</code>

Controls the type conversion mode in effect on the slave when using MySQL Cluster Replication. Its value is a comma-delimited set of zero or more elements from the list: `ALL_LOSSY`, `ALL_NON_LOSSY`. Set this variable to an empty string to dis-

allow type conversions between the master and the slave. Changes require a restart of the slave to take effect.

For additional information on type conversion modes applicable to MySQL Cluster replication attribute promotion and demotion, see [Attribute promotion and demotion \(MySQL Cluster\)](#).

This variable was added in MySQL Cluster NDB 6.3.33, 7.0.14, and 7.1.3.

- [sql\\_slave\\_skip\\_counter](#)

<b>Variable Name</b>	<a href="#">sql_slave_skip_counter</a>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
	<b>Type</b> numeric

The number of events from the master that a slave server should skip.

### Important

If skipping the number of events specified by setting this variable would cause the slave to begin in the middle of an event group, the slave continues to skip until it finds the beginning of the next event group and begins from that point. For more information, see [Section 12.5.2.6, “SET GLOBAL sql\\_slave\\_skip\\_counter Syntax”](#).

## 16.1.3.4. Binary Log Options and Variables

You can use the `mysqld` options and system variables that are described in this section to affect the operation of the binary log as well as to control which statements are written to the binary log. For additional information about the binary log, see [Section 5.2.4, “The Binary Log”](#). For additional information about using MySQL server options and system variables, see [Section 5.1.2, “Server Command Options”](#), and [Section 5.1.4, “Server System Variables”](#).

**Startup options used with binary logging.** The following list describes startup options for enabling and configuring the binary log. System variables used with binary logging are discussed later in this section.

- [--binlog-row-event-max-size=N](#)

<b>Version Introduced</b>	5.1.5
<b>Command-Line Format</b>	<a href="#">--binlog-row-event-max-size=#</a>
<b>Config-File Format</b>	<a href="#">binlog-row-event-max-size</a>
	<b>Permitted Values</b>
	<b>Platform Bit Size</b> 32
	<b>Type</b> numeric
	<b>Default</b> 1024
	<b>Range</b> 256–4294967295
	<b>Permitted Values</b>
	<b>Platform Bit Size</b> 64
	<b>Type</b> numeric
	<b>Default</b> 1024
	<b>Range</b> 256–18446744073709547520

Specify the maximum size of a row-based binary log event, in bytes. Rows are grouped into events smaller than this size if possible. The value should be a multiple of 256. The default is 1024. See [Section 16.1.2, “Replication Formats”](#). This option was added in MySQL 5.1.5.

- [--log-bin\[=base\\_name\]](#)

<b>Command-Line Format</b>	<a href="#">--log-bin</a>
----------------------------	---------------------------

<b>Config-File Format</b>	<code>log-bin</code>	
<b>Variable Name</b>	<code>log_bin</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	No	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>filename</code>
	<b>Default</b>	<code>OFF</code>

Enable binary logging. The server logs all statements that change data to the binary log, which is used for backup and replication. See [Section 5.2.4, “The Binary Log”](#).

The option value, if given, is the basename for the log sequence. The server creates binary log files in sequence by adding a numeric suffix to the basename. It is recommended that you specify a basename (see [Section B.5.8.2, “Additional Known Issues”](#), for the reason). Otherwise, MySQL uses `host_name-bin` as the basename.

Setting this option causes the `log_bin` system variable to be set to `ON` (or `1`), and not to the basename. This is a known issue; see [Bug#19614](#) for more information.

- `--log-bin-index[=file_name]`

<b>Command-Line Format</b>	<code>--log-bin-index=name</code>	
<b>Config-File Format</b>	<code>log-bin-index</code>	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>filename</code>
	<b>Default</b>	<code>OFF</code>

The index file for binary log file names. See [Section 5.2.4, “The Binary Log”](#). If you omit the file name, and if you did not specify one with `--log-bin`, MySQL uses `host_name-bin.index` as the file name.

- `--log-bin-trust-function-creators[={0|1}]`

<b>Command-Line Format</b>	<code>--log-bin-trust-function-creators</code>	
<b>Config-File Format</b>	<code>log-bin-trust-function-creators</code>	
<b>Option Sets Variable</b>	Yes, <code>log_bin_trust_function_creators</code>	
<b>Variable Name</b>	<code>log_bin_trust_function_creators</code>	
<b>Variable Scope</b>	Global	
<b>Dynamic Variable</b>	Yes	
	<b>Permitted Values</b>	
	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>FALSE</code>

This option sets the corresponding `log_bin_trust_function_creators` system variable. If no argument is given, the option sets the variable to `1`. `log_bin_trust_function_creators` affects how MySQL enforces restrictions on stored function and trigger creation. See [Section 19.7, “Binary Logging of Stored Programs”](#).

### Note

Previously, this option was known as `--log-bin-trust-routine-creators`, which is now deprecated.

**Statement selection options.** The options in the following list affect which statements are written to the binary log, and thus sent by a replication master server to its slaves. There are also options for slave servers that control which statements received from the master should be executed or ignored. For details, see [Section 16.1.3.3, “Replication Slave Options and Variables”](#).

- `--binlog-do-db=db_name`

This option affects binary logging in a manner similar to the way that `--replicate-do-db` affects replication.

The effects of this option depend on whether the statement-based or row-based logging format is in use, in the same way that the effects of `--replicate-do-db` depend on whether statement-based or row-based replication is in use. You should keep in mind that the format used to log a given statement may not necessarily be the same as that indicated by the value of `binlog_format`. For example, DDL statements such as `CREATE TABLE` and `ALTER TABLE` are always logged as statements, without regard to the logging format in effect, so the following statement-based rules for `--binlog-do-db` always apply in determining whether or not the statement is logged.

**Statement-based logging.** Only those statements are written to the binary log where the default database (that is, the one selected by `USE`) is `db_name`. To specify more than one database, use this option multiple times, once for each database; however, doing so does *not* cause cross-database statements such as `UPDATE some_db.some_table SET foo='bar'` to be logged while a different database (or no database) is selected.

### Warning

To specify multiple databases you *must* use multiple instances of this option. Because database names can contain commas, the list will be treated as the name of a single database if you supply a comma-separated list.

An example of what does not work as you might expect when using statement-based logging: If the server is started with `--binlog-do-db=sales` and you issue the following statements, the `UPDATE` statement is *not* logged:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

The main reason for this “just check the default database” behavior is that it is difficult from the statement alone to know whether it should be replicated (for example, if you are using multiple-table `DELETE` statements or multiple-table `UPDATE` statements that act across multiple databases). It is also faster to check only the default database rather than all databases if there is no need.

Another case which may not be self-evident occurs when a given database is replicated even though it was not specified when setting the option. If the server is started with `--binlog-do-db=sales`, the following `UPDATE` statement is logged even though `prices` was not included when setting `--binlog-do-db`:

```
USE sales;
UPDATE prices.discounts SET percentage = percentage + 10;
```

Because `sales` is the default database when the `UPDATE` statement is issued, the `UPDATE` is logged.

**Row-based logging.** Logging is restricted to database `db_name`. Only changes to tables belonging to `db_name` are logged; the default database has no effect on this. Suppose that the server is started with `--binlog-do-db=sales` and row-based logging is in effect, and then the following statements are executed:

```
USE prices;
UPDATE sales.february SET amount=amount+100;
```

The changes to the `february` table in the `sales` database are logged in accordance with the `UPDATE` statement; this occurs whether or not the `USE` statement was issued. However, when using the row-based logging format and `--binlog-do-db=sales`, changes made by the following `UPDATE` are not logged:

```
USE prices;
UPDATE prices.march SET amount=amount-25;
```

Even if the `USE prices` statement were changed to `USE sales`, the `UPDATE` statement's effects would still not be written to the binary log.

Another important difference in `--binlog-do-db` handling for statement-based logging as opposed to the row-based logging occurs with regard to statements that refer to multiple databases. Suppose the server is started with `--binlog-do-db=db1`, and the following statements are executed:

```
USE db1;
UPDATE db1.table1 SET col1 = 10, db2.table2 SET col2 = 20;
```

If you are using statement-based logging, the updates to both tables are written to the binary log. However, when using the row-based format, only the changes to `table1` are logged; `table2` is in a different database, so it is not changed by the `UPDATE`. Now suppose that, instead of the `USE db1` statement, a `USE db4` statement had been used:

```
USE db4;
UPDATE db1.table1 SET col1 = 10, db2.table2 SET col2 = 20;
```

In this case, the `UPDATE` statement is not written to the binary log when using statement-based logging. However, when using row-based logging, the change to `table1` is logged, but not that to `table2`—in other words, only changes to tables in the

database named by `--binlog-do-db` are logged, and the choice of default database has no effect on this behavior.

- `--binlog-ignore-db=db_name`

This option affects binary logging in a manner similar to the way that `--replicate-ignore-db` affects replication.

The effects of this option depend on whether the statement-based or row-based logging format is in use, in the same way that the effects of `--replicate-ignore-db` depend on whether statement-based or row-based replication is in use. You should keep in mind that the format used to log a given statement may not necessarily be the same as that indicated by the value of `binlog_format`. For example, DDL statements such as `CREATE TABLE` and `ALTER TABLE` are always logged as statements, without regard to the logging format in effect, so the following statement-based rules for `--binlog-ignore-db` always apply in determining whether or not the statement is logged.

**Statement-based logging.** Tells the server to not log any statement where the default database (that is, the one selected by `USE`) is `db_name`.

**Row-based format.** Tells the server not to log updates to any tables in the database `db_name`. The current database has no effect.

When using statement-based logging, the following example does not work as you might expect. Suppose that the server is started with `--binlog-ignore-db=sales` and you issue the following statements:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

The `UPDATE` statement is logged in such a case because `--binlog-ignore-db` applies only to the default database (determined by the `USE` statement). Because the `sales` database was specified explicitly in the statement, the statement has not been filtered. However, when using row-based logging, the `UPDATE` statement's effects are *not* written to the binary log, which means that no changes to the `sales.january` table are logged; in this instance, `--binlog-ignore-db=sales` causes *all* changes made to tables in the master's copy of the `sales` database to be ignored for purposes of binary logging.

To specify more than one database to ignore, use this option multiple times, once for each database. Because database names can contain commas, the list will be treated as the name of a single database if you supply a comma-separated list.

You should not use this option if you are using cross-database updates and you do not want these updates to be logged.

**Testing and debugging options.** The following binary log options are used in replication testing and debugging. They are not intended for use in normal operations.

- `--max-binlog-dump-events=N`

<b>Command-Line Format</b>	<code>--max-binlog-dump-events=#</code>
<b>Config-File Format</b>	<code>max-binlog-dump-events</code>
<b>Permitted Values</b>	
<b>Type</b>	<code>numeric</code>
<b>Default</b>	<code>0</code>

This option is used internally by the MySQL test suite for replication testing and debugging.

- `--sporadic-binlog-dump-fail`

<b>Command-Line Format</b>	<code>--sporadic-binlog-dump-fail</code>
<b>Config-File Format</b>	<code>sporadic-binlog-dump-fail</code>
<b>Permitted Values</b>	
<b>Type</b>	<code>boolean</code>
<b>Default</b>	<code>FALSE</code>

This option is used internally by the MySQL test suite for replication testing and debugging.

**System variables used with the binary log.** The following list describes system variables for controlling binary logging. They can be set at server startup and some of them can be changed at runtime using `SET`. Server options used to control binary logging are listed earlier in this section.

- `binlog_cache_size`

<b>Command-Line Format</b>	<code>--binlog_cache_size=#</code>
<b>Config-File Format</b>	<code>binlog_cache_size</code>
<b>Option Sets Variable</b>	Yes, <code>binlog_cache_size</code>
<b>Variable Name</b>	<code>binlog_cache_size</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	
<b>Platform Bit Size</b>	<code>32</code>
<b>Type</b>	<code>numeric</code>
<b>Default</b>	<code>32768</code>
<b>Range</b>	<code>4096-4294967295</code>
<b>Permitted Values</b>	
<b>Platform Bit Size</b>	<code>64</code>
<b>Type</b>	<code>numeric</code>
<b>Default</b>	<code>32768</code>
<b>Range</b>	<code>4096-18446744073709547520</code>

The size of the cache to hold the SQL statements for the binary log during a transaction. A binary log cache is allocated for each client if the server supports any transactional storage engines and if the server has the binary log enabled (`--log-bin` option). If you often use large, multiple-statement transactions, you can increase this cache size to get more performance. The `Binlog_cache_use` and `Binlog_cache_disk_use` status variables can be useful for tuning the size of this variable. See [Section 5.2.4, “The Binary Log”](#).

- `binlog_direct_non_transactional_updates`

<b>Version Introduced</b>	5.1.44
<b>Command-Line Format</b>	<code>--binlog_direct_non_transactional_updates[=value]</code>
<b>Config-File Format</b>	<code>binlog_direct_non_transactional_updates</code>
<b>Option Sets Variable</b>	Yes, <code>binlog_direct_non_transactional_updates</code>
<b>Variable Name</b>	<code>binlog_direct_non_transactional_updates</code>
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	
<b>Type</b>	<code>boolean</code>
<b>Default</b>	<code>OFF</code>

Due to concurrency issues, a slave can become inconsistent when a transaction contains updates to both transactional and non-transactional tables. MySQL tries to preserve causality among these statements by writing non-transactional statements to the transaction cache, which is flushed upon commit. However, problems arise when modifications done to nontransactional tables on behalf of a transaction become immediately visible to other connections because these changes may not be written immediately into the binary log.

Beginning with MySQL 5.1.44, the `binlog_direct_non_transactional_updates` variable offers one possible workaround to this issue. By default, this variable is disabled. Enabling `binlog_direct_non_transactional_updates` causes updates to nontransactional tables to be written directly to the binary log, rather than to the transaction cache.

`binlog_direct_non_transactional_updates` works only for statements that are replicated using the statement-based binary logging format; that is, it works only when the value of `binlog_format` is `STATEMENT`, or when `binlog_format` is `MIXED` and a given statement is being replicated using the statement-based format. This variable has no effect when the binary log format is `ROW`, or when `binlog_format` is set to `MIXED` and a given statement is replicated using the row-based format.

**Important**

Before enabling this variable, you must make certain that there are no dependencies between transactional and non-transactional tables; an example of such a dependency would be the statement `INSERT INTO myisam_table SELECT * FROM innodb_table`. Otherwise, such statements are likely to cause the slave to diverge from the master.

- `binlog_format`

<b>Version Introduced</b>	5.1.5
<b>Command-Line Format</b>	<code>--binlog-format</code>
<b>Config-File Format</b>	<code>binlog-format</code>
<b>Option Sets Variable</b>	Yes, <code>binlog_format</code>
<b>Variable Name</b>	<code>binlog_format</code>
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes
<b>Permitted Values (&gt;= 5.1.5, &lt;= 5.1.7)</b>	
<b>Type</b>	<code>enumeration</code>
<b>Default</b>	<code>STATEMENT</code>
<b>Valid Values</b>	<code>ROW, STATEMENT</code>
<b>Permitted Values (&gt;= 5.1.8, &lt;= 5.1.11)</b>	
<b>Type</b>	<code>enumeration</code>
<b>Default</b>	<code>STATEMENT</code>
<b>Valid Values</b>	<code>ROW, STATEMENT, MIXED</code>
<b>Permitted Values (&gt;= 5.1.12, &lt;= 5.1.28)</b>	
<b>Type</b>	<code>enumeration</code>
<b>Default</b>	<code>MIXED</code>
<b>Valid Values</b>	<code>ROW, STATEMENT, MIXED</code>
<b>Permitted Values (&gt;= 5.1.29)</b>	
<b>Type</b>	<code>enumeration</code>
<b>Default</b>	<code>STATEMENT</code>
<b>Valid Values</b>	<code>ROW, STATEMENT, MIXED</code>

This variable sets the binary logging format, and can be any one of `STATEMENT`, `ROW`, or `MIXED`. See [Section 16.1.2, “Replication Formats”](#). `binlog_format` is set by the `--binlog-format` option at startup, or by the `binlog_format` variable at runtime.

The startup variable was added in MySQL 5.1.5, and the runtime variable in MySQL 5.1.8. `MIXED` was added in MySQL 5.1.8.

`STATEMENT` was used by default prior to MySQL 5.1.12; in MySQL 5.1.12, the default was changed to `MIXED`. In MySQL 5.1.29, the default was changed back to `STATEMENT`.

You must have the `SUPER` privilege to set the global `binlog_format` value. Starting with MySQL 5.1.29, you must have the `SUPER` privilege to set either the global or session `binlog_format` value. ([Bug#39106](#))

The rules governing when changes to this variable take effect and how long the effect lasts are the same as for other MySQL server system variables. See [Section 12.4.4, “SET Syntax”](#), for more information.

When `MIXED` is specified, statement-based replication is used, except for cases where only row-based replication is guaranteed to lead to proper results. For example, this happens when statements contain user-defined functions (UDF) or the `UUID()` function. An exception to this rule is that `MIXED` always uses statement-based replication for stored functions and triggers.

There are exceptions when you cannot switch the replication format at runtime:

- From within a stored function or a trigger.
- If the `NDBCLUSTER` storage engine is enabled.
- If the session is currently in row-based replication mode and has open temporary tables.

Trying to switch the format in those cases results in an error.

Before MySQL 5.1.8, switching to row-based replication format would implicitly set `-log-bin-trust-function-creators=1` and `--innodb_locks_unsafe_for_binlog`. This does not occur for MySQL 5.1.8 and later.

The binary log format affects the behavior of the following server options:

- `--replicate-do-db`
- `--replicate-ignore-db`
- `--binlog-do-db`
- `--binlog-ignore-db`

These effects are discussed in detail in the descriptions of the individual options.

- `max_binlog_cache_size`

<b>Command-Line Format</b>	<code>--max_binlog_cache_size=#</code>
<b>Config-File Format</b>	<code>max_binlog_cache_size</code>
<b>Option Sets Variable</b>	Yes, <code>max_binlog_cache_size</code>
<b>Variable Name</b>	<code>max_binlog_cache_size</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes
<b>Permitted Values (&lt;= 5.1.35)</b>	<b>Permitted Values (&lt;= 5.1.35)</b>
	<b>Type</b> <code>numeric</code>
	<b>Default</b> <code>4294967295</code>
	<b>Range</b> <code>4096-4294967295</code>
<b>Permitted Values (&gt;= 5.1.36)</b>	<b>Permitted Values (&gt;= 5.1.36)</b>
	<b>Type</b> <code>numeric</code>
	<b>Default</b> <code>18446744073709547520</code>
	<b>Range</b> <code>4096-18446744073709547520</code>

If a multiple-statement transaction requires more than this many bytes of memory, the server generates a `MULTI-STATEMENT TRANSACTION REQUIRED MORE THAN 'MAX_BINLOG_CACHE_SIZE' BYTES OF STORAGE` error. The minimum value is 4096. The maximum and default values are 4GB on 32-bit platforms and 16PB (petabytes) on 64-bit platforms. As of MySQL 5.1.36, the maximum value is 16PB on all platforms.

- `max_binlog_size`

<b>Command-Line Format</b>	<code>--max_binlog_size=#</code>
<b>Config-File Format</b>	<code>max_binlog_size</code>
<b>Option Sets Variable</b>	Yes, <code>max_binlog_size</code>
<b>Variable Name</b>	<code>max_binlog_size</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Permitted Values</b>
	<b>Type</b> <code>numeric</code>
	<b>Default</b> <code>1073741824</code>
	<b>Range</b> <code>4096-1073741824</code>

If a write to the binary log causes the current log file size to exceed the value of this variable, the server rotates the binary logs (closes the current file and opens the next one). The minimum value is 4096 bytes. The maximum and default value is 1GB.

A transaction is written in one chunk to the binary log, so it is never split between several binary logs. Therefore, if you have big transactions, you might see binary log files larger than `max_binlog_size`.

If `max_relay_log_size` is 0, the value of `max_binlog_size` applies to relay logs as well.

- `sync_binlog`

<b>Command-Line Format</b>	<code>--sync-binlog=#</code>
<b>Config-File Format</b>	<code>sync_binlog</code>
<b>Option Sets Variable</b>	Yes, <code>sync_binlog</code>
<b>Variable Name</b>	<code>sync_binlog</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	
<b>Platform Bit Size</b>	<code>32</code>
<b>Type</b>	<code>numeric</code>
<b>Default</b>	<code>0</code>
<b>Range</b>	<code>0-4294967295</code>
<b>Permitted Values</b>	
<b>Platform Bit Size</b>	<code>64</code>
<b>Type</b>	<code>numeric</code>
<b>Default</b>	<code>0</code>
<b>Range</b>	<code>0-18446744073709547520</code>

If the value of this variable is greater than 0, the MySQL server synchronizes its binary log to disk (using `fdatasync()`) after every `sync_binlog` writes to the binary log. There is one write to the binary log per statement if autocommit is enabled, and one write per transaction otherwise. The default value of `sync_binlog` is 0, which does no synchronizing to disk—in this case, the server relies on the operating system to flush the binary log's contents from time to time as for any other file. A value of 1 is the safest choice because in the event of a crash you lose at most one statement or transaction from the binary log. However, it is also the slowest choice (unless the disk has a battery-backed cache, which makes synchronization very fast).

## 16.1.4. Common Replication Administration Tasks

Once replication has been started it should execute without requiring much regular administration. Depending on your replication environment, you will want to check the replication status of each slave periodically, daily, or even more frequently.

### 16.1.4.1. Checking Replication Status

The most common task when managing a replication process is to ensure that replication is taking place and that there have been no errors between the slave and the master. The primary statement for this is `SHOW SLAVE STATUS`, which you must execute on each slave:

```
mysql> SHOW SLAVE STATUS\G
***** 1. row *****
Slave_IO_State: Waiting for master to send event
 Master_Host: master1
 Master_User: root
 Master_Port: 3306
 Connect_Retry: 60
 Master_Log_File: mysql-bin.000004
Read_Master_Log_Pos: 931
 Relay_Log_File: slave1-relay-bin.000056
 Relay_Log_Pos: 950
Relay_Master_Log_File: mysql-bin.000004
 Slave_IO_Running: Yes
 Slave_SQL_Running: Yes
 Replicate_Do_DB:
 Replicate_Ignore_DB:
 Replicate_Do_Table:
```

```

Replicate_Ignore_Table:
Replicate_Wild_Do_Table:
Replicate_Wild_Ignore_Table:
 Last_Error: 0
 Last_Error:
 Skip_Counter: 0
 Exec_Master_Log_Pos: 931
 Relay_Log_Space: 1365
 Until_Condition: None
 Until_Log_File:
 Until_Log_Pos: 0
Master_SSL_Allowed: No
Master_SSL_CA_File:
Master_SSL_CA_Path:
 Master_SSL_Cert:
 Master_SSL_Cipher:
 Master_SSL_Key:
Seconds_Behind_Master: 0
Master_SSL_Verify_Server_Cert: No
 Last_IO_Errno: 0
 Last_IO_Error:
 Last_SQL_Errno: 0
 Last_SQL_Error:

```

The key fields from the status report to examine are:

- **`Slave_IO_State`**: The current status of the slave. See [Section 7.10.6, “Replication Slave I/O Thread States”](#), and [Section 7.10.7, “Replication Slave SQL Thread States”](#), for more information.
- **`Slave_IO_Running`**: Whether the I/O thread for reading the master's binary log is running. Normally, you want this to be `Yes` unless you have not yet started replication or have explicitly stopped it with `STOP SLAVE`.
- **`Slave_SQL_Running`**: Whether the SQL thread for executing events in the relay log is running. As with the I/O thread, this should normally be `Yes`.
- **`Last_IO_Error`, `Last_SQL_Error`**: The last errors registered by the I/O and SQL threads when processing the relay log. Ideally these should be blank, indicating no errors.
- **`Seconds_Behind_Master`**: The number of seconds that the slave SQL thread is behind processing the master binary log. A high number (or an increasing one) can indicate that the slave is unable to handle events from the master in a timely fashion.

A value of 0 for `Seconds_Behind_Master` can usually be interpreted as meaning that the slave has caught up with the master, but there are some cases where this is not strictly true. For example, this can occur if the network connection between master and slave is broken but the slave I/O thread has not yet noticed this—that is, `slave_net_timeout` has not yet elapsed.

It is also possible that transient values for `Seconds_Behind_Master` may not reflect the situation accurately. When the slave SQL thread has caught up on I/O, `Seconds_Behind_Master` displays 0; but when the slave I/O thread is still queuing up a new event, `Seconds_Behind_Master` may show a large value until the SQL thread finishes executing the new event. This is especially likely when the events have old timestamps; in such cases, if you execute `SHOW SLAVE STATUS` several times in a relatively short period, you may see this value change back and forth repeatedly between 0 and a relatively large value.

Several pairs of fields provide information about the progress of the slave in reading events from the master binary log and processing them in the relay log:

- (`Master_Log_file`, `Read_Master_Log_Pos`): Coordinates in the master binary log indicating how far the slave I/O thread has read events from that log.
- (`Relay_Master_Log_File`, `Exec_Master_Log_Pos`): Coordinates in the master binary log indicating how far the slave SQL thread has executed events received from that log.
- (`Relay_Log_File`, `Relay_Log_Pos`): Coordinates in the slave relay log indicating how far the slave SQL thread has executed the relay log. These correspond to the preceding coordinates, but are expressed in slave relay log coordinates rather than master binary log coordinates.

On the master, you can check the status of connected slaves using `SHOW PROCESSLIST` to examine the list of running processes. Slave connections have `Binlog Dump` in the `Command` field:

```

mysql> SHOW PROCESSLIST \G;
***** 4. row *****
Id: 10
User: root
Host: slave1:58371
db: NULL

```

```
Command: Binlog Dump
Time: 777
State: Has sent all binlog to slave; waiting for binlog to be updated
Info: NULL
```

Because it is the slave that drives the replication process, very little information is available in this report.

For slaves that were started with the `--report-host` option and are connected to the master, the `SHOW SLAVE HOSTS` statement on the master shows basic information about the slaves. The output includes the ID of the slave server, the value of the `--report-host` option, the connecting port, and master ID:

```
mysql> SHOW SLAVE HOSTS;
+-----+-----+-----+-----+
| Server_id | Host | Port | Rpl_recovery_rank | Master_id |
+-----+-----+-----+-----+
| 10 | slave1 | 3306 | 0 | 1 |
+-----+-----+-----+-----+
1 row in set (0.00 sec)
```

### 16.1.4.2. Pausing Replication on the Slave

You can stop and start the replication of statements on the slave using the `STOP SLAVE` and `START SLAVE` statements.

To stop processing of the binary log from the master, use `STOP SLAVE`:

```
mysql> STOP SLAVE;
```

When replication is stopped, the slave I/O thread stops reading events from the master binary log and writing them to the relay log, and the SQL thread stops reading events from the relay log and executing them. You can pause the I/O or SQL thread individually by specifying the thread type:

```
mysql> STOP SLAVE IO_THREAD;
mysql> STOP SLAVE SQL_THREAD;
```

To start execution again, use the `START SLAVE` statement:

```
mysql> START SLAVE;
```

To start a particular thread, specify the thread type:

```
mysql> START SLAVE IO_THREAD;
mysql> START SLAVE SQL_THREAD;
```

For a slave that performs updates only by processing events from the master, stopping only the SQL thread can be useful if you want to perform a backup or other task. The I/O thread will continue to read events from the master but they are not executed. This makes it easier for the slave to catch up when you restart the SQL thread.

Stopping only the I/O thread enables the events in the relay log to be executed by the SQL thread up to the point where the relay log ends. This can be useful when you want to pause execution to catch up with events already received from the master, when you want to perform administration on the slave but also ensure that it has processed all updates to a specific point. This method can also be used to pause event receipt on the slave while you conduct administration on the master. Stopping the I/O thread but permitting the SQL thread to run helps ensure that there is not a massive backlog of events to be executed when replication is started again.

## 16.2. Replication Implementation

Replication is based on the master server keeping track of all changes to its databases (updates, deletes, and so on) in its binary log. The binary log serves as a written record of all events that modify database structure or content (data) from the moment the server was started. Typically, `SELECT` statements are not recorded because they modify neither database structure nor content.

Each slave that connects to the master requests a copy of the binary log. That is, it pulls the data from the master, rather than the master pushing the data to the slave. The slave also executes the events from the binary log that it receives. This has the effect of repeating the original changes just as they were made on the master. Tables are created or their structure modified, and data is inserted, deleted, and updated according to the changes that were originally made on the master.

Because each slave is independent, the replaying of the changes from the master's binary log occurs independently on each slave that is connected to the master. In addition, because each slave receives a copy of the binary log only by requesting it from the master, the slave is able to read and update the copy of the database at its own pace and can start and stop the replication process at will without affecting the ability to update to the latest database status on either the master or slave side.

For more information on the specifics of the replication implementation, see [Section 16.2.1, “Replication Implementation Details”](#).

Masters and slaves report their status in respect of the replication process regularly so that you can monitor them. See [Section 7.10, “Examining Thread Information”](#), for descriptions of all replicated-related states.

The master binary log is written to a local relay log on the slave before it is processed. The slave also records information about the current position with the master's binary log and the local relay log. See [Section 16.2.2, “Replication Relay and Status Files”](#).

Database changes are filtered on the slave according to a set of rules that are applied according to the various configuration options and variables that control event evaluation. For details on how these rules are applied, see [Section 16.2.3, “How Servers Evaluate Replication Filtering Rules”](#).

## 16.2.1. Replication Implementation Details

MySQL replication capabilities are implemented using three threads, one on the master server and two on the slave:

- **Binlog dump thread.** The master creates a thread to send the binary log contents to a slave when the slave connects. This thread can be identified in the output of `SHOW PROCESSLIST` on the master as the `Binlog Dump` thread.

The binlog dump thread acquires a lock on the master's binary log for reading each event that is to be sent to the slave. As soon as the event has been read, the lock is released, even before the event is sent to the slave.

- **Slave I/O thread.** When a `START SLAVE` statement is issued on a slave server, the slave creates an I/O thread, which connects to the master and asks it to send the updates recorded in its binary logs.

The slave I/O thread reads the updates that the master's `Binlog Dump` thread sends (see previous item) and copies them to local files that comprise the slave's relay log.

The state of this thread is shown as `Slave_IO_running` in the output of `SHOW SLAVE STATUS` or as `Slave_running` in the output of `SHOW STATUS`.

- **Slave SQL thread.** The slave creates an SQL thread to read the relay log that is written by the slave I/O thread and execute the events contained therein.

In the preceding description, there are three threads per master/slave connection. A master that has multiple slaves creates one binlog dump thread for each currently connected slave, and each slave has its own I/O and SQL threads.

A slave uses two threads to separate reading updates from the master and executing them into independent tasks. Thus, the task of reading statements is not slowed down if statement execution is slow. For example, if the slave server has not been running for a while, its I/O thread can quickly fetch all the binary log contents from the master when the slave starts, even if the SQL thread lags far behind. If the slave stops before the SQL thread has executed all the fetched statements, the I/O thread has at least fetched everything so that a safe copy of the statements is stored locally in the slave's relay logs, ready for execution the next time that the slave starts. This enables the master server to purge its binary logs sooner because it no longer needs to wait for the slave to fetch their contents.

The `SHOW PROCESSLIST` statement provides information that tells you what is happening on the master and on the slave regarding replication. For information on master states, see [Section 7.10.5, “Replication Master Thread States”](#). For slave states, see [Section 7.10.6, “Replication Slave I/O Thread States”](#), and [Section 7.10.7, “Replication Slave SQL Thread States”](#).

The following example illustrates how the three threads show up in the output from `SHOW PROCESSLIST`.

On the master server, the output from `SHOW PROCESSLIST` looks like this:

```
mysql> SHOW PROCESSLIST\G
***** 1. row *****
 Id: 2
 User: root
 Host: localhost:32931
 db: NULL
Command: Binlog Dump
 Time: 94
 State: Has sent all binlog to slave; waiting for binlog to
 be updated
 Info: NULL
```

Here, thread 2 is a `Binlog Dump` replication thread that services a connected slave. The `State` information indicates that all outstanding updates have been sent to the slave and that the master is waiting for more updates to occur. If you see no `Binlog Dump` threads on a master server, this means that replication is not running; that is, no slaves are currently connected.

On a slave server, the output from `SHOW PROCESSLIST` looks like this:

```
mysql> SHOW PROCESSLIST\G
***** 1. row *****
 Id: 10
```

```
User: system user
Host:
 db: NULL
Command: Connect
Time: 11
State: Waiting for master to send event
Info: NULL
***** 2. row *****
Id: 11
User: system user
Host:
 db: NULL
Command: Connect
Time: 11
State: Has read all relay log; waiting for the slave I/O
 thread to update it
Info: NULL
```

The `State` information indicates that thread 10 is the I/O thread that is communicating with the master server, and thread 11 is the SQL thread that is processing the updates stored in the relay logs. At the time that `SHOW PROCESSLIST` was run, both threads were idle, waiting for further updates.

The value in the `Time` column can show how late the slave is compared to the master. See [Section 16.4.4, “Replication FAQ”](#). If sufficient time elapses on the master side without activity on the `Binlog Dump` thread, the master determines that the slave is no longer connected. As for any other client connection, the timeouts for this depend on the values of `net_write_timeout` and `net_retry_count`; for more information about these, see [Section 5.1.4, “Server System Variables”](#).

The `SHOW SLAVE STATUS` statement provides additional information about replication processing on a slave server. See [Section 16.1.4.1, “Checking Replication Status”](#).

## 16.2.2. Replication Relay and Status Files

During replication, a slave server creates several files that hold the binary log events relayed from the master to the slave, and to record information about the current status and location within the relay log. There are three file types used in the process:

- The *relay log* consists of the events read from the binary log of the master and written by the slave I/O thread. Events in the relay log are executed on the slave as part of the SQL thread.
- The *master.info* file contains the status and current configuration information for the slave's connectivity to the master. The file holds information on the master host name, login credentials, and coordinates indicating how far the slave has read from the master's binary log.
- The *relay-log.info* file holds the status information about the execution point within the slave's relay log.

### 16.2.2.1. The Slave Relay Log

The relay log, like the binary log, consists of a set of numbered files containing events that describe database changes, and an index file that contains the names of all used relay log files.

The term “relay log file” generally denotes an individual numbered file containing database events. The term “relay log” collectively denotes the set of numbered relay log files plus the index file.

Relay log files have the same format as binary log files and can be read using `mysqlbinlog` (see [Section 4.6.7, “mysqlbinlog — Utility for Processing Binary Log Files”](#)).

By default, relay log file names have the form `host_name-relay-bin.nnnnnn` in the data directory, where `host_name` is the name of the slave server host and `nnnnnn` is a sequence number. Successive relay log files are created using successive sequence numbers, beginning with `000001`. The slave uses an index file to track the relay log files currently in use. The default relay log index file name is `host_name-relay-bin.index` in the data directory.

The default relay log file and relay log index file names can be overridden with, respectively, the `--relay-log` and `--relay-log-index` server options (see [Section 16.1.3, “Replication and Binary Logging Options and Variables”](#)).

If a slave uses the default host-based relay log file names, changing a slave's host name after replication has been set up can cause replication to fail with the errors `FAILED TO OPEN THE RELAY LOG` and `COULD NOT FIND TARGET LOG DURING RELAY LOG INITIALIZATION`. This is a known issue (see [Bug#2122](#)). If you anticipate that a slave's host name might change in the future (for example, if networking is set up on the slave such that its host name can be modified using DHCP), you can avoid this issue entirely by using the `--relay-log` and `--relay-log-index` options to specify relay log file names explicitly when you initially set up the slave. This will make the names independent of server host name changes.

If you encounter the issue after replication has already begun, one way to work around it is to stop the slave server, prepend the contents of the old relay log index file to the new one, and then restart the slave. On a Unix system, this can be done as shown here:

```
shell> cat new_relay_log_name.index >> old_relay_log_name.index
shell> mv old_relay_log_name.index new_relay_log_name.index
```

A slave server creates a new relay log file under the following conditions:

- Each time the I/O thread starts.
- When the logs are flushed; for example, with `FLUSH LOGS` or `mysqladmin flush-logs`.
- When the size of the current relay log file becomes “too large,” determined as follows:
  - If the value of `max_relay_log_size` is greater than 0, that is the maximum relay log file size.
  - If the value of `max_relay_log_size` is 0, `max_binlog_size` determines the maximum relay log file size.

The SQL thread automatically deletes each relay log file as soon as it has executed all events in the file and no longer needs it. There is no explicit mechanism for deleting relay logs because the SQL thread takes care of doing so. However, `FLUSH LOGS` rotates relay logs, which influences when the SQL thread deletes them.

### 16.2.2.2. The Slave Status Files

A slave replication server creates two small status files. By default, these files are named `master.info` and `relay-log.info` and created in the data directory. Their names and locations can be changed by using the `--master-info-file` and `--relay-log-info-file` options. See [Section 16.1.3, “Replication and Binary Logging Options and Variables”](#).

The two status files contain information like that shown in the output of the `SHOW SLAVE STATUS` statement, which is discussed in [Section 12.5.2, “SQL Statements for Controlling Slave Servers”](#). Because the status files are stored on disk, they survive a slave server's shutdown. The next time the slave starts up, it reads the two files to determine how far it has proceeded in reading binary logs from the master and in processing its own relay logs.

The `master.info` file should be protected because it contains the password for connecting to the master. See [Section 5.3.2.1, “Administrator Guidelines for Password Security”](#).

The slave I/O thread updates the `master.info` file. The following table shows the correspondence between the lines in the file and the columns displayed by `SHOW SLAVE STATUS`.

Line	Status Column	Description
1		Number of lines in the file
2	<code>Master_Log_File</code>	The name of the master binary log currently being read from the master
3	<code>Read_Master_Log_Pos</code>	The current position within the master binary log that have been read from the master
4	<code>Master_Host</code>	The host name of the master
5	<code>Master_User</code>	The user name used to connect to the master
6	Password (not shown by <code>SHOW SLAVE STATUS</code> )	The password used to connect to the master
7	<code>Master_Port</code>	The network port used to connect to the master
8	<code>Connect_Retry</code>	The period (in seconds) that the slave will wait before trying to reconnect to the master
9	<code>Master_SSL_Allowed</code>	Indicates whether the server supports SSL connections
10	<code>Master_SSL_CA_File</code>	The file used for the Certificate Authority (CA) certificate
11	<code>Master_SSL_CA_Path</code>	The path to the Certificate Authority (CA) certificates
12	<code>Master_SSL_Cert</code>	The name of the SSL certificate file
13	<code>Master_SSL_Cipher</code>	The name of the cipher in use for the SSL connection
14	<code>Master_SSL_Key</code>	The name of the SSL key file
15	<code>Master_SSL_Verify_Server_Cert</code>	Whether to verify the server certificate (added in MySQL 5.1.18)

The slave SQL thread updates the `relay-log.info` file. The following table shows the correspondence between the lines in the file and the columns displayed by `SHOW SLAVE STATUS`.

Line	Status Column	Description
1	<code>Relay_Log_File</code>	The name of the current relay log file
2	<code>Relay_Log_Pos</code>	The current position within the relay log file; events up to this position have been executed on the slave database
3	<code>Relay_Master_Log_File</code>	The name of the master binary log file from which the events in the relay log file were read
4	<code>Exec_Master_Log_Pos</code>	The equivalent position within the master's binary log file of events that have already been executed

The contents of the `relay-log.info` file and the states shown by the `SHOW SLAVE STATUS` statement might not match if the `relay-log.info` file has not been flushed to disk. Ideally, you should only view `relay-log.info` on a slave that is off-line (that is, `mysqld` is not running). For a running system, `SHOW SLAVE STATUS` should be used.

When you back up the slave's data, you should back up these two status files as well, along with the relay log files. They are needed to resume replication after you restore the slave's data. If you lose the relay logs but still have the `relay-log.info` file, you can check it to determine how far the SQL thread has executed in the master binary logs. Then you can use `CHANGE MASTER TO` with the `MASTER_LOG_FILE` and `MASTER_LOG_POS` options to tell the slave to re-read the binary logs from that point. Of course, this requires that the binary logs still exist on the master server.

### 16.2.3. How Servers Evaluate Replication Filtering Rules

If a master server does not write a statement to its binary log, the statement is not replicated. If the server does log the statement, the statement is sent to all slaves and each slave determines whether to execute it or ignore it.

On the master, you can control which databases to log changes for by using the `--binlog-do-db` and `--binlog-ignore-db` options to control binary logging. For a description of the rules that servers use in evaluating these options, see [Section 16.2.3.1, “Evaluation of Database-Level Replication and Binary Logging Options”](#). You should not use these options to control which databases and tables are replicated. Instead, use filtering on the slave to control the events that are executed on the slave.

On the slave side, decisions about whether to execute or ignore statements received from the master are made according to the `--replicate-*` options that the slave was started with. (See [Section 16.1.3, “Replication and Binary Logging Options and Variables”](#).) The slave evaluates these options using the procedure described later in this section, which first checks the database-level options and then the table-level options.

In the simplest case, when there are no `--replicate-*` options, the slave executes all statements that it receives from the master. Otherwise, the result depends on the particular options given. In general, to make it easier to determine what effect an option set will have, it is recommended that you avoid mixing “do” and “ignore” options, or wildcard and nonwildcard options.

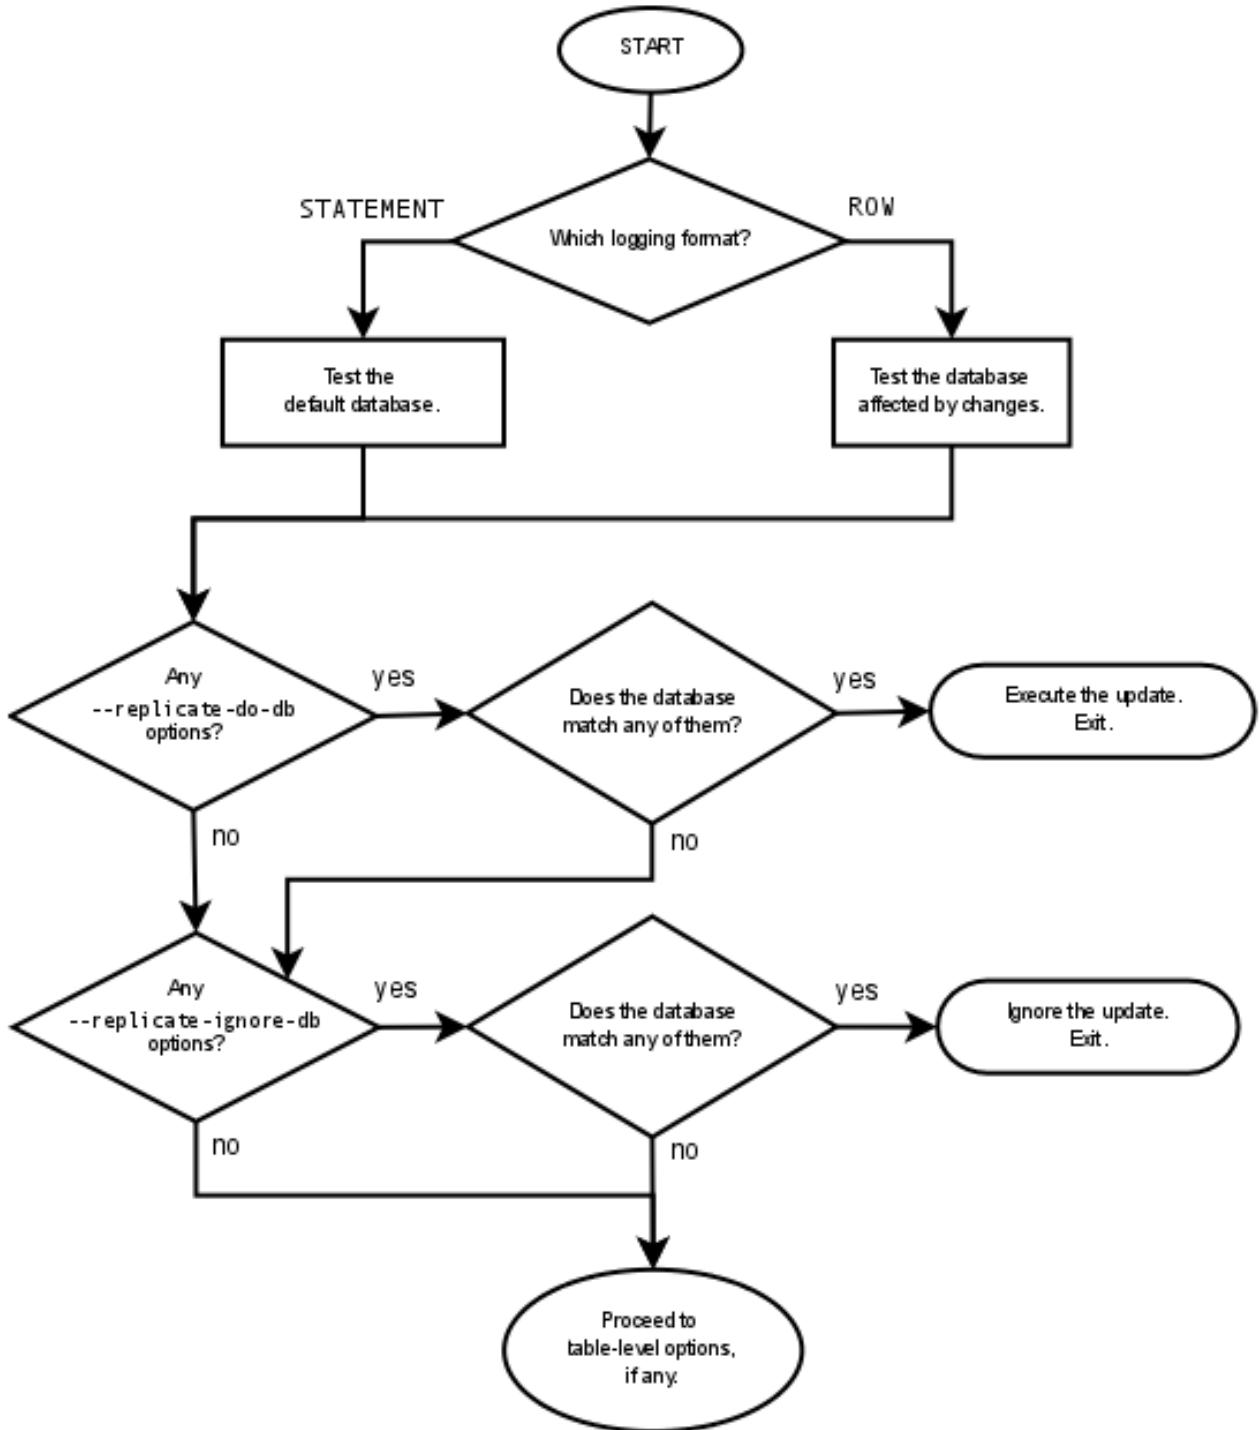

Evaluation of `--replicate-*` options is affected by whether row-based or statement-based logging is in use, but regardless of the logging format, database-level options (`--replicate-do-db`, `--replicate-ignore-db`) are checked first; see [Section 16.2.3.1, “Evaluation of Database-Level Replication and Binary Logging Options”](#), for a description of this process. If no matching database-level options are found, option checking proceeds to any table-level options that may be in use, as discussed in [Section 16.2.3.2, “Evaluation of Table-Level Replication Options”](#).

If any `--replicate-rewrite-db` options were specified, they are applied before the `--replicate-*` filtering rules are tested.

#### 16.2.3.1. Evaluation of Database-Level Replication and Binary Logging Options

When evaluating replication options, the slave begins by checking to see whether there are any `--replicate-do-db` or `--replicate-ignore-db` options that apply. When using `--binlog-do-db` or `--binlog-ignore-db`, the process is similar, but the options are checked on the master.

With statement-based replication, the default database is checked for a match. With row-based replication, the database where data is to be changed is the database that is checked. Regardless of the binary logging format, checking of database-level options proceeds as shown in the following diagram.

The steps involved are listed here:

1. Are there any `--replicate-do-db` options?
  - Yes. Do any of them match the database?
    - Yes. Execute the statement and exit.
    - No. Continue to step 2.
  - No. Continue to step 2.
2. Are there any `--replicate-ignore-db` options?

- **Yes.** Do any of them match the database?
    - **Yes.** Ignore the statement and exit.
    - **No.** Continue to step 3.
  - **No.** Continue to step 3.
3. Proceed to checking the table-level replication options, if there are any. For a description of how these options are checked, see [Section 16.2.3.2, “Evaluation of Table-Level Replication Options”](#).

### Important

A statement that is still permitted at this stage is not yet actually executed. The statement is not executed until all table-level options (if any) have also been checked, and the outcome of that process permits execution of the statement.

For binary logging, the steps involved are listed here:

1. Are there any `--binlog-do-db` or `--binlog-ignore-db` options?
  - **Yes.** Continue to step 2.
  - **No.** Log the statement and exit.
2. Is there a default database (has any database been selected by `USE`)?
  - **Yes.** Continue to step 3.
  - **No.** Ignore the statement and exit.
3. There is a default database. Are there any `--binlog-do-db` options?
  - **Yes.** Do any of them match the database?
    - **Yes.** Log the statement and exit.
    - **No.** Ignore the statement and exit.
  - **No.** Continue to step 4.
4. Do any of the `--binlog-ignore-db` options match the database?
  - **Yes.** Ignore the statement and exit.
  - **No.** Log the statement and exit.

### Important

For statement-based logging, an exception is made in the rules just given for the `CREATE DATABASE`, `ALTER DATABASE`, and `DROP DATABASE` statements. In those cases, the database being *created*, *altered*, or *dropped* replaces the default database when determining whether to log or ignore updates.

`--binlog-do-db` can sometimes mean “ignore other databases”. For example, when using statement-based logging, a server running with only `--binlog-do-db=sales` does not write to the binary log statements for which the default database differs from `sales`. When using row-based logging with the same option, the server logs only those updates that change data in `sales`.

## 16.2.3.2. Evaluation of Table-Level Replication Options

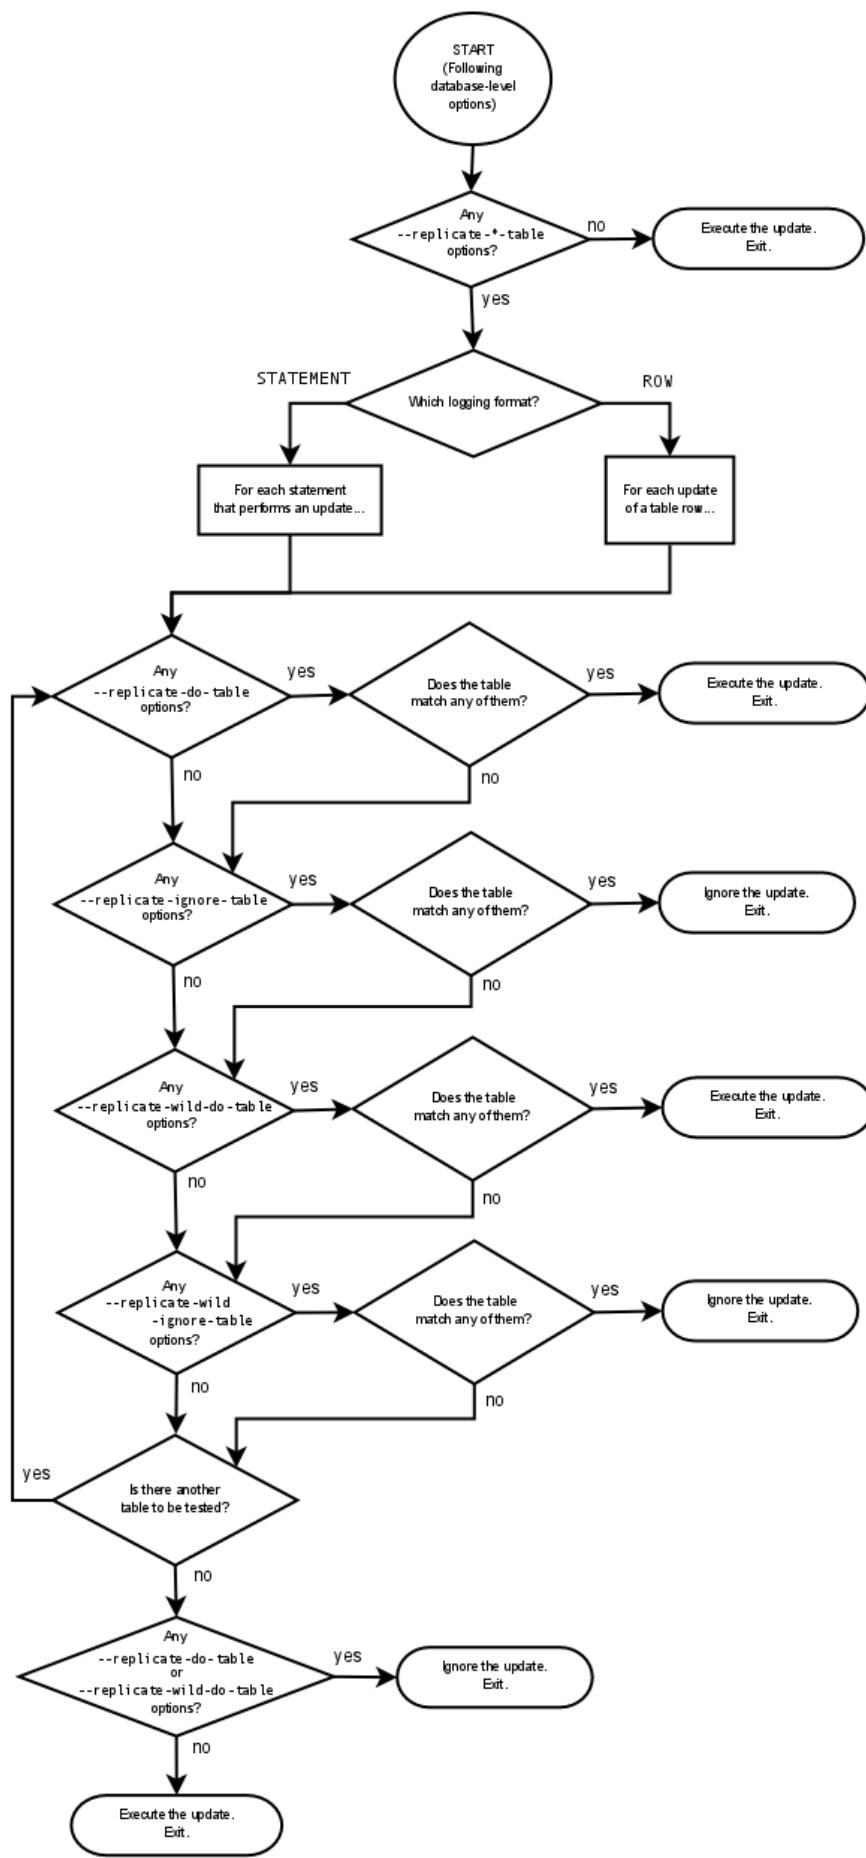

The slave checks for and evaluates table options only if no matching database options were found (see [Section 16.2.3.1, “Evaluation of Database-Level Replication and Binary Logging Options”](#)).

First, as a preliminary condition, the slave checks whether statement-based replication is enabled. If so, and the statement occurs within a stored function, the slave executes the statement and exits. If row-based replication is enabled, the slave does not know whether a statement occurred within a stored function on the master, so this condition does not apply.

### Note

For statement-based replication, replication events represent statements (all changes making up a given event are associated with a single SQL statement); for row-based replication, each event represents a change in a single table row (thus a single statement such as `UPDATE mytable SET mycol = 1` may yield many row-based events). When viewed in terms of events, the process of checking table options is the same for both row-based and statement-based replication.

Having reached this point, if there are no table options, the slave simply executes all events. If there are any `--replicate-do-table` or `--replicate-wild-do-table` options, the event must match one of these if it is to be executed; otherwise, it is ignored. If there are any `--replicate-ignore-table` or `--replicate-wild-ignore-table` options, all events are executed except those that match any of these options. This process is illustrated in the following diagram.

The following steps describe this evaluation in more detail:

1. Are there any table options?
  - **Yes.** Continue to step 2.
  - **No.** Execute the event and exit.
2. Are there any `--replicate-do-table` options?
  - **Yes.** Does the table match any of them?
    - **Yes.** Execute the event and exit.
    - **No.** Continue to step 3.
  - **No.** Continue to step 3.
3. Are there any `--replicate-ignore-table` options?
  - **Yes.** Does the table match any of them?
    - **Yes.** Ignore the event and exit.
    - **No.** Continue to step 4.
  - **No.** Continue to step 4.
4. Are there any `--replicate-wild-do-table` options?
  - **Yes.** Does the table match any of them?
    - **Yes.** Execute the event and exit.
    - **No.** Continue to step 5.
  - **No.** Continue to step 5.
5. Are there any `--replicate-wild-ignore-table` options?
  - **Yes.** Does the table match any of them?
    - **Yes.** Ignore the event and exit.
    - **No.** Continue to step 6.
  - **No.** Continue to step 6.
6. Are there any `--replicate-do-table` or `--replicate-wild-do-table` options?
  - **Yes.** Ignore the event and exit.
  - **No.** Execute the event and exit.

### 16.2.3.3. Replication Rule Application

This section provides additional explanation and examples of usage for different combinations of replication filtering options.

Some typical combinations of replication filter rule types are given in the following table:

Condition (Types of Options)	Outcome
No <code>--replicate-*</code> options at all:	The slave executes all events that it receives from the master.
<code>--replicate-*db</code> options, but no table options:	The slave accepts or ignores events using the database options. It executes all events permitted by those options because there are no table restrictions.
<code>--replicate-*-table</code> options, but no database options:	All events are accepted at the database-checking stage because there are no database conditions. The slave executes or ignores events based solely on the table options.
A combination of database and table options:	The slave accepts or ignores events using the database options. Then it eval-

Condition (Types of Options)	Outcome
	ates all events permitted by those options according to the table options. This can sometimes lead to results that seem counterintuitive, and that may be different depending on whether you are using statement-based or row-based replication; see the text for an example.

A more complex example follows, in which we examine the outcomes for both statement-based and row-based settings.

Suppose that we have two tables `mytbl1` in database `db1` and `mytbl2` in database `db2` on the master, and the slave is running with the following options (and no other replication filtering options):

```
replicate-ignore-db = db1
replicate-do-table = db2.tbl2
```

Now we execute the following statements on the master:

```
USE db1;
INSERT INTO db2.tbl2 VALUES (1);
```

The results on the slave vary considerably depending on the binary log format, and may not match initial expectations in either case.

**Statement-based replication.** The `USE` statement causes `db1` to be the default database. Thus the `--replicate-ignore-db` option matches, and the `INSERT` statement is ignored. The table options are not checked.

**Row-based replication.** The default database has no effect on how the slave reads database options when using row-based replication. Thus, the `USE` statement makes no difference in how the `--replicate-ignore-db` option is handled: the database specified by this option does not match the database where the `INSERT` statement changes data, so the slave proceeds to check the table options. The table specified by `--replicate-do-table` matches the table to be updated, and the row is inserted.

## 16.3. Replication Solutions

Replication can be used in many different environments for a range of purposes. This section provides general notes and advice on using replication for specific solution types.

For information on using replication in a backup environment, including notes on the setup, backup procedure, and files to back up, see [Section 16.3.1, “Using Replication for Backups”](#).

For advice and tips on using different storage engines on the master and slaves, see [Section 16.3.2, “Using Replication with Different Master and Slave Storage Engines”](#).

Using replication as a scale-out solution requires some changes in the logic and operation of applications that use the solution. See [Section 16.3.3, “Using Replication for Scale-Out”](#).

For performance or data distribution reasons, you may want to replicate different databases to different replication slaves. See [Section 16.3.4, “Replicating Different Databases to Different Slaves”](#).

As the number of replication slaves increases, the load on the master can increase and lead to reduced performance (because of the need to replicate the binary log to each slave). For tips on improving your replication performance, including using a single secondary server as an replication master, see [Section 16.3.5, “Improving Replication Performance”](#).

For guidance on switching masters, or converting slaves into masters as part of an emergency failover solution, see [Section 16.3.6, “Switching Masters During Failover”](#).

To secure your replication communication, you can use SSL to encrypt the communication channel. For step-by-step instructions, see [Section 16.3.7, “Setting Up Replication Using SSL”](#).

### 16.3.1. Using Replication for Backups

To use replication as a backup solution, replicate data from the master to a slave, and then back up the data slave. The slave can be paused and shut down without affecting the running operation of the master, so you can produce an effective snapshot of “live” data that would otherwise require the master to be shut down.

How you back up a database depends on its size and whether you are backing up only the data, or the data and the replication slave state so that you can rebuild the slave in the event of failure. There are therefore two choices:

- If you are using replication as a solution to enable you to back up the data on the master, and the size of your database is not too large, the `mysqldump` tool may be suitable. See [Section 16.3.1.1, “Backing Up a Slave Using `mysqldump`”](#).
- For larger databases, where `mysqldump` would be impractical or inefficient, you can back up the raw data files instead. Using the raw data files option also means that you can back up the binary and relay logs that will enable you to recreate the slave in the event of a slave failure. For more information, see [Section 16.3.1.2, “Backing Up Raw Data from a Slave”](#).

Another backup strategy, which can be used for either master or slave servers, is to put the server in a read-only state. The backup is performed against the read-only server, which then is changed back to its usual read/write operational status. See [Section 16.3.1.3, “Backing Up a Master or Slave by Making It Read Only”](#).

### 16.3.1.1. Backing Up a Slave Using `mysqldump`

Using `mysqldump` to create a copy of a database enables you to capture all of the data in the database in a format that enables the information to be imported into another instance of MySQL Server (see [Section 4.5.4, “`mysqldump` — A Database Backup Program”](#)). Because the format of the information is SQL statements, the file can easily be distributed and applied to running servers in the event that you need access to the data in an emergency. However, if the size of your data set is very large, `mysqldump` may be impractical.

When using `mysqldump`, you should stop replication on the slave before starting the dump process to ensure that the dump contains a consistent set of data:

1. Stop the slave from processing requests. You can stop replication completely on the slave using `mysqladmin`:

```
shell> mysqladmin stop-slave
```

Alternatively, you can stop only the slave SQL thread to pause event execution:

```
shell> mysql -e 'STOP SLAVE SQL_THREAD;'
```

This enables the slave to continue to receive data change events from the master's binary log and store them in the relay logs using the I/O thread, but prevents the slave from executing these events and changing its data. Within busy replication environments, permitting the I/O thread to run during backup may speed up the catch-up process when you restart the slave SQL thread.

2. Run `mysqldump` to dump your databases. You may either dump all databases or select databases to be dumped. For example, to dump all databases:

```
shell> mysqldump --all-databases > fulldb.dump
```

3. Once the dump has completed, start slave operations again:

```
shell> mysqladmin start-slave
```

In the preceding example, you may want to add login credentials (user name, password) to the commands, and bundle the process up into a script that you can run automatically each day.

If you use this approach, make sure you monitor the slave replication process to ensure that the time taken to run the backup does not affect the slave's ability to keep up with events from the master. See [Section 16.1.4.1, “Checking Replication Status”](#). If the slave is unable to keep up, you may want to add another slave and distribute the backup process. For an example of how to configure this scenario, see [Section 16.3.4, “Replicating Different Databases to Different Slaves”](#).

### 16.3.1.2. Backing Up Raw Data from a Slave

To guarantee the integrity of the files that are copied, backing up the raw data files on your MySQL replication slave should take place while your slave server is shut down. If the MySQL server is still running, background tasks may still be updating the database files, particularly those involving storage engines with background processes such as `InnoDB`. With `InnoDB`, these problems should be resolved during crash recovery, but since the slave server can be shut down during the backup process without affecting the execution of the master it makes sense to take advantage of this capability.

To shut down the server and back up the files:

1. Shut down the slave MySQL server:

```
shell> mysqladmin shutdown
```

2. Copy the data files. You can use any suitable copying or archive utility, including `cp`, `tar` or `WinZip`. For example, assuming that the data directory is located under the current directory, you can archive the entire directory as follows:

```
shell> tar cf /tmp/dbbackup.tar ./data
```

3. Start the MySQL server again. Under Unix:

```
shell> mysqld_safe &
```

Under Windows:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.1\bin\mysqld"
```

Normally you should back up the entire data directory for the slave MySQL server. If you want to be able to restore the data and operate as a slave (for example, in the event of failure of the slave), then in addition to the slave's data, you should also back up the slave status files, `master.info` and `relay-log.info`, along with the relay log files. These files are needed to resume replication after you restore the slave's data.

If you lose the relay logs but still have the `relay-log.info` file, you can check it to determine how far the SQL thread has executed in the master binary logs. Then you can use `CHANGE MASTER TO` with the `MASTER_LOG_FILE` and `MASTER_LOG_POS` options to tell the slave to re-read the binary logs from that point. This requires that the binary logs still exist on the master server.

If your slave is replicating `LOAD DATA INFILE` statements, you should also back up any `SQL_LOAD-*` files that exist in the directory that the slave uses for this purpose. The slave needs these files to resume replication of any interrupted `LOAD DATA INFILE` operations. The location of this directory is the value of the `--slave-load-tmpdir` option. If the server was not started with that option, the directory location is the value of the `tmpdir` system variable.

### 16.3.1.3. Backing Up a Master or Slave by Making It Read Only

It is possible to back up either master or slave servers in a replication setup by acquiring a global read lock and manipulating the `read_only` system variable to change the read-only state of the server to be backed up:

1. Make the server read-only, so that it processes only retrievals and blocks updates.
2. Perform the backup.
3. Change the server back to its normal read/write state.

#### Note

The instructions in this section place the server to be backed up in a state that is safe for backup methods that get the data from the server, such as `mysqldump` (see [Section 4.5.4, “`mysqldump` — A Database Backup Program”](#)). You should not attempt to use these instructions to make a binary backup by copying files directly because the server may still have modified data cached in memory and not flushed to disk.

These instructions also require MySQL 5.1.15 or higher. For earlier versions, setting `read_only` does not block while table locks or outstanding transactions are pending, so data changes can still occur during the backup operation and produce inconsistent backup results.

The following instructions describe how to do this for a master server and for a slave server. For both scenarios discussed here, suppose that you have the following replication setup:

- A master server M1
- A slave server S1 that has M1 as its master
- A client C1 connected to M1
- A client C2 connected to S1

In either scenario, the statements to acquire the global read lock and manipulate the `read_only` variable are performed on the server to be backed up and do not propagate to any slaves of that server.

#### Scenario 1: Backup with a Read-Only Master

Put the master M1 in a read-only state by executing these statements on it:

```
mysql> FLUSH TABLES WITH READ LOCK;
mysql> SET GLOBAL read_only = ON;
```

While M1 is in a read-only state, the following properties are true:

- Requests for updates sent by C1 to M1 will block because the server is in read-only mode.
- Requests for query results sent by C1 to M1 will succeed.
- Making a backup on M1 is safe.
- Making a backup on S1 is not safe. This server is still running, and might be processing the binary log or update requests coming from client C2

While M1 is read only, perform the backup. For example, you can use `mysqldump`.

After the backup operation on M1 completes, restore M1 to its normal operational state by executing these statements:

```
mysql> SET GLOBAL read_only = OFF;
mysql> UNLOCK TABLES;
```

Although performing the backup on M1 is safe (as far as the backup is concerned), it is not optimal for performance because clients of M1 are blocked from executing updates.

This strategy applies to backing up a master server in a replication setup, but can also be used for a single server in a nonreplication setting.

### Scenario 2: Backup with a Read-Only Slave

Put the slave S1 in a read-only state by executing these statements on it:

```
mysql> FLUSH TABLES WITH READ LOCK;
mysql> SET GLOBAL read_only = ON;
```

While S1 is in a read-only state, the following properties are true:

- The master M1 will continue to operate, so making a backup on the master is not safe.
- The slave S1 is stopped, so making a backup on the slave S1 is safe.

These properties provide the basis for a popular backup scenario: Having one slave busy performing a backup for a while is not a problem because it does not affect the entire network, and the system is still running during the backup. In particular, clients can still perform updates on the master server, which remains unaffected by backup activity on the slave.

While S1 is read only, perform the backup. For example, you can use `mysqldump`.

After the backup operation on S1 completes, restore S1 to its normal operational state by executing these statements:

```
mysql> SET GLOBAL read_only = OFF;
mysql> UNLOCK TABLES;
```

After the slave is restored to normal operation, it again synchronizes to the master by catching up with any outstanding updates from the binary log of the master.

## 16.3.2. Using Replication with Different Master and Slave Storage Engines

It does not matter for the replication process whether the source table on the master and the replicated table on the slave use different engine types. In fact, the system variables `storage_engine` and `table_type` are not replicated.

This provides a number of benefits in the replication process in that you can take advantage of different engine types for different replication scenarios. For example, in a typical scale-out scenario (see [Section 16.3.3, “Using Replication for Scale-Out”](#)), you want to use `InnoDB` tables on the master to take advantage of the transactional functionality, but use `MyISAM` on the slaves where transaction support is not required because the data is only read. When using replication in a data-logging environment you may want to use the `Archive` storage engine on the slave.

Configuring different engines on the master and slave depends on how you set up the initial replication process:

- If you used `mysqldump` to create the database snapshot on your master, you could edit the dump file text to change the engine type used on each table.

Another alternative for `mysqldump` is to disable engine types that you do not want to use on the slave before using the dump to build the data on the slave. For example, you can add the `--skip-innodb` option on your slave to disable the `InnoDB` engine. If a specific engine does not exist for a table to be created, MySQL will use the default engine type, usually `MyISAM`. (This requires that the `NO_ENGINE_SUBSTITUTION` SQL mode is not enabled.) If you want to disable additional engines in this way, you may want to consider building a special binary to be used on the slave that only supports the engines you want.

- If you are using raw data files (a binary backup) to set up the slave, you will be unable to change the initial table format. Instead, use `ALTER TABLE` to change the table types after the slave has been started.
- For new master/slave replication setups where there are currently no tables on the master, avoid specifying the engine type when creating new tables.

If you are already running a replication solution and want to convert your existing tables to another engine type, follow these steps:

1. Stop the slave from running replication updates:

```
mysql> STOP SLAVE;
```

This will enable you to change engine types without interruptions.

2. Execute an `ALTER TABLE ... ENGINE='engine_type'` for each table to be changed.
3. Start the slave replication process again:

```
mysql> START SLAVE;
```

Although the `storage_engine` and `table_type` variables are not replicated, be aware that `CREATE TABLE` and `ALTER TABLE` statements that include the engine specification will be correctly replicated to the slave. For example, if you have a CSV table and you execute:

```
mysql> ALTER TABLE csvtable Engine='MyISAM';
```

The above statement will be replicated to the slave and the engine type on the slave will be converted to `MyISAM`, even if you have previously changed the table type on the slave to an engine other than CSV. If you want to retain engine differences on the master and slave, you should be careful to use the `storage_engine` variable on the master when creating a new table. For example, instead of:

```
mysql> CREATE TABLE tablea (columna int) Engine=MyISAM;
```

Use this format:

```
mysql> SET storage_engine=MyISAM;
mysql> CREATE TABLE tablea (columna int);
```

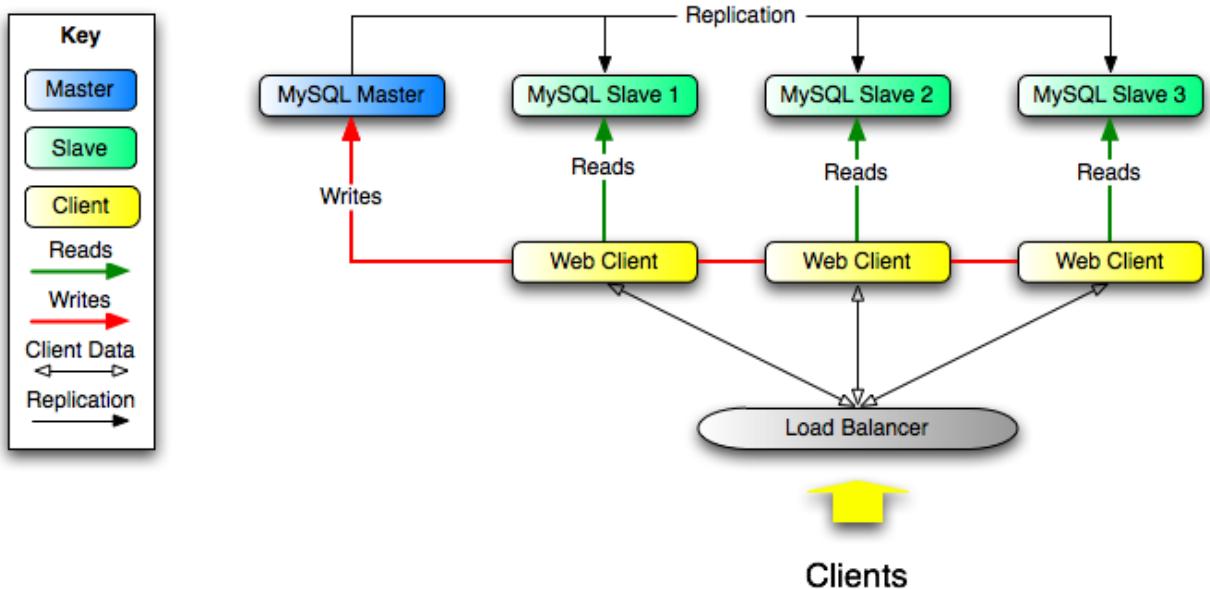

When replicated, the `storage_engine` variable will be ignored, and the `CREATE TABLE` statement will execute on the slave using the slave's default engine.

### 16.3.3. Using Replication for Scale-Out

You can use replication as a scale-out solution; that is, where you want to split up the load of database queries across multiple database servers, within some reasonable limitations.

Because replication works from the distribution of one master to one or more slaves, using replication for scale-out works best in an environment where you have a high number of reads and low number of writes/updates. Most Web sites fit into this category, where users are browsing the Web site, reading articles, posts, or viewing products. Updates only occur during session management, or when making a purchase or adding a comment/message to a forum.

Replication in this situation enables you to distribute the reads over the replication slaves, while still enabling your web servers to communicate with the replication master when a write is required. You can see a sample replication layout for this scenario in [Figure 16.1, “Using Replication to Improve Performance During Scale-Out”](#).

**Figure 16.1. Using Replication to Improve Performance During Scale-Out**

If the part of your code that is responsible for database access has been properly abstracted/modularized, converting it to run with a replicated setup should be very smooth and easy. Change the implementation of your database access to send all writes to the master, and to send reads to either the master or a slave. If your code does not have this level of abstraction, setting up a replicated system gives you the opportunity and motivation to clean it up. Start by creating a wrapper library or module that implements the following functions:

- `safe_writer_connect()`
- `safe_reader_connect()`
- `safe_reader_statement()`
- `safe_writer_statement()`

`safe_` in each function name means that the function takes care of handling all error conditions. You can use different names for the functions. The important thing is to have a unified interface for connecting for reads, connecting for writes, doing a read, and doing a write.

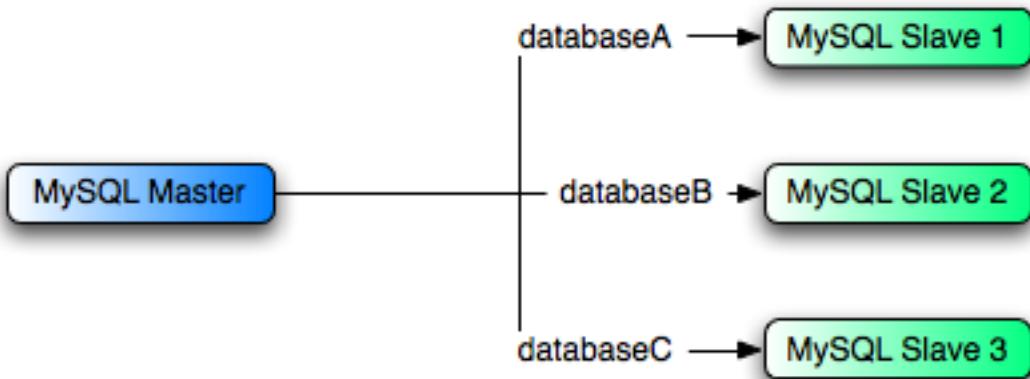

Then convert your client code to use the wrapper library. This may be a painful and scary process at first, but it pays off in the long run. All applications that use the approach just described are able to take advantage of a master/slave configuration, even one involving multiple slaves. The code is much easier to maintain, and adding troubleshooting options is trivial. You need modify only one or two functions; for example, to log how long each statement took, or which statement among those issued gave you an error.

If you have written a lot of code, you may want to automate the conversion task by using the `replace` utility that comes with standard MySQL distributions, or write your own conversion script. Ideally, your code uses consistent programming style conventions. If not, then you are probably better off rewriting it anyway, or at least going through and manually regularizing it to use a consistent style.

#### 16.3.4. Replicating Different Databases to Different Slaves

There may be situations where you have a single master and want to replicate different databases to different slaves. For example, you may want to distribute different sales data to different departments to help spread the load during data analysis. A sample of this layout is shown in Figure 16.2, “Using Replication to Replicate Databases to Separate Replication Slaves”.

**Figure 16.2. Using Replication to Replicate Databases to Separate Replication Slaves**

You can achieve this separation by configuring the master and slaves as normal, and then limiting the binary log statements that each slave processes by using the `--replicate-wild-do-table` configuration option on each slave.

### Important

You should *not* use `--replicate-do-db` for this purpose when using statement-based replication, since statement-based replication causes this option's affects to vary according to the database that is currently selected. This applies to mixed-format replication as well, since this enables some updates to be replicated using the statement-based format.

However, it should be safe to use `--replicate-do-db` for this purpose if you are using row-based replication only, since in this case the currently selected database has no effect on the option's operation.

For example, to support the separation as shown in Figure 16.2, “Using Replication to Replicate Databases to Separate Replication Slaves”, you should configure each replication slave as follows, before executing `START SLAVE`:

- Replication slave 1 should use `--replicate-wild-do-table=databaseA.%`.
- Replication slave 2 should use `--replicate-wild-do-table=databaseB.%`.
- Replication slave 3 should use `--replicate-wild-do-table=databaseC.%`.

Each slave in this configuration receives the entire binary log from the master, but executes only those events from the binary log that apply to the databases and tables included by the `--replicate-wild-do-table` option in effect on that slave.

If you have data that must be synchronized to the slaves before replication starts, you have a number of choices:

- Synchronize all the data to each slave, and delete the databases, tables, or both that you do not want to keep.
- Use `mysqldump` to create a separate dump file for each database and load the appropriate dump file on each slave.
- Use a raw data file dump and include only the specific files and databases that you need for each slave.

### Note

This does not work with `InnoDB` databases unless you use `innodb_file_per_table`.

## 16.3.5. Improving Replication Performance

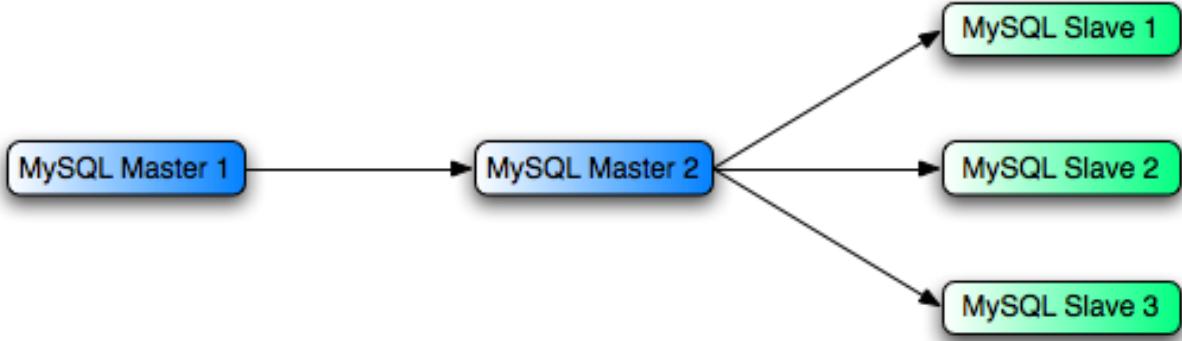

As the number of slaves connecting to a master increases, the load, although minimal, also increases, as each slave uses a client connection to the master. Also, as each slave must receive a full copy of the master binary log, the network load on the master may also increase and create a bottleneck.

If you are using a large number of slaves connected to one master, and that master is also busy processing requests (for example, as part of a scale-out solution), then you may want to improve the performance of the replication process.

One way to improve the performance of the replication process is to create a deeper replication structure that enables the master to

replicate to only one slave, and for the remaining slaves to connect to this primary slave for their individual replication requirements. A sample of this structure is shown in [Figure 16.3, “Using an Additional Replication Host to Improve Performance”](#).

**Figure 16.3. Using an Additional Replication Host to Improve Performance**

For this to work, you must configure the MySQL instances as follows:

- Master 1 is the primary master where all changes and updates are written to the database. Binary logging should be enabled on this machine.
- Master 2 is the slave to the Master 1 that provides the replication functionality to the remainder of the slaves in the replication structure. Master 2 is the only machine permitted to connect to Master 1. Master 2 also has binary logging enabled, and the `--log-slave-updates` option so that replication instructions from Master 1 are also written to Master 2's binary log so that they can then be replicated to the true slaves.
- Slave 1, Slave 2, and Slave 3 act as slaves to Master 2, and replicate the information from Master 2, which actually consists of the upgrades logged on Master 1.

The above solution reduces the client load and the network interface load on the primary master, which should improve the overall performance of the primary master when used as a direct database solution.

If your slaves are having trouble keeping up with the replication process on the master, there are a number of options available:

- If possible, put the relay logs and the data files on different physical drives. To do this, use the `--relay-log` option to specify the location of the relay log.
- If the slaves are significantly slower than the master, you may want to divide up the responsibility for replicating different databases to different slaves. See [Section 16.3.4, “Replicating Different Databases to Different Slaves”](#).
- If your master makes use of transactions and you are not concerned about transaction support on your slaves, use `MyISAM` or another nontransactional engine on the slaves. See [Section 16.3.2, “Using Replication with Different Master and Slave Storage Engines”](#).
- If your slaves are not acting as masters, and you have a potential solution in place to ensure that you can bring up a master in the event of failure, then you can switch off `--log-slave-updates`. This prevents “dumb” slaves from also logging events they have executed into their own binary log.

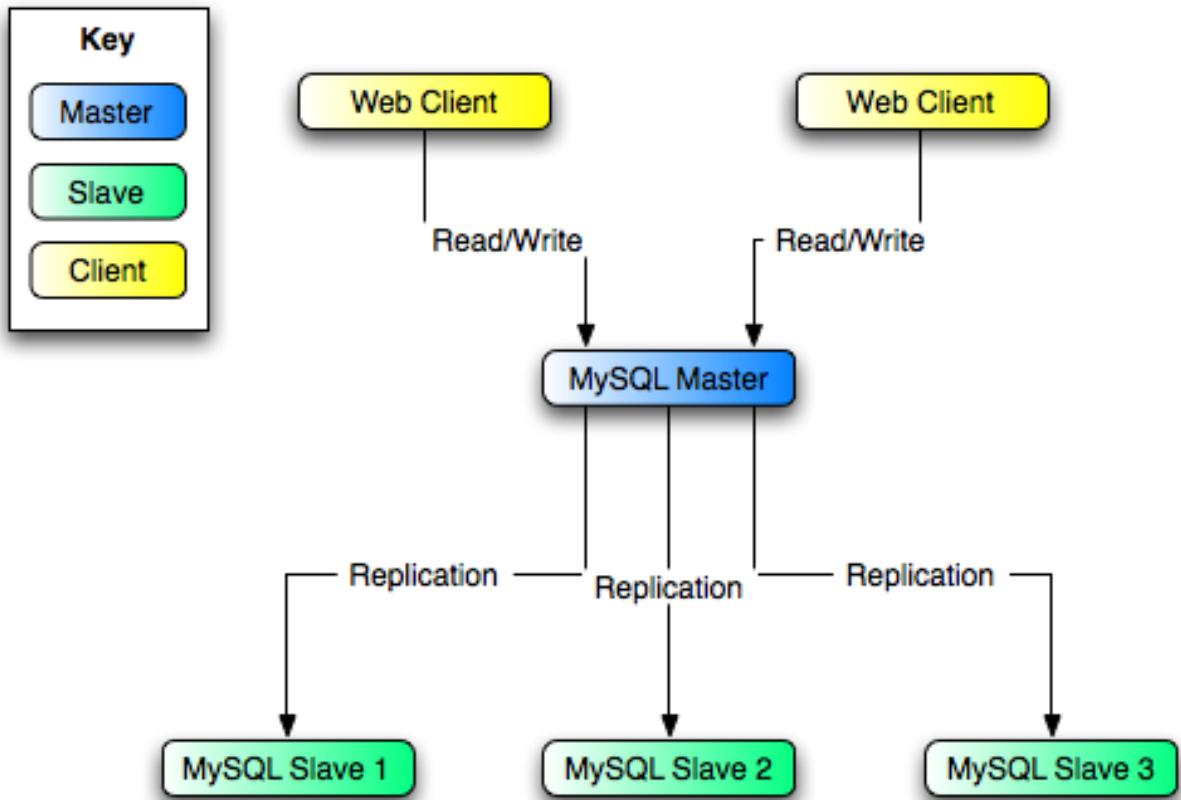

### 16.3.6. Switching Masters During Failover

There is currently no official solution for providing failover between master and slaves in the event of a failure. With the currently available features, you would have to set up a master and a slave (or several slaves), and to write a script that monitors the master to check whether it is up. Then instruct your applications and the slaves to change master in case of failure.

Remember that you can tell a slave to change its master at any time, using the `CHANGE MASTER TO` statement. The slave will not check whether the databases on the master are compatible with the slave, it will just start reading and executing events from the specified binary log coordinates on the new master. In a failover situation, all the servers in the group are typically executing the same events from the same binary log file, so changing the source of the events should not affect the database structure or integrity providing you are careful.

Run your slaves with the `--log-bin` option and without `--log-slave-updates`. In this way, the slave is ready to become a master as soon as you issue `STOP SLAVE`; `RESET MASTER`, and `CHANGE MASTER TO` statement on the other slaves. For example, assume that you have the structure shown in Figure 16.4, “Redundancy Using Replication, Initial Structure”.

**Figure 16.4. Redundancy Using Replication, Initial Structure**

In this diagram, the `MySQL Master` holds the master database, the `MySQL Slave` hosts are replication slaves, and the `Web Client` machines are issuing database reads and writes. Web clients that issue only reads (and would normally be connected to the slaves) are not shown, as they do not need to switch to a new server in the event of failure. For a more detailed example of a read/write scale-out replication structure, see [Section 16.3.3, “Using Replication for Scale-Out”](#).

Each MySQL Slave (`Slave 1`, `Slave 2`, and `Slave 3`) is a slave running with `--log-bin` and without `--log-slave-updates`. Because updates received by a slave from the master are not logged in the binary log unless `--log-slave-updates` is specified, the binary log on each slave is empty initially. If for some reason `MySQL Master` becomes unavailable, you can pick one of the slaves to become the new master. For example, if you pick `Slave 1`, all `Web Clients` should be redirected to `Slave 1`, which will log updates to its binary log. `Slave 2` and `Slave 3` should then replicate from `Slave 1`.

The reason for running the slave without `--log-slave-updates` is to prevent slaves from receiving updates twice in case you cause one of the slaves to become the new master. Suppose that `Slave 1` has `--log-slave-updates` enabled. Then it will write updates that it receives from `Master` to its own binary log. When `Slave 2` changes from `Master` to `Slave 1` as its master, it may receive updates from `Slave 1` that it has already received from `Master`.

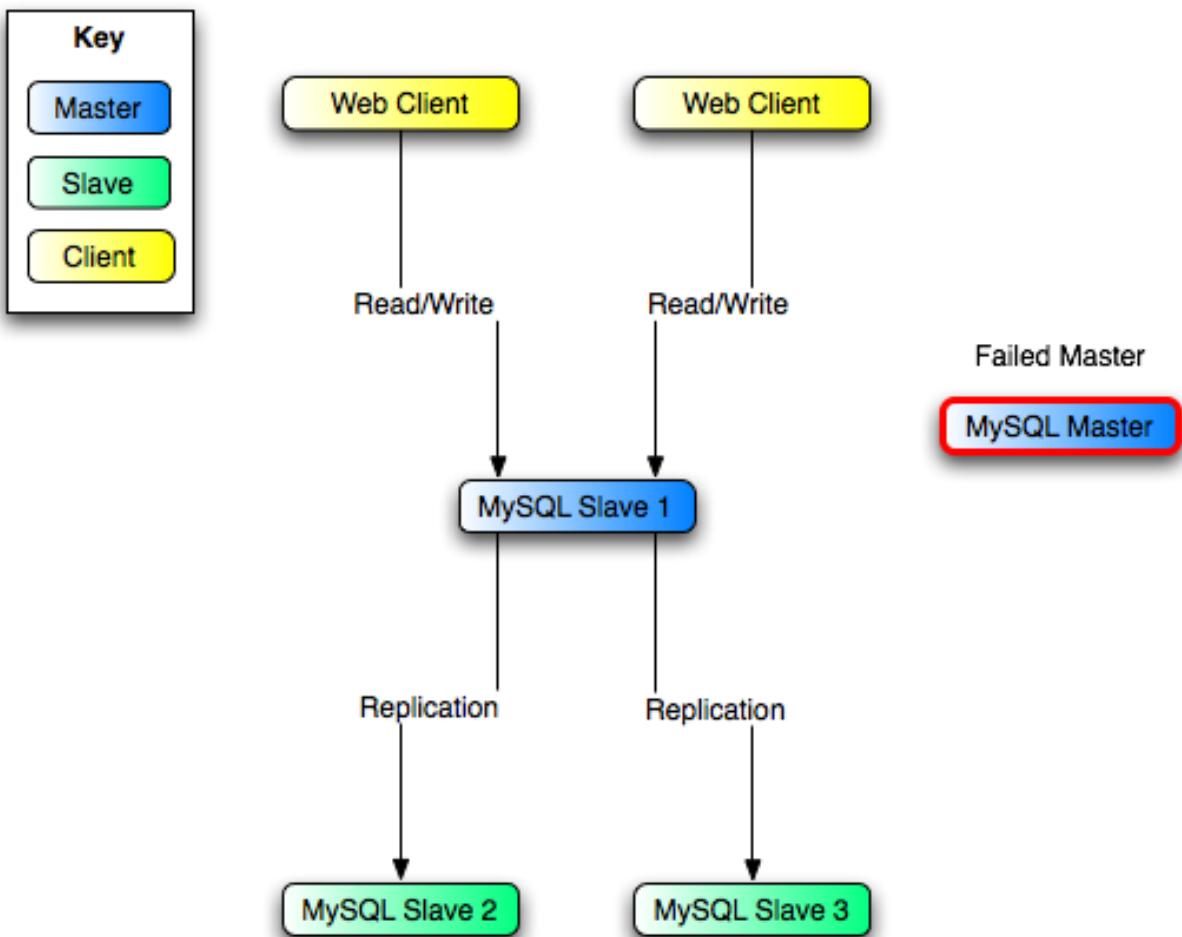

Make sure that all slaves have processed any statements in their relay log. On each slave, issue `STOP SLAVE IO_THREAD`, then check the output of `SHOW PROCESSLIST` until you see `Has read all relay log`. When this is true for all slaves, they can be reconfigured to the new setup. On the slave `Slave 1` being promoted to become the master, issue `STOP SLAVE` and `RESET MASTER`.

On the other slaves `Slave 2` and `Slave 3`, use `STOP SLAVE` and `CHANGE MASTER TO MASTER_HOST='Slave1'` (where '`Slave1`' represents the real host name of `Slave 1`). To use `CHANGE MASTER TO`, add all information about how to connect to `Slave 1` from `Slave 2` or `Slave 3` (`user`, `password`, `port`). In `CHANGE MASTER TO`, there is no need to specify the name of the `Slave 1` binary log file or log position to read from: We know it is the first binary log file and position 4, which are the defaults for `CHANGE MASTER TO`. Finally, use `START SLAVE` on `Slave 2` and `Slave 3`.

Once the new replication is in place, you will then need to instruct each `Web Client` to direct its statements to `Slave 1`. From that point on, all update statements sent by `Web Client` to `Slave 1` are written to the binary log of `Slave 1`, which then contains every update statement sent to `Slave 1` since `Master` died.

The resulting server structure is shown in [Figure 16.5, “Redundancy Using Replication, After Master Failure”](#).

**Figure 16.5. Redundancy Using Replication, After Master Failure**

When `Master` is up again, you must issue on it the same `CHANGE MASTER TO` as that issued on `Slave 2` and `Slave 3`, so that `Master` becomes a slave of `S1` and picks up each `Web Client` writes that it missed while it was down.

To make `Master` a master again (for example, because it is the most powerful machine), use the preceding procedure as if `Slave 1` was unavailable and `Master` was to be the new master. During this procedure, do not forget to run `RESET MASTER` on `Master` before making `Slave 1`, `Slave 2`, and `Slave 3` slaves of `Master`. Otherwise, they may pick up old `Web Client` writes from before the point at which `Master` became unavailable.

Note that there is no synchronization between the different slaves to a master. Some slaves might be ahead of others. This means that the concept outlined in the previous example might not work. In practice, however, the relay logs of different slaves will most likely not be far behind the master, so it would work, anyway (but there is no guarantee).

A good way to keep your applications informed as to the location of the master is by having a dynamic DNS entry for the master. With `bind` you can use `nsupdate` to dynamically update your DNS.

### 16.3.7. Setting Up Replication Using SSL

To use SSL for encrypting the transfer of the binary log required during replication, both the master and the slave must support SSL network connections. If either host does not support SSL connections (because it has not been compiled or configured for SSL), replication through an SSL connection is not possible.

Setting up replication using an SSL connection is similar to setting up a server and client using SSL. You must obtain (or create) a suitable security certificate that you can use on the master, and a similar certificate (from the same certificate authority) on each slave.

For more information on setting up a server and client for SSL connectivity, see [Section 5.5.6.2, “Using SSL Connections”](#).

To enable SSL on the master you must create or obtain suitable certificates, and then add the following configuration options to the master's configuration within the `[mysqld]` section of the master's `my.cnf` file:

```
[mysqld]
ssl-ca=cacert.pem
ssl-cert=server-cert.pem
ssl-key=server-key.pem
```

The paths to the certificates may be relative or absolute; we recommend that you always use complete paths for this purpose.

The options are as follows:

- `ssl-ca` identifies the Certificate Authority (CA) certificate.
- `ssl-cert` identifies the server public key. This can be sent to the client and authenticated against the CA certificate that it has.
- `ssl-key` identifies the server private key.

On the slave, you have two options available for setting the SSL information. You can either add the slave certificates to the `[client]` section of the slave's `my.cnf` file, or you can explicitly specify the SSL information using the `CHANGE MASTER TO` statement:

- To add the slave certificates using an option file, add the following lines to the `[client]` section of the slave's `my.cnf` file:

```
[client]
ssl-ca=cacert.pem
ssl-cert=client-cert.pem
ssl-key=client-key.pem
```

Restart the slave server, using the `--skip-slave-start` option to prevent the slave from connecting to the master. Use `CHANGE MASTER TO` to specify the master configuration, using the `MASTER_SSL` option to enable SSL connectivity:

```
mysql> CHANGE MASTER TO
 -> MASTER_HOST='master_hostname',
 -> MASTER_USER='replicate',
 -> MASTER_PASSWORD='password',
 -> MASTER_SSL=1;
```

- To specify the SSL certificate options using the `CHANGE MASTER TO` statement, append the SSL options:

```
mysql> CHANGE MASTER TO
 -> MASTER_HOST='master_hostname',
 -> MASTER_USER='replicate',
 -> MASTER_PASSWORD='password',
 -> MASTER_SSL=1,
 -> MASTER_SSL_CA = 'ca_file_name',
 -> MASTER_SSL_CAPATH = 'ca_directory_name',
 -> MASTER_SSL_CERT = 'cert_file_name',
 -> MASTER_SSL_KEY = 'key_file_name';
```

After the master information has been updated, start the slave replication process:

```
mysql> START SLAVE;
```

You can use the `SHOW SLAVE STATUS` statement to confirm that the SSL connection was established successfully.

For more information on the `CHANGE MASTER TO` statement, see [Section 12.5.2.1, “`CHANGE MASTER TO` Syntax”](#).

If you want to enforce the use of SSL connections during replication, then create a user with the `REPLICATION SLAVE` privilege and use the `REQUIRE SSL` option for that user. For example:

```
mysql> CREATE USER 'repl'@'%mydomain.com' IDENTIFIED BY 'slavepass';
mysql> GRANT REPLICATION SLAVE ON *.*
 -> TO 'repl'@'%mydomain.com' REQUIRE SSL;
```

If the account already exists, you can add `REQUIRE SSL` to it with this statement:

```
mysql> GRANT USAGE ON *.*
-> TO 'repl'@'%mydomain.com' REQUIRE SSL;
```

## 16.4. Replication Notes and Tips

### 16.4.1. Replication Features and Issues

The following sections provide information about what is supported and what is not in MySQL replication, and about specific issues and situations that may occur when replicating certain statements.

Statement-based replication depends on compatibility at the SQL level between the master and slave. In others, successful SBR requires that any SQL features used be supported by both the master and the slave servers. For example, if you use a feature on the master server that is available only in MySQL 5.1 (or later), you cannot replicate to a slave that uses MySQL 5.0 (or earlier).

Such incompatibilities also can occur within a release series when using pre-production releases of MySQL. For example, the `SLEEP()` function is available beginning with MySQL 5.0.12. If you use this function on the master, you cannot replicate to a slave that uses MySQL 5.0.11 or earlier.

For this reason, use Generally Available (GA) releases of MySQL for statement-based replication in a production setting, since we do not introduce new SQL statements or change their behavior within a given release series once that series reaches GA release status.

If you are planning to use statement-based replication between MySQL 5.1 and a previous MySQL release series, it is also a good idea to consult the edition of the *MySQL Reference Manual* corresponding to the earlier release series for information regarding the replication characteristics of that series.

With MySQL's statement-based replication, there may be issues with replicating stored routines or triggers. You can avoid these issues by using MySQL's row-based replication instead. For a detailed list of issues, see [Section 19.7, “Binary Logging of Stored Programs”](#). For more information about row-based logging and row-based replication, see [Section 5.2.4.1, “Binary Logging Formats”](#), and [Section 16.1.2, “Replication Formats”](#).

For additional information specific to replication and `InnoDB`, see [Section 13.6.4.5, “InnoDB and MySQL Replication”](#). For information relating to replication with MySQL Cluster, see [Section 17.6, “MySQL Cluster Replication”](#).

#### 16.4.1.1. Replication and `AUTO_INCREMENT`

Statement-based replication of `AUTO_INCREMENT`, `LAST_INSERT_ID()`, and `TIMESTAMP` values is done correctly, subject to the following exceptions:

- Prior to MySQL 5.1.12, a stored procedure that uses `LAST_INSERT_ID()` does not replicate properly using statement-based binary logging.
- Prior to MySQL 5.1.12, when a stored routine or trigger caused an `INSERT` into an `AUTO_INCREMENT` column, the generated `AUTO_INCREMENT` value was not written into the binary log, so a different value could in some cases be inserted on the slave.
- An insert into an `AUTO_INCREMENT` column caused by a stored routine or trigger running on a master that uses MySQL 5.0.60 or earlier does not replicate correctly to a slave running MySQL 5.1.12 through 5.1.23 (inclusive). ([Bug#33029](#))
- The `AUTO_INCREMENT` table option was not replicated correctly prior to MySQL 5.1.31. ([Bug#41986](#))
- Adding an `AUTO_INCREMENT` column to a table with `ALTER TABLE` might not produce the same ordering of the rows on the slave and the master. This occurs because the order in which the rows are numbered depends on the specific storage engine used for the table and the order in which the rows were inserted. If it is important to have the same order on the master and slave, the rows must be ordered before assigning an `AUTO_INCREMENT` number. Assuming that you want to add an `AUTO_INCREMENT` column to a table `t1` that has columns `col1` and `col2`, the following statements produce a new table `t2` identical to `t1` but with an `AUTO_INCREMENT` column:

```
CREATE TABLE t2 LIKE t1;
ALTER TABLE t2 ADD id INT AUTO_INCREMENT PRIMARY KEY;
INSERT INTO t2 SELECT * FROM t1 ORDER BY col1, col2;
```

#### Important

To guarantee the same ordering on both master and slave, the `ORDER BY` clause must name *all* columns of `t1`.

The instructions just given are subject to the limitations of `CREATE TABLE ... LIKE`: Foreign key definitions are ignored, as are the `DATA DIRECTORY` and `INDEX DIRECTORY` table options. If a table definition includes any of those characteristics, create `t2` using a `CREATE TABLE` statement that is identical to the one used to create `t1`, but with the addition of the `AUTO_INCREMENT` column.

Regardless of the method used to create and populate the copy having the `AUTO_INCREMENT` column, the final step is to drop the original table and then rename the copy:

```
DROP t1;
ALTER TABLE t2 RENAME t1;
```

See also [Section B.5.7.1, “Problems with ALTER TABLE”](#).

### 16.4.1.2. Replication and Character Sets

The following applies to replication between MySQL servers that use different character sets:

- If the master uses MySQL 4.1, you must *always* use the same *global* character set and collation on the master and the slave, regardless of the slave MySQL version. (These are controlled by the `--character-set-server` and `--collation-server` options.) Otherwise, you may get duplicate-key errors on the slave, because a key that is unique in the master character set might not be unique in the slave character set. Note that this is not a cause for concern when master and slave are both MySQL 5.0 or later.
- If the master is older than MySQL 4.1.3, the character set of any client should never be made different from its global value because this character set change is not known to the slave. In other words, clients should not use `SET NAMES`, `SET CHARACTER SET`, and so forth. If both the master and the slave are 4.1.3 or newer, clients can freely set session values for character set variables because these settings are written to the binary log and so are known to the slave. That is, clients can use `SET NAMES` or `SET CHARACTER SET` or can set variables such as `collation_client` or `collation_server`. However, clients are prevented from changing the *global* value of these variables; as stated previously, the master and slave must always have identical global character set values. This is true whether you are using statement-based or row-based replication.
- If the master has databases with a character set different from the global `character_set_server` value, you should design your `CREATE TABLE` statements so that they do not implicitly rely on the database default character set. A good workaround is to state the character set and collation explicitly in `CREATE TABLE` statements.

### 16.4.1.3. Replication of `CREATE ... IF NOT EXISTS` Statements

This section discusses the rules that are applied when various `CREATE ... IF NOT EXISTS` statements are replicated.

**Previous to MySQL 5.1.38.** `CREATE DATABASE IF NOT EXISTS` was replicated only if the database named in the statement did not exist on the master. `CREATE TABLE IF NOT EXISTS` was replicated only if the table named in the statement did not exist on the master.

**MySQL 5.1.39 and later.** Every `CREATE DATABASE IF NOT EXISTS` statement is replicated, whether or not the database already exists on the master. Similarly, every `CREATE TABLE IF NOT EXISTS` statement is replicated, whether or not the table already exists on the master. This includes `CREATE TABLE IF NOT EXISTS ... LIKE`. However, replication of `CREATE TABLE IF NOT EXISTS ... SELECT` follows somewhat different rules; see [Section 16.4.1.4, “Replication of CREATE TABLE ... SELECT Statements”](#), for more information.

**Replication of `CREATE EVENT IF NOT EXISTS`.** `CREATE EVENT IF NOT EXISTS` is always replicated, whether or not the event named in the statement already exists on the master. This is true for all MySQL 5.1 releases beginning with MySQL 5.1.6, when this statement was introduced.

See also [Bug#45574](#).

### 16.4.1.4. Replication of `CREATE TABLE ... SELECT` Statements

This section discusses how MySQL replicates `CREATE TABLE ... SELECT` statements.

These behaviors are not dependent on MySQL version:

- `CREATE TABLE ... SELECT` always performs an implicit commit ([Section 12.3.3, “Statements That Cause an Implicit Commit”](#)).
- If destination table does not exist, logging occurs as follows. It does not matter whether `IF NOT EXISTS` is present.

- `STATEMENT` or `MIXED` format: The statement is logged as written.
- `ROW` format: The statement is logged as a `CREATE TABLE` statement followed by a series of insert-row events.
- If the statement fails, nothing is logged. This includes the case that the destination table exists and `IF NOT EXISTS` is not given.

When the destination table exists and `IF NOT EXISTS` is given, MySQL handles the statement in a version-dependent way.

In MySQL 5.1 before 5.1.51 and in MySQL 5.5 before 5.5.6 (this is the original behavior):

- `STATEMENT` or `MIXED` format: The statement is logged as written.
- `ROW` format: The statement is logged as a `CREATE TABLE` statement followed by a series of insert-row events.

In MySQL 5.1 as of 5.1.51:

- `STATEMENT` or `MIXED` format: The statement is logged as the equivalent pair of `CREATE TABLE` and `INSERT INTO ... SELECT` statements.
- `ROW` format: The statement is logged as a `CREATE TABLE` statement followed by a series of insert-row events.

In MySQL 5.5 as of 5.5.6:

- Nothing is inserted or logged.

These version dependencies arise due to a change in MySQL 5.5.6 in handling of `CREATE TABLE ... SELECT` not to insert rows if the destination table already exists, and a change made in MySQL 5.1.51 to preserve forward compatibility in replication of such statements from a 5.1 master to a 5.5 slave. For details, see [Section 12.1.17.1, “`CREATE TABLE ... SELECT` Syntax”](#).

#### 16.4.1.5. Replication of `CURRENT_USER()`

The following statements support use of the `CURRENT_USER()` function to take the place of the name of (and, possibly, the host for) an affected user or a definer; in such cases, `CURRENT_USER()` is expanded where and as needed:

- `DROP USER`
- `RENAME USER`
- `GRANT`
- `REVOKE`
- `CREATE FUNCTION`
- `CREATE PROCEDURE`
- `CREATE TRIGGER`
- `CREATE EVENT`
- `CREATE VIEW`
- `ALTER EVENT`
- `ALTER VIEW`
- `SET PASSWORD`

In all MySQL 5.1 releases, when `CURRENT_USER()` and `CURRENT_USER` is used as the definer in any of the statements `CREATE FUNCTION`, `CREATE PROCEDURE`, `CREATE TRIGGER`, `CREATE EVENT`, `CREATE VIEW`, or `ALTER VIEW` when binary logging is enabled, the function reference is expanded before it is written to the binary log, so that the statement refers to the

same user on both the master and the slave when the statement is replicated. Beginning with MySQL 5.1.49, `CURRENT_USER()` or `CURRENT_USER` is also expanded prior to being written to the binary log when used in `DROP USER`, `RENAME USER`, `GRANT`, `REVOKE`, or `ALTER EVENT`. ([Bug#48321](#))

### 16.4.1.6. Replication of `DROP ... IF EXISTS` Statements

The `DROP DATABASE IF EXISTS`, `DROP TABLE IF EXISTS`, and `DROP VIEW IF EXISTS` statements are always replicated, even if the database, table, or view to be dropped does not exist on the master. This is to ensure that the object to be dropped no longer exists on either the master or the slave, once the slave has caught up with the master.

Beginning with MySQL 5.1.33, `DROP ... IF EXISTS` statements for stored programs (stored procedures and functions, triggers, and events) are also replicated, even if the stored program to be dropped does not exist on the master. ([Bug#13684](#))

### 16.4.1.7. Replication with Differing Table Definitions on Master and Slave

Starting with MySQL 5.1.21, source and target tables for replication do not have to be identical. A table on the master can have more or fewer columns than the slave's copy of the table. In addition, corresponding table columns on the master and the slave can use different data types, subject to certain conditions.

In all cases where the source and target tables do not have identical definitions, the following must be true for replication to work:

- You must be using row-based replication. (Using `MIXED` for the binary logging format does not work.)
- The database and table names must be the same on both the master and the slave.

Additional conditions are discussed, with examples, in the following two sections.

#### 16.4.1.7.1. Replication with More Columns on Master or Slave

Starting with MySQL 5.1.21, you can replicate a table from the master to the slave such that the master and slave copies of the table have differing numbers of columns, subject to the following conditions:

- Columns common to both versions of the table must be defined in the same order on the master and the slave.  
(This is true even if both tables have the same number of columns.)
- Columns common to both versions of the table must be defined before any additional columns.

This means that executing an `ALTER TABLE` statement on the slave where a new column is inserted into the table within the range of columns common to both tables causes replication to fail, as shown in the following example:

Suppose a table `t`, existing on the master and the slave, defined by the following `CREATE TABLE` statement:

```
CREATE TABLE t (
 c1 INT,
 c2 INT,
 c3 INT
);
```

Suppose the `ALTER TABLE` statement shown here is executed on the slave:

```
ALTER TABLE t ADD COLUMN cnew1 INT AFTER c3;
```

The previous `ALTER TABLE` is permitted on the slave because the columns `c1`, `c2`, and `c3` that are common to both versions of table `t` remain grouped together in both versions of the table, before any columns that differ.

However, the following `ALTER TABLE` statement cannot be executed on the slave without causing replication to break:

```
ALTER TABLE t ADD COLUMN cnew2 INT AFTER c3;
```

Replication fails after execution on the slave of the `ALTER TABLE` statement just shown, because the new column `cnew2` comes between columns common to both versions of `t`.

- Each “extra” column in the version of the table having more columns must have a default value.

#### Note

A column's default value is determined by a number of factors, including its type, whether it is defined with a `DEFAULT` option, whether it is declared as `NULL`, and the server SQL mode in effect at the time of its creation; for more

■ information, see [Section 10.1.4, “Data Type Default Values”](#)).

In addition, when the slave's copy of the table has more columns than the master's copy, each column common to the tables must use the same data type in both tables.

**Examples.** The following examples illustrate some valid and invalid table definitions:

- **More columns on the master.** The following table definitions are valid and replicate correctly:

```
master> CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
slave> CREATE TABLE t1 (c1 INT, c2 INT);
```

The following table definitions would raise Error 1532 ([ER\\_BINLOG\\_ROW\\_RBR\\_TO\\_SBR](#)) because the definitions of the columns common to both versions of the table are in a different order on the slave than they are on the master:

```
master> CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
slave> CREATE TABLE t1 (c2 INT, c1 INT);
```

The following table definitions would also raise Error 1532 because the definition of the extra column on the master appears before the definitions of the columns common to both versions of the table:

```
master> CREATE TABLE t1 (c3 INT, c1 INT, c2 INT);
slave> CREATE TABLE t1 (c1 INT, c2 INT);
```

- **More columns on the slave.** The following table definitions are valid and replicate correctly:

```
master> CREATE TABLE t1 (c1 INT, c2 INT);
slave> CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
```

The following definitions raise Error 1532 because the columns common to both versions of the table are not defined in the same order on both the master and the slave:

```
master> CREATE TABLE t1 (c1 INT, c2 INT);
slave> CREATE TABLE t1 (c2 INT, c1 INT, c3 INT);
```

The following table definitions also raise Error 1532 because the definition for the extra column in the slave's version of the table appears before the definitions for the columns which are common to both versions of the table:

```
master> CREATE TABLE t1 (c1 INT, c2 INT);
slave> CREATE TABLE t1 (c3 INT, c1 INT, c2 INT);
```

The following table definitions fail because the slave's version of the table has additional columns compared to the master's version, and the two versions of the table use different data types for the common column `c2`:

```
master> CREATE TABLE t1 (c1 INT, c2 BIGINT);
slave> CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
```

### 16.4.1.7.2. Replication of Columns Having Different Data Types

Corresponding columns on the master's and the slave's copies of the same table ideally should have the same data type. However, beginning with MySQL 5.1.21, this is not always strictly enforced, as long as certain conditions are met.

All other things being equal, it is always possible to replicate from a column of a given data type to another column of the same type and same size or width, where applicable, or larger. For example, you can replicate from a `CHAR(10)` column to another `CHAR(10)`, or from a `CHAR(10)` column to a `CHAR(25)` column without any problems. In certain cases, it is also possible to replicate from a column having one data type (on the master) to a column having a different data type (on the slave); when the data type of the master's version of the column is promoted to a type that is the same size or larger on the slave, this is known as *attribute promotion*.

Attribute promotion can be used with both statement-based and row-based replication, and is not dependent on the storage engine used by either the master or the slave. However, the choice of logging format does have an effect on the type conversions that are permitted; the particulars are discussed later in this section.

#### Important

Whether you use statement-based or row-based replication, the slave's copy of the table cannot contain more columns than the master's copy if you wish to employ attribute promotion.

**Statement-based replication.** When using statement-based replication, a simple rule of thumb to follow is, “If the statement run on the master would also execute successfully on the slave, it should also replicate successfully”. In other words, if the statement uses a value that is compatible with the type of a given column on the slave, the statement can be replicated. For example, you can

insert any value that fits in a `TINYINT` column into a `BIGINT` column as well; it follows that, even if you change the type of a `TINYINT` column in the slave's copy of a table to `BIGINT`, any insert into that column on the master that succeeds should also succeed on the slave, since it is impossible to have a legal `TINYINT` value that is large enough to exceed a `BIGINT` column.

### Note

The restrictions described in the next few paragraphs do not apply to MySQL Cluster Replication, beginning with MySQL Cluster NDB 6.3.33, 7.0.14, and 7.1.3. These and later versions of MySQL Cluster support attribute promotion and demotion (such as `TINYINT` to `BIGINT`, and `VARCHAR(50)` to `CHAR(25)`, respectively) in replication; see [Attribute promotion and demotion \(MySQL Cluster\)](#), for more information.

**Row-based replication.** For row-based replication, the case is not so simple, due to the fact that changes rather than statements are replicated, and these changes are transmitted from master to slave using formats that do not always map directly to MySQL server column data types. For example, with row-based binary logging, you cannot replicate between different `INT` subtypes, such as from `TINYINT` to `BIGINT`, because changes to columns of these types are represented differently from one another in the binary log when using row-based logging. However, you can replicate from `BLOB` to `TEXT` using row-based replication because changes to `BLOB` and `TEXT` columns are represented using the same format in the binary log.

Supported conversions for attribute promotion when using row-based replication are shown in the following table:

From (Master)	To (Slave)
<code>BINARY</code>	<code>CHAR</code>
<code>BLOB</code>	<code>TEXT</code>
<code>CHAR</code>	<code>BINARY</code>
<code>DECIMAL</code>	<code>NUMERIC</code>
<code>NUMERIC</code>	<code>DECIMAL</code>
<code>TEXT</code>	<code>BLOB</code>
<code>VARBINARY</code>	<code>VARCHAR</code>
<code>VARCHAR</code>	<code>VARBINARY</code>

### Note

In all cases, the size or width of the column on the slave must be equal to or greater than that of the column on the master. For example, you can replicate from a `CHAR(10)` column on the master to a column that uses `BINARY(10)` or `BINARY(25)` on the slave, but you cannot replicate from a `CHAR(10)` column on the master to `BINARY(5)` column on the slave.

For `DECIMAL` and `NUMERIC` columns, both the mantissa (*M*) and the number of decimals (*D*) must be the same size or larger on the slave as compared with the master. For example, replication from a `NUMERIC(5,4)` to a `DECIMAL(6,4)` works, but not from a `NUMERIC(5,4)` to a `DECIMAL(5,3)`.

MySQL (except for MySQL Cluster, as described elsewhere in this section) does *not* support attribute promotion of any of the following data types to or from any other data type when using row-based replication:

- `INT` (including `TINYINT`, `SMALLINT`, `MEDIUMINT`, `BIGINT`). Promotion between `INT` subtypes—for example, from `SMALLINT` to `BIGINT`—is also not supported.
- `SET` or `ENUM`.
- `FLOAT` or `DOUBLE`.
- All of the data types relating to dates, times, or both: `DATE`, `TIME`, `DATETIME`, `TIMESTAMP`, and `YEAR`.

**Attribute promotion and demotion (MySQL Cluster).** Beginning with MySQL Cluster NDB 6.3.33, 7.0.14, and 7.1.3, MySQL Cluster Replication supports attribute promotion and demotion between smaller data types and larger types. It is also possible to specify whether or not to permit lossy (truncated) or non-lossy conversions of demoted column values, as explained later in this section.

**Lossy and non-lossy conversions.** In the event that the target type cannot represent the value being inserted, a decision must be made on how to handle the conversion. If we permit the conversion but truncate (or otherwise modify) the source value to achieve a “fit” in the target column, we make what is known as a *lossy conversion*. A conversion which does not require truncation or similar modifications to fit the source column value in the target column is a *non-lossy* conversion.

**Type conversion modes (`slave_type_conversions` variable).** The setting of the `slave_type_conversions` global

server variable controls the type conversion mode used on the slave. This variable takes a set of values from the following table, which shows the effects of each mode on the slave's type-conversion behavior:

Mode	Effect
<code>ALL_LOSSY</code>	<p>In this mode, type conversions that would mean loss of information are permitted.</p> <p>This does not imply that non-lossy conversions are permitted, merely that only cases requiring either lossy conversions or no conversion at all are permitted; for example, enabling <i>only</i> this mode permits an <code>INT</code> column to be converted to <code>TINYINT</code> (a lossy conversion), but not <code>TINYINT</code> column to an <code>INT</code> column (non-lossy). Attempting the latter conversion in this case would cause replication to stop with an error on the slave.</p>
<code>ALL_NON_LOSSY</code>	<p>This mode permits conversions that do not require truncation or other special handling of the source value; that is, it permits conversions where the source type has a wider range than the target type.</p> <p>Setting this mode has no bearing on whether lossy conversions are permitted; this is controlled with the <code>ALL_LOSSY</code> mode. If only <code>ALL_NON_LOSSY</code> is set, but not <code>ALL_LOSSY</code>, then attempting a conversion that would result in the loss of data (such as <code>INT</code> to <code>TINYINT</code>, or <code>CHAR(25)</code> to <code>VARCHAR(20)</code>) causes the slave to stop with an error.</p>
<code>ALL_LOSSY, ALL_NON_LOSSY</code>	When this mode is set, all supported type conversions are permitted, whether or not they are lossy conversions.
[empty]	<p>When <code>slave_type_conversions</code> is not set, no attribute promotion or demotion is permitted; this means that all columns in the source and target tables must be of the same types.</p> <p>This mode is the default.</p>

Changing the type conversion mode requires restarting the slave with the new `slave_type_conversions` setting.

**Supported conversions.** Supported conversions between different but similar data types are shown in the following list:

- Between any of the integer types `TINYINT`, `SMALLINT`, `MEDIUMINT`, `INT`, and `BIGINT`.

This includes conversions between the signed and unsigned versions of these types.

Lossy conversions are made by truncating the source value to the maximum (or minimum) permitted by the target column. For insuring non-lossy conversions when going from unsigned to signed types, the target column must be large enough to accommodate the range of values in the source column. For example, you can demote `TINYINT UNSIGNED` non-lossily to `SMALLINT`, but not to `TINYINT`.

- Between any of the decimal types `DECIMAL`, `FLOAT`, `DOUBLE`, and `NUMERIC`.

`FLOAT` to `DOUBLE` is a non-lossy conversion; `DOUBLE` to `FLOAT` can only be handled lossily. A conversion from `DECIMAL(M,D)` to `DECIMAL(M',D')` where  $M' \Rightarrow M$  and  $D' \Rightarrow D$  is non-lossy; for any case where  $M' < M, D' < D$ , or both, only a lossy conversion can be made.

For any of the decimal types, if a value to be stored cannot be fit in the target type, the value is rounded down according to the rounding rules defined for the server elsewhere in the documentation. See [Section 11.18.4, “Rounding Behavior”](#), for information about how this is done for decimal types.

- Between any of the string types `CHAR`, `VARCHAR`, and `TEXT`, including conversions between different widths.

Conversion of a `CHAR`, `VARCHAR`, or `TEXT` to a `CHAR`, `VARCHAR`, or `TEXT` column the same size or larger is never lossy. Lossy conversion is handled by inserting only the first  $N$  characters of the string on the slave, where  $N$  is the width of the target column.

### Important

Replication between columns using different character sets is not supported.

- Between any of the binary data types `BINARY`, `VARBINARY`, and `BLOB`, including conversions between different widths.

Conversion of a `BINARY`, `VARBINARY`, or `BLOB` to a `BINARY`, `VARBINARY`, or `BLOB` column the same size or larger is never lossy. Lossy conversion is handled by inserting only the first  $N$  bytes of the string on the slave, where  $N$  is the width of the target column.

- Between any 2 `BIT` columns of any 2 sizes.

When inserting a value from a `BIT(M)` column into a `BIT(M')` column, where  $M' > M$ , the most significant bits of the `BIT(M')` columns are cleared (set to zero) and the  $M$  bits of the `BIT(M)` value are set as the least significant bits of the `BIT(M')` column.

When inserting a value from a source `BIT(M)` column into a target `BIT(M')` column, where  $M' < M$ , the maximum possible value for the `BIT(M')` column is assigned; in other words, an “all-set” value is assigned to the target column.

Conversions between types not in the previous list are not permitted.

#### 16.4.1.8. Replication and `DIRECTORY` Table Options

If a `DATA DIRECTORY` or `INDEX DIRECTORY` table option is used in a `CREATE TABLE` statement on the master server, the table option is also used on the slave. This can cause problems if no corresponding directory exists in the slave host file system or if it exists but is not accessible to the slave server. This can be overridden by using the `NO_DIR_IN_CREATE` server SQL mode on the slave, which causes the slave to ignore the `DATA DIRECTORY` and `INDEX DIRECTORY` table options when replicating `CREATE TABLE` statements. The result is that `MyISAM` data and index files are created in the table's database directory.

For more information, see [Section 5.1.7, “Server SQL Modes”](#).

#### 16.4.1.9. Replication of Invoked Features

Replication of invoked features such as user-defined functions (UDFs) and stored programs (stored procedures and functions, triggers, and events) was re-implemented in MySQL 5.1.18 to provide the following characteristics:

- The effects of the feature are always replicated.
- The following statements are replicated using statement-based replication:
  - `CREATE EVENT`
  - `ALTER EVENT`
  - `DROP EVENT`
  - `CREATE PROCEDURE`
  - `DROP PROCEDURE`
  - `CREATE FUNCTION`
  - `DROP FUNCTION`
  - `CREATE TRIGGER`
  - `DROP TRIGGER`

However, the *effects* of features created, modified, or dropped using these statements are replicated using row-based replication.

##### Note

Attempting to replicate invoked features using statement-based replication produces the warning `STATEMENT MAY NOT BE SAFE TO LOG IN STATEMENT FORMAT`. (Prior to MySQL 5.1.36, this was `STATEMENT IS NOT SAFE TO LOG IN STATEMENT FORMAT`; see [Bug#42415](#).) For example, trying to replicate a UDF with statement-based replication generates this warning because it currently cannot be determined by the MySQL server whether the UDF is deterministic. If you are absolutely certain that the invoked feature's effects are deterministic, you can safely disregard such warnings.

- In the case of `CREATE EVENT` and `ALTER EVENT`:
  - The status of the event is set to `SLAVESIDE_DISABLED` on the slave regardless of the state specified (this does not apply to `DROP EVENT`).
  - The master on which the event was created is identified on the slave by its server ID. The `ORIGINATOR` column in `INFORMATION_SCHEMA.EVENTS` and the `originator` column in `mysql.event` were added to these tables in MySQL 5.1.18 to store this information. See [Section 20.20, “The INFORMATION\\_SCHEMA EVENTS Table”](#), and [Section 12.4.5.19, “SHOW EVENTS Syntax”](#), for more information.
- The feature implementation resides on the slave in a renewable state so that if the master fails, the slave can be used as the mas-

ter without loss of event processing.

To determine whether there are any scheduled events on a MySQL server that were created on a different server (that was acting as a replication master), query the `INFORMATION_SCHEMA.EVENTS` table in a manner similar to what is shown here:

```
SELECT EVENT_SCHEMA, EVENT_NAME
 FROM INFORMATION_SCHEMA.EVENTS
 WHERE STATUS = 'SLAVESIDE_DISABLED';
```

Alternatively, you can use the `SHOW EVENTS` statement, like this:

```
SHOW EVENTS
 WHERE STATUS = 'SLAVESIDE_DISABLED';
```

When promoting a replication slave having such events to a replication master, you must enable each event using `ALTER EVENT event_name ENABLED`, where `event_name` is the name of the event. You can do this with a stored procedure, such as the one shown here:

```
CREATE PROCEDURE enable_events()
BEGIN
 DECLARE done INT DEFAULT 0;
 DECLARE db, name VARCHAR(64);

 DECLARE cur CURSOR FOR
 SELECT EVENT_SCHEMA, EVENT_NAME
 FROM INFORMATION_SCHEMA.EVENTS
 WHERE STATUS = 'SLAVESIDE_DISABLED';

 DECLARE CONTINUE HANDLER FOR NOT FOUND SET done = 1;

 OPEN cur;

 REPEAT
 FETCH cur INTO db, name;
 IF NOT done THEN
 SET @str = CONCAT('ALTER EVENT ', db, '.', name, ' ENABLE');
 PREPARE stmt FROM @str;
 EXECUTE stmt;
 DEALLOCATE PREPARE stmt;
 END IF;
 UNTIL done END REPEAT;

 CLOSE cur;
END
```

If more than one master was involved in creating events on this slave, and you wish to identify events that were created only on a given master having the server ID `master_id`, modify the previous query on the `EVENTS` table to include the `ORIGINATOR` column, as shown here:

```
SELECT EVENT_SCHEMA, EVENT_NAME, ORIGINATOR
 FROM INFORMATION_SCHEMA.EVENTS
 WHERE STATUS = 'SLAVESIDE_DISABLED'
 AND ORIGINATOR = 'master_id'
```

You can employ `ORIGINATOR` with the `SHOW EVENTS` statement in a similar fashion:

```
SHOW EVENTS
 WHERE STATUS = 'SLAVESIDE_DISABLED'
 AND ORIGINATOR = 'master_id'
```

Before enabling events that were replicated from the master, you should disable the MySQL Event Scheduler on the slave (using a statement such as `SET GLOBAL event_scheduler = OFF;`), run any necessary `ALTER EVENT` statements, restart the server, then re-enable the Event Scheduler on the slave afterward (using a statement such as `SET GLOBAL event_scheduler = ON;`).

If you later demote the new master back to being a replication slave, you must disable manually all events enabled by the `UPDATE` statement. You can do this by storing in a separate table the event names from the `SELECT` statement shown previously, or using an `UPDATE` statement to rename the events with a common prefix to identify them. We can incorporate the latter action into a new stored procedure that also accepts the master's server ID as a parameter:

```
CREATE PROCEDURE enable_events_from(IN server_id BIGINT)
BEGIN
 DECLARE done INT DEFAULT 0;
 DECLARE db, name VARCHAR(64);
 DECLARE orig BIGINT;

 DECLARE cur CURSOR FOR
 SELECT EVENT_SCHEMA, EVENT_NAME, ORIGINATOR
 FROM INFORMATION_SCHEMA.EVENTS
```

```

 WHERE STATUS = 'SLAVESIDE_DISABLED';

DECLARE CONTINUE HANDLER FOR NOT FOUND SET done = 1;

OPEN cur;

REPEAT
 FETCH cur INTO db, name, orig;
 IF NOT done THEN
 SET @str = CONCAT('ALTER EVENT ', db, '.', name,
 ' RENAME TO ', CONCAT(db, '.replicated_', name),
 ' ENABLE');
 PREPARE stmt FROM @str;
 EXECUTE stmt;
 DEALLOCATE PREPARE stmt;
 END IF;
 END IF;
 UNTIL done END REPEAT;

CLOSE cur;
END

```

When demoting this server back to being a replication slave, you can identify these renamed events by querying the `EVENTS` table, as shown here:

```

SELECT CONCAT(EVENT_SCHEMA, '.', EVENT_NAME) AS 'Db.Event'
 FROM INFORMATION_SCHEMA.EVENTS
 WHERE INSTR(EVENT_NAME, 'replicated_') = 1;

```

You can rename and disable these events using a stored procedure like this one:

```

CREATE PROCEDURE disable_replicated_events()
BEGIN
 DECLARE done INT DEFAULT 0;
 DECLARE db, name VARCHAR(64);

 DECLARE cur CURSOR FOR
 SELECT EVENT_SCHEMA, EVENT_NAME
 FROM INFORMATION_SCHEMA.EVENTS
 WHERE INSTR(EVENT_NAME, 'replicated_') = 1;

 DECLARE CONTINUE HANDLER FOR NOT FOUND SET done = 1;

 OPEN cur;

 REPEAT
 FETCH cur INTO db, name;
 IF NOT done THEN
 SET @str = CONCAT('ALTER EVENT ', db, '.', name,
 ' RENAME TO ', db, '.' REPLACE(name, 'replicated_', ''),
 ' SLAVESIDE_DISABLED');
 PREPARE stmt FROM @str;
 EXECUTE stmt;
 DEALLOCATE PREPARE stmt;
 END IF;
 END IF;
 UNTIL done END REPEAT;

 CLOSE cur;
END

```

### 16.4.1.10. Replication and Floating-Point Values

With statement-based replication, values are converted from decimal to binary. Because conversions between decimal and binary representations of them may be approximate, comparisons involving floating-point values are inexact. This is true for operations that use floating-point values explicitly, or that use values that are converted to floating-point implicitly. Comparisons of floating-point values might yield different results on master and slave servers due to differences in computer architecture, the compiler used to build MySQL, and so forth. See [Section 11.2, “Type Conversion in Expression Evaluation”](#), and [Section B.5.5.8, “Problems with Floating-Point Values”](#).

### 16.4.1.11. Replication and `FLUSH`

Some forms of the `FLUSH` statement are not logged because they could cause problems if replicated to a slave: `FLUSH LOGS`, `FLUSH MASTER`, `FLUSH SLAVE`, and `FLUSH TABLES WITH READ LOCK`. For a syntax example, see [Section 12.4.6.3, “`FLUSH` Syntax”](#). The `FLUSH TABLES`, `ANALYZE TABLE`, `OPTIMIZE TABLE`, and `REPAIR TABLE` statements are written to the binary log and thus replicated to slaves. This is not normally a problem because these statements do not modify table data.

However, this behavior can cause difficulties under certain circumstances. If you replicate the privilege tables in the `mysql` database and update those tables directly without using `GRANT`, you must issue a `FLUSH PRIVILEGES` on the slaves to put the new privileges into effect. In addition, if you use `FLUSH TABLES` when renaming a `MyISAM` table that is part of a `MERGE` table, you must issue `FLUSH TABLES` manually on the slaves. These statements are written to the binary log unless you specify `NO_WRITE_TO_BINLOG` or its alias `LOCAL`.

### 16.4.1.12. Replication and System Functions

Certain functions do not replicate well under some conditions:

- The `USER()`, `CURRENT_USER()` (or `CURRENT_USER`), `UUID()`, `VERSION()`, `LOAD_FILE()`, and `RAND()` functions are replicated without change and thus do not work reliably on the slave unless row-based replication is enabled. (See [Section 16.1.2, “Replication Formats”](#).)

For early implementations of mixed-format logging, stored functions, triggers, and views that use these functions in their body do not replicate reliably in mixed-format logging mode because the logging did not switch from statement-based to row-based format. For example, `INSERT INTO t SELECT FROM v`, where `v` is a view that selects `UUID()` could cause problems. This limitation is lifted in MySQL 5.1.12.

Beginning with MySQL 5.1.23, `USER()` and `CURRENT_USER()` are automatically replicated using row-based replication when using `MIXED` mode, and generate a warning in `STATEMENT` mode. ([Bug#28086](#)) Beginning with MySQL 5.1.42, the same is true for `VERSION()`. ([Bug#47995](#)) Beginning with MySQL 5.1.43, this is also true with regard to the `RAND()` function. ([Bug#49222](#))

- For `NOW()`, the binary log includes the timestamp. This means that the value *as returned by the call to this function on the master* is replicated to the slave. This can lead to a possibly unexpected result when replicating between MySQL servers in different time zones. Suppose that the master is located in New York, the slave is located in Stockholm, and both servers are using local time. Suppose further that, on the master, you create a table `mytable`, perform an `INSERT` statement on this table, and then select from the table, as shown here:

```
mysql> CREATE TABLE mytable (mycol TEXT);
Query OK, 0 rows affected (0.06 sec)

mysql> INSERT INTO mytable VALUES (NOW());
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM mytable;
+-----+
| mycol |
+-----+
| 2009-09-01 12:00:00 |
+-----+
1 row in set (0.00 sec)
```

Local time in Stockholm is 6 hours later than in New York; so, if you issue `SELECT NOW()` on the slave at that exact same instant, the value `2009-09-01 18:00:00` is returned. For this reason, if you select from the slave's copy of `mytable` after the `CREATE TABLE` and `INSERT` statements just shown have been replicated, you might expect `mycol` to contain the value `2009-09-01 18:00:00`. However, this is not the case; when you select from the slave's copy of `mytable`, you obtain exactly the same result as on the master:

```
mysql> SELECT * FROM mytable;
+-----+
| mycol |
+-----+
| 2009-09-01 12:00:00 |
+-----+
1 row in set (0.00 sec)
```

Unlike `NOW()`, the `SYSDATE()` function is not replication-safe because it is not affected by `SET TIMESTAMP` statements in the binary log and is nondeterministic if statement-based logging is used. This is not a problem if row-based logging is used.

An alternative is to use the `--sysdate-is-now` option to cause `SYSDATE()` to be an alias for `NOW()`. This must be done on the master and the slave to work correctly. In such cases, a warning is still issued by this function, but can safely be ignored as long as `--sysdate-is-now` is used on both the master and the slave.

Beginning with MySQL 5.1.42, `SYSDATE()` is automatically replicated using row-based replication when using `MIXED` mode, and generates a warning in `STATEMENT` mode. ([Bug#47995](#))

See also [Section 16.4.1.27, “Replication and Time Zones”](#).

- The following restriction applies to statement-based replication only, not to row-based replication.* The `GET_LOCK()`, `RELEASE_LOCK()`, `IS_FREE_LOCK()`, and `IS_USED_LOCK()` functions that handle user-level locks are replicated without the slave knowing the concurrency context on the master. Therefore, these functions should not be used to insert into a master table because the content on the slave would differ. For example, do not issue a statement such as `INSERT INTO mytable VALUES(GET_LOCK(...))`.

Beginning with MySQL 5.1.42, these functions are automatically replicated using row-based replication when using `MIXED` mode, and generate a warning in `STATEMENT` mode. ([Bug#47995](#))

As a workaround for the preceding limitations when statement-based replication is in effect, you can use the strategy of saving the problematic function result in a user variable and referring to the variable in a later statement. For example, the following single-row `INSERT` is problematic due to the reference to the `UUID()` function:

```
INSERT INTO t VALUES(UUID());
```

To work around the problem, do this instead:

```
SET @my_uuid = UUID();
INSERT INTO t VALUES(@my_uuid);
```

That sequence of statements replicates because the value of `@my_uuid` is stored in the binary log as a user-variable event prior to the `INSERT` statement and is available for use in the `INSERT`.

The same idea applies to multiple-row inserts, but is more cumbersome to use. For a two-row insert, you can do this:

```
SET @my_uuid1 = UUID(); @my_uuid2 = UUID();
INSERT INTO t VALUES(@my_uuid1), (@my_uuid2);
```

However, if the number of rows is large or unknown, the workaround is difficult or impracticable. For example, you cannot convert the following statement to one in which a given individual user variable is associated with each row:

```
INSERT INTO t2 SELECT UUID(), * FROM t1;
```

Within a stored function, `RAND()` replicates correctly as long as it is invoked only once during the execution of the function. (You can consider the function execution timestamp and random number seed as implicit inputs that are identical on the master and slave.)

The `FOUND_ROWS()` and `ROW_COUNT()` functions are not replicated reliably using statement-based replication. A workaround is to store the result of the function call in a user variable, and then use that in the `INSERT` statement. For example, if you wish to store the result in a table named `mytable`, you might normally do so like this:

```
SELECT SQL_CALC_FOUND_ROWS FROM mytable LIMIT 1;
INSERT INTO mytable VALUES(FOUND_ROWS());
```

However, if you are replicating `mytable`, you should use `SELECT INTO`, and then store the variable in the table, like this:

```
SELECT SQL_CALC_FOUND_ROWS INTO @found_rows FROM mytable LIMIT 1;
INSERT INTO mytable VALUES(@found_rows);
```

In this way, the user variable is replicated as part of the context, and applied on the slave correctly.

Beginning with MySQL 5.1.23, these functions are automatically replicated using row-based replication when using `MIXED` mode, and generate a warning in `STATEMENT` mode. ([Bug#12092](#), [Bug#30244](#))

### 16.4.1.13. Replication and `LIMIT`

Statement-based replication of `LIMIT` clauses in `DELETE`, `UPDATE`, and `INSERT ... SELECT` statements is unsafe since the order of the rows affected is not defined. (Such statements can be replicated correctly with statement-based replication only if they also contain an `ORDER BY` clause.) Beginning with MySQL 5.1.24, when such a statement is encountered:

- When using `STATEMENT` mode, a warning that the statement is not safe for statement-based replication is now issued. Currently, when using `STATEMENT` mode, warnings are issued for DML statements containing `LIMIT` even when they also have an `ORDER BY` clause (and so are made deterministic). This is a known issue. ([Bug#42851](#))
- When using `MIXED` mode, the statement is now automatically replicated using row-based mode.

### 16.4.1.14. Replication and `LOAD DATA INFILE`

The `LOAD DATA INFILE` statement was not always replicated correctly to a slave running MySQL 5.1.42 or earlier from a master running MySQL 4.0 or earlier. When using statement-based replication, the `LOAD DATA INFILE` statement `CONCURRENT` option was not replicated. This issue was fixed in MySQL 5.1.43. This issue does not have any impact on `CONCURRENT` option handling when using row-based replication in MySQL 5.1 or later. ([Bug#34628](#))

In MySQL 5.1.50 and later, `LOAD DATA INFILE` is considered unsafe (see [Section 16.1.2.3, “Safe and Unsafe Statements in Logging and Replication”](#)). It causes a warning when using statement-based logging format, and is logged using row-based format when using mixed-format logging.

### 16.4.1.15. Replication and the Slow Query Log

Prior to MySQL 5.1.45, replication slaves did not write replicated queries to the slow query log, even if the same queries were written to the slow query log on the master. ([Bug#23300](#))

### 16.4.1.16. Replication and REPAIR TABLE

When used on a corrupted or otherwise damaged table, it is possible for the `REPAIR TABLE` statement to delete rows that cannot be recovered. However, any such modifications of table data performed by this statement are not replicated, which can cause master and slave to lose synchronization. For this reason, in the event that a table on the master becomes damaged and you use `REPAIR TABLE` to repair it, you should first stop replication (if it is still running) before using `REPAIR TABLE`, then afterward compare the master's and slave's copies of the table and be prepared to correct any discrepancies manually, before restarting replication.

### 16.4.1.17. Replication and Master or Slave Shutdowns

It is safe to shut down a master server and restart it later. When a slave loses its connection to the master, the slave tries to reconnect immediately and retries periodically if that fails. The default is to retry every 60 seconds. This may be changed with the `CHANGE MASTER TO` statement or `--master-connect-retry` option. A slave also is able to deal with network connectivity outages. However, the slave notices the network outage only after receiving no data from the master for `slave_net_timeout` seconds. If your outages are short, you may want to decrease `slave_net_timeout`. See [Section 5.1.4, “Server System Variables”](#).

An unclean shutdown (for example, a crash) on the master side can result in the master binary log having a final position less than the most recent position read by the slave, due to the master binary log file not being flushed. This can cause the slave not to be able to replicate when the master comes back up. Setting `sync_binlog=1` in the master `my.cnf` file helps to minimize this problem because it causes the master to flush its binary log more frequently.

Shutting down a slave cleanly is safe because it keeps track of where it left off. However, be careful that the slave does not have temporary tables open; see [Section 16.4.1.20, “Replication and Temporary Tables”](#). Unclean shutdowns might produce problems, especially if the disk cache was not flushed to disk before the problem occurred:

- For transactions, the slave commits and then updates `relay-log.info`. If a crash occurs between these two operations, relay log processing will have proceeded further than the information file indicates and the slave will re-execute the events from the last transaction in the relay log after it has been restarted.
- A similar problem can occur if the slave updates `relay-log.info` but the server host crashes before the write has been flushed to disk. Writes are not forced to disk because the server relies on the operating system to flush the file from time to time.

The fault tolerance of your system for these types of problems is greatly increased if you have a good uninterruptible power supply.

### 16.4.1.18. Replication and max\_allowed\_packet

`max_allowed_packet` sets an upper limit on the size of any single message between the MySQL server and clients, including replication slaves. If you are replicating large column values (such as might be found in `TEXT` or `BLOB` columns) and `max_allowed_packet` is too small on the master, the master fails with an error, and the slave shuts down the I/O thread. If `max_allowed_packet` is too small on the slave, this also causes the slave to stop the I/O thread.

Prior to MySQL 5.1.40, `Last_IO_Error` and `Last_IO_Errno` in the output of `SHOW SLAVE STATUS` were not set in the event that replication failed due to exceeding `max_allowed_packet` ([Bug#42914](#)).

Row-based replication currently sends all columns and column values for updated rows from the master to the slave, including values of columns that were not actually changed by the update. This means that, when you are replicating large column values using row-based replication, you must take care to set `max_allowed_packet` large enough to accommodate the largest row in any table to be replicated, even if you are replicating updates only, or you are inserting only relatively small values.

### 16.4.1.19. Replication and MEMORY Tables

When a master server shuts down and restarts, its `MEMORY` tables become empty. To replicate this effect to slaves, the first time that the master uses a given `MEMORY` table after startup, it logs an event that notifies slaves that the table must to be emptied by writing a `DELETE` statement for that table to the binary log.

When a slave server shuts down and restarts, its `MEMORY` tables become empty. This causes the slave to be out of synchrony with the master and may lead to other failures or cause the slave to stop:

- Row-format updates and deletes received from the master may fail with `Can't find record in 'memory_table'`.
- Statements such as `INSERT INTO ... SELECT FROM memory_table` may insert a different set of rows on the master and slave.

The safe way to restart a slave that is replicating `MEMORY` tables is to first drop or delete all rows from the `MEMORY` tables on the master and wait until those changes have replicated to the slave. Then it is safe to restart the slave.

An alternative restart method may apply in some cases. When `binlog_format=ROW`, you can prevent the slave from stopping if you set `slave_exec_mode=IDEMPOTENT` before you start the slave again. This allows the slave to continue to replicate, but its `MEMORY` tables will still be different from those on the master. This can be okay if the application logic is such that the contents of `MEMORY` tables can be safely lost (for example, if the `MEMORY` tables are used for caching). `slave_exec_mode=IDEMPOTENT` applies globally to all tables, so it may hide other replication errors in non-`MEMORY` tables.

See [Section 13.9, “The `MEMORY` Storage Engine”](#), for more information about `MEMORY` tables.

#### 16.4.1.20. Replication and Temporary Tables

This section does not apply when row-based replication is in use because in that case temporary tables are not replicated. It does apply with mixed-format replication for statements involving temporary tables that can be logged safely using statement-based format. See [Section 16.1.2.2, “Usage of Row-Based Logging and Replication”](#).

**Safe slave shutdown when using temporary tables.** Temporary tables are replicated except in the case where you stop the slave server (not just the slave threads) and you have replicated temporary tables that are open for use in updates that have not yet been executed on the slave. If you stop the slave server, the temporary tables needed by those updates are no longer available when the slave is restarted. To avoid this problem, do not shut down the slave while it has temporary tables open. Instead, use the following procedure:

1. Issue a `STOP SLAVE SQL_THREAD` statement.
2. Use `SHOW STATUS` to check the value of the `Slave_open_temp_tables` variable.
3. If the value is not 0, restart the slave SQL thread with `START SLAVE SQL_THREAD` and repeat the procedure later.
4. When the value is 0, issue a `mysqladmin shutdown` command to stop the slave.

**Temporary tables and replication options.** By default, all temporary tables are replicated; this happens whether or not there are any matching `--replicate-do-db`, `--replicate-do-table`, or `--replicate-wild-do-table` options in effect. However, the `--replicate-ignore-table` and `--replicate-wild-ignore-table` options are honored for temporary tables.

A recommended practice when using statement-based or mixed-format replication is to designate a prefix for exclusive use in naming temporary tables that you do not want replicated, then employ a `--replicate-wild-ignore-table` option to match that prefix. For example, you might give all such tables names beginning with `norep` (such as `norepmutable`, `norepyourtable`, and so on), then use `--replicate-wild-ignore-table=norep%` to prevent them from being replicated.

#### 16.4.1.21. Replication of the `mysql` System Database

**MySQL 5.1.14 and later.** Data modification statements made to tables in the `mysql` database are replicated according to the value of `binlog_format`; if this value is `MIXED`, these statements are replicated using the row-based format. However, statements that would normally update this information indirectly—such `GRANT`, `REVOKE`, and statements manipulating triggers, stored routines, and views—are replicated to slaves using statement-based replication.

**MySQL 5.1.13 and earlier.** User privileges are replicated only if the `mysql` database is replicated. That is, the `GRANT`, `REVOKE`, `SET PASSWORD`, `CREATE USER`, and `DROP USER` statements take effect on the slave only if the replication setup includes the `mysql` database.

#### 16.4.1.22. Replication and the Query Optimizer

It is possible for the data on the master and slave to become different if a statement is written in such a way that the data modification is nondeterministic; that is, left up the query optimizer. (In general, this is not a good practice, even outside of replication.) Examples of nondeterministic statements include `DELETE` or `UPDATE` statements that use `LIMIT` with no `ORDER BY` clause; see [Section 16.4.1.13, “Replication and `LIMIT`”](#), for a detailed discussion of these.

#### 16.4.1.23. Replication and Reserved Words

You can encounter problems when you attempt to replicate from an older master to a newer slave and you make use of identifiers

on the master that are reserved words in the newer MySQL version running on the slave. An example of this is using a table column named `current_user` on a 4.0 master that is replicating to a 4.1 or higher slave because `CURRENT_USER` is a reserved word beginning in MySQL 4.1. Replication can fail in such cases with Error 1064 `YOU HAVE AN ERROR IN YOUR SQL SYNTAX . . . , even if a database or table named using the reserved word or a table having a column named using the reserved word is excluded from replication.` This is due to the fact that each SQL event must be parsed by the slave prior to execution, so that the slave knows which database object or objects would be affected; only after the event is parsed can the slave apply any filtering rules defined by `--replicate-do-db`, `--replicate-do-table`, `--replicate-ignore-db`, and `--replicate-ignore-table`.

To work around the problem of database, table, or column names on the master which would be regarded as reserved words by the slave, do one of the following:

- Use one or more `ALTER TABLE` statements on the master to change the names of any database objects where these names would be considered reserved words on the slave, and change any SQL statements that use the old names to use the new names instead.
- In any SQL statements using these database object names, write the names as quoted identifiers using backtick characters (`).

For listings of reserved words by MySQL version, see [Reserved Words](#), in the *MySQL Server Version Reference*. For identifier quoting rules, see [Section 8.2, “Schema Object Names”](#).

#### 16.4.1.24. Slave Errors During Replication

If a statement produces the same error (identical error code) on both the master and the slave, the error is logged, but replication continues.

If a statement produces different errors on the master and the slave, the slave SQL thread terminates, and the slave writes a message to its error log and waits for the database administrator to decide what to do about the error. This includes the case that a statement produces an error on the master or the slave, but not both. To address the issue, connect to the slave manually and determine the cause of the problem. `SHOW SLAVE STATUS` is useful for this. Then fix the problem and run `START SLAVE`. For example, you might need to create a nonexistent table before you can start the slave again.

If this error code validation behavior is not desirable, some or all errors can be masked out (ignored) with the `--slave-skip-errors` option.

For nontransactional storage engines such as `MyISAM`, it is possible to have a statement that only partially updates a table and returns an error code. This can happen, for example, on a multiple-row insert that has one row violating a key constraint, or if a long update statement is killed after updating some of the rows. If that happens on the master, the slave expects execution of the statement to result in the same error code. If it does not, the slave SQL thread stops as described previously.

If you are replicating between tables that use different storage engines on the master and slave, keep in mind that the same statement might produce a different error when run against one version of the table, but not the other, or might cause an error for one version of the table, but not the other. For example, since `MyISAM` ignores foreign key constraints, an `INSERT` or `UPDATE` statement accessing an `InnoDB` table on the master might cause a foreign key violation but the same statement performed on a `MyISAM` version of the same table on the slave would produce no such error, causing replication to stop.

#### 16.4.1.25. Replication and Server SQL Mode

Using different server SQL mode settings on the master and the slave may cause the same `INSERT` statements to be handled differently on the master and the slave, leading the master and slave to diverge. For best results, you should always use the same server SQL mode on the master and on the slave. This advice applies whether you are using statement-based or row-based replication.

If you are replicating partitioned tables, using different SQL modes on the master and the slave is likely to cause issues. At a minimum, this is likely to cause the distribution of data among partitions to be different in the master's and slave's copies of a given table. It may also cause inserts into partitioned tables that succeed on the master to fail on the slave.

For more information, see [Section 5.1.7, “Server SQL Modes”](#).

#### 16.4.1.26. Replication Retries and Timeouts

The global system variable `slave_transaction_retries` affects replication as follows: If the slave SQL thread fails to execute a transaction because of an `InnoDB` deadlock or because it exceeded the `InnoDB innodb_lock_wait_timeout` value, or the `NDBCLUSTER TransactionDeadlockDetectionTimeout` or `TransactionInactiveTimeout` value, the slave automatically retries the transaction `slave_transaction_retries` times before stopping with an error. The default value is 10. The total retry count can be seen in the output of `SHOW STATUS`; see [Section 5.1.6, “Server Status Variables”](#).

#### 16.4.1.27. Replication and Time Zones

---

The same system time zone should be set for both master and slave. Otherwise, statements depending on the local time on the master are not replicated properly, such as statements that use the `NOW()` or `FROM_UNIXTIME()` functions. You can set the time zone in which MySQL server runs by using the `--timezone=timezone_name` option of the `mysqld_safe` script or by setting the `TZ` environment variable. See also [Section 16.4.1.12, “Replication and System Functions”](#).

If the master is MySQL 4.1 or earlier, both master and slave should also use the same default connection time zone. That is, the `--default-time-zone` parameter should have the same value for both master and slave.

`CONVERT_TZ( . . . , . . . ,@session.time_zone)` is properly replicated only if both master and slave are running MySQL 5.0.4 or newer.

## 16.4.1.28. Replication and Transactions

**Mixing transactional and nontransactional statements within the same transaction.** In general, you should avoid transactions that update both transactional and nontransactional tables in a replication environment. You should also avoid using any statement that accesses both transactional (or temporary) and nontransactional tables and writes to any of them.

As of MySQL 5.1.44, the server uses these rules for binary logging:

- If the initial statements in a transaction are nontransactional, they are written to the binary log immediately. The remaining statements in the transaction are cached and not written to the binary log until the transaction is committed. (If the transaction is rolled back, the cached statements are written to the binary log only if they make nontransactional changes that cannot be rolled back. Otherwise, they are discarded.)
- For statement-based logging, logging of nontransactional statements is affected by the `bin-log-direct-non-transactional-updates` system variable. When this variable is `OFF` (the default), logging is as just described. When this variable is `ON`, logging occurs immediately for nontransactional statements occurring anywhere in the transaction (not just initial nontransactional statements). Other statements are kept in the transaction cache and logged when the transaction commits. `binlog-direct-non-transactional-updates` has no effect for row-format or mixed-format binary logging.

**Transactional, nontransactional, and mixed statements.** To apply those rules, the server considers a statement nontransactional if it changes only nontransactional tables, and transactional if it changes only transactional tables. A statement that changes both nontransactional and transactional tables is considered “mixed”. Mixed statements, like transactional statements, are cached and logged when the transaction commits.

### Note

A mixed statement is unrelated to mixed binary logging format.

Before MySQL 5.1.44, the rules for binary logging are similar to those just described, except that there is no `bin-log-direct-non-transactional-updates` system variable to affect logging of transactional statements. Thus, the server immediately logs only the initial nontransactional statements in a transaction and caches the rest until commit time.

Before MySQL 5.1.31, the *effect* of the rules differs because the definition of transactional statement is different: In these earlier versions, a statement is nontransactional if the first changes it makes change nontransactional tables, transactional if the first changes it makes change transactional tables. “First” applies in the sense that a statement may have several effects if it involves such things as triggers, stored functions, or multiple-table updates. A mixed statement that changes both nontransactional and transactional tables is handled as nontransactional or transactional depending on the type of changes it makes first.

In situations where transactions mix updates to transactional and nontransactional tables, the order of statements in the binary log is correct, and all needed statements are written to the binary log even in case of a `ROLLBACK`. However, when a second connection updates the nontransactional table before the first connection transaction is complete, statements can be logged out of order because the second connection update is written immediately after it is performed, regardless of the state of the transaction being performed by the first connection.

**Using different storage engines on master and slave.** It is possible to replicate transactional tables on the master using nontransactional tables on the slave. For example, you can replicate an `InnoDB` master table as a `MyISAM` slave table. However, if you do this, there are problems if the slave is stopped in the middle of a `BEGIN ... COMMIT` block because the slave restarts at the beginning of the `BEGIN` block.

Beginning with MySQL 5.1.48, it is also safe to replicate transactions from `MyISAM` tables on the master to transactional tables—such as tables that use the `InnoDB` storage engine—on the slave. In such cases (beginning with MySQL 5.1.48), an `AUTOCOMMIT=1` statement issued on the master is replicated, thus enforcing `AUTOCOMMIT` mode on the slave.

When the storage engine type of the slave is nontransactional, transactions on the master that mix updates of transactional and nontransactional tables should be avoided because they can cause inconsistency of the data between the master transactional table and the slave nontransactional table. That is, such transactions can lead to master storage engine-specific behavior with the possible ef-

fect of replication going out of synchrony. MySQL does not issue a warning about this currently, so extra care should be taken when replicating transactional tables from the master to nontransactional tables on the slaves.

#### 16.4.1.29. Replication and Triggers

With statement-based replication, triggers executed on the master also execute on the slave. With row-based replication, triggers executed on the master do not execute on the slave. Instead, the row changes on the master resulting from trigger execution are replicated and applied on the slave.

This behavior is by design. If under row-based replication the slave applied the triggers as well as the row changes caused by them, the changes would in effect be applied twice on the slave, leading to different data on the master and the slave.

If you want triggers to execute on both the master and the slave—perhaps because you have different triggers on the master and slave—you must use statement-based replication. However, to enable slave-side triggers, it is not necessary to use statement-based replication exclusively. It is sufficient to switch to statement-based replication only for those statements where you want this effect, and to use row-based replication the rest of the time.

Before MySQL 5.1.31, a trigger that was defined on a transactional table but that updated a nontransactional table could cause updates on the transactional table to be replicated before they were actually committed on the master, and not be rolled back correctly on the slave if they were rolled back on the master. ([Bug#40116](#)) See also [Section 16.4.1.28, “Replication and Transactions”](#).

#### 16.4.1.30. Replication and Views

Views are always replicated to slaves. Views are filtered by their own name, not by the tables they refer to. This means that a view can be replicated to the slave even if the view contains a table that would normally be filtered out by `replication-ignore-table` rules. Care should therefore be taken to ensure that views do not replicate table data that would normally be filtered for security reasons.

#### 16.4.1.31. Replication and `TRUNCATE TABLE`

`TRUNCATE TABLE` is normally regarded as a DML statement, and so would be expected to be logged and replicated using row-based format when the binary logging mode is `ROW` or `MIXED`. However this caused issues when logging or replicating, in `STATEMENT` or `MIXED` mode, tables that used transactional storage engines such as `InnoDB` when the transaction isolation level was `READ COMMITTED` or `READ UNCOMMITTED`, which precludes statement-based logging.

Beginning with MySQL 5.1.32, `TRUNCATE TABLE` is treated for purposes of logging and replication as DDL rather than DML so that it can be logged and replicated as a statement. However, the effects of the statement as applicable to `InnoDB` and other transactional tables on replication slaves still follow the rules described in [Section 12.2.10, “`TRUNCATE TABLE` Syntax”](#) governing such tables. ([Bug#36763](#))

#### 16.4.1.32. Replication and Variables

System variables are not replicated correctly when using `STATEMENT` mode, except for the following variables when they are used with session scope:

- `auto_increment_increment`
- `auto_increment_offset`
- `character_set_client`
- `character_set_connection`
- `character_set_database`
- `character_set_server`
- `collation_connection`
- `collation_database`
- `collation_server`
- `foreign_key_checks`
- `identity`
- `last_insert_id`

- `lc_time_names`
- `pseudo_thread_id`
- `sql_auto_is_null`
- `time_zone`
- `timestamp`
- `unique_checks`

When `MIXED` mode is used, the variables in the preceding list, when used with session scope, cause a switch from statement-based to row-based logging. See [Section 5.2.4.3, “Mixed Binary Logging Format”](#).

`sql_mode` is also replicated except for the `NO_DIR_IN_CREATE` mode; the slave always preserves its own value for `NO_DIR_IN_CREATE`, regardless of changes to it on the master. This is true for all replication formats.

However, when `mysqlbinlog` parses a `SET @@sql_mode = mode` statement, the full `mode` value, including `NO_DIR_IN_CREATE`, is passed to the receiving server. For this reason, replication of such a statement may not be safe when `STATEMENT` mode is in use.

The `storage_engine` system variable is not replicated, regardless of the logging mode; this is intended to facilitate replication between different storage engines.

In statement-based replication, session variables are not replicated properly when used in statements that update tables. For example, the following sequence of statements will not insert the same data on the master and the slave:

```
SET max_join_size=1000;
INSERT INTO mytable VALUES(@@max_join_size);
```

This does not apply to the common sequence:

```
SET time_zone=...;
INSERT INTO mytable VALUES(CONVERT_TZ(..., ..., @@time_zone));
```

Replication of session variables is not a problem when row-based replication is being used, in which case, session variables are always replicated safely. See [Section 16.1.2, “Replication Formats”](#).

In MySQL 5.1.20 and later (and in MySQL 5.0.46 and later in MySQL 5.0, for backward compatibility), the following session variables are written to the binary log and honored by the replication slave when parsing the binary log, regardless of the logging format:

- `sql_mode`
- `foreign_key_checks`
- `unique_checks`
- `character_set_client`
- `collation_connection`
- `collation_database`
- `collation_server`
- `sql_auto_is_null`

### Important

Even though session variables relating to character sets and collations are written to the binary log, replication between different character sets is not supported.

## 16.4.2. Replication Compatibility Between MySQL Versions

MySQL supports replication from one major version to the next higher major version. For example, you can replicate from a master running MySQL 4.1 to a slave running MySQL 5.0, from a master running MySQL 5.0 to a slave running MySQL 5.1, and so

on.

The use of more than 2 MySQL Server versions is not supported in replication setups involving multiple masters, regardless of the number of master or slave MySQL servers. This restriction applies not only to major versions, but to minor versions within the same major version as well. For example, if you are using a chained or circular replication setup, you cannot use MySQL 5.1.31, MySQL 5.1.32, and MySQL 5.1.34 concurrently, although you could use any 2 of these releases together.

In some cases, it is also possible to replicate between a master and a slave that is more than one major version newer than the master. However, there are known issues with trying to replicate from a master running MySQL 4.1 or earlier to a slave running MySQL 5.1 or later. To work around such problems, you can insert a MySQL server running an intermediate version between the two; for example, rather than replicating directly from a MySQL 4.1 master to a MySQL 5.1 slave, it is possible to replicate from a MySQL 4.1 server to a MySQL 5.0 server, and then from the MySQL 5.0 server to a MySQL 5.1 server.

### Important

It is strongly recommended to use the most recent release available within a given MySQL major version because replication (and other) capabilities are continually being improved. It is also recommended to upgrade masters and slaves that use early releases of a major version of MySQL to GA (production) releases when the latter become available for that major version.

Replication from newer masters to older slaves may be possible, but is generally not supported. This is due to a number of factors:

- **Binary log format changes.** The binary log format can change between major releases. While we attempt to maintain backward compatibility, this is not always possible. For example, the binary log format implemented in MySQL 5.0 changed considerably from that used in previous versions, especially with regard to handling of character sets, `LOAD DATA INFILE`, and time zones. This means that replication from a MySQL 5.0 (or later) master to a MySQL 4.1 (or earlier) slave is generally not supported.

This also has significant implications for upgrading replication servers; see [Section 16.4.3, “Upgrading a Replication Setup”](#), for more information.

- **Use of row-based replication.** Row-based replication was implemented in MySQL 5.1.5, so you cannot replicate using row-based replication from any MySQL 5.1 or later master to a slave older than MySQL 5.1.5.

For more information about row-based replication, see [Section 16.1.2, “Replication Formats”](#).

- **SQL incompatibilities.** You cannot replicate from a newer master to an older slave using statement-based replication if the statements to be replicated use SQL features available on the master but not on the slave.

However, if both the master and the slave support row-based replication, and there are no data definition statements to be replicated that depend on SQL features found on the master but not on the slave, you can use row-based replication to replicate the effects of data modification statements even if the DDL run on the master is not supported on the slave.

For more information on potential replication issues, see [Section 16.4.1, “Replication Features and Issues”](#).

## 16.4.3. Upgrading a Replication Setup

When you upgrade servers that participate in a replication setup, the procedure for upgrading depends on the current server versions and the version to which you are upgrading.

This section applies to upgrading replication from older versions of MySQL to MySQL 5.1. A 4.0 server should be 4.0.3 or newer.

When you upgrade a master to 5.1 from an earlier MySQL release series, you should first ensure that all the slaves of this master are using the same 5.1.x release. If this is not the case, you should first upgrade the slaves. To upgrade each slave, shut it down, upgrade it to the appropriate 5.1.x version, restart it, and restart replication. The 5.1 slave is able to read the old relay logs written prior to the upgrade and to execute the statements they contain. Relay logs created by the slave after the upgrade are in 5.1 format.

After the slaves have been upgraded, shut down the master, upgrade it to the same 5.1.x release as the slaves, and restart it. The 5.1 master is able to read the old binary logs written prior to the upgrade and to send them to the 5.1 slaves. The slaves recognize the old format and handle it properly. Binary logs created by the master subsequent to the upgrade are in 5.1 format. These too are recognized by the 5.1 slaves.

In other words, when upgrading to MySQL 5.1, the slaves must be MySQL 5.1 before you can upgrade the master to 5.1. Note that downgrading from 5.1 to older versions does not work so simply: You must ensure that any 5.1 binary log or relay log has been fully processed, so that you can remove it before proceeding with the downgrade.

Downgrading a replication setup to a previous version cannot be done once you have switched from statement-based to row-based replication, and after the first row-based statement has been written to the binlog. See [Section 16.1.2, “Replication Formats”](#).

Some upgrades may require that you drop and re-create database objects when you move from one MySQL series to the next. For example, collation changes might require that table indexes be rebuilt. Such operations, if necessary, will be detailed at [Section 2.12.1.1, “Upgrading from MySQL 5.0 to 5.1”](#). It is safest to perform these operations separately on the slaves and the master, and to disable replication of these operations from the master to the slave. To achieve this, use the following procedure:

1. Stop all the slaves and upgrade them. Restart them with the `--skip-slave-start` option so that they do not connect to the master. Perform any table repair or rebuilding operations needed to re-create database objects, such as use of `REPAIR TABLE` or `ALTER TABLE`, or dumping and reloading tables or triggers.
2. Disable the binary log on the master. To do this without restarting the master, execute a `SET sql_log_bin = 0` statement. Alternatively, stop the master and restart it without the `--log-bin` option. If you restart the master, you might also want to disallow client connections. For example, if all clients connect using TCP/IP, use the `--skip-networking` option when you restart the master.
3. With the binary log disabled, perform any table repair or rebuilding operations needed to re-create database objects. The binary log must be disabled during this step to prevent these operations from being logged and sent to the slaves later.
4. Re-enable the binary log on the master. If you set `sql_log_bin` to 0 earlier, execute a `SET sql_log_bin = 1` statement. If you restarted the master to disable the binary log, restart it with `--log-bin`, and without `--skip-networking` so that clients and slaves can connect.
5. Restart the slaves, this time without the `--skip-slave-start` option.

## 16.4.4. Replication FAQ

### Questions

- [17.4.4.1](#): Must the slave be connected to the master all the time?
- [17.4.4.2](#): Must I enable networking on my master and slave to enable replication?

- [17.4.4.14](#): Does replication work on mixed hardware architectures (for example, the master runs on a 64-bit machine while slaves run on 32-bit machines)?

### Questions and Answers

#### **17.4.4.1: Must the slave be connected to the master all the time?**

No, it does not. The slave can go down or stay disconnected for hours or even days, and then reconnect and catch up on updates. For example, you can set up a master/slave relationship over a dial-up link where the link is up only sporadically and for short periods of time. The implication of this is that, at any given time, the slave is not guaranteed to be in synchrony with the master unless you take some special measures.

To ensure that catchup can occur for a slave that has been disconnected, you must not remove binary log files from the master that contain information that has not yet been replicated to the slaves. Asynchronous replication can work only if the slave is able to continue reading the binary log from the point where it last read events.

#### 17.4.4.2: Must I enable networking on my master and slave to enable replication?

Yes, networking must be enabled on the master and slave. If networking is not enabled, the slave cannot connect to the master and transfer the binary log. Check that the `skip-networking` option has not been enabled in the configuration file for either server.

#### 17.4.4.3: How do I know how late a slave is compared to the master? In other words, how do I know the date of the last statement replicated by the slave?

Check the `Seconds_Behind_Master` column in the output from `SHOW SLAVE STATUS`. See [Section 16.1.4.1, “Checking Replication Status”](#).

When the slave SQL thread executes an event read from the master, it modifies its own time to the event timestamp. (This is why `TIMESTAMP` is well replicated.) In the `Time` column in the output of `SHOW PROCESSLIST`, the number of seconds displayed for the slave SQL thread is the number of seconds between the timestamp of the last replicated event and the real time of the slave machine. You can use this to determine the date of the last replicated event. Note that if your slave has been disconnected from the master for one hour, and then reconnects, you may immediately see large `Time` values such as 3600 for the slave SQL thread in `SHOW PROCESSLIST`. This is because the slave is executing statements that are one hour old. See [Section 16.2.1, “Replication Implementation Details”](#).

#### 17.4.4.4: How do I force the master to block updates until the slave catches up?

Use the following procedure:

1. On the master, execute these statements:

```
mysql> FLUSH TABLES WITH READ LOCK;
mysql> SHOW MASTER STATUS;
```

Record the replication coordinates (the current binary log file name and position) from the output of the `SHOW` statement.

2. On the slave, issue the following statement, where the arguments to the `MASTER_POS_WAIT()` function are the replication coordinate values obtained in the previous step:

```
mysql> SELECT MASTER_POS_WAIT('log_name', log_pos);
```

The `SELECT` statement blocks until the slave reaches the specified log file and position. At that point, the slave is in synchrony with the master and the statement returns.

3. On the master, issue the following statement to enable the master to begin processing updates again:

```
mysql> UNLOCK TABLES;
```

#### 17.4.4.5: What issues should I be aware of when setting up two-way replication?

MySQL replication currently does not support any locking protocol between master and slave to guarantee the atomicity of a distributed (cross-server) update. In other words, it is possible for client A to make an update to co-master 1, and in the meantime, before it propagates to co-master 2, client B could make an update to co-master 2 that makes the update of client A work differently than it did on co-master 1. Thus, when the update of client A makes it to co-master 2, it produces tables that are different from what you have on co-master 1, even after all the updates from co-master 2 have also propagated. This means that you should not chain two servers together in a two-way replication relationship unless you are sure that your updates can safely happen in any order, or unless you take care of mis-ordered updates somehow in the client code.

You should also realize that two-way replication actually does not improve performance very much (if at all) as far as updates are concerned. Each server must do the same number of updates, just as you would have a single server do. The only difference is that there is a little less lock contention because the updates originating on another server are serialized in one slave thread. Even this benefit might be offset by network delays.

#### 17.4.4.6: How can I use replication to improve performance of my system?

Set up one server as the master and direct all writes to it. Then configure as many slaves as you have the budget and rackspace for, and distribute the reads among the master and the slaves. You can also start the slaves with the `--skip-innodb`, `--low-priority-updates`, and `--delay-key-write=ALL` options to get speed improvements on the slave end. In this case, the slave uses nontransactional `MyISAM` tables instead of `InnoDB` tables to get more speed by eliminating transactional overhead.

**17.4.4.7: What should I do to prepare client code in my own applications to use performance-enhancing replication?**

See the guide to using replication as a scale-out solution, [Section 16.3.3, “Using Replication for Scale-Out”](#).

**17.4.4.8: When and how much can MySQL replication improve the performance of my system?**

MySQL replication is most beneficial for a system that processes frequent reads and infrequent writes. In theory, by using a single-master/multiple-slave setup, you can scale the system by adding more slaves until you either run out of network bandwidth, or your update load grows to the point that the master cannot handle it.

To determine how many slaves you can use before the added benefits begin to level out, and how much you can improve performance of your site, you must know your query patterns, and determine empirically by benchmarking the relationship between the throughput for reads and writes on a typical master and a typical slave. The example here shows a rather simplified calculation of what you can get with replication for a hypothetical system. Let `reads` and `writes` denote the number of reads and writes per second, respectively.

Let's say that system load consists of 10% writes and 90% reads, and we have determined by benchmarking that `reads` is  $1200 - 2 \times \text{writes}$ . In other words, the system can do 1,200 reads per second with no writes, the average write is twice as slow as the average read, and the relationship is linear. Suppose that the master and each slave have the same capacity, and that we have one master and  $N$  slaves. Then we have for each server (master or slave):

$$\text{reads} = 1200 - 2 \times \text{writes}$$

$$\text{reads} = 9 \times \text{writes} / (N + 1) \quad (\text{reads are split, but writes replicated to all slaves})$$

$$9 \times \text{writes} / (N + 1) + 2 \times \text{writes} = 1200$$

$$\text{writes} = 1200 / (2 + 9/(N + 1))$$

The last equation indicates the maximum number of writes for  $N$  slaves, given a maximum possible read rate of 1,200 per minute and a ratio of nine reads per write.

This analysis yields the following conclusions:

- If  $N = 0$  (which means we have no replication), our system can handle about  $1200/11 = 109$  writes per second.
- If  $N = 1$ , we get up to 184 writes per second.
- If  $N = 8$ , we get up to 400 writes per second.
- If  $N = 17$ , we get up to 480 writes per second.
- Eventually, as  $N$  approaches infinity (and our budget negative infinity), we can get very close to 600 writes per second, increasing system throughput about 5.5 times. However, with only eight servers, we increase it nearly four times.

Note that these computations assume infinite network bandwidth and neglect several other factors that could be significant on your system. In many cases, you may not be able to perform a computation similar to the one just shown that accurately predicts what will happen on your system if you add  $N$  replication slaves. However, answering the following questions should help you decide whether and by how much replication will improve the performance of your system:

- What is the read/write ratio on your system?
- How much more write load can one server handle if you reduce the reads?
- For how many slaves do you have bandwidth available on your network?

**17.4.4.9: How can I use replication to provide redundancy or high availability?**

How you implement redundancy is entirely dependent on your application and circumstances. High-availability solutions (with automatic failover) require active monitoring and either custom scripts or third party tools to provide the failover support from the original MySQL server to the slave.

To handle the process manually, you should be able to switch from a failed master to a pre-configured slave by altering your application to talk to the new server or by adjusting the DNS for the MySQL server from the failed server to the new server.

For more information and some example solutions, see [Section 16.3.6, “Switching Masters During Failover”](#).

**17.4.4.10: How do I tell whether a master server is using statement-based or row-based binary logging format?**

Check the value of the `binlog_format` system variable:

```
mysql> SHOW VARIABLES LIKE 'binlog_format';
```

The value shown will be one of `STATEMENT`, `ROW`, or `MIXED`. For `MIXED` mode, row-based logging is preferred but replication switches automatically to statement-based logging under certain conditions; for information about when this may occur, see [Section 5.2.4.3, “Mixed Binary Logging Format”](#).

#### 17.4.4.11: How do I tell a slave to use row-based replication?

Slaves automatically know which format to use.

#### 17.4.4.12: How do I prevent `GRANT` and `REVOKE` statements from replicating to slave machines?

Start the server with the `--replicate-wild-ignore-table=mysql.%` option to ignore replication for tables in the `mysql` database.

#### 17.4.4.13: Does replication work on mixed operating systems (for example, the master runs on Linux while slaves run on Mac OS X and Windows)?

Yes.

#### 17.4.4.14: Does replication work on mixed hardware architectures (for example, the master runs on a 64-bit machine while slaves run on 32-bit machines)?

Yes.

### 16.4.5. Troubleshooting Replication

If you have followed the instructions but your replication setup is not working, the first thing to do is *check the error log for messages*. Many users have lost time by not doing this soon enough after encountering problems.

If you cannot tell from the error log what the problem was, try the following techniques:

- Verify that the master has binary logging enabled by issuing a `SHOW MASTER STATUS` statement. If logging is enabled, `Position` is nonzero. If binary logging is not enabled, verify that you are running the master with the `--log-bin` option.
- Verify that the master and slave both were started with the `--server-id` option and that the ID value is unique on each server.
- Verify that the slave is running. Use `SHOW SLAVE STATUS` to check whether the `Slave_IO_Running` and `Slave_SQL_Running` values are both `Yes`. If not, verify the options that were used when starting the slave server. For example, `--skip-slave-start` prevents the slave threads from starting until you issue a `START SLAVE` statement.
- If the slave is running, check whether it established a connection to the master. Use `SHOW PROCESSLIST`, find the I/O and SQL threads and check their `State` column to see what they display. See [Section 16.2.1, “Replication Implementation Details”](#). If the I/O thread state says `Connecting to master`, check the following:
  - Verify the privileges for the user being used for replication on the master.
  - Check that the host name of the master is correct and that you are using the correct port to connect to the master. The port used for replication is the same as used for client network communication (the default is `3306`). For the host name, ensure that the name resolves to the correct IP address.
  - Check that networking has not been disabled on the master or slave. Look for the `skip-networking` option in the configuration file. If present, comment it out or remove it.
  - If the master has a firewall or IP filtering configuration, ensure that the network port being used for MySQL is not being filtered.
  - Check that you can reach the master by using `ping` or `traceroute/tracert` to reach the host.
- If the slave was running previously but has stopped, the reason usually is that some statement that succeeded on the master failed on the slave. This should never happen if you have taken a proper snapshot of the master, and never modified the data on the slave outside of the slave thread. If the slave stops unexpectedly, it is a bug or you have encountered one of the known replication limitations described in [Section 16.4.1, “Replication Features and Issues”](#). If it is a bug, see [Section 16.4.6, “How to Report Replication Bugs or Problems”](#), for instructions on how to report it.
- If a statement that succeeded on the master refuses to run on the slave, try the following procedure if it is not feasible to do a

full database resynchronization by deleting the slave's databases and copying a new snapshot from the master:

1. Determine whether the affected table on the slave is different from the master table. Try to understand how this happened. Then make the slave's table identical to the master's and run `START SLAVE`.
2. If the preceding step does not work or does not apply, try to understand whether it would be safe to make the update manually (if needed) and then ignore the next statement from the master.
3. If you decide that the slave can skip the next statement from the master, issue the following statements:

```
mysql> SET GLOBAL sql_slave_skip_counter = N;
mysql> START SLAVE;
```

The value of `N` should be 1 if the next statement from the master does not use `AUTO_INCREMENT` or `LAST_INSERT_ID()`. Otherwise, the value should be 2. The reason for using a value of 2 for statements that use `AUTO_INCREMENT` or `LAST_INSERT_ID()` is that they take two events in the binary log of the master.

See also [Section 12.5.2.6, “SET GLOBAL sql\\_slave\\_skip\\_counter Syntax”](#).

4. If you are sure that the slave started out perfectly synchronized with the master, and that no one has updated the tables involved outside of the slave thread, then presumably the discrepancy is the result of a bug. If you are running the most recent version of MySQL, please report the problem. If you are running an older version, try upgrading to the latest production release to determine whether the problem persists.

## 16.4.6. How to Report Replication Bugs or Problems

When you have determined that there is no user error involved, and replication still either does not work at all or is unstable, it is time to send us a bug report. We need to obtain as much information as possible from you to be able to track down the bug. Please spend some time and effort in preparing a good bug report.

If you have a repeatable test case that demonstrates the bug, please enter it into our bugs database using the instructions given in [Section 1.7, “How to Report Bugs or Problems”](#). If you have a “phantom” problem (one that you cannot duplicate at will), use the following procedure:

1. Verify that no user error is involved. For example, if you update the slave outside of the slave thread, the data goes out of synchrony, and you can have unique key violations on updates. In this case, the slave thread stops and waits for you to clean up the tables manually to bring them into synchrony. *This is not a replication problem. It is a problem of outside interference causing replication to fail.*
2. Run the slave with the `--log-slave-updates` and `--log-bin` options. These options cause the slave to log the updates that it receives from the master into its own binary logs.
3. Save all evidence before resetting the replication state. If we have no information or only sketchy information, it becomes difficult or impossible for us to track down the problem. The evidence you should collect is:
  - All binary log files from the master
  - All binary log files from the slave
  - The output of `SHOW MASTER STATUS` from the master at the time you discovered the problem
  - The output of `SHOW SLAVE STATUS` from the slave at the time you discovered the problem
  - Error logs from the master and the slave
4. Use `mysqlbinlog` to examine the binary logs. The following should be helpful to find the problem statement. `log_file` and `log_pos` are the `Master_Log_File` and `Read_Master_Log_Pos` values from `SHOW SLAVE STATUS`.

```
shell> mysqlbinlog --start-position=log_pos log_file | head
```

After you have collected the evidence for the problem, try to isolate it as a separate test case first. Then enter the problem with as much information as possible into our bugs database using the instructions at [Section 1.7, “How to Report Bugs or Problems”](#).

---

# Chapter 17. MySQL Cluster NDB 6.X/7.X

This chapter contains information about *MySQL Cluster*, which is a high-availability, high-redundancy version of MySQL adapted for the distributed computing environment. Current releases of MySQL Cluster use versions 6 and 7 of the `NDBCLUSTER` storage engine (also known as `NDB`) to enable running several computers with MySQL servers and other software in a cluster.

Beginning with MySQL 5.1.24, support for the `NDBCLUSTER` storage engine was removed from the standard MySQL server binaries built by MySQL. Instead, users of MySQL Cluster binaries built by MySQL should upgrade to the most recent binary release of MySQL Cluster NDB 7.0 or MySQL Cluster 7.1 for supported platforms—these include RPMs that should work with most Linux distributions. MySQL Cluster users who build from source should be aware that, also beginning with MySQL 5.1.24, `NDBCLUSTER` sources in the standard MySQL 5.1 tree are no longer maintained; these users should use the sources provided for MySQL Cluster NDB 7.0 or later. (Locations where the sources can be obtained are listed later in this section.)

## Note

MySQL Cluster NDB 6.1, 6.2, and 6.3 were formerly known as “MySQL Cluster Carrier Grade Edition”. Beginning with MySQL Cluster NDB 6.2.15 and MySQL Cluster NDB 6.3.14, this term is no longer applied to the MySQL Cluster software—which is now known simply as “MySQL Cluster”—but rather to a commercial licensing and support package. You can learn more about available options for commercial licensing of MySQL Cluster from [MySQL Cluster Features](#), on the MySQL web site.

This chapter contains information about MySQL Cluster in MySQL 5.1 mainline releases through MySQL 5.1.23, MySQL Cluster NDB 6.2 releases through 5.1.47-ndb-6.2.19, MySQL Cluster NDB 6.3 releases through 5.1.47-ndb-6.3.38, MySQL Cluster NDB 7.0 releases through 5.1.47-ndb-7.0.19 and MySQL Cluster NDB 7.1 releases through 5.1.47-ndb-7.1.8. Currently, the MySQL Cluster NDB 7.0 (formerly known as “MySQL Cluster NDB 6.4”) and MySQL Cluster NDB 7.1 release series are Generally Available (GA). MySQL Cluster NDB 6.2 and MySQL Cluster NDB 6.3 are previous GA release series; although these are still supported, we recommend that new deployments use MySQL Cluster NDB 7.0 or MySQL Cluster NDB 7.1.

This chapter also contains historical information about MySQL Cluster NDB 6.1, although this release series is no longer in active development, and no longer supported for new deployments. You should upgrade to MySQL Cluster 6.3 or a MySQL Cluster NDB 7.x release series as soon as possible.

**Platforms supported.** MySQL Cluster is currently available and supported on a number of platforms, including Linux, Solaris, Mac OS X, and other Unix-style operating systems on a variety of hardware. Beginning with MySQL Cluster NDB 7.1.3, MySQL Cluster is also available for production use on Microsoft Windows platforms. For exact levels of support available for MySQL Cluster on specific combinations of operating system versions, operating system distributions, and hardware platforms, please refer to <http://www.mysql.com/support/supportedplatforms/cluster.html>, maintained by the MySQL Support Team on the MySQL web site.

**Availability.** MySQL Cluster NDB 6.3, MySQL Cluster NDB 7.0, and MySQL Cluster NDB 7.1 binary and source packages are available for supported platforms from <http://dev.mysql.com/downloads/cluster/>.

## Note

Binary releases and RPMs were not available for MySQL Cluster NDB 6.2 prior to MySQL Cluster NDB 6.2.15.

**MySQL Cluster release numbers.** Starting with MySQL Cluster NDB 6.1 and MySQL Cluster NDB 6.2, MySQL Cluster follows a somewhat different release pattern from the mainline MySQL 5.1 Cluster series of releases. In this *Manual* and other MySQL documentation, we identify these and later MySQL Cluster releases employing a version number that begins with “NDB”. This version number is that of the `NDBCLUSTER` storage engine used in the release, and not of the MySQL server version on which the MySQL Cluster release is based.

**Version strings used in MySQL Cluster NDB 6.x and 7.x software.** The version string displayed by MySQL Cluster NDB 6.x and 7.x software uses this format:

```
mysql> mysql_server_version-ndb-ndbcluster_engine_version
```

`mysql_server_version` represents the version of the MySQL Server on which the MySQL Cluster release is based. For all MySQL Cluster NDB 6.x and 7.x releases, this is “5.1”. `ndbcluster_engine_version` is the version of the `NDBCLUSTER` storage engine used by this release of the MySQL Cluster software. You can see this format used in the `mysql` client, as shown here:

```
shell> mysql
Welcome to the MySQL monitor. Commands end with ; or \g.
Your MySQL connection id is 2
Server version: 5.1.47-ndb-7.1.8 Source distribution

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SELECT VERSION()\G
***** 1. row *****
VERSION(): 5.1.47-ndb-7.1.8
1 row in set (0.00 sec)
```

This version string is also displayed in the output of the `SHOW` command in the `ndb_mgm` client:

```
ndb_mgm> SHOW
Connected to Management Server at: localhost:1186
Cluster Configuration

[ndbd(NDB)] 2 node(s)
id=1 @10.0.10.6 (5.1.47-ndb-7.1.8, Nodegroup: 0, Master)
id=2 @10.0.10.8 (5.1.47-ndb-7.1.8, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)
id=3 @10.0.10.2 (5.1.47-ndb-7.1.8)

[mysqld(API)] 2 node(s)
id=4 @10.0.10.10 (5.1.47-ndb-7.1.8)
id=5 (not connected, accepting connect from any host)
```

The version string identifies the mainline MySQL version from which the MySQL Cluster release was branched and the version of the `NDBCLUSTER` storage engine used. For example, the full version string for MySQL Cluster NDB 7.0.5 (the first GA MySQL Cluster NDB 7.0 binary release) was `mysql-5.1.32-ndb-7.0.5`. From this we can determine the following:

- Since the portion of the version string preceding “`-ndb-`” is the base MySQL Server version, this means that MySQL Cluster NDB 7.0.5 derives from the MySQL 5.1.32, and contains all feature enhancements and bugfixes from MySQL 5.1 up to and including MySQL 5.1.32.
- Since the portion of the version string following “`-ndb-`” represents the version number of the `NDB` (or `NDBCLUSTER`) storage engine, MySQL Cluster NDB 7.0.5 uses version 7.0.5 of the `NDBCLUSTER` storage engine.

New MySQL Cluster releases are numbered according to updates in the `NDB` storage engine, and do not necessarily correspond in a linear fashion with mainline MySQL Server releases. For example, MySQL Cluster NDB 7.0.5 (as previously noted) is based on MySQL 5.1.32, and MySQL Cluster NDB 7.0.6 is based on MySQL 5.1.34 (version string: `mysql-5.1.34-ndb-7.0.6`).

**Compatibility with standard MySQL 5.1 releases.** While many standard MySQL schemas and applications can work using MySQL Cluster, it is also true that unmodified applications and database schemas may be slightly incompatible or have suboptimal performance when run using MySQL Cluster (see [Section 17.1.5, “Known Limitations of MySQL Cluster”](#)). Most of these issues can be overcome, but this also means that you are very unlikely to be able to switch an existing application datastore—that currently uses, for example, `MyISAM` or `InnoDB`—to use the `NDB` storage engine without allowing for the possibility of changes in schemas, queries, and applications. Moreover, from MySQL 5.1.24 onwards, the MySQL Server and MySQL Cluster codebases diverge considerably (and `NDB` storage engine support dropped from subsequent MySQL Server releases), so that the standard `mysqld` cannot function as a dropin replacement for the version of `mysqld` that is supplied with MySQL Cluster.

**MySQL Cluster development source trees.** MySQL Cluster development trees can also be accessed from <https://code.launchpad.net/~mysql/>:

- [MySQL Cluster NDB 6.1 \(OBSOLETE—no longer maintained\)](#)
- [MySQL Cluster NDB 6.2 \(PAST CURRENT; continues to be maintained\)](#)
- [MySQL Cluster NDB 6.3 \(CURRENT\)](#)
- [MySQL Cluster NDB 7.0 \(CURRENT\)](#)

The MySQL Cluster development sources maintained at <https://code.launchpad.net/~mysql/> are licensed under the GPL. For information about obtaining MySQL sources using Bazaar and building them yourself, see [Section 2.3.4, “Installing from the Development Source Tree”](#).

Currently, MySQL Cluster NDB 6.2, MySQL Cluster NDB 6.3, and MySQL Cluster NDB 7.0 releases are all Generally Available (GA), although we recommend that new deployments use MySQL Cluster 6.3 or MySQL Cluster 7.0. MySQL Cluster NDB 7.1 is in early development; we intend to make the source tree for this release series available in the near future. MySQL Cluster NDB 6.1 is no longer in active development. For an overview of major features added in MySQL Cluster NDB 6.x and 7.x, see [Section 17.1.4, “MySQL Cluster Development History”](#).

This chapter represents a work in progress, and its contents are subject to revision as MySQL Cluster continues to evolve. Additional information regarding MySQL Cluster can be found on the MySQL Web site at <http://www.mysql.com/products/cluster/>.

**Additional Resources.** More information may be found in the following places:

- Answers to some commonly asked questions about Cluster may be found in the [Section A.10, “MySQL 5.1 FAQ: MySQL Cluster”](#).
- The MySQL Cluster mailing list: <http://lists.mysql.com/cluster>.

- The MySQL Cluster Forum: <http://forums.mysql.com/list.php?25>.
- Many MySQL Cluster users and some of the MySQL Cluster developers blog about their experiences with Cluster, and make feeds of these available through [PlanetMySQL](#).
- If you are new to MySQL Cluster, you may find our Developer Zone article [How to set up a MySQL Cluster for two servers](#) to be helpful.

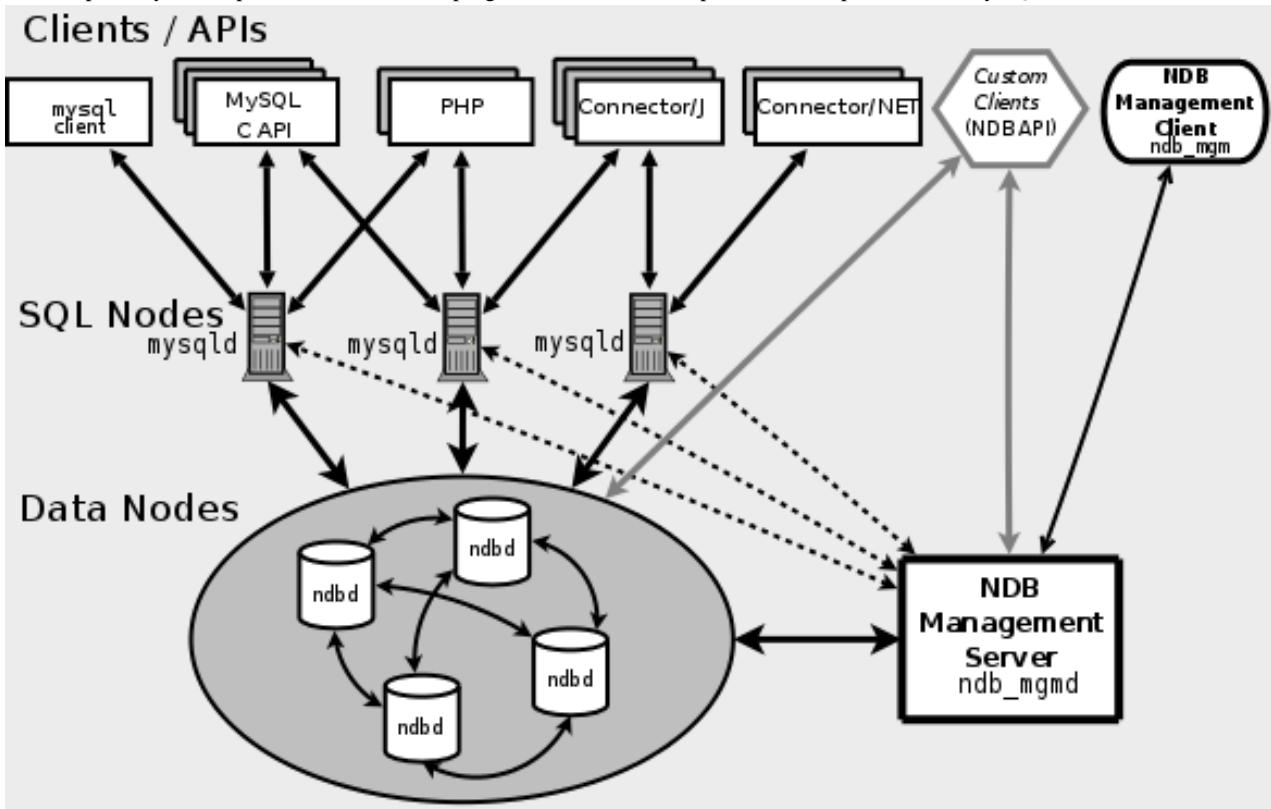

## 17.1. MySQL Cluster Overview

*MySQL Cluster* is a technology that enables clustering of in-memory databases in a shared-nothing system. The shared-nothing architecture enables the system to work with very inexpensive hardware, and with a minimum of specific requirements for hardware or software.

MySQL Cluster is designed not to have any single point of failure. In a shared-nothing system, each component is expected to have its own memory and disk, and the use of shared storage mechanisms such as network shares, network file systems, and SANs is not recommended or supported.

MySQL Cluster integrates the standard MySQL server with an in-memory clustered storage engine called **NDB** (which stands for “Network DataBase”). In our documentation, the term **NDB** refers to the part of the setup that is specific to the storage engine, whereas “MySQL Cluster” refers to the combination of one or more MySQL servers with the **NDB** storage engine.

A MySQL Cluster consists of a set of computers, known as *hosts*, each running one or more processes. These processes, known as *nodes*, may include MySQL servers (for access to NDB data), data nodes (for storage of the data), one or more management servers, and possibly other specialized data access programs. The relationship of these components in a MySQL Cluster is shown here:

All these programs work together to form a MySQL Cluster (see [Section 17.4, “MySQL Cluster Programs”](#)). When data is stored by the **NDB** storage engine, the tables (and table data) are stored in the data nodes. Such tables are directly accessible from all other MySQL servers (SQL nodes) in the cluster. Thus, in a payroll application storing data in a cluster, if one application updates the salary of an employee, all other MySQL servers that query this data can see this change immediately.

Although a MySQL Cluster SQL node uses the `mysqld` server daemon, it differs in a number of critical respects from the `mysqld` binary supplied with the MySQL 5.1 distributions, and the two versions of `mysqld` are not interchangeable.

In addition, a MySQL server that is not connected to a MySQL Cluster cannot use the **NDB** storage engine and cannot access any MySQL Cluster data.

The data stored in the data nodes for MySQL Cluster can be mirrored; the cluster can handle failures of individual data nodes with no other impact than that a small number of transactions are aborted due to losing the transaction state. Because transactional applications are expected to handle transaction failure, this should not be a source of problems.

Individual nodes can be stopped and restarted, and can then rejoin the system (cluster). Rolling restarts (in which all nodes are restarted in turn) are used in making configuration changes and software upgrades (see [Section 17.2.5.1, “Performing a Rolling Restart of a MySQL Cluster”](#)). In MySQL Cluster NDB 7.0 and later, rolling restarts are also used as part of the process of adding new data nodes online (see [Section 17.5.11, “Adding MySQL Cluster Data Nodes Online”](#)). For more information about data nodes, how they are organized in a MySQL Cluster, and how they handle and store MySQL Cluster data, see [Section 17.1.2, “MySQL Cluster Nodes, Node Groups, Replicas, and Partitions”](#).

Backing up and restoring MySQL Cluster databases can be done using the NDB native functionality found in the MySQL Cluster management client and the `ndb_restore` program included in the MySQL Cluster distribution. For more information, see [Section 17.5.3, “Online Backup of MySQL Cluster”](#), and [Section 17.4.17, “`ndb\_restore` — Restore a MySQL Cluster Backup”](#). You can also use the standard MySQL functionality provided for this purpose in `mysqldump` and the MySQL server. See [Section 4.5.4, “`mysqldump` — A Database Backup Program”](#), for more information.

MySQL Cluster nodes can use a number of different transport mechanisms for inter-node communications, including TCP/IP using standard 100 Mbps or faster Ethernet hardware. It is also possible to use the high-speed *Scalable Coherent Interface* (SCI) protocol with MySQL Cluster, although this is not required to use MySQL Cluster. SCI requires special hardware and software; see [Section 17.3.5, “Using High-Speed Interconnects with MySQL Cluster”](#), for more about SCI and using it with MySQL Cluster.

## 17.1.1. MySQL Cluster Core Concepts

`NDBCLUSTER` (also known as `NDB`) is an in-memory storage engine offering high-availability and data-persistence features.

The `NDBCLUSTER` storage engine can be configured with a range of failover and load-balancing options, but it is easiest to start with the storage engine at the cluster level. MySQL Cluster's `NDB` storage engine contains a complete set of data, dependent only on other data within the cluster itself.

The “Cluster” portion of MySQL Cluster is configured independently of the MySQL servers. In a MySQL Cluster, each part of the cluster is considered to be a *node*.

### Note

In many contexts, the term “node” is used to indicate a computer, but when discussing MySQL Cluster it means a *process*. It is possible to run multiple nodes on a single computer; for a computer on which one or more cluster nodes are being run we use the term *cluster host*.

There are three types of cluster nodes, and in a minimal MySQL Cluster configuration, there will be at least three nodes, one of each of these types:

- *Management node* (MGM node): The role of this type of node is to manage the other nodes within the MySQL Cluster, performing such functions as providing configuration data, starting and stopping nodes, running backup, and so forth. Because this node type manages the configuration of the other nodes, a node of this type should be started first, before any other node. An MGM node is started with the command `ndb_mgmd`.
- *Data node*: This type of node stores cluster data. There are as many data nodes as there are replicas, times the number of fragments (see [Section 17.1.2, “MySQL Cluster Nodes, Node Groups, Replicas, and Partitions”](#)). For example, with two replicas, each having two fragments, you need four data nodes. One replica is sufficient for data storage, but provides no redundancy; therefore, it is recommended to have 2 (or more) replicas to provide redundancy, and thus high availability. A data node is started with the command `ndbd` (see [Section 17.4.2, “`ndbd` — The MySQL Cluster Data Node Daemon”](#)). In MySQL Cluster NDB 7.0 and later, `ndbmttd` can also be used for the data node process; see [Section 17.4.3, “`ndbmttd` — The MySQL Cluster Data Node Daemon \(Multi-Threaded\)”](#), for more information.

MySQL Cluster tables in MySQL 5.1 are normally stored completely in memory rather than on disk (this is why we refer to MySQL cluster as an *in-memory* database). In MySQL 5.1, MySQL Cluster NDB 6.X, and later, some MySQL Cluster data can be stored on disk; see [Section 17.5.10, “MySQL Cluster Disk Data Tables”](#), for more information.

- *SQL node*: This is a node that accesses the cluster data. In the case of MySQL Cluster, an SQL node is a traditional MySQL server that uses the `NDBCLUSTER` storage engine. An SQL node is a `mysqld` process started with the `--ndbcluster` and `-ndb-connectstring` options, which are explained elsewhere in this chapter, possibly with additional MySQL server options as well.

An SQL node is actually just a specialized type of *API node*, which designates any application which accesses Cluster data. Another example of an API node is the `ndb_restore` utility that is used to restore a cluster backup. It is possible to write such applications using the NDB API. For basic information about the NDB API, see [Getting Started with the NDB API](#).

## Important

It is not realistic to expect to employ a three-node setup in a production environment. Such a configuration provides no redundancy; to benefit from MySQL Cluster's high-availability features, you must use multiple data and SQL nodes. The use of multiple management nodes is also highly recommended.

For a brief introduction to the relationships between nodes, node groups, replicas, and partitions in MySQL Cluster, see [Section 17.1.2, “MySQL Cluster Nodes, Node Groups, Replicas, and Partitions”](#).

Configuration of a cluster involves configuring each individual node in the cluster and setting up individual communication links between nodes. MySQL Cluster is currently designed with the intention that data nodes are homogeneous in terms of processor power, memory space, and bandwidth. In addition, to provide a single point of configuration, all configuration data for the cluster as a whole is located in one configuration file.

The management server (MGM node) manages the cluster configuration file and the cluster log. Each node in the cluster retrieves the configuration data from the management server, and so requires a way to determine where the management server resides. When interesting events occur in the data nodes, the nodes transfer information about these events to the management server, which then writes the information to the cluster log.

In addition, there can be any number of cluster client processes or applications. These are of two types:

- **Standard MySQL clients.** MySQL Cluster can be used with existing MySQL applications written in PHP, Perl, C, C++, Java, Python, Ruby, and so on. Such client applications send SQL statements to and receive responses from MySQL servers acting as MySQL Cluster SQL nodes in much the same way that they interact with standalone MySQL servers.

MySQL clients using a MySQL Cluster as a data source can be modified to take advantage of the ability to connect with multiple MySQL servers to achieve load balancing and failover. For example, Java clients using Connector/J 5.0.6 and later can use `jdbc:mysql:loadbalance://` URLs (improved in Connector/J 5.1.7) to achieve load balancing transparently .

- **Management clients.** These clients connect to the management server and provide commands for starting and stopping nodes gracefully, starting and stopping message tracing (debug versions only), showing node versions and status, starting and stopping backups, and so on. Such clients—such as the `ndb_mgm` management client supplied with MySQL Cluster (see [Section 17.4.5, “`ndb\_mgm` — The MySQL Cluster Management Client”](#))—are written using the MGM API, a C-language API that communicates directly with one or more MySQL Cluster management servers. For more information, see [The MGM API](#).

**Event logs.** MySQL Cluster logs events by category (startup, shutdown, errors, checkpoints, and so on), priority, and severity. A complete listing of all reportable events may be found in [Section 17.5.4, “Event Reports Generated in MySQL Cluster”](#). Event logs are of two types:

- **Cluster log.** Keeps a record of all desired reportable events for the cluster as a whole.
- **Node log.** A separate log which is also kept for each individual node.

## Note

Under normal circumstances, it is necessary and sufficient to keep and examine only the cluster log. The node logs need be consulted only for application development and debugging purposes.

**Checkpoint.** Generally speaking, when data is saved to disk, it is said that a checkpoint has been reached. More specific to Cluster, it is a point in time where all committed transactions are stored on disk. With regard to the `NDB` storage engine, there are two types of checkpoints which work together to ensure that a consistent view of the cluster's data is maintained:

- **Local Checkpoint (LCP).** This is a checkpoint that is specific to a single node; however, LCP's take place for all nodes in the cluster more or less concurrently. An LCP involves saving all of a node's data to disk, and so usually occurs every few minutes. The precise interval varies, and depends upon the amount of data stored by the node, the level of cluster activity, and other factors.
- **Global Checkpoint (GCP).** A GCP occurs every few seconds, when transactions for all nodes are synchronized and the redo-log is flushed to disk.

## 17.1.2. MySQL Cluster Nodes, Node Groups, Replicas, and Partitions

This section discusses the manner in which MySQL Cluster divides and duplicates data for storage.

Central to an understanding of this topic are the following concepts, listed here with brief definitions:

- **(Data) Node.** An `ndbd` process, which stores a *replica* —that is, a copy of the *partition* (see below) assigned to the node group of which the node is a member.

Each data node should be located on a separate computer. While it is also possible to host multiple `ndbd` processes on a single computer, such a configuration is not supported.

It is common for the terms “node” and “data node” to be used interchangeably when referring to an `ndbd` process; where mentioned, management (MGM) nodes (`ndb_mgmd` processes) and SQL nodes (`mysql` processes) are specified as such in this discussion.

- **Node Group.** A node group consists of one or more nodes, and stores partitions, or sets of *replicas* (see next item).

The number of node groups in a MySQL Cluster is not directly configurable; it is function of the number of data nodes and of the number of replicas (`NumberOfReplicas` configuration parameter), as shown here:

```
[number_of_node_groups] = number_of_data_nodes / NumberOfReplicas
```

Thus, a MySQL Cluster with 4 data nodes has 4 node groups if `NumberOfReplicas` is set to 1 in the `config.ini` file, 2 node groups if `NumberOfReplicas` is set to 2, and 1 node group if `NumberOfReplicas` is set to 4. Replicas are discussed later in this section; for more information about `NumberOfReplicas`, see [Section 17.3.2.6, “Defining MySQL Cluster Data Nodes”](#).

### Note

All node groups in a MySQL Cluster must have the same number of data nodes.

Prior to MySQL Cluster NDB 7.0, it was not possible to add new data nodes to a MySQL Cluster without shutting down the cluster completely and reloading all of its data. In MySQL Cluster NDB 7.0 (beginning with MySQL Cluster version NDB 6.4.0), you can add new node groups (and thus new data nodes) to a running MySQL Cluster—see [Section 17.5.11, “Adding MySQL Cluster Data Nodes Online”](#), for information about how this can be done.

- **Partition.** This is a portion of the data stored by the cluster. There are as many cluster partitions as nodes participating in the cluster. Each node is responsible for keeping at least one copy of any partitions assigned to it (that is, at least one replica) available to the cluster.

A replica belongs entirely to a single node; a node can (and usually does) store several replicas.

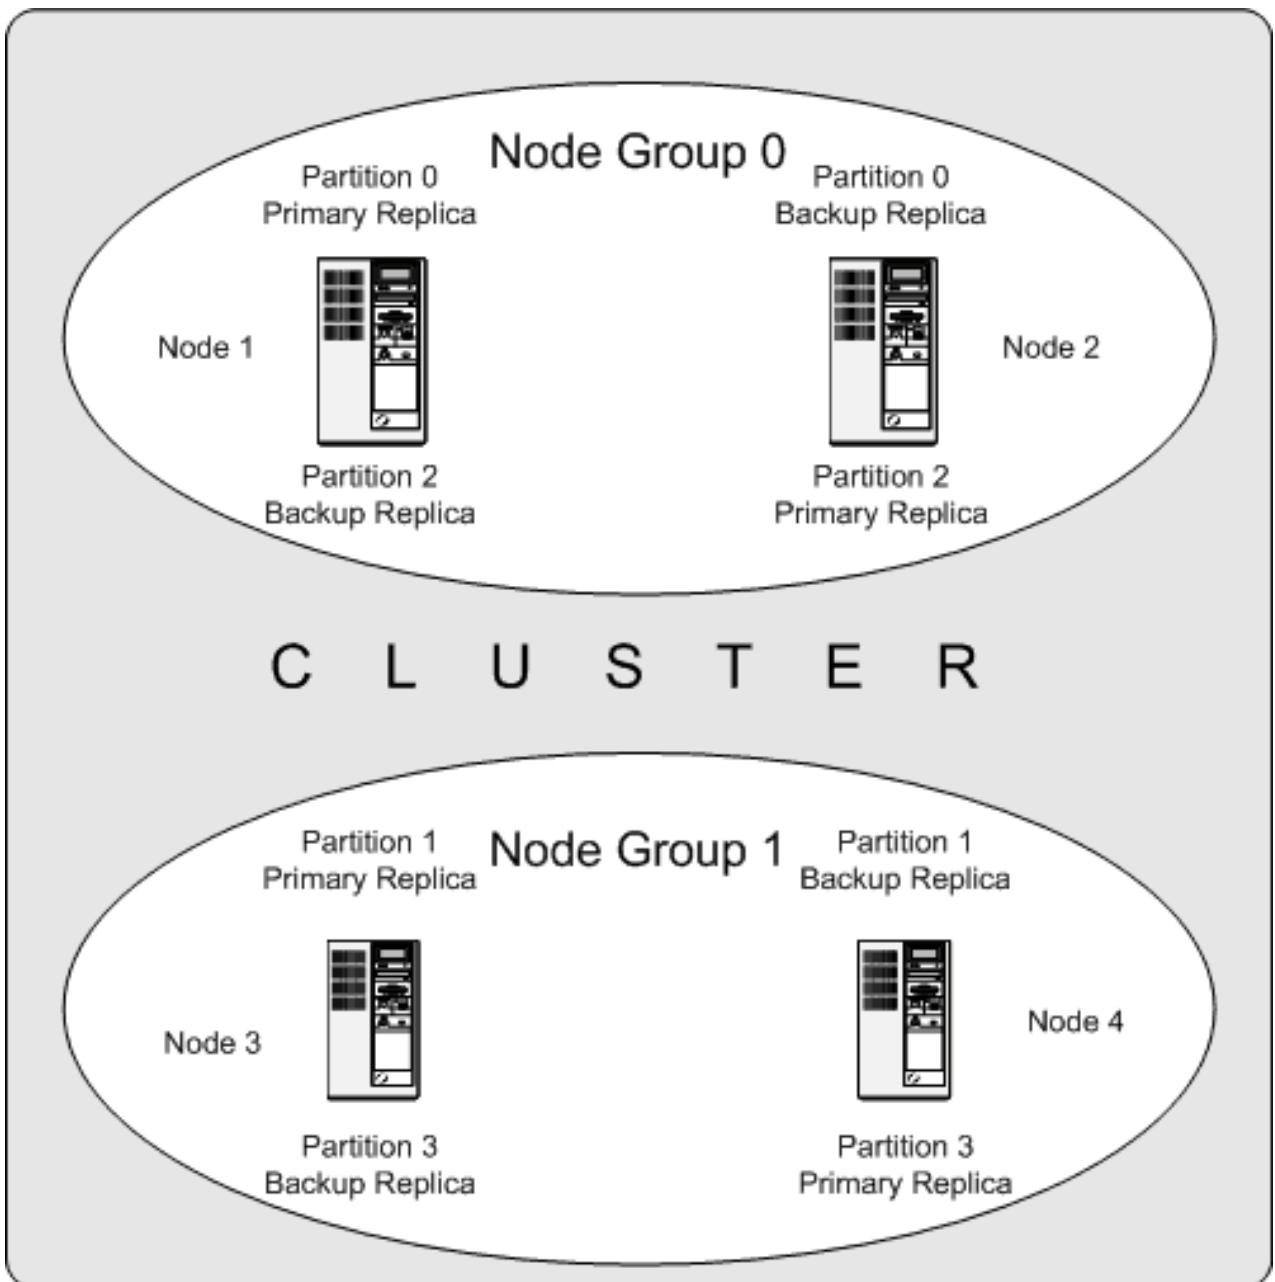

MySQL Cluster normally partitions `NDBCLUSTER` tables automatically. However, in MySQL 5.1 and later MySQL Cluster releases, it is possible to employ user-defined partitioning with `NDBCLUSTER` tables. This is subject to the following limitations:

1. Only `KEY` and `LINEAR KEY` partitioning schemes can be used with `NDBCLUSTER` tables.
2. The maximum number of partitions that may be defined explicitly for any `NDBCLUSTER` table is 8 per node group. (The number of node groups in a MySQL Cluster is determined as discussed previously in this section.)

For more information relating to MySQL Cluster and user-defined partitioning, see [Section 17.1.5, “Known Limitations of MySQL Cluster”](#), and [Section 18.5.2, “Partitioning Limitations Relating to Storage Engines”](#).

- **Replica.** This is a copy of a cluster partition. Each node in a node group stores a replica. Also sometimes known as a *partition replica*. The number of replicas is equal to the number of nodes per node group.

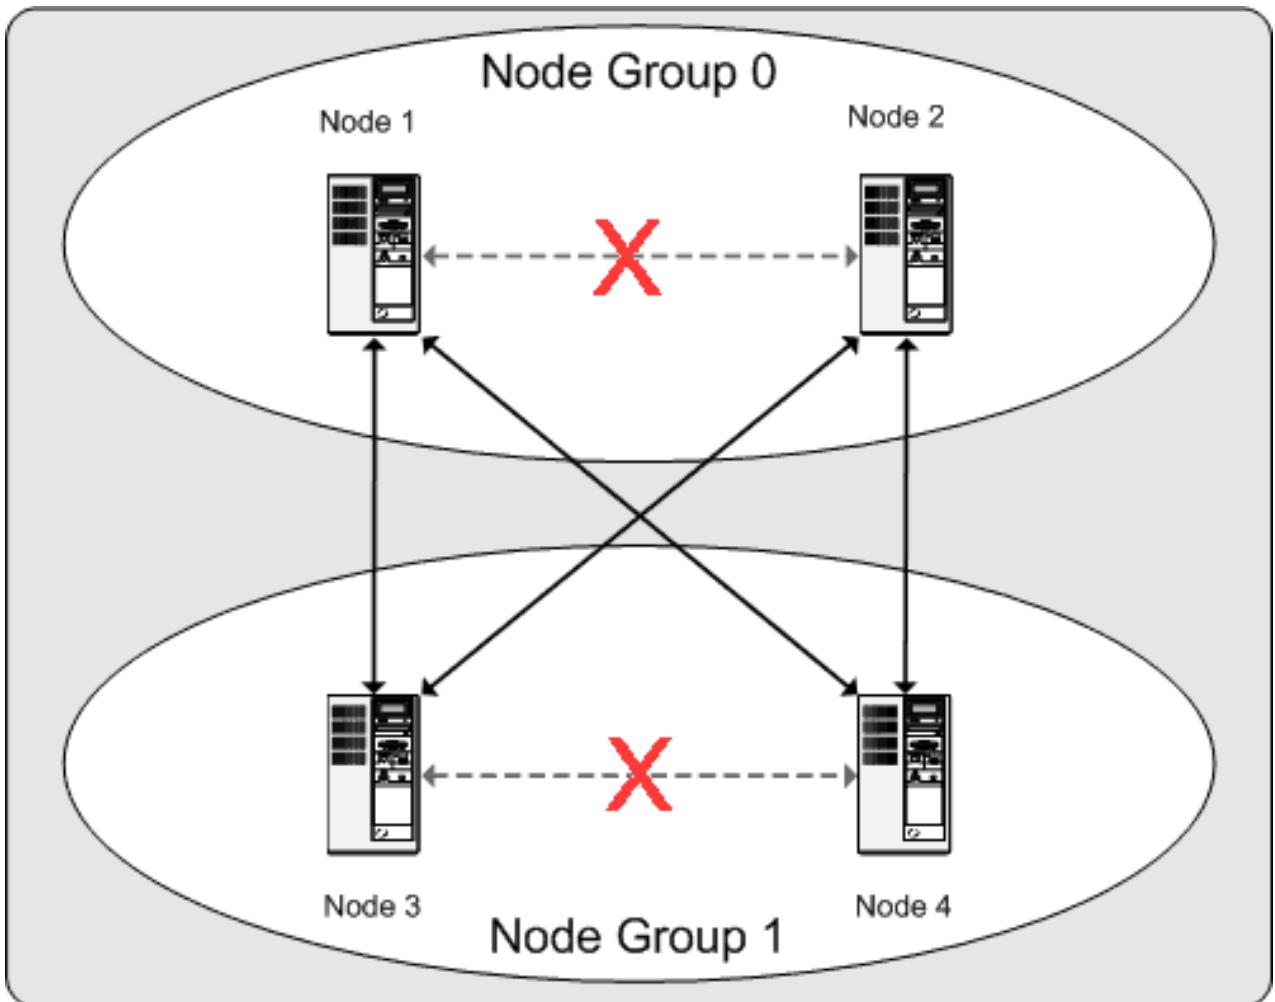

The following diagram illustrates a MySQL Cluster with four data nodes, arranged in two node groups of two nodes each; nodes 1 and 2 belong to node group 0, and nodes 3 and 4 belong to node group 1. Note that only data (`ndbd`) nodes are shown here; although a working cluster requires an `ndb_mgmd` process for cluster management and at least one SQL node to access the data stored by the cluster, these have been omitted in the figure for clarity.

The data stored by the cluster is divided into four partitions, numbered 0, 1, 2, and 3. Each partition is stored—in multiple copies—on the same node group. Partitions are stored on alternate node groups:

- Partition 0 is stored on node group 0; a *primary replica* (primary copy) is stored on node 1, and a *backup replica* (backup copy of the partition) is stored on node 2.
- Partition 1 is stored on the other node group (node group 1); this partition's primary replica is on node 3, and its backup replica is on node 4.
- Partition 2 is stored on node group 0. However, the placing of its two replicas is reversed from that of Partition 0; for Partition 2, the primary replica is stored on node 2, and the backup on node 1.
- Partition 3 is stored on node group 1, and the placement of its two replicas are reversed from those of partition 1. That is, its primary replica is located on node 4, with the backup on node 3.

What this means regarding the continued operation of a MySQL Cluster is this: so long as each node group participating in the cluster has at least one node operating, the cluster has a complete copy of all data and remains viable. This is illustrated in the next diagram.

In this example, where the cluster consists of two node groups of two nodes each, any combination of at least one node in node group 0 and at least one node in node group 1 is sufficient to keep the cluster “alive” (indicated by arrows in the diagram). However, if *both* nodes from *either* node group fail, the remaining two nodes are not sufficient (shown by the arrows marked out with an X); in either case, the cluster has lost an entire partition and so can no longer provide access to a complete set of all cluster data.

### 17.1.3. MySQL Cluster Hardware, Software, and Networking Requirements

One of the strengths of MySQL Cluster is that it can be run on commodity hardware and has no unusual requirements in this regard, other than for large amounts of RAM, due to the fact that all live data storage is done in memory. (It is possible to reduce this requirement using Disk Data tables—see [Section 17.5.10, “MySQL Cluster Disk Data Tables”](#), for more information about these.) Naturally, multiple and faster CPUs can enhance performance. Memory requirements for other MySQL Cluster processes are relatively small.

The software requirements for MySQL Cluster are also modest. Host operating systems do not require any unusual modules, services, applications, or configuration to support MySQL Cluster. For supported operating systems, a standard installation should be sufficient. The MySQL software requirements are simple: all that is needed is a production release of MySQL 5.1.47-ndb-7.0.19 or 5.1.47-ndb-7.1.8 to have MySQL Cluster support. It is not necessary to compile MySQL yourself merely to be able to use MySQL Cluster. We assume that you are using the server binary appropriate to your platform, available from the MySQL Cluster software downloads page at <http://dev.mysql.com/downloads/cluster/>.

For communication between nodes, MySQL Cluster supports TCP/IP networking in any standard topology, and the minimum expected for each host is a standard 100 Mbps Ethernet card, plus a switch, hub, or router to provide network connectivity for the cluster as a whole. We strongly recommend that a MySQL Cluster be run on its own subnet which is not shared with machines not forming part of the cluster for the following reasons:

- **Security.** Communications between MySQL Cluster nodes are not encrypted or shielded in any way. The only means of protecting transmissions within a MySQL Cluster is to run your MySQL Cluster on a protected network. If you intend to use MySQL Cluster for Web applications, the cluster should definitely reside behind your firewall and not in your network’s Demilitarized Zone ([DMZ](#)) or elsewhere.

See [Section 17.5.9.1, “MySQL Cluster Security and Networking Issues”](#), for more information.

- **Efficiency.** Setting up a MySQL Cluster on a private or protected network enables the cluster to make exclusive use of bandwidth between cluster hosts. Using a separate switch for your MySQL Cluster not only helps protect against unauthorized access to MySQL Cluster data, it also ensures that MySQL Cluster nodes are shielded from interference caused by transmissions between other computers on the network. For enhanced reliability, you can use dual switches and dual cards to remove the network as a single point of failure; many device drivers support failover for such communication links.

It is also possible to use the high-speed Scalable Coherent Interface (SCI) with MySQL Cluster, but this is not a requirement. See [Section 17.3.5, “Using High-Speed Interconnects with MySQL Cluster”](#), for more about this protocol and its use with MySQL Cluster.

## 17.1.4. MySQL Cluster Development History

In this section, we discuss changes in the implementation of MySQL Cluster in MySQL 5.1, MySQL Cluster NDB 6.x, and MySQL Cluster NDB 7.x, as compared to earlier MySQL Cluster releases.

There are a number of significant changes in the implementation of the `NDBCLUSTER` storage engine in mainline MySQL 5.1 releases up to and including MySQL 5.1.23 as compared to that in MySQL 5.0; MySQL Cluster NDB 6.x and 7.x make further changes and improvements in MySQL Cluster in addition to these. The changes and features most likely to be of interest are shown in the following tables:

<b>MySQL Cluster NDB 7.1</b>
Production-level support for MySQL Cluster on Microsoft Windows platforms.
<code>ndbinfo</code> meta-information database
MySQL Cluster Connector for Java, including ClusterJ and OpenJPA (ClusterJPA) support
Native support for default column values

<b>MySQL Cluster NDB 7.0</b>
Multi-threaded data nodes ( <code>ndbmtd</code> data node daemon)
Online addition of data nodes; online data redistribution
MySQL on Windows (alpha; source releases only)
Configuration cache
Backup snapshots ( <code>START BACKUP ... SNAPSHOTSTART</code> , <code>START BACKUP ... SNAPSHOTEND</code> commands)
IPv6 support for geo-replication
Protected DDL operations
Dynamic buffering for NDB transporters
Increased flexibility in determining arbitration handling, using a new <code>Arbitration</code> data node configuration parameter

<b>MySQL Cluster NDB 6.3</b>
Conflict detection and resolution for multi-master replication
Compressed backups and local checkpoints
Support for <code>OPTIMIZE TABLE</code>
Parallel data node recovery
Enhanced transaction coordinator selection
Improved SQL statement performance metrics
Transaction batching
<code>ndb_restore</code> attribute promotion
Support for <code>epoll1</code> (Linux only)
Distribution awareness
<code>NDB</code> thread locks; realtime extensions for multiple CPUs

**MySQL Cluster NDB 6.2**

Improved backup status reporting ( <code>BackupReportFrequency</code> , <code>REPORT BackupStatus</code> )
Multiple connections per SQL node
Data access with <code>NdbRecord</code> (NDB API)
<code>REPORT MemoryUsage</code> command
Memory allocation improvements
Management client connection control
Micro-GCPs
Online <code>ADD COLUMN</code> ; improved online index creation

**MySQL Cluster NDB 6.1**

Greater number of cluster nodes
Disabling of arbitration
Additional <code>DUMP</code> commands
Faster Disk Data backups
Batched slave updates

**MySQL 5.1 (through 5.1.23)**

MySQL Cluster Replication
Disk Data storage
Variable-size columns
User-defined partitioning
Autodiscovery of table schema changes
Online adding and dropping of indexes

### 17.1.4.1. MySQL Cluster Development in MySQL Cluster NDB 7.1

The following improvements to MySQL Cluster have been made in MySQL Cluster NDB 7.1.

**Important**

*These features are in early development phase.* Timing, availability, and implementation details are not guaranteed, and are subject to change at any time without notice.

- **Java connectors for MySQL Cluster.** The MySQL Cluster distribution now includes 2 new Java user APIs, ClusterJ and ClusterJPA. ClusterJ is an object-relational interface in a manner similar to that of Java persistence frameworks such as Hibernate. Cluster JPA is a reimplementation of OpenJPA. ClusterJ uses a backend library (NdbJtie) that provides access to the NDB storage engine without using a MySQL Server connection or JDBC. ClusterJPA also uses NdbJtie when it improves performance, but can also process complex queries using JDBC and a MySQL Server connection, where it can take advantage of the MySQL query optimizer.

ClusterJ and Cluster JPA can also be made to work with recent MySQL Cluster NDB 7.0 releases although the necessary library and JAR files are included only in MySQL Cluster NDB 7.1.1 and later.

- **MySQL Cluster information database (`ndbinfo`).** The `ndbinfo` information database makes it possible to obtain real-time characteristics of a MySQL Cluster by issuing queries from the `mysql` client or other MySQL client applications. `ndbinfo` provides metadata specific to MySQL Cluster similarly to how the `INFORMATION_SCHEMA` database provides metadata for the standard MySQL Server. This eliminates much of the need to read log files, issue `REPORT` or `DUMP` commands in the `ndb_mgm` client, or parse the output of `ndb_config` in order to get configuration and status information from a running MySQL Cluster.

For more information, see [Section 17.5.8, “The `ndbinfo` MySQL Cluster Information Database”](#).

- **New `CHANGE MASTER TO` option for circular replication.** Beginning with MySQL Cluster NDB 7.1.0, the `CHANGE MASTER TO` statement supports an `IGNORE_SERVER_IDS` option which takes a comma-separated list of server IDs and causes events originating from the corresponding servers to be ignored. (Log rotation and log deletion events are preserved.)

See [Section 12.5.2.1, “CHANGE MASTER TO Syntax”](#), as well as [Section 12.4.5.36, “SHOW SLAVE STATUS Syntax”](#), for more information.

- **Native support for default column values.** Starting with MySQL Cluster NDB 7.1.4, default values for table columns are stored in the NDB kernel rather than by the MySQL server as was done previously. This means that inserts on tables having column value defaults can be smaller and faster than before, because less data must be sent from SQL nodes to [NDBCLUSTER](#).

Tables created using previous MySQL Cluster releases can still be used in MySQL Cluster 7.1.4 and later; however, they do not support native default values until they are upgraded. You can upgrade a table with non-native default values to support native default values using an offline [ALTER TABLE](#) statement.

- **MySQL Cluster on Windows (*Production*).** Beginning with MySQL Cluster NDB 7.1.3, MySQL Cluster is available for production use on Microsoft Windows operating systems; MySQL Cluster NDB 7.1 binaries for Windows can be obtained from <http://dev.mysql.com/downloads/cluster/>.

Features and behavior are generally comparable to those found on previously supported platforms such as Linux and Solaris. However, you must install the binaries manually. In addition, there is currently no support for running MySQL Cluster processes as Windows services.

If you wish to build MySQL Cluster from source on Windows, you must configure the build using the [WITH\\_NDBCLUSTER\\_STORAGE\\_ENGINE](#) option. For more information, see [Section 2.4.9, “Installing MySQL from Source on Windows”](#).

- **--nowait-nodes option for management servers.** It is now possible to configure a cluster with two management servers, but to start the cluster using only one of them by starting the management node daemon with the [--nowait-nodes](#) option. The other management server can then be started at a later time to join the running MySQL Cluster.
- **Improved lock handling for primary key lookups on BLOB tables.** A MySQL Cluster table stores all but the first 256 bytes of any [BLOB](#) or [TEXT](#) column values in a separate [BLOB](#) table; when executing queries against such tables, a shared lock is obtained. Prior to MySQL Cluster NDB 7.1.1, when the query used a primary key lookup and took place within a transaction, the lock was held for the duration of the transaction, even after no more data was being read from the [NDB](#) table. Now in such cases, the lock is released when all [BLOB](#) data associated with the table has been read. ([Bug#49190](#))

### Note

A shared lock is also taken for unique key lookups; it is still the case that this lock is held for the duration of the transaction.

- **Heartbeat thread policy and priority.** Beginning with MySQL Cluster NDB 7.1.2, a new configuration parameter [HeartbeatThreadPriority](#) makes it possible to set the policy and the priority for the heartbeat thread on management and API nodes.
- **Improved access to partitioning information.** The [ndb\\_desc](#) utility now provides additional information about the partitioning of data stored in MySQL Cluster. Beginning with MySQL Cluster NDB 7.1.2, the [--blob-info](#) option causes this program to include partition information for [BLOB](#) tables in its output. Also beginning with MySQL Cluster NDB 7.1.2, the [--extra-node-info](#) option causes [ndb\\_desc](#) to include information about data distribution (that is, which table fragments are stored on which data nodes). Each of these options also requires the use of the [--extra-partition-info](#) option.

Information about partition-to-node mappings can also be obtained using the [Table::getFragmentNodes\(\)](#) method, also added in MySQL Cluster NDB 7.1.2.

- **Replication attribute promotion and demotion.** Beginning with MySQL Cluster NDB 7.1.3, MySQL Cluster Replication supports attribute promotion and demotion when replicating between columns of different but similar types on the master and the slave. For example, it is possible to promote an [INT](#) column on the master to a [BIGINT](#) column on the slave, and to demote a [TEXT](#) column to a [VARCHAR](#) column.

The implementation of type demotion distinguishes between lossy and non-lossy type conversions, and their use on the slave can be controlled by setting the [slave\\_type\\_conversions](#) global server system variable.

For more information, see [Attribute promotion and demotion \(MySQL Cluster\)](#).

- **Change in `ndbinfo` database.** The experimental `ndbinfo.pools` table was removed from `ndbinfo` in MySQL Cluster NDB 7.1.3. Applications which used this table can and should be rewritten to use other `ndbinfo` tables. For more information, see [Section 17.5.8.8, “The `ndbinfo` pools Table”](#).
- **Configuration caching control.** Beginning with MySQL Cluster NDB 7.1.4, it is possible to disable the management server's configuration cache using the `--config-cache` option, which forces `ndb_mgmd` to read its configuration data from the `config.ini` configuration file every time it starts. For more information about configuration caching and this option, see [Section 17.3.2, “MySQL Cluster Configuration Files”](#), as well as [Section 17.4.4, “`ndb\_mgmd` — The MySQL Cluster Management Server”](#).

“Daemon”.

- **Incompatible change in NDB API event reporting.** Beginning with MySQL Cluster NDB 7.1.4, DDL events are no longer reported on Event objects by default. Instead such event reporting must be enabled explicitly using the `Event::setReport()` method. For more information, see [Event::setReport\(\)](#), and [The Event::EventReport Type](#).
- **Number of table attributes.** Beginning with MySQL Cluster NDB 7.1.4, the maximum number of attributes (columns plus indexes) per table has been increased from 128 to 512.
- **InnoDB support in commercial binaries.** Beginning with MySQL Cluster NDB 7.1.4b, all commercial binary releases of MySQL Cluster provide support for the [InnoDB](#) storage engine.
- **Heartbeat ordering.** Beginning with MySQL Cluster NDB 7.1.5, it is possible to set a specific order for transmission of heartbeats between datat nodes, using the `HeartbeatOrder` data node configuration parameter introduced in this version. This parameter can be useful in situations where multiple data nodes are running on the same host and a temporary disruption in connectivity between hosts would otherwise cause the loss of a node group (and thus failure of the cluster).
- **Relaxed `ndb_restore` column comparison rules.** When restoring data, `ndb_restore` compares the attributes of a column for equality with the definition of the column in the target table. However, not all of these attributes need to be the same for `ndb_restore` to be meaningful, safe and useful. Beginning with MySQL Cluster NDB 7.1.5, `ndb_restore` automatically ignores differences in certain column attributes which do not necessarily have to match between the version of the column in a backup and the version of that column in the MySQL Cluster to which the column data is being restored. These attributes include the following:
  - `COLUMN_FORMAT` setting ([FIXED](#), [DYNAMIC](#), or [DEFAULT](#))
  - `STORAGE` setting ([MEMORY](#) or [DISK](#))
  - The default value
  - The distribution key

In such cases, `ndb_restore` reports any such differences to minimize any chance of user error.

- **Storage of user data in `anyValue`.** When writing NDB events to the binary log, MySQL Cluster uses `OperationOptions::anyValue` to store the server ID. Beginning with MySQL Cluster NDB 7.1.6, it is possible to store user data from an NDB API application in part of the `anyValue` when `mysqld` has been started with the `--server-id-bits` option set to a non-default value. Also beginning with MySQL Cluster NDB 7.1.6, it is possible to view this data in the output of `mysql-binlog`, for which its own `--server-id-bits` option is added.
- **--add-drop-trigger option for `mysqldump`.** Beginning with MySQL Cluster NDB 7.1.8, this option can be used to force all `CREATE TRIGGER` statements in `mysqldump` output to be preceded by a `DROP TRIGGER IF EXISTS` statement.

## 17.1.4.2. MySQL Cluster Development in MySQL Cluster NDB 7.0

The following list provides an overview of significant feature additions and changes made in MySQL Cluster NDB 7.0. For more detailed information about all feature changes and bugfixes made in MySQL Cluster NDB 7.0, see [Section 17.7.2, “Changes in MySQL Cluster NDB 7.0”](#).

### Important

Early development versions of MySQL Cluster NDB 7.0 were known as “MySQL Cluster NDB 6.4”, and the first four releases in this series were identified as MySQL Cluster NDB 6.4.0 through 6.4.3. Any information relating to these MySQL Cluster NDB 6.4.x releases appearing in this documentation apply to MySQL Cluster NDB 7.0.

MySQL Cluster NDB 7.0.4 is the fifth MySQL Cluster NDB 7.0 release; it is the successor to MySQL Cluster NDB 6.4.3.

- **MySQL Cluster on Windows (*alpha*).** MySQL Cluster NDB 7.0 is available on an experimental basis for Windows operating systems (for production use on Windows, you should use MySQL Cluster NDB 7.1.3 or later). Features and behavior comparable to those found on platforms that are already supported—such as Linux and Solaris—are planned for MySQL Cluster on Windows. In MySQL Cluster NDB 7.0, you must build from source (Windows binaries are available for MySQL Cluster NDB 7.1 releases). To enable MySQL Cluster support on Windows when building from source, you must configure the build using the `WITH_NDBCLUSTER_STORAGE_ENGINE` option. For more information, see [Section 2.4.9, “Installing MySQL from Source on Windows”](#).

- **Ability to add nodes and node groups online.** Beginning with MySQL Cluster NDB 6.4.0, it is possible to add new node groups (and thus new data nodes) to a running MySQL Cluster without shutting down and reloading the cluster. As part of enabling this feature, a new command `CREATE NODEGROUP` has been added to the cluster management client and the functionality of the `ALTER ONLINE TABLE ... REORGANIZE PARTITION` SQL statement has been extended. For more information, see [Section 17.5.11, “Adding MySQL Cluster Data Nodes Online”](#).
- **Data node multithreading support.** Beginning with MySQL Cluster NDB 6.4.0, a multithreaded version of the data node daemon, named `ndbmtd`, is available for use on data node hosts with multiple CPU cores. This binary is built automatically when compiling with MySQL Cluster support; no additional options other than those needed to provide MySQL Cluster support are needed when configuring the build. In most respects, `ndbmtd` functions in the same way as `ndbd`, and can use the same command-line options and configuration parameters. In addition, the new `MaxNoOfExecutionThreads` configuration parameter can be used to determine the number of data node process threads for `ndbmtd`. For more information, see [Section 17.4.3, “`ndbmtd` — The MySQL Cluster Data Node Daemon \(Multi-Threaded\)”](#).

### Note

Disk Data tables are not yet supported for use with `ndbmtd`.

- **Configuration cache.** Formerly, MySQL Cluster configuration was stateless—that is, configuration information was reloaded from the cluster's global configuration file (usually `config.ini`) each time `ndb_mgmd` was started. Beginning with MySQL Cluster NDB 6.4.0, the cluster's configuration is cached internally, and the global configuration file is no longer automatically re-read when the management server is restarted. This behavior can be controlled using the management server options `--configdir`, `--initial`, and `--reload`. In MySQL Cluster NDB 7.0.15 and later, the configuration cache can be disabled using the `--config-cache` option. For more information about these changes, see [Section 17.3.2, “MySQL Cluster Configuration Files”](#). For more information about the new management server options, see [Section 17.4.4, “`ndb\_mgmd` — The MySQL Cluster Management Server Daemon”](#).
- **Detection of NDB API client connection errors.** In MySQL Cluster NDB 7.0 (6.4.0 and later releases), the NDB API's `Ndb_cluster_connection` class provides additional methods for catching and diagnosing problems with NDB API client connections. For more information, see `Ndb_cluster_connection::get_latest_error()`, and `Ndb_cluster_connection::get_latest_error_msg()`.
- **Snapshot options for backups.** Beginning with MySQL Cluster NDB 6.4.0, you can determine when performing a cluster backup whether the backup matches the state of the data when the backup was started or when it was completed, using the new options `SNAPSHOTSTART` and `SNAPSHOTEND` for the management client's `START BACKUP` command. See [Section 17.5.3.2, “Using The MySQL Cluster Management Client to Create a Backup”](#), for more information.
- **Dynamic NDB transporter send buffer memory allocation.** Previously, the NDB kernel used a fixed-size send buffer for every data node in the cluster, which was allocated when the node started. Because the size of this buffer could not be changed after the cluster was started, it was necessary to make it large enough in advance to accommodate the maximum possible load on any transporter socket. However, this was an inefficient use of memory, since much of it often went unused. Beginning with MySQL Cluster NDB 6.4.0, send buffer memory is allocated dynamically from a memory pool shared between all transporters, which means that the size of the send buffer can be adjusted as necessary. This change is reflected by the addition of the configuration parameters `TotalSendBufferMemory`, `ReservedSendBufferMemory`, and `OverLoadLimit`, as well as a change in how the existing `SendBufferMemory` configuration parameter is used. For more information, see [Section 17.3.2.13, “Configuring MySQL Cluster Send Buffer Parameters”](#).
- **Robust DDL operations.** Beginning with MySQL Cluster NDB 6.4.0, DDL operations (such as `CREATE TABLE` or `ALTER TABLE`) are protected from data node failures; in the event of a data node failure, such operations are now rolled back gracefully. Previously, if a data node failed while trying to perform a DDL operation, the MySQL Cluster data dictionary became locked and no further DDL statements could be executed without restarting the cluster.
- **IPv6 support in MySQL Cluster Replication.** Beginning with MySQL Cluster NDB 6.4.1, IPv6 networking is supported between MySQL Cluster SQL nodes, which makes it possible to replicate between instances of MySQL Cluster using IPv6 addresses. However, IPv6 is supported only for direct connections between MySQL servers; all connections *within* an individual MySQL Cluster must use IPv4. For more information, see [Section 17.6.3, “Known Issues in MySQL Cluster Replication”](#).
- **Restoring specific databases, tables, or columns from a MySQL Cluster backup.** It is now possible to exercise more fine-grained control when restoring a MySQL Cluster from backup using `ndb_restore`. Beginning with MySQL Cluster NDB 6.4.3, you can choose to restore only specified tables or databases, or exclude specific tables or databases from being restored, using the new `ndb_restore` options `--include-tables`, `--include-databases`, `--exclude-tables`, and `--exclude-databases`. Beginning with MySQL Cluster NDB 7.0.7, it is also possible to restore to a table having fewer columns than the original using the `--exclude-missing-columns` option. For more information about all of these options, see [Section 17.4.17, “`ndb\_restore` — Restore a MySQL Cluster Backup”](#).
- **Improved Disk Data filesystem configuration.** As of MySQL Cluster NDB 6.4.3, you can specify default locations for MySQL Cluster Disk Data data files and undo log files using the data node configuration parameters `FileSystemPathDD`, `FileSystemPathDataFiles`, and `FileSystemPathUndoFiles`. This eliminates the need to use symbolic links to place Disk Data files separately from other files in data node filesystems to improve Disk Data performance. For more information, see [Disk Data filesystem parameters](#).

- **Automatic creation of Disk Data log file groups and tablespaces.** Beginning with MySQL Cluster NDB 6.4.3, using the data node configuration parameters `InitialLogFileGroup` and `InitialTablespace`, you can cause the creation of a MySQL Cluster Disk Data log file group, tablespace, or both, when the cluster is first started. When using these parameters, no SQL statements are required to create these Disk Data objects. For more information, see [Disk Data object creation parameters](#).
- **Improved internal message passing and record handling.** MySQL Cluster NDB 7.0 contains 2 changes that optimize the use of network connections by addressing the size and number of messages passed between data nodes, and between data nodes and API nodes, which can increase MySQL Cluster and application performance:
  - **Packed reads.** Formerly, each read request signal contained a list of columns to be retrieved, each of these column identifiers using 4 bytes within the message. This meant that the message size increased as the number of columns being fetched increased. In addition, in the response from the data node, each column result was packed to a 4-byte boundary, which resulted in wasted space. In MySQL Cluster NDB 7.0, messaging for read operations is optimized in both directions, using a bitmap in the read request to specify the columns to be fetched. Where many fields are requested, this can result in a significant message size reduction as compared with the old method. In addition, the 4-byte packing in responses is no longer used, which means that smaller fields consume less space.
  - **Long signal transactions.** This enhancement reduces the number of messages and signals that are sent to data nodes for complex requests. Prior to MySQL Cluster NDB 7.0, there was a 100 byte limit on the size of the request signal, which meant that complex requests had to be split up between multiple messages prior to transmission, then reassembled on the receiving end. In addition to actual payload data, each message required its own operating system and protocol overhead such as header information. This often wasted network bandwidth and data node CPU. The maximum size of the message is now 32 KB, which is sufficient to accommodate most queries.

Both of these optimizations are internal to the NDB API, and so is transparent to applications; this is true whether an application uses the NDB API directly or does so indirectly through an SQL node.

- **Configuration parameter data dumps.** Starting with MySQL Cluster NDB 7.0.6, the `ndb_config` utility supports a `--configinfo` option that causes it to dump a list of all configuration parameters supported by the cluster, along with brief descriptions, information about the parameters' default and permitted values, and the sections of the `config.ini` file in which the parameters apply. An additional `--xml` switch causes `ndb_config` to use XML rather than plaintext output. Using `ndb_config --configinfo` or `ndb_config --configinfo --xml` requires no access to a running MySQL Cluster, any other programs, or any files. For more information and examples, see [Section 17.4.6, “`ndb\_config` — Extract MySQL Cluster Configuration Information”](#).
- **Per-table reporting of free space on disk.** The `INFORMATION_SCHEMA.FILES` table shows information about used and free space in MySQL Cluster Disk Data data files, but this information is not applicable to individual tables. In MySQL Cluster NDB 7.0.8 and later, the `ndb_desc` utility provides two additional columns in its output that show the amount of space allocated on disk for a given `NDB` table as well the amount of space that remains available for additional storage of disk-based column data for that table. For more information, see [Section 17.4.9, “`ndb\_desc` — Describe NDB Tables”](#).
- **Improved restart times.** Optimizations in redo log handling and other filesystem operations introduced in MySQL Cluster NDB 7.0.9 have the potential to reduce considerably the time required for restarts. While actual performance benefits observed in production setups will naturally vary depending on database size, hardware, and other conditions, our own preliminary testing has shown that these improvements can yield startup times that are faster than those typical of previous MySQL Cluster NDB 7.0 releases by a factor of 50 or more.
- **Native support for default column values.** Starting with MySQL Cluster NDB 7.0.15, default values for table columns are stored in the NDB kernel rather than by the MySQL server as was done previously. This means that inserts on tables having column value defaults can be smaller and faster than before, because less data must be sent from SQL nodes to `NDBCLUSTER`.

Tables created using previous MySQL Cluster releases can still be used in MySQL Cluster 7.0.15 and later; however, they do not support native default values until they are upgraded. You can upgrade a table with non-native default values to support native default values using an offline `ALTER TABLE` statement.

- **--nowait-nodes option for management servers.** Starting with MySQL Cluster NDB 7.0.10, it is possible to configure a cluster with two management servers, but to start the cluster using only one of them by starting the management node daemon with the `--nowait-nodes` option. The other management server can then be started at a later time to join the running MySQL Cluster.
- **Increased flexibility in online upgrade procedure.** Previously, when performing an upgrade of a running MySQL cluster, the order in which the types of cluster nodes had to be upgraded was very strict. However, beginning with MySQL Cluster NDB 7.0.10, MySQL Cluster supports online upgrading of API nodes (including MySQL servers running as SQL nodes) online upgrading management nodes, data nodes, or both.

## Important

Before attempting to use this new upgrade functionality, see [Section 17.2.5.1, “Performing a Rolling Restart of a MySQL Cluster”](#), for additional information, especially if you are planning an online upgrade to MySQL Cluster

- NDB 7.0 from MySQL Cluster NDB 6.3.
- New **`CHANGE MASTER TO`** option for circular replication. Beginning with MySQL Cluster NDB 7.0.11, the `CHANGE MASTER TO` statement supports an `IGNORE_SERVER_IDS` option which takes a comma-separated list of server IDs and causes events originating from the corresponding servers to be ignored. (Log rotation and log deletion events are preserved.) See [Section 12.5.2.1, “`CHANGE MASTER TO` Syntax”](#), as well as [Section 12.4.5.36, “`SHOW SLAVE STATUS` Syntax”](#), for more information.
- New replication conflict resolution strategy. Beginning with MySQL Cluster NDB 7.0.11, the function `NDB$MAX_DELETE_WIN()` is available to implement “greatest timestamp, delete wins” conflict resolution. See `NDB$MAX_DELETE_WIN(column_name)`, for more information.
- Improved lock handling for primary key lookups on **`BLOB` tables**. A MySQL Cluster table stores all but the first 256 bytes of any `BLOB` or `TEXT` column values in a separate `BLOB` table; when executing queries against such tables, a shared lock is obtained. Prior to MySQL Cluster NDB 7.0.12, when the query used a primary key lookup and took place within a transaction, the lock was held for the duration of the transaction, even after no more data was being read from the `NDB` table. Now in such cases, the lock is released when all `BLOB` data associated with the table has been read. ([Bug#49190](#))

### Note

A shared lock is also taken for unique key lookups; it is still the case that this lock is held for the duration of the transaction.

- Heartbeat thread policy and priority. Beginning with MySQL Cluster NDB 7.0.13, a new configuration parameter `HeartbeatThreadPriority` makes it possible to set the policy and the priority for the heartbeat thread on management and API nodes.
- Improved access to partitioning information. The `ndb_desc` utility now provides additional information about the partitioning of data stored in MySQL Cluster. Beginning with MySQL Cluster NDB 7.0.13, the `--blob-info` option causes this program to include partition information for `BLOB` tables in its output. Beginning with MySQL Cluster NDB 7.0.14, the `--extra-node-info` option causes `ndb_desc` to include information about data distribution (that is, which table fragments are stored on which data nodes). Each of these options also requires the use of the `--extra-partition-info` option.

Information about partition-to-node mappings can also be obtained using the `Table::getFragmentNodes()` method, also added in MySQL Cluster NDB 7.0.14.

- Replication attribute promotion and demotion. Beginning with MySQL Cluster NDB 7.0.14, MySQL Cluster Replication supports attribute promotion and demotion when replicating between columns of different but similar types on the master and the slave. For example, it is possible to promote an `INT` column on the master to a `BIGINT` column on the slave, and to demote a `TEXT` column to a `VARCHAR` column.

The implementation of type demotion distinguishes between lossy and non-lossy type conversions, and their use on the slave can be controlled by setting the `slave_type_conversions` global server system variable.

For more information, see [Attribute promotion and demotion \(MySQL Cluster\)](#).

- Incompatible change in NDB API event reporting. Beginning with MySQL Cluster NDB 7.0.15, DDL events are no longer reported on Event objects by default. Instead such event reporting must be enabled explicitly using the `Event::setReport()` method. For more information, see [Event::setReport\(\)](#), and [The Event::EventReport Type](#).
- Number of table attributes. Beginning with MySQL Cluster NDB 7.0.15, the maximum number of attributes (columns plus indexes) per table has been increased from 128 to 512.
- Heartbeat ordering. Beginning with MySQL Cluster NDB 7.0.16, it is possible to set a specific order for transmission of heartbeats between data nodes, using the `HeartbeatOrder` data node configuration parameter introduced in this version. This parameter can be useful in situations where multiple data nodes are running on the same host and a temporary disruption in connectivity between hosts would otherwise cause the loss of a node group (and thus failure of the cluster).
- Relaxed `ndb_restore` column comparison rules. When restoring data, `ndb_restore` compares the attributes of a column for equality with the definition of the column in the target table. However, not all of these attributes need to be the same for `ndb_restore` to be meaningful, safe and useful. Beginning with MySQL Cluster NDB 7.0.16, `ndb_restore` automatically ignores differences in certain column attributes which do not necessarily have to match between the version of the column in a backup and the version of that column in the MySQL Cluster to which the column data is being restored. These attributes include the following:

- `COLUMN_FORMAT` setting (`FIXED`, `DYNAMIC`, or `DEFAULT`)
- `STORAGE` setting (`MEMORY` or `DISK`)

- The default value
- The distribution key

In such cases, `ndb_restore` reports any such differences to minimize any chance of user error.

- **Storage of user data in `anyValue`.** When writing NDB events to the binary log, MySQL Cluster uses `OperationOperations::anyValue` to store the server ID. Beginning with MySQL Cluster NDB 7.0.17, it is possible to store user data from an NDB API application in part of the `anyValue` when `mysqld` has been started with the `--server-id-bits` option set to a non-default value. Also beginning with MySQL Cluster NDB 7.0.17, it is possible to view this data in the output of mysql-binlog, for which its own `--server-id-bits` option is added.
- **--add-drop-trigger option for `mysqldump`.** Beginning with MySQL Cluster NDB 7.0.19, this option can be used to force all `CREATE TRIGGER` statements in `mysqldump` output to be preceded by a `DROP TRIGGER IF EXISTS` statement.

#### 17.1.4.3. MySQL Cluster Development in MySQL Cluster NDB 6.3

The following list provides an overview of significant feature additions and changes first made in MySQL Cluster NDB 6.3. For more detailed information about all feature changes and bugfixes made in MySQL Cluster NDB 6.3, see [Section 17.7.3, “Changes in MySQL Cluster NDB 6.3”](#).

- **Conflict detection and resolution.** It is now possible to detect and resolve conflicts that arise in multi-master replication scenarios, such as circular replication, when different masters may try to update the same row on the slave with different data. Both “greatest timestamp wins” and “same timestamp wins” scenarios are supported. For more information, see [Section 17.6.11, “MySQL Cluster Replication Conflict Resolution”](#).
- **Recovery of “one master, many slaves” replication setups.** Recovery of multi-way replication setups (“one master, many slaves”) is now supported using the `--ndb-log-orig` server option and changes in the `mysql.ndb_binlog_index` table. See [Section 17.6.4, “MySQL Cluster Replication Schema and Tables”](#), for more information.
- **Enhanced selection options for transaction coordinator.** New values and behaviors are introduced for `-ndb_optimized_node_selection`, enabling greater flexibility when an SQL node chooses a transaction coordinator. For more information, see the description of `ndb_optimized_node_selection` in [Section 17.3.4.3, “MySQL Cluster System Variables”](#).
- **Replication heartbeats.** Replication heartbeats facilitate the task of monitoring and detecting failures in master-slave connections in real time. This feature is implemented using a new `MASTER_HEARTBEAT_PERIOD = value` clause for the `CHANGE MASTER TO` statement and the addition of two status variables `Slave_heartbeat_period` and `Slave_received_heartbeats`. For more information, see [Section 12.5.2.1, “CHANGE MASTER TO Syntax”](#).
- **NDB thread locks.** It is possible to lock NDB execution threads and maintenance threads (such as file system and other operating system threads) to specific CPUs on multiprocessor data node hosts, and to leverage real-time scheduling.
- **Improved performance of updates using primary keys or unique keys.** The number of unnecessary reads when performing a primary key or unique key update has been greatly reduced. Since it is seldom necessary to read a record prior to an update, this can yield a considerable improvement in performance. In addition, primary key columns are no longer written to when not needed during update operations.
- **Batching improvements.** Support of batched `DELETE` and `UPDATE` operations has been significantly improved. Batching of `UPDATE WHERE...` and multiple `DELETE` operations is also now implemented.
- **Improved SQL statement performance metrics.** The `Ndb_execute_count` system status variable measures the number of round trips made by SQL statements to the NDB kernel, providing an improved metric for determining efficiency with which statements are executed. For more information, see [MySQL Cluster Status Variables: Ndb\\_execute\\_count](#).
- **Compressed LCPs and backups.** Compressed local checkpoints and backups can save 50% or more of the disk space used by uncompressed LCPs and backups. These can be enabled using the two new data node configuration parameters `CompressedLCP` and `CompressedBackup`, respectively. See [MySQL Cluster Status Variables: CompressedBackup](#), and [MySQL Cluster Status Variables: CompressedLCP](#), for more information about these parameters.
- **OPTIMIZE TABLE support with NDBCLUSTER tables.** `OPTIMIZE TABLE` is supported for dynamic columns of in-memory NDB tables. In such cases, it is no longer necessary to drop (and possibly to re-create) a table, or to perform a rolling restart, in order to recover memory from deleted rows for general re-use by Cluster. The performance of `OPTIMIZE` on Cluster tables can be tuned by adjusting the value of the `ndb_optimization_delay` system variable, which controls the number of milliseconds to wait between processing batches of rows by `OPTIMIZE TABLE`. In addition, `OPTIMIZE TABLE` on an NDBCLUSTER table can be interrupted by, for example, killing the SQL thread performing the `OPTIMIZE` operation.

- **Batching of transactions.** It is possible to cause statements occurring within the same transaction to be run as a batch by setting the session variable `transaction_allow_batching` to `1` or `ON`. To use this feature, `autocommit` must be set to `0` or `OFF`. Batch sizes can be controlled using the `--ndb-batch-size` option for `mysqld`. For additional information, see [Section 17.3.4.2, “`mysqld` Command Options for MySQL Cluster”](#), and [Section 17.3.4.3, “MySQL Cluster System Variables”](#).
- **Attribute promotion with `ndb_restore`.** It is possible using `ndb_restore` to restore data reliably from a column of a given type to a column that uses a “larger” type. This is sometimes referred to as *attribute promotion*. For example, MySQL Cluster backup data that originated in a `SMALLINT` column can be restored to a `MEDIUMINT`, `INT`, or `BIGINT` column. See [Section 17.4.17, “`ndb\_restore` — Restore a MySQL Cluster Backup”](#), for more information.
- **Parallel data node recovery.** Recovery of multiple data nodes can now be done in parallel, rather than sequentially. In other words, several data nodes can be restored concurrently, which can often result in much faster recovery times than when they are restored one at a time.
- **Increased local checkpoint efficiency.** Only 2 local checkpoints are stored, rather than 3, lowering disk space requirements and the size and number of redo log files.
- **NDBCLUSTER table persistence control.** Persistence of NDB tables can be controlled using the session variables `ndb_table_temporary` and `ndb_table_no_logging`. `ndb_table_no_logging` causes NDB tables not to be checkpointed to disk; `ndb_table_temporary` does the same, and in addition, no schema files are created. See [Section 17.3.4.1, “MySQL Cluster Server Option and Variable Reference”](#).
- **Epoll support (Linux only).** *Epoll* is an improved method for handling file descriptors, which is more efficient than scanning to determine whether a file descriptor has data to be read. (The term *epoll* is specific to Linux and equivalent functionality is known by other names on other platforms such as Solaris and FreeBSD.) Currently, MySQL Cluster supports this functionality on Linux only.
- **Distribution awareness (SQL nodes).** In MySQL Cluster NDB 6.3, SQL nodes can take advantage of [distribution awareness](#). Here we provide a brief example showing how to design a table to make a given class of queries distribution-aware. Suppose an `NDBCLUSTER` table `t1` has the following schema:

```
CREATE TABLE t1 (
 userid INT NOT NULL,
 serviceid INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
 data VARCHAR(255)
) ENGINE=NDBCLUSTER;
```

Suppose further that most of the queries to be used in our application test values of the `userid` column of this table. The form of such a query looks something like this:

```
SELECT columns FROM t1
WHERE userid relation value;
```

In this query, `relation` represents some relational operator, such as `=`, `<`, `>`, and so on. Queries using `IN` and a list of values can also be used:

```
SELECT columns FROM t1
WHERE userid IN value_list;
```

To make use of distribution awareness, we need to make the `userid` column part of the table's primary key, then explicitly partition the table with this column being used as the partitioning key. (Recall that for a partitioned table having one or more unique keys, all columns of the table's partitioning key must also be part of all of the unique keys—for more information and examples, see [Section 18.5.1, “Partitioning Keys, Primary Keys, and Unique Keys”](#).) In other words, the table schema should be equivalent to the following `CREATE TABLE` statement:

```
CREATE TABLE t1 (
 userid INT NOT NULL,
 serviceid INT NOT NULL AUTO_INCREMENT,
 data VARCHAR(255),
 PRIMARY KEY p (userid,serviceid)
) ENGINE=NDBCLUSTER
PARTITION BY KEY(userid);
```

When the table is partitioned in this way, all rows having the same `userid` value are found on the same node group, and the MySQL Server can immediately select the optimal node to use as the transaction coordinator.

- **Realtime extensions for multiple CPUs.** When running MySQL Cluster data nodes on hosts with multiple processors, the realtime extensions make it possible to give priority to the data node process and control on which CPU cores it should operate. This can be done using the data node configuration parameters `RealtimeScheduler`, `SchedulerExecutionTimer` and `SchedulerSpinTimer`. Doing so properly can significantly lower response times and make them much more predictable response. For more information about using these parameters, see [Defining Data Nodes: Realtime Performance Parameters](#)
- **Fully automatic database discovery.** It is no longer a requirement for database autodiscovery that an SQL node already be connected to the cluster at the time that a database is created on another SQL node, or for a `CREATE DATABASE` or `CREATE SCHEMA` statement to be issued on the new SQL node after it joins the cluster.

- **Detection of NDB API client connection errors.** Beginning with MySQL Cluster NDB 6.3.20, the NDB API's `Ndb_cluster_connection` class provides additional methods for catching and diagnosing problems with NDB API client connections. For more information, see `Ndb_cluster_connection::get_latest_error()`, and `Ndb_cluster_connection::get_latest_error_msg()`.
- **Restoring specific databases, tables, or columns from a MySQL Cluster backup.** It is now possible to exercise more fine-grained control when restoring a MySQL Cluster from backup using `ndb_restore`. Beginning with MySQL Cluster NDB 6.3.22, you can choose to restore only specified tables or databases, or exclude specific tables or databases from being restored, using the new `ndb_restore` options `--include-tables`, `--include-databases`, `--exclude-tables`, and `--exclude-databases`. Beginning with MySQL Cluster NDB 6.3.26, it is also possible to restore to a table having fewer columns than the original using the `--exclude-missing-columns` option. For more information about all of these options, see [Section 17.4.17, “`ndb\_restore` — Restore a MySQL Cluster Backup”](#).
- **Improved Disk Data filesystem configuration.** As of MySQL Cluster NDB 6.3.22, you can specify default locations for MySQL Cluster Disk Data data files and undo log files using the data node configuration parameters `FileSystemPathDD`, `FileSystemPathDataFiles`, and `FileSystemPathUndoFiles`. This eliminates the need to use symbolic links to place Disk Data files separately from other files in data node filesystems to improve Disk Data performance. For more information, see [Disk Data filesystem parameters](#).
- **Automatic creation of Disk Data log file groups and tablespaces.** Beginning with MySQL Cluster NDB 6.3.22, using the data node configuration parameters `InitialLogFileGroup` and `InitialTablespace`, you can cause the creation of a MySQL Cluster Disk Data log file group, tablespace, or both, when the cluster is first started. When using these parameters, no SQL statements are required to create these Disk Data objects. For more information, see [Disk Data object creation parameters](#).
- **Configuration parameter data dumps.** Starting with MySQL Cluster NDB 6.3.25, the `ndb_config` utility supports a `--configinfo` option that causes it to dump a list of all configuration parameters supported by the cluster, along with brief descriptions, information about the parameters' default and permitted values, and the sections of the `config.ini` file in which the parameters apply. An additional `--xml` switch causes `ndb_config` to use XML rather than plaintext output. Using `ndb_config --configinfo` or `ndb_config --configinfo --xml` requires no access to a running MySQL Cluster, any other programs, or any files. For more information and examples, see [Section 17.4.6, “`ndb\_config` — Extract MySQL Cluster Configuration Information”](#).
- **Per-table reporting of free space on disk.** The `INFORMATION_SCHEMA.FILES` table shows information about used and free space in MySQL Cluster Disk Data data files, but this information is not applicable to individual tables. In MySQL Cluster NDB 6.3.27 and later, the `ndb_desc` utility provides two additional columns in its output that show the amount of space allocated on disk for a given `NDB` table as well the amount of space that remains available for additional storage of disk-based column data for that table. For more information, see [Section 17.4.9, “`ndb\_desc` — Describe NDB Tables”](#).
- **Improved restart times.** Optimizations in redo log handling and other filesystem operations introduced in MySQL Cluster NDB 6.3.28 have the potential to reduce considerably the time required for restarts. While actual performance benefits observed in production setups will naturally vary depending on database size, hardware, and other conditions, our own preliminary testing has shown that these improvements can yield startup times that are faster than those typical of previous MySQL Cluster NDB 6.3 releases by a factor of 50 or more.
- **Increased flexibility in online upgrade procedure.** Previously, when performing an upgrade of a running MySQL cluster, the order in which the types of cluster nodes had to be upgraded was very strict. However, beginning with MySQL Cluster NDB 6.3.29, MySQL Cluster supports online upgrading of API nodes (including MySQL servers running as SQL nodes) before upgrading management nodes, data nodes, or both.

### Important

Before attempting to use this new upgrade functionality, see [Section 17.2.5.1, “Performing a Rolling Restart of a MySQL Cluster”](#), for additional information, especially if you are planning an online upgrade from MySQL Cluster NDB 6.3 to MySQL Cluster NDB 7.0.

- **New replication conflict resolution strategy.** Beginning with MySQL Cluster NDB 6.3.31, the function `NDB$MAX_DELETE_WIN()` is available to implement “greatest timestamp, delete wins” conflict resolution. See `NDB$MAX_DELETE_WIN(column_name)`, for more information.
  - **New `CHANGE MASTER TO` option for circular replication.** Beginning with MySQL Cluster NDB 6.3.31, the `CHANGE MASTER TO` statement supports an `IGNORE_SERVER_IDS` option which takes a comma-separated list of server IDs and causes events originating from the corresponding servers to be ignored. (Log rotation and log deletion events are preserved.)
- See [Section 12.5.2.1, “`CHANGE MASTER TO` Syntax”](#), as well as [Section 12.4.5.36, “`SHOW SLAVE STATUS` Syntax”](#), for more information.
- **Heartbeat thread policy and priority.** Beginning with MySQL Cluster NDB 6.3.32, a new configuration parameter `HeartbeatThreadPriority` makes it possible to set the policy and the priority for the heartbeat thread on management and API nodes.

- **Improved access to partitioning information.** The `ndb_desc` utility now provides additional information about the partitioning of data stored in MySQL Cluster. Beginning with MySQL Cluster NDB 6.3.32, the `--blob-info` option causes this program to include partition information for `BLOB` tables in its output. Beginning with MySQL Cluster NDB 6.3.33, the `--extra-node-info` option causes `ndb_desc` to include information about data distribution (that is, which table fragments are stored on which data nodes). Each of these options also requires the use of the `--extra-partition-info` option.

Information about partition-to-node mappings can also be obtained using the `Table::getFragmentNodes()` method, also added in MySQL Cluster NDB 6.3.33.

- **Replication attribute promotion and demotion.** Beginning with MySQL Cluster NDB 6.3.33, MySQL Cluster Replication supports attribute promotion and demotion when replicating between columns of different but similar types on the master and the slave. For example, it is possible to promote an `INT` column on the master to a `BIGINT` column on the slave, and to demote a `TEXT` column to a `VARCHAR` column.

The implementation of type demotion distinguishes between lossy and non-lossy type conversions, and their use on the slave can be controlled by setting the `slave_type_conversions` global server system variable.

For more information, see [Attribute promotion and demotion \(MySQL Cluster\)](#).

- **Incompatible change in NDB API event reporting.** Beginning with MySQL Cluster NDB 6.3.34, DDL events are no longer reported on Event objects by default. Instead such event reporting must be enabled explicitly using the `Event::setReport()` method. For more information, see [Event::setReport\(\)](#), and [The Event::EventReport Type](#).
- **Heartbeat ordering.** Beginning with MySQL Cluster NDB 6.3.35, it is possible to set a specific order for transmission of heartbeats between datanodes, using the `HeartbeatOrder` data node configuration parameter introduced in this version. This parameter can be useful in situations where multiple data nodes are running on the same host and a temporary disruption in connectivity between hosts would otherwise cause the loss of a node group (and thus failure of the cluster).
- **Relaxed `ndb_restore` column comparison rules.** When restoring data, `ndb_restore` compares the attributes of a column for equality with the definition of the column in the target table. However, not all of these attributes need to be the same for `ndb_restore` to be meaningful, safe and useful. Beginning with MySQL Cluster NDB 6.3.35, `ndb_restore` automatically ignores differences in certain column attributes which do not necessarily have to match between the version of the column in a backup and the version of that column in the MySQL Cluster to which the column data is being restored. These attributes include the following:

- `COLUMN_FORMAT` setting (`FIXED`, `DYNAMIC`, or `DEFAULT`)
- `STORAGE` setting (`MEMORY` or `DISK`)
- The default value
- The distribution key

In such cases, `ndb_restore` reports any such differences to minimize any chance of user error.

- **--add-drop-trigger option for `mysqldump`.** Beginning with MySQL Cluster NDB 6.3.38, this option can be used to force all `CREATE TRIGGER` statements in `mysqldump` output to be preceded by a `DROP TRIGGER IF EXISTS` statement.

#### 17.1.4.4. MySQL Cluster Development in MySQL Cluster NDB 6.2

The following list provides an overview of significant feature additions and changes made in MySQL Cluster NDB 6.2. All of the changes in this list are also available in MySQL Cluster NDB 6.3. For more detailed information about all feature changes and bugfixes made in MySQL Cluster NDB 6.2, see [Section 17.7.4, “Changes in MySQL Cluster NDB 6.2”](#).

- **Enhanced backup status reporting.** Backup status reporting has been improved, aided in part by the introduction of a `BackupReportFrequency` configuration parameter; see [Defining Data Nodes: BackupReportFrequency](#), for more information.
- **Multiple cluster connections per SQL node.** A single MySQL server acting as a MySQL Cluster SQL node can employ multiple connections to the cluster using the `--ndb-cluster-connection-pool` startup option for `mysqld`. This option is described in [MySQL Cluster-Related Command Options for mysqld: --ndb-cluster-connection-pool option](#).
- **New data access interface.** The `NdbRecord` interface provides a new and simplified data handler for use in NDB API applications. See [The NdbRecord Interface](#), for more information.
- **New reporting commands.** The new management client `REPORT BackupStatus` and `REPORT MemoryUsage` commands provide better access to information about the status of MySQL Cluster backups and how much memory is being used

by MySQL Cluster for data and index storage. See [Section 17.5.2, “Commands in the MySQL Cluster Management Client”](#), for more information about the `REPORT` commands. In addition, in-progress status reporting is provided by the `ndb_restore` utility; see [Section 17.4.17, “`ndb\_restore` — Restore a MySQL Cluster Backup”](#).

- **Improved memory allocation and configuration.** Memory is now allocated by the `NDB` kernel to tables on a page-by-page basis, which significantly reduces the memory overhead required for maintaining `NDBCLUSTER` tables. In addition, the `MaxAllocate` configuration parameter now makes it possible to set the maximum size of the allocation unit used for table memory; for more information about this configuration parameter, see [Defining Data Nodes: `MaxAllocate`](#).
- **Choice of fixed-width or variable-width columns.** You can control whether fixed-width or variable-width storage is used for a given column of an `NDB` table by employing of the `COLUMN_FORMAT` specifier as part of the column's definition in a `CREATE TABLE` or `ALTER TABLE` statement. In addition, the ability to control whether a given column of an `NDB` table is stored in memory or on disk, using the `STORAGE` specifier as part of the column's definition in a `CREATE TABLE` or `ALTER TABLE` statement. For more information, see [Section 12.1.17, “`CREATE TABLE` Syntax”](#), and [Section 12.1.7, “`ALTER TABLE` Syntax”](#).
- **Controlling management client connections.** The `--bind-address` cluster management server startup option makes it possible to restrict management client connections to `ndb_mgmd` to a single host (IP address or host name) and port, which can make MySQL Cluster management operations more secure. For more information about this option, see [Section 17.4.4, “`ndb\_mgmd` — The MySQL Cluster Management Server Daemon”](#).
- **Micro-GCPs.** Due to a change in the protocol for handling of global checkpoints (GCPs handled in this manner sometimes being referred to as “micro-GCPs”), it is now possible to control how often the GCI number is updated, and how often global checkpoints are written to disk, using the `TimeBetweenEpochs` configuration parameter. This improves the reliability and performance of MySQL Cluster Replication. For more information, see [Defining Data Nodes: `TimeBetweenEpochs`](#) and [Defining Data Nodes: `TimeBetweenEpochsTimeout`](#).
- **Core online schema change support.** Support for the online `ALTER TABLE` operations `ADD COLUMN`, `ADD INDEX`, and `DROP INDEX` is available. When the `ONLINE` keyword is used, the `ALTER TABLE` is noncopying, which means that indexes do not have to be re-created, which provides these benefits:
  - Single user mode is no longer required for `ALTER TABLE` operations that can be performed online.
  - Transactions can continue during `ALTER TABLE` operations that can be performed online.
  - Tables being altered online are not locked against access by other SQL nodes.

However, such tables are locked against other operations on the *same* SQL node for the duration of the `ALTER TABLE`. We are working to overcome this limitation in a future MySQL Cluster release.

Online `CREATE INDEX` and `DROP INDEX` statements are also supported. Online changes can be suppressed using the `OFF-LINE` key word. See [Section 12.1.7, “`ALTER TABLE` Syntax”](#), [Section 12.1.13, “`CREATE INDEX` Syntax”](#), and [Section 12.1.24, “`DROP INDEX` Syntax”](#), for more detailed information.

- **`mysql.ndb_binlog_index` improvements.** More information has been added to the `mysql.ndb_binlog_index` table so that it is possible to determine which originating epochs have been applied inside an epoch. This is particularly useful for 3-way replication. See [Section 17.6.4, “MySQL Cluster Replication Schema and Tables”](#), for more information.
- **Epoch lag control.** The `MaxBufferedEpochs` data node configuration parameter provides a means to control the maximum number of unprocessed epochs by which a subscribing node can lag. Subscribers which exceed this number are disconnected and forced to reconnect. For a discussion of this configuration parameter, see [Defining Data Nodes: `MaxBufferedEpochs`](#).
- **Fully automatic database discovery.** It is no longer a requirement for database autodiscovery that an SQL node already be connected to the cluster at the time that a database is created on another SQL node, or for a `CREATE DATABASE` or `CREATE SCHEMA` statement to be issued on the new SQL node after it joins the cluster.
- **Multiple data node processes per host.** In earlier MySQL Cluster release series, we did not support MySQL Cluster deployments in production where more than one `ndbd` process was run on a single physical machine. However, beginning with MySQL Cluster NDB 6.2.0, you can use multiple data node processes on a single host.

### Note

A multi-threaded version of `ndbd` tailored for use on hosts with multiple CPUs or cores was introduced in MySQL Cluster NDB 7.0. See [Section 17.1.4.2, “MySQL Cluster Development in MySQL Cluster NDB 7.0”](#), and [Section 17.4.3, “`ndbmtd` — The MySQL Cluster Data Node Daemon \(Multi-Threaded\)”](#), for more information.

- **Improved Disk Data filesystem configuration.** As of MySQL Cluster NDB 6.2.17, you can specify default locations for MySQL Cluster Disk Data data files and undo log files using the data node configuration parameters `FileSystemPathDD`, `FileSystemPathDataFiles`, and `FileSystemPathUndoFiles`. This eliminates the need to use symbolic links to place Disk Data files separately from other files in data node filesystems to improve Disk Data performance. For more informa-

tion, see [Disk Data filesystem parameters](#).

- **Automatic creation of Disk Data log file groups and tablespaces.** Beginning with MySQL Cluster NDB 6.2.17, using the data node configuration parameters `InitialLogFileGroup` and `InitialTablespace`, you can cause the creation of a MySQL Cluster Disk Data log file group, tablespace, or both, when the cluster is first started. When using these parameters, no SQL statements are required to create these Disk Data objects. For more information, see [Disk Data object creation parameters](#).
- **Improved access to partitioning information.** The `ndb_desc` utility now provides additional information about the partitioning of data stored in MySQL Cluster. Beginning with MySQL Cluster NDB 6.2.19, the `--extra-node-info` option causes `ndb_desc` to include information about data distribution (that is, which table fragments are stored on which data nodes). This option also requires the use of the `--extra-partition-info` option.

Information about partition-to-node mappings can also be obtained using the `Table::getFragmentNodes()` method, also added in MySQL Cluster NDB 6.2.19.

- **New `CHANGE MASTER TO` option for circular replication.** Beginning with MySQL Cluster NDB 6.2.19, the `CHANGE MASTER TO` statement supports an `IGNORE_SERVER_IDS` option which takes a comma-separated list of server IDs and causes events originating from the corresponding servers to be ignored. (Log rotation and log deletion events are preserved.)

See [Section 12.5.2.1, “`CHANGE MASTER TO` Syntax”](#), as well as [Section 12.4.5.36, “`SHOW SLAVE STATUS` Syntax”](#), for more information.

#### 17.1.4.5. MySQL Cluster Development in MySQL Cluster NDB 6.1

The following list provides an overview of significant feature additions and changes made in MySQL Cluster NDB 6.1. All of the changes in this list are also available in MySQL Cluster NDB 6.2 and 6.3 releases. For detailed information about all changes made in MySQL Cluster NDB 6.1, see [Section 17.7.5, “Changes in MySQL Cluster NDB 6.1”](#).

- **Increased number of cluster nodes.** The maximum number of all nodes in a MySQL Cluster has been increased to 255. For more information, see [Section 17.1.5.10, “Limitations Relating to Multiple MySQL Cluster Nodes”](#).
- **Disabling arbitration.** It is now possible to disable arbitration by setting `ArbitrationRank=0` on all cluster management and SQL nodes. For more information, see [Defining the Management Server: ArbitrationRank](#) and [Defining SQL and Other API Nodes: ArbitrationRank](#).
- **Additional `DUMP` commands.** New management client `DUMP` commands provide help with tracking transactions, scan operations, and locks. See [Section 17.5.2, “Commands in the MySQL Cluster Management Client”](#), and [DUMP Commands](#), for more information.
- **Faster Disk Data backups.** Improvements in backups of Disk Data tables can yield a 10 to 15% increase in backup speed of Disk Data tables.
- **Batched slave updates.** Batching of updates on cluster replication slaves, enabled using the `--slave-allow-batching` option for `mysqld`, increases replication efficiency. For more information, see [Section 17.6.6, “Starting MySQL Cluster Replication \(Single Replication Channel\)”](#).

#### 17.1.4.6. Development History of MySQL Cluster in MySQL 5.1

A number of features for MySQL Cluster were implemented in MySQL 5.1 through MySQL 5.1.23, when support for MySQL Cluster was moved to MySQL Cluster NDB. All of the features in the following list are also available in all MySQL Cluster NDB (6.1 and later) releases.

- **Integration of MySQL Cluster into MySQL Replication.** MySQL Cluster Replication makes it possible to replicate from one MySQL Cluster to another. Updates on any SQL node (MySQL server) in the cluster acting as the master are replicated to the slave cluster; the state of the slave side remains consistent with the cluster acting as the master. This is sometimes referred to as *asynchronous replication* between clusters, providing *geographic redundancy*. It is also possible to replicate from a MySQL Cluster acting as the master to a standalone MySQL server acting as the slave, or from a standalone MySQL master server to a slave cluster; in either of these cases, the standalone MySQL server uses a storage engine other than `NDB-CLUSTER`. Multi-master replication setups such as circular replication are also supported.

See [Section 17.6, “MySQL Cluster Replication”](#).

- **Support for storage of rows on disk.** Storage of `NDBCCLUSTER` table data on disk is now supported. Indexed columns, including the primary key hash index, must still be stored in RAM; however, all other columns can be stored on disk.

See [Section 17.5.10, “MySQL Cluster Disk Data Tables”](#).

- **Variable-size columns.** In MySQL 5.0, an `NDBCLUSTER` table column defined as `VARCHAR(255)` used 260 bytes of storage independent of what was stored in any particular record. In MySQL 5.1 Cluster tables, only the portion of the column actually taken up by the record is stored. This makes possible a significant reduction in space requirements for such columns as compared to previous release series—by a factor of up to 5 in many cases.
- **User-defined partitioning.** Users can define partitions based on columns that are part of the primary key. It is possible to partition `NDB` tables based on `KEY` and `LINEAR KEY` schemes. This feature is also available for many other MySQL storage engines, which support additional partitioning types that are not available with `NDBCLUSTER` tables.

For additional general information about user-defined partitioning in MySQL 5.1, see [Chapter 18, Partitioning](#). Specifics of partitioning types are discussed in [Section 18.2, “Partition Types”](#).

The MySQL Server can also determine whether it is possible to “prune away” some of the partitions from the `WHERE` clause, which can greatly speed up some queries. See [Section 18.4, “Partition Pruning”](#), for information about designing tables and queries to take advantage of partition pruning.

- **Autodiscovery of table schema changes.** In MySQL 5.0, it was necessary to issue a `FLUSH TABLES` statement or a “dummy” `SELECT` for new `NDBCLUSTER` tables or changes made to schemas of existing `NDBCLUSTER` tables on one SQL node to be visible on the cluster’s other SQL nodes. In MySQL 5.1, this is no longer necessary; new Cluster tables and changes in the definitions of existing `NDBCLUSTER` tables made on one SQL node are immediately visible to all SQL nodes connected to the cluster.

#### **Note**

When creating a new database, it is still necessary in MySQL 5.1 to issue a `CREATE DATABASE` or `CREATE SCHEMA` statement on each SQL node in the cluster.

- **Distribution awareness (NDB API).** *Distribution awareness* is a mechanism by which the best data node is automatically selected to be queried for information. (Conceptually, it is similar in some ways to partition pruning (see [Section 18.4, “Partition Pruning”](#)). To take advantage of distribution awareness, you should do the following:

1. Determine which table column is most likely to be used for finding matching records.
2. Make this column part of the table’s primary key.
3. Explicitly partition the table by `KEY`, using this column as the table’s partitioning key.

Following these steps causes records with the same value for the partitioning column to be stored on the same partition (that is, in the same node group). When reading data, transactions are begun on the data node actually having the desired rows instead of this node being determined by the usual round-robin mechanism.

#### **Important**

To see a measurable impact on performance, the cluster must have at least four data nodes, since, with only two data nodes, both data nodes have exactly the same data.

Using distribution awareness can yield performance increase of as great as 45% when using four data nodes, and possibly more when using a greater number of data nodes.

#### **Note**

In mainline MySQL 5.1 releases, distribution awareness was supported only when using the NDB API; support was added for SQL and API nodes in MySQL Cluster NDB 6.3 (see [Section 17.1.4.3, “MySQL Cluster Development in MySQL Cluster NDB 6.3”](#), which includes an example showing how to create a table to take advantage of distribution awareness).

See [Section 17.1.5.11, “Previous MySQL Cluster Issues Resolved in MySQL 5.1, MySQL Cluster NDB 6.x, and MySQL Cluster NDB 7.x”](#), for more information.

### 17.1.5. Known Limitations of MySQL Cluster

In the sections that follow, we discuss known limitations in current releases of MySQL Cluster as compared with the features available when using the `MyISAM` and `InnoDB` storage engines. If you check the “Cluster” category in the MySQL bugs database at <http://bugs.mysql.com>, you can find known bugs in the following categories under “MySQL Server:” in the MySQL bugs database at <http://bugs.mysql.com>, which we intend to correct in upcoming releases of MySQL Cluster:

- Cluster

- Cluster Direct API (NDBAPI)
- Cluster Disk Data
- Cluster Replication

This information is intended to be complete with respect to the conditions just set forth. You can report any discrepancies that you encounter to the MySQL bugs database using the instructions given in [Section 1.7, “How to Report Bugs or Problems”](#). If we do not plan to fix the problem in MySQL Cluster NDB 6.X or 7.X, we will add it to the list.

See [Section 17.1.5.11, “Previous MySQL Cluster Issues Resolved in MySQL 5.1, MySQL Cluster NDB 6.x, and MySQL Cluster NDB 7.x”](#) for a list of issues in MySQL Cluster in MySQL 5.0 that have been resolved in the current version.

#### **Note**

Limitations and other issues specific to MySQL Cluster Replication are described in [Section 17.6.3, “Known Issues in MySQL Cluster Replication”](#).

### 17.1.5.1. Noncompliance with SQL Syntax in MySQL Cluster

Some SQL statements relating to certain MySQL features produce errors when used with **NDB** tables, as described in the following list:

- **Temporary tables.** Temporary tables are not supported. Trying either to create a temporary table that uses the **NDB** storage engine or to alter an existing temporary table to use **NDB** fails with the error `TABLE STORAGE ENGINE 'NDBCCLUSTER' DOES NOT SUPPORT THE CREATE OPTION 'TEMPORARY'.`
- **Indexes and keys in NDB tables.** Keys and indexes on MySQL Cluster tables are subject to the following limitations:
  - **Column width.** Attempting to create an index on an **NDB** table column whose width is greater than 3072 bytes succeeds, but only the first 3072 bytes are actually used for the index. In such cases, a warning `SPECIFIED KEY WAS TOO LONG; MAX KEY LENGTH IS 3072 BYTES` is issued, and a `SHOW CREATE TABLE` statement shows the length of the index as 3072.
  - **TEXT and BLOB columns.** You cannot create indexes on **NDB** table columns that use any of the **TEXT** or **BLOB** data types.
  - **FULLTEXT indexes.** The **NDB** storage engine does not support **FULLTEXT** indexes, which are possible for **MyISAM** tables only.

However, you can create indexes on **VARCHAR** columns of **NDB** tables.

- **Prefixes.** There are no prefix indexes; only entire columns can be indexed. (The size of an **NDB** column index is always the same as the width of the column in bytes, up to and including 3072 bytes, as described earlier in this section. Also see [Section 17.1.5.6, “Unsupported or Missing Features in MySQL Cluster”](#), for additional information.)
- **BIT columns.** A **BIT** column cannot be a primary key, unique key, or index, nor can it be part of a composite primary key, unique key, or index.
- **AUTO\_INCREMENT columns.** Like other MySQL storage engines, the **NDB** storage engine can handle a maximum of one **AUTO\_INCREMENT** column per table. However, in the case of a Cluster table with no explicit primary key, an **AUTO\_INCREMENT** column is automatically defined and used as a “hidden” primary key. For this reason, you cannot define a table that has an explicit **AUTO\_INCREMENT** column unless that column is also declared using the **PRIMARY KEY** option. Attempting to create a table with an **AUTO\_INCREMENT** column that is not the table’s primary key, and using the **NDB** storage engine, fails with an error.

- **MySQL Cluster and geometry data types.** Geometry data types (**WKT** and **WKB**) are supported in **NDB** tables in MySQL 5.1 (including MySQL Cluster NDB 6.X and 7.X through 7.1). However, spatial indexes are not supported.
- **Character sets and binary log files.** Currently, the **ndb\_apply\_status** and **ndb\_binlog\_index** tables are created using the **latin1** (ASCII) character set. Because names of binary logs are recorded in this table, binary log files named using non-Latin characters are not referenced correctly in these tables. This is a known issue, which we are working to fix. ([Bug#50226](#))

To work around this problem, use only Latin-1 characters when naming binary log files or setting any the `--basedir`, `-log-bin`, or `--log-bin-index` options.

- **Creating NDBCCLUSTER tables with user-defined partitioning.** Support for user-defined partitioning for MySQL Cluster in MySQL 5.1 (including MySQL Cluster NDB 6.X and 7.X through 7.1) is restricted to [**LINEAR**] **KEY** partitioning. Beginning with MySQL 5.1.12, using any other partitioning type with **ENGINE=NDB** or **ENGINE=NDBCCLUSTER** in a `CREATE TABLE`

statement results in an error.

**Default partitioning scheme.** As of MySQL 5.1.6, all MySQL Cluster tables are by default partitioned by `KEY` using the table's primary key as the partitioning key. If no primary key is explicitly set for the table, the "hidden" primary key automatically created by the `NDBCLUSTER` storage engine is used instead. For additional discussion of these and related issues, see [Section 18.2.4, "KEY Partitioning"](#).

Beginning with MySQL Cluster NDB 6.2.18, MySQL Cluster NDB 6.3.25, and MySQL Cluster NDB 7.0.6, `CREATE TABLE` and `ALTER TABLE` statements that would cause a user-partitioned `NDBCLUSTER` table not to meet either or both of the following two requirements are not permitted, and fail with an error ([Bug#40709](#)):

1. The table must have an explicit primary key.
2. All columns listed in the table's partitioning expression must be part of the primary key.

**Exception.** If a user-partitioned `NDBCLUSTER` table is created using an empty column-list (that is, using `PARTITION BY [LINEAR] KEY()`), then no explicit primary key is required.

**Maximum number of partitions for `NDBCLUSTER` tables.** The maximum number of partitions that can be defined for a `NDBCLUSTER` table when employing user-defined partitioning is 8 per node group. (See [Section 17.1.2, "MySQL Cluster Nodes, Node Groups, Replicas, and Partitions"](#), for more information about MySQL Cluster node groups.)

**DROP PARTITION not supported.** It is not possible to drop partitions from `NDB` tables using `ALTER TABLE ... DROP PARTITION`. The other partitioning extensions to `ALTER TABLE`—`ADD PARTITION`, `REORGANIZE PARTITION`, and `COALESCE PARTITION`—are supported for Cluster tables, but use copying and so are not optimised. See [Section 18.3.1, "Management of RANGE and LIST Partitions"](#) and [Section 12.1.7, "ALTER TABLE Syntax"](#).

- **Row-based replication.** When using row-based replication with MySQL Cluster, binary logging cannot be disabled. That is, the `NDB` storage engine ignores the value of `sql_log_bin`. ([Bug#16680](#))

### 17.1.5.2. Limits and Differences of MySQL Cluster from Standard MySQL Limits

In this section, we list limits found in MySQL Cluster that either differ from limits found in, or that are not found in, standard MySQL.

**Memory usage and recovery.** Memory consumed when data is inserted into an `NDB` table is not automatically recovered when deleted, as it is with other storage engines. Instead, the following rules hold true:

- A `DELETE` statement on an `NDB` table makes the memory formerly used by the deleted rows available for re-use by inserts on the same table only. This memory cannot be used by other `NDB` tables.
- A `DROP TABLE` or `TRUNCATE TABLE` operation on an `NDB` table frees the memory that was used by this table for re-use by any `NDB` table, either by the same table or by another `NDB` table.

#### Note

Recall that `TRUNCATE TABLE` drops and re-creates the table. See [Section 12.2.10, "TRUNCATE TABLE Syntax"](#).

Memory freed by `DELETE` operations but still allocated to a specific table can also be made available for general re-use by performing a rolling restart of the cluster. See [Section 17.2.5.1, "Performing a Rolling Restart of a MySQL Cluster"](#).

Beginning with MySQL Cluster NDB 6.3.7, this limitation can be overcome using `OPTIMIZE TABLE`. See [Section 17.1.5.11, "Previous MySQL Cluster Issues Resolved in MySQL 5.1, MySQL Cluster NDB 6.x, and MySQL Cluster NDB 7.x"](#), for more information.

- **Limits imposed by the cluster's configuration.** A number of hard limits exist which are configurable, but available main memory in the cluster sets limits. See the complete list of configuration parameters in [Section 17.3.2, "MySQL Cluster Configuration Files"](#). Most configuration parameters can be upgraded online. These hard limits include:

- Database memory size and index memory size (`DataMemory` and `IndexMemory`, respectively).

`DataMemory` is allocated as 32KB pages. As each `DataMemory` page is used, it is assigned to a specific table; once allocated, this memory cannot be freed except by dropping the table.

See [Section 17.3.2.6, "Defining MySQL Cluster Data Nodes"](#), for further information about `DataMemory` and `IndexMemory`.

- The maximum number of operations that can be performed per transaction is set using the configuration parameters `MaxNoOfConcurrentOperations` and `MaxNoOfLocalOperations`.

**Note**

Bulk loading, `TRUNCATE TABLE`, and `ALTER TABLE` are handled as special cases by running multiple transactions, and so are not subject to this limitation.

- Different limits related to tables and indexes. For example, the maximum number of ordered indexes in the cluster is determined by `MaxNoOfOrderedIndexes`, and the maximum number of ordered indexes per table is 16.
- **Node and data object maximums.** The following limits apply to numbers of cluster nodes and metadata objects:
  - The maximum number of data nodes is 48.

A data node must have a node ID in the range of 1 to 48, inclusive. (Previous to MySQL Cluster NDB 6.1.1, management and API nodes were restricted to the range 1 to 63 inclusive as a node ID; starting with MySQL Cluster NDB 6.1.1, management and API nodes may use node IDs in the range 1 to 255, inclusive.)

- Prior to MySQL Cluster NDB 6.1.1, the total maximum number of nodes in a MySQL Cluster was 63. Beginning with MySQL Cluster NDB 6.1.1, the total maximum number of nodes in a MySQL Cluster is 255. In either case, this number includes all SQL nodes (MySQL Servers), API nodes (applications accessing the cluster other than MySQL servers), data nodes, and management servers.
- The maximum number of metadata objects in current versions of MySQL Cluster is 20320. This limit is hard-coded.

See [Section 17.1.5.11, “Previous MySQL Cluster Issues Resolved in MySQL 5.1, MySQL Cluster NDB 6.x, and MySQL Cluster NDB 7.x”](#), for more information.

### 17.1.5.3. Limits Relating to Transaction Handling in MySQL Cluster

A number of limitations exist in MySQL Cluster with regard to the handling of transactions. These include the following:

- **Transaction isolation level.** The `NDBCLUSTER` storage engine supports only the `READ COMMITTED` transaction isolation level. (`InnoDB`, for example, supports `READ COMMITTED`, `READ UNCOMMITTED`, `REPEATABLE READ`, and `SERIALIZABLE`.) See [Section 17.5.3.4, “MySQL Cluster Backup Troubleshooting”](#), for information on how this can affect backing up and restoring Cluster databases.)
- **Transactions and `BLOB` or `TEXT` columns.** `NDBCLUSTER` stores only part of a column value that uses any of MySQL's `BLOB` or `TEXT` data types in the table visible to MySQL; the remainder of the `BLOB` or `TEXT` is stored in a separate internal table that is not accessible to MySQL. This gives rise to two related issues of which you should be aware whenever executing `SELECT` statements on tables that contain columns of these types:
  1. For any `SELECT` from a MySQL Cluster table: If the `SELECT` includes a `BLOB` or `TEXT` column, the `READ COMMITTED` transaction isolation level is converted to a read with read lock. This is done to guarantee consistency.
  2. Prior to MySQL Cluster NDB 7.0.12, for any `SELECT` which used a primary key lookup or unique key lookup to retrieve any columns that used any of the `BLOB` or `TEXT` data types and that was executed within a transaction, a shared read lock was held on the table for the duration of the transaction—that is, until the transaction was either committed or aborted.

In MySQL Cluster NDB 7.0.12 and later, for primary key lookups, the lock is released as soon as all `BLOB` or `TEXT` data has been read. ([Bug#49190](#)) However, for unique key lookups, the shared lock continues to be held for the lifetime of the transaction.

This issue does not occur for queries that use index or table scans, even against `NDB` tables having `BLOB` or `TEXT` columns.

For example, consider the table `t` defined by the following `CREATE TABLE` statement:

```
CREATE TABLE t (
 a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
 b INT NOT NULL,
 c INT NOT NULL,
 d TEXT,
 INDEX i(b),
 UNIQUE KEY u(c)
) ENGINE = NDB;
```

Either of the following queries on `t` causes a shared read lock, because the first query uses a primary key lookup and the second uses a unique key lookup:

```
SELECT * FROM t WHERE a = 1;
```

```
SELECT * FROM t WHERE c = 1;
```

However, none of the four queries shown here causes a shared read lock:

```
SELECT * FROM t WHERE b 1;
SELECT * FROM t WHERE d = '1';
SELECT * FROM t;
SELECT b,c WHERE a = 1;
```

This is because, of these four queries, the first uses an index scan, the second and third use table scans, and the fourth, while using a primary key lookup, does not retrieve the value of any `BLOB` or `TEXT` columns.

You can help minimize issues with shared read locks by avoiding queries that use unique key lookups (or primary key lookups in MySQL Cluster NDB 7.0.11 and earlier) that retrieve `BLOB` or `TEXT` columns, or, in cases where such queries are not avoidable, by committing transactions as soon as possible afterward.

- **Transactions and memory usage.** As noted elsewhere in this chapter, MySQL Cluster does not handle large transactions well; it is better to perform a number of small transactions with a few operations each than to attempt a single large transaction containing a great many operations. Among other considerations, large transactions require very large amounts of memory. Because of this, the transactional behavior of a number of MySQL statements is effected as described in the following list:
  - `TRUNCATE TABLE` is not transactional when used on `NDB` tables. If a `TRUNCATE TABLE` fails to empty the table, then it must be re-run until it is successful.
  - `DELETE FROM` (even with no `WHERE` clause) *is* transactional. For tables containing a great many rows, you may find that performance is improved by using several `DELETE FROM ... LIMIT ...` statements to “chunk” the delete operation. If your objective is to empty the table, then you may wish to use `TRUNCATE TABLE` instead.
  - **LOAD DATA statements.** `LOAD DATA INFILE` is not transactional when used on `NDB` tables.

### Important

When executing a `LOAD DATA INFILE` statement, the `NDB` engine performs commits at irregular intervals that enable better utilization of the communication network. It is not possible to know ahead of time when such commits take place.

`LOAD DATA FROM MASTER` is not supported in MySQL Cluster.

- **ALTER TABLE and transactions.** When copying an `NDB` table as part of an `ALTER TABLE`, the creation of the copy is nontransactional. (In any case, this operation is rolled back when the copy is deleted.)
- **Transactions and the COUNT() function.** When using MySQL Cluster Replication, it is not possible to guarantee the transactional consistency of the `COUNT()` function on the slave. In other words, when performing on the master a series of statements (`INSERT`, `DELETE`, or both) that changes the number of rows in a table within a single transaction, executing `SELECT COUNT(*) FROM table` queries on the slave may yield intermediate results. This is due to the fact that `SELECT COUNT(...)` may perform dirty reads, and is not a bug in the `NDB` storage engine. (See Bug#31321 for more information.)

## 17.1.5.4. MySQL Cluster Error Handling

Starting, stopping, or restarting a node may give rise to temporary errors causing some transactions to fail. These include the following cases:

- **Temporary errors.** When first starting a node, it is possible that you may see Error 1204 `TEMPORARY FAILURE, DISTRIBUTION CHANGED` and similar temporary errors.
- **Errors due to node failure.** The stopping or failure of any data node can result in a number of different node failure errors. (However, there should be no aborted transactions when performing a planned shutdown of the cluster.)

In either of these cases, any errors that are generated must be handled within the application. This should be done by retrying the transaction.

See also [Section 17.1.5.2, “Limits and Differences of MySQL Cluster from Standard MySQL Limits”](#).

## 17.1.5.5. Limits Associated with Database Objects in MySQL Cluster

Some database objects such as tables and indexes have different limitations when using the `NDBCLUSTER` storage engine:

- **Table names containing special characters.** `NDB` tables whose names contain characters other than letters, numbers, dashes, and underscores and which are created on one SQL node were not always discovered correctly by other SQL nodes. ([Bug#31470](#))

### Note

This issue was fixed in MySQL 5.1.23, MySQL Cluster NDB 6.2.7, and MySQL Cluster NDB 6.3.4.

- **Number of database objects.** The maximum number of *all* `NDB` database objects in a single MySQL Cluster—including databases, tables, and indexes—is limited to 20320.
- **Attributes per table.** Prior to MySQL Cluster NDB 7.0.15 and MySQL Cluster NDB 7.1.4, the maximum number of attributes (that is, columns and indexes) per table is limited to 128.

Beginning with MySQL Cluster NDB 7.0.15 and MySQL Cluster NDB 7.1.4, this limit is increased to 512.

- **Attributes per key.** The maximum number of attributes per key is 32.
- **Row size.** The maximum permitted size of any one row is 8052 bytes. Each `BLOB` or `TEXT` column contributes  $256 + 8 = 264$  bytes to this total.

## 17.1.5.6. Unsupported or Missing Features in MySQL Cluster

A number of features supported by other storage engines are not supported for `NDB` tables. Trying to use any of these features in MySQL Cluster does not cause errors in or of itself; however, errors may occur in applications that expects the features to be supported or enforced:

- **Foreign key constraints.** The foreign key construct is ignored, just as it is in `MyISAM` tables.
- **Index prefixes.** Prefixes on indexes are not supported for `NDBCLUSTER` tables. If a prefix is used as part of an index specification in a statement such as `CREATE TABLE`, `ALTER TABLE`, or `CREATE INDEX`, the prefix is ignored.
- **OPTIMIZE operations.** `OPTIMIZE` operations are not supported.

Beginning with MySQL Cluster NDB 6.3.7, this limitation has been lifted. See [Section 17.1.5.11, “Previous MySQL Cluster Issues Resolved in MySQL 5.1, MySQL Cluster NDB 6.x, and MySQL Cluster NDB 7.x”](#), for more information.

- **LOAD TABLE ... FROM MASTER.** `LOAD TABLE ... FROM MASTER` is not supported.
- **Savepoints and rollbacks.** Savepoints and rollbacks to savepoints are ignored as in `MyISAM`.
- **Durability of commits.** There are no durable commits on disk. Commits are replicated, but there is no guarantee that logs are flushed to disk on commit.
- **Replication.** Statement-based replication is not supported. Use `--binlog-format=ROW` (or `--binlog-format=MIXED`) when setting up cluster replication. See [Section 17.6, “MySQL Cluster Replication”](#), for more information.
- **InnoDB plugin not supported.** Currently, MySQL Cluster is not compatible with the `InnoDB Plugin`. You must use the version of `InnoDB` that is supplied with the MySQL Server. See [Section 17.2.1.1, “MySQL Cluster Multi-Computer Installation”](#), for information about enabling `InnoDB` storage engine support with MySQL Cluster.

### Note

See [Section 17.1.5.3, “Limits Relating to Transaction Handling in MySQL Cluster”](#), for more information relating to limitations on transaction handling in `NDB`.

## 17.1.5.7. Limitations Relating to Performance in MySQL Cluster

The following performance issues are specific to or especially pronounced in MySQL Cluster:

- **Range scans.** There are query performance issues due to sequential access to the `NDB` storage engine; it is also relatively more expensive to do many range scans than it is with either `MyISAM` or `InnoDB`.
- **Reliability of Records in range.** The `Records in range` statistic is available but is not completely tested or officially supported. This may result in nonoptimal query plans in some cases. If necessary, you can employ `USE INDEX` or `FORCE INDEX` to alter the execution plan. See [Section 12.2.8.2, “Index Hint Syntax”](#), for more information on how to do this.
- **Unique hash indexes.** Unique hash indexes created with `USING HASH` cannot be used for accessing a table if `NULL` is given as part of the key.

### 17.1.5.8. Issues Exclusive to MySQL Cluster

The following are limitations specific to the `NDBCLUSTER` storage engine:

- **Machine architecture.** All machines used in the cluster must have the same architecture. That is, all machines hosting nodes must be either big-endian or little-endian, and you cannot use a mixture of both. For example, you cannot have a management node running on a PowerPC which directs a data node that is running on an x86 machine. This restriction does not apply to machines simply running `mysql` or other clients that may be accessing the cluster's SQL nodes.
- **Binary logging.** MySQL Cluster has the following limitations or restrictions with regard to binary logging:
  - `sql_log_bin` has no effect on data operations; however, it is supported for schema operations.
  - MySQL Cluster cannot produce a binlog for tables having `BLOB` columns but no primary key.
  - Only the following schema operations are logged in a cluster binlog which is *not* on the `mysqld` executing the statement:
    - `CREATE TABLE`
    - `ALTER TABLE`
    - `DROP TABLE`
    - `CREATE DATABASE / CREATE SCHEMA`
    - `DROP DATABASE / DROP SCHEMA`
    - `CREATE TABLESPACE`
    - `ALTER TABLESPACE`
    - `DROP TABLESPACE`
    - `CREATE LOGFILE GROUP`
    - `ALTER LOGFILE GROUP`
    - `DROP LOGFILE GROUP`

See also [Section 17.1.5.10, “Limitations Relating to Multiple MySQL Cluster Nodes”](#).

### 17.1.5.9. Limitations Relating to MySQL Cluster Disk Data Storage

**Disk Data object maximums and minimums.** Disk data objects are subject to the following maximums and minimums:

- Maximum number of tablespaces:  $2^{32}$  (4294967296)
- Maximum number of data files per tablespace:  $2^{16}$  (65536)
- The theoretical maximum number of extents per tablespace data file is  $2^{16}$  (65536); however, for practical purposes, the recommended maximum number of extents per data file is  $2^{15}$  (32768).
- Maximum data file size: The theoretical limit is 64G; however, in MySQL 5.1 (including MySQL Cluster NDB 6.X and 7.X through 7.1), the practical upper limit is 32G. This is equivalent to 32768 extents of 1M each.

The minimum and maximum possible sizes of extents for tablespace data files are 32K and 2G, respectively. See [Section 12.1.18, “CREATE TABLESPACE Syntax”](#), for more information.

**Disk Data tables and diskless mode.** Use of Disk Data tables is not supported when running the cluster in diskless mode. Beginning with MySQL 5.1.12, it is prohibited altogether. ([Bug#20008](#))

### 17.1.5.10. Limitations Relating to Multiple MySQL Cluster Nodes

**Multiple SQL nodes.** The following are issues relating to the use of multiple MySQL servers as MySQL Cluster SQL nodes, and are specific to the `NDBCLUSTER` storage engine:

- **No distributed table locks.** A `LOCK TABLES` works only for the SQL node on which the lock is issued; no other SQL node in the cluster “sees” this lock. This is also true for a lock issued by any statement that locks tables as part of its operations. (See next item for an example.)
- **ALTER TABLE operations.** `ALTER TABLE` is not fully locking when running multiple MySQL servers (SQL nodes). (As discussed in the previous item, MySQL Cluster does not support distributed table locks.)

**Multiple management nodes.** When using multiple management servers:

- You must give nodes explicit IDs in connectstrings because automatic allocation of node IDs does not work across multiple management servers.
- You must take extreme care to have the same configurations for all management servers. No special checks for this are performed by the cluster.

**Multiple network addresses.** Multiple network addresses per data node are not supported. Use of these is liable to cause problems: In the event of a data node failure, an SQL node waits for confirmation that the data node went down but never receives it because another route to that data node remains open. This can effectively make the cluster inoperable.

#### Note

It is possible to use multiple network hardware *interfaces* (such as Ethernet cards) for a single data node, but these must be bound to the same address. This also means that it is not possible to use more than one `[tcp]` section per connection in the `config.ini` file. See [Section 17.3.2.8, “MySQL Cluster TCP/IP Connections”](#), for more information.

### 17.1.5.11. Previous MySQL Cluster Issues Resolved in MySQL 5.1, MySQL Cluster NDB 6.x, and MySQL Cluster NDB 7.x

A number of limitations and related issues existing in earlier versions of MySQL Cluster have been resolved:

- **Variable-length column support.** The `NDBCLUSTER` storage engine now supports variable-length column types for in-memory tables.

Previously, for example, any Cluster table having one or more `VARCHAR` fields which contained only relatively small values, much more memory and disk space were required when using the `NDBCLUSTER` storage engine than would have been the case for the same table and data using the `MyISAM` engine. In other words, in the case of a `VARCHAR` column, such a column required the same amount of storage as a `CHAR` column of the same size. In MySQL 5.1, this is no longer the case for in-memory tables, where storage requirements for variable-length column types such as `VARCHAR` and `BINARY` are comparable to those for these column types when used in `MyISAM` tables (see [Section 10.5, “Data Type Storage Requirements”](#)).

#### Important

For MySQL Cluster Disk Data tables, the fixed-width limitation continues to apply. See [Section 17.5.10, “MySQL Cluster Disk Data Tables”](#).

- **Replication with MySQL Cluster.** It is now possible to use MySQL replication with Cluster databases. For details, see [Section 17.6, “MySQL Cluster Replication”](#).

**Circular Replication.** Circular replication is also supported with MySQL Cluster, beginning with MySQL 5.1.18. See [Section 17.6.10, “MySQL Cluster Replication: Multi-Master and Circular Replication”](#).

- **`auto_increment_increment` and `auto_increment_offset`.** The `auto_increment_increment` and `auto_increment_offset` server system variables are supported for Cluster replication beginning with MySQL 5.1.20, MySQL Cluster NDB 6.2.5, and MySQL Cluster 6.3.2.

- **Database autodiscovery and online schema changes.** Autodiscovery of databases is now supported for multiple MySQL servers accessing the same MySQL Cluster. Formerly, autodiscovery in MySQL Cluster 5.1 and MySQL Cluster NDB 6.x releases required that a given `mysqld` was already running and connected to the cluster at the time that the database was created on a different `mysqld`—in other words, when a `mysqld` process connected to the cluster after a database named `db_name` was created, it was necessary to issue a `CREATE DATABASE db_name` or `CREATE SCHEMA db_name` statement on the “new” MySQL server when it first accessed that MySQL Cluster. Beginning with MySQL Cluster NDB 6.2.16 and MySQL Cluster NDB 6.3.18, such a `CREATE` statement is no longer required. ([Bug#39612](#))

This also means that online schema changes in `NDB` tables are now possible. That is, the result of operations such as `ALTER TABLE` and `CREATE INDEX` performed on one SQL node in the cluster are now visible to the cluster's other SQL nodes without any additional action being taken.

- **Backup and restore between architectures.** Beginning with MySQL 5.1.10, it is possible to perform a Cluster backup and restore between different architectures. Previously—for example—you could not back up a cluster running on a big-endian platform and then restore from that backup to a cluster running on a little-endian system. ([Bug#19255](#))
- **Character set directory.** Beginning with MySQL 5.1.10, it is possible to install MySQL with Cluster support to a nondefault location and change the search path for font description files using either the `--basedir` or `--character-sets-dir` options. (Previously, `ndbd` in MySQL 5.1 searched only the default path—typically `/usr/local/mysql/share/mysql/charsets`—for character sets.)
- **Multiple management servers.** In MySQL 5.1 (including all MySQL Cluster NDB 6.x and later versions), it is no longer necessary, when running multiple management servers, to restart all the cluster's data nodes to enable the management nodes to see one another.

Also, when using multiple management servers and starting concurrently several API nodes (possibly including one or more SQL nodes) whose connectstrings listed the management servers in different order, it was possible for 2 API nodes to be assigned the same node ID. This issue is resolved in MySQL Cluster NDB 6.2.17, 6.3.23, and 6.4.3. ([Bug#42973](#))

- **Multiple data node processes per host.** Beginning with MySQL Cluster NDB 6.2.0, you can use multiple data node processes on a single host. (In MySQL Cluster NDB 6.1, MySQL 5.1, and earlier release series, we did not support production MySQL Cluster deployments in which more than one `ndbd` process was run on a single physical machine.)

In addition, MySQL Cluster NDB 7.0 introduces support for multi-threaded data nodes (`ndbmttd`). See [Section 17.1.4.2, “MySQL Cluster Development in MySQL Cluster NDB 7.0”](#), and [Section 17.4.3, “`ndbmttd` — The MySQL Cluster Data Node Daemon \(Multi-Threaded\)”](#), for more information.

- **Identifiers.** Formerly (in MySQL 5.0 and earlier), database names, table names and attribute names could not be as long for `NDB` tables as tables using other storage engines, because attribute names were truncated internally. In MySQL 5.1 and later, names of MySQL Cluster databases, tables, and table columns follow the same rules regarding length as they do for any other storage engine.
- **Length of `CREATE TABLE` statements.** `CREATE TABLE` statements may be no more than 4096 characters in length. *This limitation affects MySQL 5.1.6, 5.1.7, and 5.1.8 only.* (See [Bug#17813](#))
- **`IGNORE` and `REPLACE` functionality.** In MySQL 5.1.7 and earlier, `INSERT IGNORE`, `UPDATE IGNORE`, and `REPLACE` were supported only for primary keys, but not for unique keys. It was possible to work around this issue by removing the constraint, then dropping the unique index, performing any inserts, and then adding the unique index again.

This limitation was removed for `INSERT IGNORE` and `REPLACE` in MySQL 5.1.8. (See [Bug#17431](#).)

- **`AUTO_INCREMENT` columns.** In MySQL 5.1.10 and earlier versions, the maximum number of tables having `AUTO_INCREMENT` columns—including those belonging to hidden primary keys—was 2048.

This limitation was lifted in MySQL 5.1.11.

- **Maximum number of cluster nodes.** Prior to MySQL Cluster NDB 6.1.1, the total maximum number of nodes in a MySQL Cluster was 63, including all SQL nodes (MySQL Servers), API nodes (applications accessing the cluster other than MySQL servers), data nodes, and management servers.

Starting with MySQL Cluster NDB 6.1.1, the total maximum number of nodes in a MySQL Cluster is 255, including all SQL nodes (MySQL Servers), API nodes (applications accessing the cluster other than MySQL servers), data nodes, and management servers. The total number of data nodes and management nodes beginning with this version is 63, of which up to 48 can be data nodes.

## Note

The limitation that a data node cannot have a node ID greater than 49 continues to apply.

- **Recovery of memory from deleted rows.** Beginning with MySQL Cluster NDB 6.3.7, memory can be reclaimed from an

NDB table for reuse with any NDB table by employing `OPTIMIZE TABLE`, subject to the following limitations:

- Only in-memory tables are supported; the `OPTIMIZE TABLE` statement still has no effect on MySQL Cluster Disk Data tables.
- Only variable-length columns (such as those declared as `VARCHAR`, `TEXT`, or `BLOB`) are supported.

However, you can force columns defined using fixed-length data types (such as `CHAR`) to be dynamic using the `ROW_FORMAT` or `COLUMN_FORMAT` option with a `CREATE TABLE` or `ALTER TABLE` statement.

See [Section 12.1.17, “CREATE TABLE Syntax”](#), and [Section 12.1.7, “ALTER TABLE Syntax”](#), for information on these options.

You can regulate the effects of `OPTIMIZE` on performance by adjusting the value of the global system variable `ndb_optimization_delay`, which sets the number of milliseconds to wait between batches of rows being processed by `OPTIMIZE`. The default value is 10 milliseconds. It is possible to set a lower value (to a minimum of 0), but not recommended. The maximum is 100000 milliseconds (that is, 100 seconds).

- **Implicit Rollbacks.** Prior to MySQL Cluster NDB 6.2.17 and MySQL Cluster NDB 6.3.19, MySQL Cluster did not automatically roll back a transaction that was aborted by a duplicate key or similar error, and subsequent statements raised `ERROR 1296 (HY000) : GOT ERROR 4350 'TRANSACTION ALREADY ABORTED' FROM NDBCLUSTER`. In such cases, it was necessary to issue an explicit `ROLLBACK` statement first, and then to retry the entire transaction.

Beginning with MySQL Cluster NDB 6.2.17 and MySQL Cluster NDB 6.3.19, this limitation has been removed; now, an error which causes a transaction to be aborted generates an implicit rollback of the entire transaction. This is logged with the warning `STORAGE ENGINE NDB DOES NOT SUPPORT ROLLBACK FOR THIS STATEMENT. TRANSACTION ROLLED BACK AND MUST BE RESTARTED`. A statement subsequent to this starts a new transaction. ([Bug#32656](#))

### Note

The `NDBCLUSTER` storage engine does not support partial transactions or partial rollbacks of transactions in any version of MySQL Cluster.

- **Number of tables.** Previously, the maximum number of `NDBCLUSTER` tables in a single MySQL Cluster was 1792, but this is no longer the case in MySQL 5.1 and later MySQL Cluster releases. However, the number of tables is still included in the total maximum number of `NDBCLUSTER` database objects (20320). (See [Section 17.1.5.5, “Limits Associated with Database Objects in MySQL Cluster”](#).)
- **DDL operations.** Beginning with MySQL Cluster NDB 6.4.0, DDL operations (such as `CREATE TABLE` or `ALTER TABLE`) are protected from data node failures. Previously, if a data node failed while trying to perform one of these, the data dictionary became locked and no further DDL statements could be executed without restarting the cluster ([Bug#36718](#)).
- **Adding and dropping of data nodes.** In MySQL Cluster NDB 6.3 and previous versions of MySQL Cluster, the online adding or dropping of data nodes was not possible; such operations required a complete shutdown and restart of the entire cluster. In MySQL Cluster NDB 7.0 (beginning with MySQL Cluster NDB 6.4.0) and later MySQL Cluster release series, it is possible to add new data nodes to a running MySQL Cluster by performing a rolling restart, so that the cluster and the data stored in it remain available to applications.

When planning to increase the number of data nodes in the cluster online in MySQL Cluster NDB 7.0 or MySQL Cluster NDB 7.1, you should be aware of and take into account the following issues:

- New data nodes can be added online to a MySQL Cluster only as part of a new node group.
- New data nodes can be added online, but cannot yet be dropped online. Reducing the number of data nodes still requires a system restart of the cluster.
- As in previous MySQL Cluster releases, it is not possible to change online either the number of replicas (`NoOfReplicas` configuration parameter) or the number of data nodes per node group. These changes require a system restart.
- Redistribution of existing cluster data using the new data nodes is not automatic; however, this can be accomplished using simple SQL statements in the `mysql` client or other MySQL client application once the nodes have been added. During this procedure, it is not possible to perform DDL operations, although DML operations can continue as normal.

The distribution of new cluster data (that is, data stored in the cluster *after* the new nodes have been added) uses the new nodes without manual intervention.

For more information, see [Section 17.5.11, “Adding MySQL Cluster Data Nodes Online”](#).

- **Native support for default column values.** Starting with MySQL Cluster NDB 7.1.0, default values for table columns are stored by `NDBCLUSTER`, rather than by the MySQL server as was previously the case. Because less data must be sent from an SQL node to the data nodes, inserts on tables having column value defaults can be performed more efficiently than before.

Tables created using previous MySQL Cluster releases can still be used in MySQL Cluster 7.1.0 and later, although they do not support native default values and continue to use defaults supplied by the MySQL server until they are upgraded. This can be done by means of an offline `ALTER TABLE` statement.

### Important

You cannot set or change a table column's default value using an online `ALTER TABLE` operation

## 17.2. MySQL Cluster Multi-Computer How-To

This section is a “How-To” that describes the basics for how to plan, install, configure, and run a MySQL Cluster. Whereas the examples in [Section 17.3, “MySQL Cluster Configuration”](#) provide more in-depth information on a variety of clustering options and configuration, the result of following the guidelines and procedures outlined here should be a usable MySQL Cluster which meets the *minimum* requirements for availability and safeguarding of data.

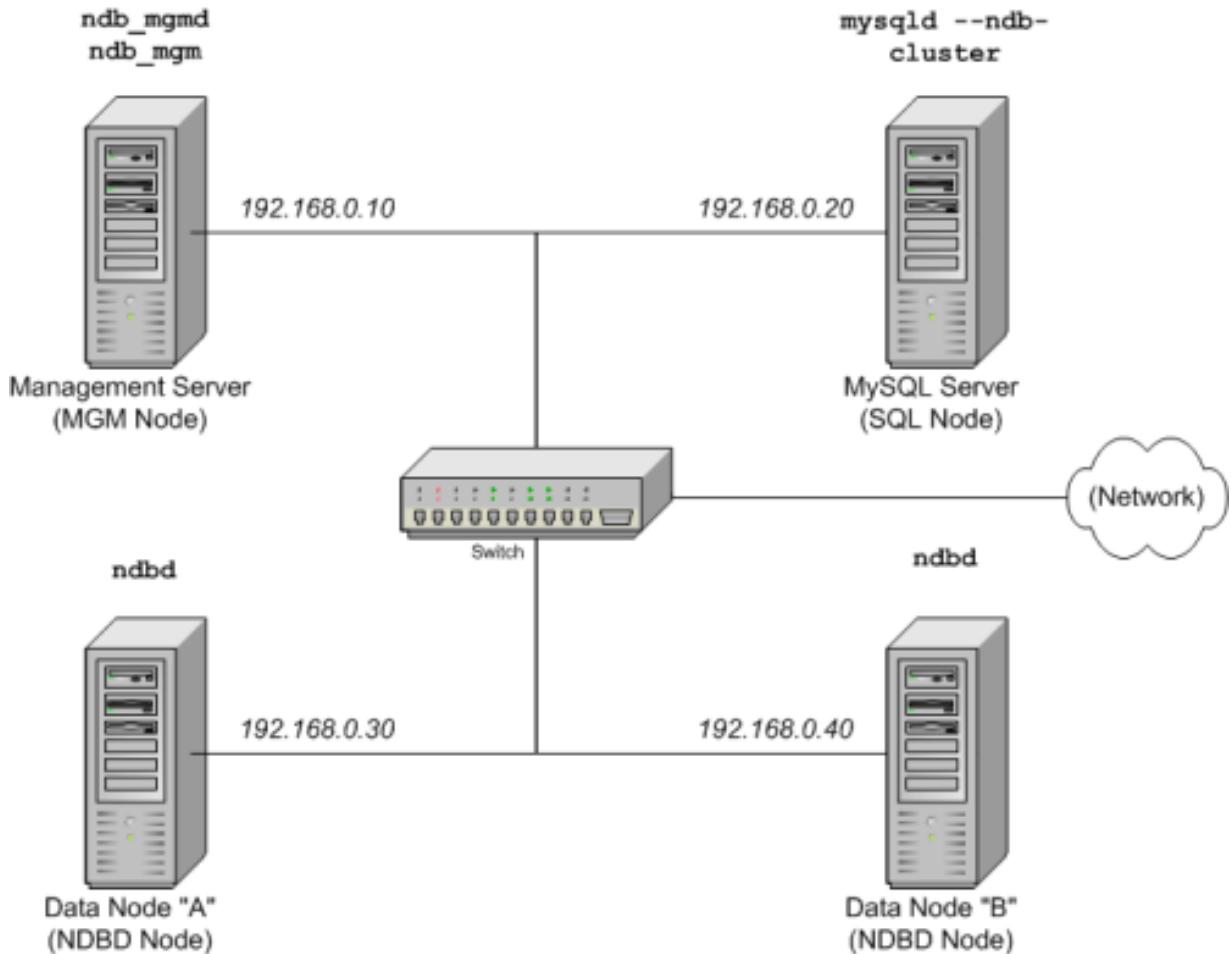

This section covers hardware and software requirements; networking issues; installation of MySQL Cluster; configuration issues; starting, stopping, and restarting the cluster; loading of a sample database; and performing queries.

**Basic assumptions.** This *How-To* makes the following assumptions:

1. The cluster is to be set up with four nodes, each on a separate host, and each with a fixed network address on a typical Ethernet network as shown here:

Node	IP Address
Management (MGMD) node	192.168.0.10
MySQL server (SQL) node	192.168.0.20
Data (NDBD) node "A"	192.168.0.30
Data (NDBD) node "B"	192.168.0.40

This may be made clearer in the following diagram:

In the interest of simplicity (and reliability), this *How-To* uses only numeric IP addresses. However, if DNS resolution is available on your network, it is possible to use host names in lieu of IP addresses in configuring Cluster. Alternatively, you can use the `hosts` file (typically `/etc/hosts` for Linux and other Unix-like operating systems, `C:\WINDOWS\system32\drivers\etc\hosts` on Windows, or your operating system's equivalent) for providing a means to do host lookup if such is available.

### Note

A common problem when trying to use host names for Cluster nodes arises because of the way in which some operating systems (including some Linux distributions) set up the system's own host name in the `/etc/hosts` during installation. Consider two machines with the host names `ndb1` and `ndb2`, both in the `cluster` network domain. Red Hat Linux (including some derivatives such as CentOS and Fedora) places the following entries in these machines' `/etc/hosts` files:

```
ndb1 /etc/hosts:
127.0.0.1 ndb1.cluster ndb1 localhost.localdomain localhost
```

```
ndb2 /etc/hosts:
127.0.0.1 ndb2.cluster ndb2 localhost.localdomain localhost
```

SUSE Linux (including OpenSUSE) places these entries in the machines' `/etc/hosts` files:

```
ndb1 /etc/hosts:
127.0.0.1 localhost
127.0.0.2 ndb1.cluster ndb1
```

```
ndb2 /etc/hosts:
127.0.0.1 localhost
127.0.0.2 ndb2.cluster ndb2
```

In both instances, `ndb1` routes `ndb1.cluster` to a loopback IP address, but gets a public IP address from DNS for `ndb2.cluster`, while `ndb2` routes `ndb2.cluster` to a loopback address and obtains a public address for

**ndb1.cluster**. The result is that each data node connects to the management server, but cannot tell when any other data nodes have connected, and so the data nodes appear to hang while starting.

You should also be aware that you cannot mix `localhost` and other host names or IP addresses in `config.ini`. For these reasons, the solution in such cases (other than to use IP addresses for all `config.ini HostName` entries) is to remove the fully qualified host names from `/etc/hosts` and use these in `config.ini` for all cluster hosts.

2. Each host in our scenario is an Intel-based desktop PC running a supported operating system installed to disk in a standard configuration, and running no unnecessary services. The core operating system with standard TCP/IP networking capabilities should be sufficient. Also for the sake of simplicity, we also assume that the file systems on all hosts are set up identically. In the event that they are not, you should adapt these instructions accordingly.
3. Standard 100 Mbps or 1 gigabit Ethernet cards are installed on each machine, along with the proper drivers for the cards, and that all four hosts are connected through a standard-issue Ethernet networking appliance such as a switch. (All machines should use network cards with the same throughout. That is, all four machines in the cluster should have 100 Mbps cards *or* all four machines should have 1 Gbps cards.) MySQL Cluster works in a 100 Mbps network; however, gigabit Ethernet provides better performance.

Note that MySQL Cluster is *not* intended for use in a network for which throughput is less than 100 Mbps or which experiences a high degree of latency. For this reason (among others), attempting to run a MySQL Cluster over a wide area network such as the Internet is not likely to be successful, and is not supported in production.

4. For our sample data, we use the `world` database which is available for download from the MySQL Web site (see <http://dev.mysql.com/doc/index-other.html>). We assume that each machine has sufficient memory for running the operating system, host NDB process, and (on the data nodes) storing the database.

We assume that you already know how to perform a minimal installation and configuration of the operating system with networking capability, or that you are able to obtain assistance in this elsewhere if needed.

For information relating to installation of MySQL Cluster on Linux and other Unix-like operating systems, see [Section 17.2.1, “Installing MySQL Cluster on Linux”](#). For information relating to installation of MySQL Cluster on Windows operating systems, see [Section 17.2.2, “Installing MySQL Cluster on Windows”](#).

For information about MySQL Cluster hardware, software, and networking requirements, see [Section 17.1.3, “MySQL Cluster Hardware, Software, and Networking Requirements”](#).

## 17.2.1. Installing MySQL Cluster on Linux

The next few sections refer to a Linux operating system, but the instructions and procedures given there should be easily adaptable to other supported Unix-like operating systems.

Beginning with MySQL Cluster NDB 7.1.3, MySQL Cluster is also supported for production use on Windows operating systems; for basic setup instructions specific to Windows, see [Section 17.2.2, “Installing MySQL Cluster on Windows”](#).

### 17.2.1.1. MySQL Cluster Multi-Computer Installation

Each MySQL Cluster host computer running an SQL node must have installed on it a MySQL binary. For management nodes and data nodes, it is not necessary to install the MySQL server binary, but management nodes require the management server daemon (`ndb_mgmd`) and data nodes require the data node daemon (`ndbd`; in MySQL Cluster NDB 7.0 and later, you can use `ndbmt` instead). It is also a good idea to install the management client (`ndb_mgm`) on the management server host. This section covers the steps necessary to install the correct binaries for each type of Cluster node.

Oracle provides precompiled binaries that support MySQL Cluster. However, we also include information relating to installing a MySQL Cluster after building MySQL from source. For setting up a cluster using MySQL's binaries, the first step in the installation process for each cluster host is to download the latest MySQL Cluster NDB 6.3, MySQL Cluster NDB 7.0, or MySQL Cluster NDB 7.1 binary archive (`mysql-cluster-gpl-6.3.38-linux-i686-glibc23.tar.gz`, `mysql-cluster-gpl-7.0.19-linux-i686-glibc23.tar.gz`, or `mysql-cluster-gpl-7.1.8-linux-i686-glibc23.tar.gz`, respectively) from the [MySQL Cluster downloads area](#). We assume that you have placed this file in each machine's `/var/tmp` directory. (If you do require a custom binary, see [Section 2.3.4, “Installing from the Development Source Tree”](#).)

When compiling MySQL Cluster NDB 7.0 or later from source, no special options are required for building multi-threaded data node binaries. On Unix platforms, configuring the build with any of the options `--plugins=ndbcluster`, `--plugins=max`, or, `--plugins=max-no-innodb` causes `ndbmt` to be built automatically; `make install` places the `ndbmt` binary in the `libexec` directory along with `mysqld`, `ndbd`, and `ndb_mgm`.

#### Important

Currently, MySQL Cluster is not compatible with the `InnoDB Plugin`. You must use the version of `InnoDB` that

is supplied with the MySQL Server. You can build MySQL Cluster with InnoDB storage engine support using the `--with-plugins=max` or `--with-innodb` option for `configure`.

RPMs are also available for both 32-bit and 64-bit Linux platforms. For a MySQL Cluster, three RPMs are required:

- The **Server** RPM (for example, `MySQL-Cluster-gpl-server-6.3.38-0.sles10.i586.rpm`, `MySQL-Cluster-gpl-server-7.0.19-0.sles10.i586.rpm`, or `MySQL-Cluster-gpl-server-7.1.8-0.sles10.i586.rpm`), which supplies the core files needed to run a MySQL Server with `NDBCCLUSTER` storage engine support (that is, as a MySQL Cluster SQL node).

If you do not have your own client application capable of administering a MySQL server, you should also obtain and install the **Client** RPM (for example, `MySQL-Cluster-gpl-client-6.3.38-0.sles10.i586.rpm`, `MySQL-Cluster-gpl-client-7.0.19-0.sles10.i586.rpm`, or `MySQL-Cluster-gpl-client-7.1.8-0.sles10.i586.rpm`).

- The **Cluster storage engine** RPM (for example, `MySQL-Cluster-gpl-storage-6.3.38-0.sles10.i586.rpm`, `MySQL-Cluster-gpl-storage-7.0.19-0.sles10.i586.rpm`, or `MySQL-Cluster-gpl-storage-7.1.8-0.sles10.i586.rpm`), which supplies the MySQL Cluster data node binary (`ndbd`).
- The **Cluster storage engine management** RPM (for example, `MySQL-Cluster-gpl-management-6.3.38-0.sles10.i586.rpm`, `MySQL-Cluster-gpl-management-7.0.19-0.sles10.i586.rpm`, or `MySQL-Cluster-gpl-management-7.1.8-0.sles10.i586.rpm`) which provides the MySQL Cluster management server binary (`ndb_mgmd`).

In addition, you should also obtain the **NDB Cluster - Storage engine basic tools** RPM (for example, `MySQL-Cluster-gpl-tools-6.3.38-0.sles10.i586.rpm`, `MySQL-Cluster-gpl-tools-7.0.19-0.sles10.i586.rpm`, or `MySQL-Cluster-gpl-tools-7.1.8-0.sles10.i586.rpm`), which supplies several useful applications for working with a MySQL Cluster. The most important of these is the MySQL Cluster management client (`ndb_mgm`). The **NDB Cluster - Storage engine extra tools** RPM (for example, `MySQL-Cluster-gpl-extra-6.3.38-0.sles10.i586.rpm`, `MySQL-Cluster-gpl-extra-7.0.19-0.sles10.i586.rpm`, or `MySQL-Cluster-gpl-extra-7.1.8-0.sles10.i586.rpm`) contains some additional testing and monitoring programs, but is not required to install a MySQL Cluster. (For more information about these additional programs, see [Section 17.4, “MySQL Cluster Programs”](#).)

The MySQL Cluster version number in the RPM file names (shown here as `6.3.38`, `7.0.19`, or `7.1.8`) can vary according to the version which you are actually using. *It is very important that all of the Cluster RPMs to be installed have the same version number.* The `libc` version number (if present), and architecture designation (shown here as `i586`) should be appropriate to the machine on which the RPM is to be installed.

See [Section 2.6.1, “Installing MySQL from RPM Packages on Linux”](#), for general information about installing MySQL using RPMs supplied by Oracle.

After installing from RPM, you still need to configure the cluster as discussed in [Section 17.2.1.2, “MySQL Cluster Multi-Computer Configuration”](#).

### Note

After completing the installation, do not yet start any of the binaries. We show you how to do so following the configuration of all nodes.

**Data and SQL Node Installation: `.tar.gz` Binary.** On each of the machines designated to host data or SQL nodes, perform the following steps as the system `root` user:

1. Check your `/etc/passwd` and `/etc/group` files (or use whatever tools are provided by your operating system for managing users and groups) to see whether there is already a `mysql` group and `mysql` user on the system. Some OS distributions create these as part of the operating system installation process. If they are not already present, create a new `mysql` user group, and then add a `mysql` user to this group:

```
shell> groupadd mysql
shell> useradd -g mysql mysql
```

The syntax for `useradd` and `groupadd` may differ slightly on different versions of Unix, or they may have different names such as `adduser` and `addgroup`.

2. Change location to the directory containing the downloaded file, unpack the archive, and create a symlink to the `mysql` directory named `mysql`. Note that the actual file and directory names vary according to the MySQL Cluster version number.

```
shell> cd /var/tmp
shell> tar -C /usr/local -xzvf mysql-cluster-gpl-7.1.8-linux-i686-glibc23.tar.gz
shell> ln -s /usr/local/mysql-cluster-gpl-7.1.8-linux-i686-glibc23.tar.gz /usr/local/mysql
```

3. Change location to the `mysql` directory and run the supplied script for creating the system databases:

```
shell> cd mysql
shell> scripts/mysql_install_db --user=mysql
```

4. Set the necessary permissions for the MySQL server and data directories:

```
shell> chown -R root .
shell> chown -R mysql data
shell> chgrp -R mysql .
```

Note that the data directory on each machine hosting a data node is `/usr/local/mysql/data`. This piece of information is essential when configuring the management node. (See [Section 17.2.1.2, “MySQL Cluster Multi-Computer Configuration”](#).)

5. Copy the MySQL startup script to the appropriate directory, make it executable, and set it to start when the operating system is booted up:

```
shell> cp support-files/mysql.server /etc/rc.d/init.d/
shell> chmod +x /etc/rc.d/init.d/mysql.server
shell> chkconfig --add mysql.server
```

(The startup scripts directory may vary depending on your operating system and version—for example, in some Linux distributions, it is `/etc/init.d`.)

Here we use Red Hat's `chkconfig` for creating links to the startup scripts; use whatever means is appropriate for this purpose on your operating system and distribution, such as `update-rc.d` on Debian.

Remember that the preceding steps must be repeated on each machine where an SQL node is to reside.

**SQL node installation: RPM files.** On each machine to be used for hosting a cluster SQL node, install the **Server** RPM by executing the following command as the system root user, replacing the name shown for the RPM as necessary to match the name of the RPM downloaded from the MySQL web site:

```
shell> rpm -Uvh MySQL-Cluster-gpl-server-7.1.8-0.sles10.i586.rpm
```

This installs the MySQL server binary (`mysqld`) in the `/usr/sbin` directory, as well as all needed MySQL Server support files. It also installs the `mysql.server` and `mysqld_safe` startup scripts in `/usr/share/mysql` and `/usr/bin`, respectively. The RPM installer should take care of general configuration issues (such as creating the `mysql` user and group, if needed) automatically.

### Note

To administer the SQL node (MySQL server), you should also install the **Client** RPM, as shown here:

```
shell> rpm -Uvh MySQL-Cluster-gpl-client-7.1.8-0.sles10.i586.rpm
```

This installs the `mysql` client program.

**SQL node installation: building from source.** If you compile MySQL with clustering support (for example, by using the `BUILD/compile-platform_name-max` script appropriate to your platform), and perform the default installation (using `make install` as the root user), `mysqld` is placed in `/usr/local/mysql/bin`. Follow the steps given in [Section 2.3, “Installing MySQL Using a Source Distribution”](#) to make `mysqld` ready for use. If you want to run multiple SQL nodes, you can use a copy of the same `mysqld` executable and its associated support files on several machines. The easiest way to do this is to copy the entire `/usr/local/mysql` directory and all directories and files contained within it to the other SQL node host or hosts, then repeat the steps from [Section 2.3, “Installing MySQL Using a Source Distribution”](#) on each machine. If you configure the build with a nondefault `--prefix`, you need to adjust the directory accordingly.

**Data node installation: RPM Files.** On a computer that is to host a cluster data node it is necessary to install only the **NDB Cluster - Storage engine** RPM. To do so, copy this RPM to the data node host, and run the following command as the system root user, replacing the name shown for the RPM as necessary to match that of the RPM downloaded from the MySQL web site:

```
shell> rpm -Uvh MySQL-Cluster-gpl-storage-7.1.8-0.sles10.i586.rpm
```

The previous command installs the MySQL Cluster data node binary (`ndbd`) in the `/usr/sbin` directory.

**Data node installation: building from source.** The only executable required on a data node host is `ndbd` or (in MySQL Cluster

NDB 7.0 and later) `ndbmtd` (`mysqld`, for example, does not have to be present on the host machine). By default when doing a source build, this file is placed in the directory `/usr/local/mysql/libexec`. For installing on multiple data node hosts, only `ndbd` need be copied to the other host machine or machines. (This assumes that all data node hosts use the same architecture and operating system; otherwise you may need to compile separately for each different platform.) `ndbd` need not be in any particular location on the host's file system, as long as the location is known.

**Management node installation: .tar.gz binary.** Installation of the management node does not require the `mysqld` binary. Only the MySQL Cluster management server (`ndb_mgmd`) is required; you most likely want to install the management client (`ndb_mgm`) as well. Both of these binaries also be found in the `.tar.gz` archive. Again, we assume that you have placed this archive in `/var/tmp`.

As system `root` (that is, after using `sudo su root`, or your system's equivalent for temporarily assuming the system administrator account's privileges), perform the following steps to install `ndb_mgmd` and `ndb_mgm` on the Cluster management node host:

1. Change location to the `/var/tmp` directory, and extract the `ndb_mgm` and `ndb_mgmd` from the archive into a suitable directory such as `/usr/local/bin`:

```
shell> cd /var/tmp
shell> tar -zxvf mysql-5.1.47-ndb-7.1.8-linux-i686-glibc23.tar.gz
shell> cd mysql-5.1.47-ndb-7.1.8-linux-i686-glibc23
shell> cp bin/ndb_mgm* /usr/local/bin
```

(You can safely delete the directory created by unpacking the downloaded archive, and the files it contains, from `/var/tmp` once `ndb_mgm` and `ndb_mgmd` have been copied to the executables directory.)

2. Change location to the directory into which you copied the files, and then make both of them executable:

```
shell> cd /usr/local/bin
shell> chmod +x ndb_mgm*
```

**Management node installation: RPM file.** To install the MySQL Cluster management server, it is necessary only to use the **NDB Cluster - Storage engine management** RPM. Copy this RPM to the computer intended to host the management node, and then install it by running the following command as the system root user (replace the name shown for the RPM as necessary to match that of the **Storage engine management** RPM downloaded from the MySQL web site):

```
shell> rpm -Uvh MySQL-Cluster-gpl-management-7.1.8-0.sles10.i586.rpm
```

This installs the management server binary (`ndb_mgmd`) to the `/usr/sbin` directory.

You should also install the **NDB** management client, which is supplied by the **Storage engine basic tools** RPM. Copy this RPM to the same computer as the management node, and then install it by running the following command as the system root user (again, replace the name shown for the RPM as necessary to match that of the **Storage engine basic tools** RPM downloaded from the MySQL web site):

```
shell> rpm -Uvh MySQL-Cluster-gpl-tools-7.1.8-0.sles10.i586.rpm
```

The **Storage engine basic tools** RPM installs the MySQL Cluster management client (`ndb_mgm`) to the `/usr/bin` directory.

### Note

You can also install the **Cluster storage engine extra tools** RPM, if you wish, as shown here:

```
shell> rpm -Uvh MySQL-Cluster-gpl-extra-7.1.8-0.sles10.i586.rpm
```

You may find the extra tools useful; however the **Cluster storage engine extra tools** RPM is *not* required to install a working MySQL Cluster.

**Management node installation: building from source.** When building from source and running the default `make install`, the management server binary (`ndb_mgmd`) is placed in `/usr/local/mysql/libexec`, while the management client binary (`ndb_mgm`) can be found in `/usr/local/mysql/bin`. Only `ndb_mgmd` is required to be present on a management node host; however, it is also a good idea to have `ndb_mgm` present on the same host machine. Neither of these executables requires a specific location on the host machine's file system.

In Section 17.2.1.2, “MySQL Cluster Multi-Computer Configuration”, we create configuration files for all of the nodes in our example MySQL Cluster.

**MySQL Cluster on Windows.** Experimental support for MySQL Cluster on Microsoft Windows operating systems was introduced in MySQL Cluster NDB 7.0. Beginning with MySQL Cluster NDB 7.1.3, production support is provided for MySQL Cluster on Windows, and MySQL Cluster binaries for Windows can be obtained from <http://dev.mysql.com/downloads/cluster/>. If you wish to compile MySQL Cluster from source on Windows, you must configure the build using the

`WITH_NDBCLUSTER_STORAGE_ENGINE` option before creating the Visual Studio project files and compiling the project. After running `make_win_bin_dist`, the MySQL Cluster binaries can be found in the `bin` directory of the resulting archive. For more information, see [Section 2.4.9, “Installing MySQL from Source on Windows”](#).

### 17.2.1.2. MySQL Cluster Multi-Computer Configuration

For our four-node, four-host MySQL Cluster, it is necessary to write four configuration files, one per node host.

- Each data node or SQL node requires a `my.cnf` file that provides two pieces of information: a *connectstring* that tells the node where to find the management node, and a line telling the MySQL server on this host (the machine hosting the data node) to enable the `NDBCLUSTER` storage engine.

For more information on connectstrings, see [Section 17.3.2.3, “The MySQL Cluster Connectstring”](#).

- The management node needs a `config.ini` file telling it how many replicas to maintain, how much memory to allocate for data and indexes on each data node, where to find the data nodes, where to save data to disk on each data node, and where to find any SQL nodes.

#### Configuring the Storage and SQL Nodes

The `my.cnf` file needed for the data nodes is fairly simple. The configuration file should be located in the `/etc` directory and can be edited using any text editor. (Create the file if it does not exist.) For example:

```
shell> vi /etc/my.cnf
```

#### Note

We show `vi` being used here to create the file, but any text editor should work just as well.

For each data node and SQL node in our example setup, `my.cnf` should look like this:

```
[mysqld]
Options for mysqld process:
ndbcluster # run NDB storage engine
ndb-connectstring=192.168.0.10 # location of management server

[mysql_cluster]
Options for ndbd process:
ndb-connectstring=192.168.0.10 # location of management server
```

After entering the preceding information, save this file and exit the text editor. Do this for the machines hosting data node “A”, data node “B”, and the SQL node.

#### Important

Once you have started a `mysqld` process with the `NDBCLUSTER` and `ndb-connectstring` parameters in the `[mysqld]` in the `my.cnf` file as shown previously, you cannot execute any `CREATE TABLE` or `ALTER TABLE` statements without having actually started the cluster. Otherwise, these statements will fail with an error. *This is by design.*

**Configuring the management node.** The first step in configuring the management node is to create the directory in which the configuration file can be found and then to create the file itself. For example (running as `root`):

```
shell> mkdir /var/lib/mysql-cluster
shell> cd /var/lib/mysql-cluster
shell> vi config.ini
```

For our representative setup, the `config.ini` file should read as follows:

```
[ndbd default]
Options affecting ndbd processes on all data nodes:
NoOfReplicas=2 # Number of replicas
DataMemory=80M # How much memory to allocate for data storage
IndexMemory=18M # How much memory to allocate for index storage
For DataMemory and IndexMemory, we have used the
default values. Since the "world" database takes up
only about 500KB, this should be more than enough for
this example Cluster setup.

[tcp default]
TCP/IP options:
portnumber=2202 # This is the default; however, you can use any
port that is free for all the hosts in the cluster
Note: It is recommended that you do not specify the port
number at all and simply allow the default value to be used
```

```

instead

[ndb_mgmd]
Management process options:
hostname=192.168.0.10 # Hostname or IP address of MGM node
datadir=/var/lib/mysql-cluster # Directory for MGM node log files

[ndbd]
Options for data node "A":
hostname=192.168.0.30 # Hostname or IP address
datadir=/usr/local/mysql/data # Directory for this data node's data files

[ndbd]
Options for data node "B":
hostname=192.168.0.40 # Hostname or IP address
datadir=/usr/local/mysql/data # Directory for this data node's data files

[mysqld]
SQL node options:
hostname=192.168.0.20 # Hostname or IP address
 # (additional mysqld connections can be
 # specified for this node for various
 # purposes such as running ndb_restore)

```

**Note**

The `world` database can be downloaded from <http://dev.mysql.com/doc/>, where it can be found listed under “Examples”.

After all the configuration files have been created and these minimal options have been specified, you are ready to proceed with starting the cluster and verifying that all processes are running. We discuss how this is done in [Section 17.2.1.3, “Initial Startup of MySQL Cluster”](#).

For more detailed information about the available MySQL Cluster configuration parameters and their uses, see [Section 17.3.2, “MySQL Cluster Configuration Files”](#), and [Section 17.3, “MySQL Cluster Configuration”](#). For configuration of MySQL Cluster as relates to making backups, see [Section 17.5.3.3, “Configuration for MySQL Cluster Backups”](#).

**Note**

The default port for Cluster management nodes is 1186; the default port for data nodes is 2202. However, the cluster can automatically allocate ports for data nodes from those that are already free.

### 17.2.1.3. Initial Startup of MySQL Cluster

Starting the cluster is not very difficult after it has been configured. Each cluster node process must be started separately, and on the host where it resides. The management node should be started first, followed by the data nodes, and then finally by any SQL nodes:

1. On the management host, issue the following command from the system shell to start the management node process:

```
shell> ndb_mgmd -f /var/lib/mysql-cluster/config.ini
```

**Note**

`ndb_mgmd` must be told where to find its configuration file, using the `-f` or `--config-file` option. (See [Section 17.4.4, “`ndb\_mgmd` — The MySQL Cluster Management Server Daemon”](#), for details.)

For additional options which can be used with `ndb_mgmd`, see [Section 17.4.23, “Options Common to MySQL Cluster Programs”](#).

2. On each of the data node hosts, run this command to start the `ndbd` process:

```
shell> ndbd
```

3. If you used RPM files to install MySQL on the cluster host where the SQL node is to reside, you can (and should) use the supplied startup script to start the MySQL server process on the SQL node.

If all has gone well, and the cluster has been set up correctly, the cluster should now be operational. You can test this by invoking the `ndb_mgm` management node client. The output should look like that shown here, although you might see some slight differences in the output depending upon the exact version of MySQL that you are using:

```
shell> ndb_mgm
-- NDB Cluster -- Management Client --
```

```

ndb_mgm> SHOW
Connected to Management Server at: localhost:1186
Cluster Configuration

[ndbd(NDB)] 2 node(s)
id=2 @192.168.0.30 (Version: 5.1.47-ndb-6.3.38, Nodegroup: 0, Master)
id=3 @192.168.0.40 (Version: 5.1.47-ndb-6.3.38, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)
id=1 @192.168.0.10 (Version: 5.1.47-ndb-6.3.38)

[mysqld(API)] 1 node(s)
id=4 @192.168.0.20 (Version: 5.1.47-ndb-6.3.38)

```

The SQL node is referenced here as `[mysqld(API)]`, which reflects the fact that the `mysqld` process is acting as a MySQL Cluster API node.

#### Note

The IP address shown for a given MySQL Cluster SQL or other API node in the output of `SHOW` is the address used by the SQL or API node to connect to the cluster data nodes, and not to any management node.

You should now be ready to work with databases, tables, and data in MySQL Cluster. See [Section 17.2.3, “Loading Sample Data into MySQL Cluster and Performing Queries”](#), for a brief discussion.

## 17.2.2. Installing MySQL Cluster on Windows

Experimental support for MySQL Cluster on Microsoft Windows operating systems was introduced in MySQL Cluster NDB 7.0. Beginning with MySQL Cluster NDB 7.1.3, production support is provided for MySQL Cluster on Windows, and MySQL Cluster binaries for Windows can be obtained from <http://dev.mysql.com/downloads/cluster/>. For information about installing MySQL Cluster on Windows from a binary release provided by Oracle, see [Section 17.2.2.1, “Installing MySQL Cluster on Windows from a Binary Release”](#).

It is also possible to compile and install MySQL Cluster from source on Windows using Microsoft Visual Studio. For more information, see [Section 17.2.2.2, “Compiling and Installing MySQL Cluster from Source on Windows”](#).

### 17.2.2.1. Installing MySQL Cluster on Windows from a Binary Release

This section describes a basic installation of MySQL Cluster on Windows using a binary `no-install` MySQL Cluster release provided by Oracle, using the same 4-node setup outlined in the beginning of this section (see [Section 17.2, “MySQL Cluster Multi-Computer How-To”](#)), as shown in the following table:

Node	IP Address
Management (MGMD) node	192.168.0.10
MySQL server (SQL) node	192.168.0.20
Data (NDBD) node "A"	192.168.0.30
Data (NDBD) node "B"	192.168.0.40

As on other platforms, the MySQL Cluster host computer running an SQL node must have installed on it a MySQL Server binary (`mysqld.exe`). You should also have the MySQL client (`mysql.exe`) on this host. For management nodes and data nodes, it is not necessary to install the MySQL Server binary; however, each management node requires the management server daemon (`ndb_mgmd.exe`); each data node requires the data node daemon (`ndbd.exe` or `ndbmttd.exe`). For this example, we refer to `ndbd.exe` as the data node executable, but you can install `ndbmttd.exe`, the multi-threaded version of this program, instead, in exactly the same way. You should also install the management client (`ndb_mgm.exe`) on the management server host. This section covers the steps necessary to install the correct Windows binaries for each type of MySQL Cluster node.

`ndbmttd.exe` was not included in MySQL Cluster NDB 7.1.3 binary releases for Windows, due to a problem with `make_win_bin_dist`. This issue was corrected in MySQL Cluster NDB 7.1.5.

#### Note

As with other Windows programs, MySQL Cluster executables are named with the `.exe` file extension. However, it is not necessary to include the `.exe` extension when invoking these programs from the command line. Therefore, we often simply refer to these programs in this documentation as `mysqld`, `mysql`, `ndb_mgmd`, and so on. You should understand that, whether we refer (for example) to `mysqld` or `mysqld.exe`, either name means the same thing (the MySQL Server program).

For setting up a MySQL Cluster using Oracle's `no-install` binaries, the first step in the installation process is to download the latest MySQL Cluster Windows binary archive from <http://dev.mysql.com/downloads/cluster/>. This archive has a filename of the form `mysql-cluster-gpl-noinstall-ver-winarch.zip`, where `ver` is the NDB storage engine version (such as

[7.1.3](#)), and `arch` is the architecture ([32](#) for 32-bit binaries, and [64](#) for 64-bit binaries). For example, the MySQL Cluster NDB 7.1.3 `no-install` archive for 32-bit Windows systems is named `mysql-cluster-gpl-noinstall-7.1.3-win32.zip`.

You can run 32-bit MySQL Cluster binaries on both 32-bit and 64-bit versions of Windows; however, 64-bit MySQL Cluster binaries can be used only on 64-bit versions of Windows. If you are using a 32-bit version of Windows on a computer that has a 64-bit CPU, then you must use the 32-bit MySQL Cluster binaries.

To minimize the number of files that need to be downloaded from the Internet or copied between machines, we start with the computer where you intend to run the SQL node.

**SQL node.** We assume that you have placed a copy of the `no-install` archive in the directory `C:\Documents and Settings\username\My Documents\Downloads` on the computer having the IP address 192.168.0.20, where `username` is the name of the current user. (You can obtain this name using `ECHO %USERNAME%` on the command line.) To install and run MySQL Cluster executables as Windows services, this user should be a member of the `Administrators` group.

Extract all the files from the archive. The Extraction Wizard integrated with Windows Explorer is adequate for this task. (If you use a different archive program, be sure that it extracts all files and directories from the archive, and that it preserves the archive's directory structure.) When you are asked for a destination directory, enter `C:\`, which causes the Extraction Wizard to extract the archive to the directory `C:\mysql-cluster-gpl-noinstall-ver-winarch`. Rename this directory to `C:\mysql`.

It is possible to install the MySQL Cluster binaries to directories other than `C:\mysql\bin`; however, if you do so, you must modify the paths shown in this procedure accordingly. In particular, if the MySQL Server (SQL node) binary is installed to a location other than `C:\mysql` or `C:\Program Files\MySQL\MySQL Server 5.1`, or if the SQL node's data directory is in a location other than `C:\mysql\data` or `C:\Program Files\MySQL\MySQL Server 5.1\data`, extra configuration options must be used on the command line or added to the `my.ini` or `my.cnf` file when starting the SQL node. For more information about configuring a MySQL Server to run in a nonstandard location, see [Section 2.4.5, “Installing MySQL on Microsoft Windows from a noinstall Zip Archive”](#).

For a MySQL Server with MySQL Cluster support to run as part of a MySQL Cluster, it must be started with the options `-ndbcluster` and `--ndb-connectstring`. While you can specify these options on the command line, it is usually more convenient to place them in an option file. To do this, create a new text file in Notepad or another text editor. Enter the following configuration information into this file:

```
[mysqld]
Options for mysqld process:
ndbcluster # run NDB storage engine
ndb-connectstring=192.168.0.10 # location of management server
```

You can add other options used by this MySQL Server if desired (see [Section 2.4.5.2, “Creating an Option File”](#)), but the file must contain the options shown, at a minimum. Save this file as `C:\mysql\my.ini`. This completes the installation and setup for the SQL node.

**Data nodes.** A MySQL Cluster data node on a Windows host requires only a single executable, one of either `ndbd.exe` or `ndb-mtd.exe`. For this example, we assume that you are using `ndbd.exe`, but the same instructions apply when using `ndbmttd.exe`. On each computer where you wish to run a data node (the computers having the IP addresses 192.168.0.30 and 192.168.0.40), create the directories `C:\mysql`, `C:\mysql\bin`, and `C:\mysql\cluster-data`; then, on the computer where you downloaded and extracted the `no-install` archive, locate `ndbd.exe` in the `C:\mysql\bin` directory. Copy this file to the `C:\mysql\bin` directory on each of the two data node hosts.

To function as part of a MySQL Cluster, each data node must be given the address or hostname of the management server. You can supply this information on the command line using the `--ndb-connectstring` or `-c` option when starting each data node process. However, it is usually preferable to put this information in an option file. To do this, create a new text file in Notepad or another text editor and enter the following text:

```
[mysql_cluster]
Options for data node process:
ndb-connectstring=192.168.0.10 # location of management server
```

Save this file as `C:\mysql\my.ini` on the data node host. Create another text file containing the same information and save it on as `C:\mysql\my.ini` on the other data node host, or copy the `my.ini` file from the first data node host to the second one, making sure to place the copy in the second data node's `C:\mysql` directory. Both data node hosts are now ready to be used in the MySQL Cluster, which leaves only the management node to be installed and configured.

**Management node.** The only executable program required on a computer used for hosting a MySQL Cluster management node is the management server program `ndb_mgmd.exe`. However, in order to administer the MySQL Cluster once it has been started, you should also install the MySQL Cluster management client program `ndb_mgm.exe` on the same machine as the management server. Locate these two programs on the machine where you downloaded and extracted the `no-install` archive; this should be the directory `C:\mysql\bin` on the SQL node host. Create the directory `C:\mysql\bin` on the computer having the IP address 192.168.0.10, then copy both programs to this directory.

You should now create two configuration files for use by `ndb_mgmd.exe`:

1. A local configuration file to supply configuration data specific to the management node itself. Typically, this file needs only to supply the location of the MySQL Cluster global configuration file (see item 2).

To create this file, start a new text file in Notepad or another text editor, and enter the following information:

```
[mysql_cluster]
Options for management node process
config-file=C:/mysql/bin/config.ini
```

Save this file as the plaintext file `C:\mysql\bin\my.ini`.

2. A global configuration file from which the management node can obtain configuration information governing the MySQL Cluster as a whole. At a minimum, this file must contain a section for each node in the MySQL Cluster, and the IP addresses or hostnames for the management node and all data nodes (`HostName` configuration parameter). It is also advisable to include the following additional information:

- The IP address or hostname of any SQL nodes
- The data memory and index memory allocated to each data node (`DataMemory` and `IndexMemory` configuration parameters)
- The number of replicas, using the `NoOfReplicas` configuration parameter (see [Section 17.1.2, “MySQL Cluster Nodes, Node Groups, Replicas, and Partitions”](#))
- The directory where each data node stores its data and log file, and the directory where the management node keeps its log files (in both cases, the `DataDir` configuration parameter)

Create a new text file using a text editor such as Notepad, and input the following information:

```
[ndbd default]
Options affecting ndbd processes on all data nodes:
NoOfReplicas=2 # Number of replicas
DataDir=C:/mysql/bin/cluster-data # Directory for each data node's data files
 # Forward slashes used in directory path,
 # rather than backslashes. This is correct;
 # see Important note in text
DataMemory=80M # Memory allocated to data storage
IndexMemory=18M # Memory allocated to index storage
 # For DataMemory and IndexMemory, we have used the
 # default values. Since the "world" database takes up
 # only about 500KB, this should be more than enough for
 # this example Cluster setup.

[ndb_mgmd]
Management process options:
HostName=192.168.0.10 # Hostname or IP address of management node
DataDir=C:/mysql/bin/cluster-logs # Directory for management node log files

[ndbd]
Options for data node "A":
HostName=192.168.0.30 # (one [ndbd] section per data node)
 # Hostname or IP address

[ndbd]
Options for data node "B":
HostName=192.168.0.40 # Hostname or IP address

[mysqld]
SQL node options:
HostName=192.168.0.20 # Hostname or IP address
```

Save this file as the plaintext file `C:\mysql\bin\config.ini`.

### Important

A single backslash character (`\`) cannot be used when specifying directory paths in program options or configuration files used by MySQL Cluster on Windows. Instead, you must either escape each backslash character with a second backslash (`\\\`), or replace the backslash with a forward slash character (`/`). For example, the following line from the `[ndb_mgmd]` section of a MySQL Cluster `config.ini` file does not work:

```
DataDir=C:\mysql\bin\cluster-logs
```

Instead, you may use either of the following:

```
DataDir=C:\\mysql\\\\bin\\\\cluster-logs # Escaped backslashes
```

```
DataDir=C:/mysql/bin/cluster-logs # Forward slashes
```

For reasons of brevity and legibility, we recommend that you use forward slashes in directory paths used in MySQL Cluster program options and configuration files on Windows.

### 17.2.2.2. Compiling and Installing MySQL Cluster from Source on Windows

Oracle provides precompiled MySQL Cluster binaries for Windows which should be adequate for most users. However, if you wish, it is also possible to compile MySQL Cluster for Windows from source code. The procedure for doing this is almost identical to the procedure used to compile the standard MySQL Server binaries for Windows, and uses the same tools. However, there are two major differences:

- To build MySQL Cluster, you must use the MySQL Cluster sources, which you can obtain from <http://dev.mysql.com/downloads/cluster/>.

Attempting to build MySQL Cluster from the source code for the standard MySQL Server is likely not to be successful, and is not supported by Oracle.

- You must configure the build using the `WITH_NDBCLUSTER_STORAGE_ENGINE` option in addition to any other build options you wish to use before creating the Visual Studio project files. Once you have run `configure.js` with the desired options, you can create the project files and build from them in the same manner as you do when compiling the standard MySQL Server. For more information, see [Section 2.4.9, “Installing MySQL from Source on Windows”](#).

#### Important

Currently, MySQL Cluster is not compatible with the `InnoDB Plugin`. You must use the version of `InnoDB` that is supplied with the MySQL Server. You can also build MySQL Cluster with `InnoDB` storage engine support on Windows using `WITH_INNOBASE_STORAGE_ENGINE` with `configure.js`.

Once the build process is complete, you can create a ZIP archive containing the compiled binaries by running `make_win_bin_dist`. The MySQL Cluster binaries can be found in the `bin` directory of the resulting archive, which is equivalent to the `no-install` archive, and which can be installed and configured in the same manner. For basic information about how to accomplish these tasks, see [Section 17.2.2.1, “Installing MySQL Cluster on Windows from a Binary Release”](#).

On Windows, beginning with MySQL Cluster NDB 7.0.11, using `WITH_NDBCLUSTER_STORAGE_ENGINE` with `configure.js` causes `ndbmttd.exe` to be built automatically, and to be found in the `bin` directory of the archive created by `make_win_bin_dist`. (It was not possible to build `ndbmttd.exe` on Windows prior to MySQL Cluster NDB 7.0.11.)

### 17.2.2.3. Initial Startup of MySQL Cluster on Windows

Once the MySQL Cluster executables and needed configuration files are in place, performing an initial start of the cluster is simply a matter of starting the MySQL Cluster executables for all nodes in the cluster. Each cluster node process must be started separately, and on the host computer where it resides. The management node should be started first, followed by the data nodes, and then finally by any SQL nodes.

1. On the management node host, issue the following command from the command line to start the management node process:

```
C:\mysql\bin> ndb_mgmd
2010-06-23 07:53:34 [MgmtSrvr] INFO -- NDB Cluster Management Server. mysql-5.1.47-ndb-7.1.8
2010-06-23 07:53:34 [MgmtSrvr] INFO -- Reading cluster configuration from 'config.ini'
```

The management node process continues to print logging output to the console. This is normal, because the management node is not running as a Windows service. (If you have used MySQL Cluster on a Unix-like platform such as Linux, you may notice that the management node's default behavior in this regard on Windows is effectively the opposite of its behavior on Unix systems, where it runs by default as a Unix daemon process. This behavior is also true of MySQL Cluster data node processes running on Windows.) For this reason, do not close the window in which `ndb_mgmd.exe` is running; doing so kills the management node process. (See [Section 17.2.2.4, “Installing MySQL Cluster Processes as Windows Services”](#), where we show how to install and run MySQL Cluster processes as Windows services.)

The required `-f` option tells the management node where to find the global configuration file (`config.ini`). The long form of this option is `--config-file`.

#### Important

A MySQL Cluster management node caches the configuration data that it reads from `config.ini`; once it has created a configuration cache, it ignores the `config.ini` file on subsequent starts unless forced to do otherwise. This means that, if the management node fails to start due to an error in this file, you must make the management node re-

read `config.ini` after you have corrected any errors in it. You can do this by starting `ndb_mgmd.exe` with the `--reload` or `--initial` option on the command line. Either of these options works to refresh the configuration cache.

It is not necessary or advisable to use either of these options in the management node's `my.ini` file.

For additional information about options which can be used with `ndb_mgmd`, see [Section 17.4.4, “`ndb\_mgmd` — The MySQL Cluster Management Server Daemon”](#), as well as [Section 17.4.23, “Options Common to MySQL Cluster Programs”](#).

2. On each of the data node hosts, run the command shown here to start the data node processes:

```
C:\mysql\bin> ndbd
2010-06-23 07:53:46 [ndbd] INFO -- Configuration fetched from 'localhost:1186', generation: 1
```

In each case, the first line of output from the data node process should resemble what is shown in the preceding example, and is followed by additional lines of logging output. As with the management node process, this is normal, because the data node is not running as a Windows service. For this reason, do not close the console window in which the data node process is running; doing so kills `ndbd.exe`. (For more information, see [Section 17.2.4, “Installing MySQL Cluster Processes as Windows Services”](#).)

3. Do not start the SQL node yet; it cannot connect to the cluster until the data nodes have finished starting, which may take some time. Instead, in a new console window on the management node host, start the MySQL Cluster management client `ndb_mgm.exe`, which should be in `C:\mysql\bin` on the management node host. (Do not try to re-use the console window where `ndb_mgmd.exe` is running by typing `CTRL+C`, as this kills the management node.) The resulting output should look like this:

```
C:\mysql\bin> ndb_mgm
-- NDB Cluster -- Management Client --
ndb_mgm>
```

When the prompt `ndb_mgm>` appears, this indicates that the management client is ready to receive MySQL Cluster management commands. You can observe the status of the data nodes as they start by entering `ALL STATUS` at the management client prompt. This command causes a running report of the data nodes's startup sequence, which should look something like this:

```
ndb_mgm> ALL STATUS
Connected to Management Server at: localhost:1186
Node 2: starting (Last completed phase 3) (mysql-5.1.47-ndb-7.1.8)
Node 3: starting (Last completed phase 3) (mysql-5.1.47-ndb-7.1.8)

Node 2: starting (Last completed phase 4) (mysql-5.1.47-ndb-7.1.8)
Node 3: starting (Last completed phase 4) (mysql-5.1.47-ndb-7.1.8)

Node 2: Started (version 7.1.8)
Node 3: Started (version 7.1.8)

ndb_mgm>
```

## Note

Commands issued in the management client are not case-sensitive; we use uppercase as the canonical form of these commands, but you are not required to observe this convention when inputting them into the `ndb_mgm` client. For more information, see [Section 17.5.2, “Commands in the MySQL Cluster Management Client”](#).

The output produced by `ALL STATUS` is likely to vary from what is shown here, according to the speed at which the data nodes are able to start, the release version number of the MySQL Cluster software you are using, and other factors. What is significant is that, when you see that both data nodes have started, you are ready to start the SQL node.

You can leave `ndb_mgm.exe` running; it has no negative impact on the performance of the MySQL Cluster, and we use it in the next step to verify that the SQL node is connected to the cluster after you have started it.

4. On the computer designated as the SQL node host, open a console window and navigate to the directory where you unpacked the MySQL Cluster binaries (if you are following our example, this is `C:\mysql\bin`).

Start the SQL node by invoking `mysqld.exe` from the command line, as shown here:

```
C:\mysql\bin> mysqld --console
```

The `--console` option causes logging information to be written to the console, which can be helpful in the event of problems. (Once you are satisfied that the SQL node is running in a satisfactory manner, you can stop it and restart it out without the `--console` option, so that logging is performed normally.)

In the console window where the management client (`ndb_mgm.exe`) is running on the management node host, enter the

`SHOW` command, which should produce output similar to what is shown here:

```
ndb_mgm> SHOW
Connected to Management Server at: localhost:1186
Cluster Configuration

[ndbd(NDB)] 2 node(s)
id=2 @192.168.0.30 (Version: 5.1.47-ndb-7.1.8, Nodegroup: 0, Master)
id=3 @192.168.0.40 (Version: 5.1.47-ndb-7.1.8, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)
id=1 @192.168.0.10 (Version: 5.1.47-ndb-7.1.8)

[mysqld(API)] 1 node(s)
id=4 @192.168.0.20 (Version: 5.1.47-ndb-7.1.8)
```

You can also verify that the SQL node is connected to the MySQL Cluster in the `mysql` client (`mysql.exe`) using the `SHOW ENGINE NDB STATUS` statement.

You should now be ready to work with database objects and data using MySQL Cluster's `NDBCCLUSTER` storage engine. See [Section 17.2.3, “Loading Sample Data into MySQL Cluster and Performing Queries”](#), for more information and examples.

Beginning with MySQL Cluster NDB 7.0.16 and MySQL Cluster NDB 7.1.5, you can install `ndb_mgmd.exe`, `ndbd.exe`, and `ndbmttd.exe` as Windows services. For information on how to do this, see [Section 17.2.4, “Installing MySQL Cluster Processes as Windows Services”](#)).

## 17.2.2.4. Installing MySQL Cluster Processes as Windows Services

Once you are satisfied that MySQL Cluster is running as desired, you can—beginning with MySQL Cluster NDB 7.0.16 and MySQL Cluster NDB 7.1.5—install the management nodes and data nodes as Windows services, so that these processes are started and stopped automatically whenever Windows is started or stopped. This also makes it possible to control these processes from the command line with the appropriate `NET START` or `NET STOP` command, or using the Windows graphical `Services` utility.

Installing programs as Windows services usually must be done using an account that has Administrator rights on the system.

To install the management node as a service on Windows, invoke `ndb_mgmd.exe` from the command line on the machine hosting the management node, using the `--install` option, as shown here:

```
C:\> C:\mysql\bin\ndb_mgmd.exe --install
Installing service 'MySQL Cluster Management Server' as '"C:\mysql\bin\ndbd.exe" "--service=ndb_mgmd"'
Service successfully installed.
```

### Important

When installing a MySQL Cluster program as a Windows service, you should always specify the complete path; otherwise the service installation may fail with the error `THE SYSTEM CANNOT FIND THE FILE SPECIFIED`.

The `--install` option must be used first, ahead of any other options that might be specified for `ndb_mgmd.exe`. However, it is preferable to specify such options in an options file instead. If your options file is not in one of the default locations as shown in the output of `ndb_mgmd.exe --help`, you can specify the location using the `--config-file` option.

Now you should be able to start and stop the management server like this:

```
C:\> NET START ndb_mgmd
The MySQL Cluster Management Server service is starting.
The MySQL Cluster Management Server service was started successfully.

C:\> NET STOP ndb_mgmd
The MySQL Cluster Management Server service is stopping..
The MySQL Cluster Management Server service was stopped successfully.
```

You can also start or stop the management server as a Windows service using the descriptive name, as shown here:

```
C:\> NET START 'MySQL Cluster Management Server'
The MySQL Cluster Management Server service is starting.
The MySQL Cluster Management Server service was started successfully.

C:\> NET STOP 'MySQL Cluster Management Server'
The MySQL Cluster Management Server service is stopping..
The MySQL Cluster Management Server service was stopped successfully.
```

However, it is usually simpler to specify a short service name or to permit the default service name to be used when installing the service, and then reference that name when starting or stopping the service. To specify a service name other than `ndb_mgmd`, append it to the `--install` option, as shown in this example:

```
C:\> C:\mysql\bin\ndb_mgmd.exe --install=mgm1
Installing service 'MySQL Cluster Management Server' as '"C:\mysql\bin\ndb_mgmd.exe" "--service=mgm1"'
Service successfully installed.
```

Now you should be able to start or stop the service using the name you have specified, like this:

```
C:\> NET START mgm1
The MySQL Cluster Management Server service is starting.
The MySQL Cluster Management Server service was started successfully.

C:\> NET STOP mgm1
The MySQL Cluster Management Server service is stopping..
The MySQL Cluster Management Server service was stopped successfully.
```

To remove the management node service, invoke `ndb_mgmd.exe` with the `--remove` option, as shown here:

```
C:\> C:\mysql\bin\ndb_mgmd.exe --remove
Removing service 'MySQL Cluster Management Server'
Service successfully removed.
```

If you installed the service using a service name other than the default, you can remove the service by passing this name as the value of the the `--remove` option, like this:

```
C:\> C:\mysql\bin\ndb_mgmd.exe --remove=mgm1
Removing service 'mgm1'
Service successfully removed.
```

Installation of a MySQL Cluster data node processs as a Windows service can be done in a similar fashion, using the `--install` option for `ndbd.exe` (or `ndbmted.exe`), as shown here:

```
C:\> C:\mysql\bin\ndbd.exe --install
Installing service 'MySQL Cluster Data Node Daemon' as '"C:\mysql\bin\ndbd.exe" "--service=ndbd"'
Service successfully installed.
```

Now you can start or stop the data node using either the default service name or the descriptive name with `net start` or `net stop`, as shown in the following example:

```
C:\> NET START ndbd
The MySQL Cluster Data Node Daemon service is starting.
The MySQL Cluster Data Node Daemon service was started successfully.

C:\> NET STOP ndbd
The MySQL Cluster Data Node Daemon service is stopping..
The MySQL Cluster Data Node Daemon service was stopped successfully.

C:\> NET START 'MySQL Cluster Data Node Daemon'
The MySQL Cluster Data Node Daemon service is starting.
The MySQL Cluster Data Node Daemon service was started successfully.

C:\> NET STOP 'MySQL Cluster Data Node Daemon'
The MySQL Cluster Data Node Daemon service is stopping..
The MySQL Cluster Data Node Daemon service was stopped successfully.
```

To remove the data node service, invoke `ndbd.exe` with the `--remove` option, as shown here:

```
C:\> C:\mysql\bin\ndbd.exe --remove
Removing service 'MySQL Cluster Data Node Daemon'
Service successfully removed.
```

As with `ndb_mgmd.exe` (and `mysqld.exe`), when installing `ndbd.exe` as a Windows service, you can also specify a name for the service as the value of `--install`, and then use it when starting or stopping the service, like this:

```
C:\> C:\mysql\bin\ndbd.exe --install=dnode1
Installing service 'dnode1' as '"C:\mysql\bin\ndbd.exe" "--service=dnode1"'
Service successfully installed.

C:\> NET START dnode1
The MySQL Cluster Data Node Daemon service is starting.
The MySQL Cluster Data Node Daemon service was started successfully.

C:\> NET STOP dnode1
The MySQL Cluster Data Node Daemon service is stopping..
The MySQL Cluster Data Node Daemon service was stopped successfully.
```

If you specified a service name when installing the data node service, you can use this name when removing it as well, by passing it as the value of the `--remove` option, as shown here:

```
C:\> C:\mysql\bin\ndbd.exe --remove=dnode1
Removing service 'dnode1'
```

```
Service successfully removed.
```

Installation of the SQL node as a Windows service, starting the service, stopping the service, and removing the service are done in a similar fashion, using `mysqld --install`, `NET START`, `NET STOP`, and `mysqld --remove`. For additional information, see [Section 2.4.5.7, “Starting MySQL Server as a Microsoft Windows Service”](#).

## 17.2.3. Loading Sample Data into MySQL Cluster and Performing Queries

### Note

The information in this section applies to MySQL Cluster running on both Unix and Windows platforms.

Working with data in MySQL Cluster is not much different from doing so in MySQL without clustering support. There are two points to keep in mind:

- For a table to be replicated in the cluster, it must use the `NDBCLUSTER` storage engine. To specify this, use the `ENGINE=NDBCLUSTER` or `ENGINE=NDB` option when creating the table:

```
CREATE TABLE tbl_name (col_name column_definitions) ENGINE=NDBCLUSTER;
```

Alternatively, for an existing table that uses a different storage engine, use `ALTER TABLE` to change the table to use `NDBCLUSTER`:

```
ALTER TABLE tbl_name ENGINE=NDBCLUSTER;
```

- Each `NDBCLUSTER` table *must* have a primary key. If no primary key is defined by the user when a table is created, the `NDBCLUSTER` storage engine automatically generates a hidden one.

### Note

This hidden key takes up space just as does any other table index. It is not uncommon to encounter problems due to insufficient memory for accommodating these automatically created indexes.)

If you are importing tables from an existing database using the output of `mysqldump`, you can open the SQL script in a text editor and add the `ENGINE` option to any table creation statements, or replace any existing `ENGINE` options. Suppose that you have the `world` sample database on another MySQL server that does not support MySQL Cluster, and you want to export the `City` table:

```
shell> mysqldump --add-drop-table world City > city_table.sql
```

The resulting `city_table.sql` file will contain this table creation statement (and the `INSERT` statements necessary to import the table data):

```
DROP TABLE IF EXISTS `City`;
CREATE TABLE `City` (
 `ID` int(11) NOT NULL auto_increment,
 `Name` char(35) NOT NULL default '',
 `CountryCode` char(3) NOT NULL default '',
 `District` char(20) NOT NULL default '',
 `Population` int(11) NOT NULL default '0',
 PRIMARY KEY (`ID`)
) ENGINE=MyISAM DEFAULT CHARSET=latin1;

INSERT INTO `City` VALUES (1,'Kabul','AFG','Kabul',1780000);
INSERT INTO `City` VALUES (2,'Qandahar','AFG','Qandahar',237500);
INSERT INTO `City` VALUES (3,'Herat','AFG','Herat',186800);
(remaining INSERT statements omitted)
```

You need to make sure that MySQL uses the `NDBCLUSTER` storage engine for this table. There are two ways that this can be accomplished. One of these is to modify the table definition *before* importing it into the Cluster database. Using the `City` table as an example, modify the `ENGINE` option of the definition as follows:

```
DROP TABLE IF EXISTS `City`;
CREATE TABLE `City` (
 `ID` int(11) NOT NULL auto_increment,
 `Name` char(35) NOT NULL default '',
 `CountryCode` char(3) NOT NULL default '',
 `District` char(20) NOT NULL default '',
 `Population` int(11) NOT NULL default '0',
 PRIMARY KEY (`ID`)
) ENGINE=NDBCLUSTER DEFAULT CHARSET=latin1;

INSERT INTO `City` VALUES (1,'Kabul','AFG','Kabul',1780000);
INSERT INTO `City` VALUES (2,'Qandahar','AFG','Qandahar',237500);
INSERT INTO `City` VALUES (3,'Herat','AFG','Herat',186800);
```

```
(remaining INSERT statements omitted)
```

This must be done for the definition of each table that is to be part of the clustered database. The easiest way to accomplish this is to do a search-and-replace on the file that contains the definitions and replace all instances of `TYPE=engine_name` or `ENGINE=engine_name` with `ENGINE=NDBCLUSTER`. If you do not want to modify the file, you can use the unmodified file to create the tables, and then use `ALTER TABLE` to change their storage engine. The particulars are given later in this section.

Assuming that you have already created a database named `world` on the SQL node of the cluster, you can then use the `mysql` command-line client to read `city_table.sql`, and create and populate the corresponding table in the usual manner:

```
shell> mysql world < city_table.sql
```

It is very important to keep in mind that the preceding command must be executed on the host where the SQL node is running (in this case, on the machine with the IP address `192.168.0.20`).

To create a copy of the entire `world` database on the SQL node, use `mysqldump` on the noncluster server to export the database to a file named `world.sql`; for example, in the `/tmp` directory. Then modify the table definitions as just described and import the file into the SQL node of the cluster like this:

```
shell> mysql world < /tmp/world.sql
```

If you save the file to a different location, adjust the preceding instructions accordingly.

Running `SELECT` queries on the SQL node is no different from running them on any other instance of a MySQL server. To run queries from the command line, you first need to log in to the MySQL Monitor in the usual way (specify the `root` password at the `Enter password:` prompt):

```
shell> mysql -u root -p
Enter password:
Welcome to the MySQL monitor. Commands end with ; or \g.
Your MySQL connection id is 1 to server version: 5.1.47-ndb-6.2.19
Type 'help;' or '\h' for help. Type '\c' to clear the buffer.
mysql>
```

We simply use the MySQL server's `root` account and assume that you have followed the standard security precautions for installing a MySQL server, including setting a strong `root` password. For more information, see [Section 2.13.2, “Securing the Initial MySQL Accounts”](#).

It is worth taking into account that Cluster nodes do *not* make use of the MySQL privilege system when accessing one another. Setting or changing MySQL user accounts (including the `root` account) effects only applications that access the SQL node, not interaction between nodes. See [Section 17.5.9.2, “MySQL Cluster and MySQL Privileges”](#), for more information.

If you did not modify the `ENGINE` clauses in the table definitions prior to importing the SQL script, you should run the following statements at this point:

```
mysql> USE world;
mysql> ALTER TABLE City ENGINE=NDBCLUSTER;
mysql> ALTER TABLE Country ENGINE=NDBCLUSTER;
mysql> ALTER TABLE CountryLanguage ENGINE=NDBCLUSTER;
```

Selecting a database and running a `SELECT` query against a table in that database is also accomplished in the usual manner, as is exiting the MySQL Monitor:

```
mysql> USE world;
mysql> SELECT Name, Population FROM City ORDER BY Population DESC LIMIT 5;
+-----+-----+
| Name | Population |
+-----+-----+
| Bombay | 10500000 |
| Seoul | 9981619 |
| São Paulo | 9968485 |
| Shanghai | 996300 |
| Jakarta | 9604900 |
+-----+-----+
5 rows in set (0.34 sec)

mysql> \q
Bye

shell>
```

Applications that use MySQL can employ standard APIs to access `NDB` tables. It is important to remember that your application must access the SQL node, and not the management or data nodes. This brief example shows how we might execute the `SELECT` statement just shown by using the PHP 5.X `mysqli` extension running on a Web server elsewhere on the network:

```

<!DOCTYPE HTML PUBLIC "-//W3C//DTD HTML 4.01 Transitional//EN"
 "http://www.w3.org/TR/html4/loose.dtd">
<html>
<head>
 <meta http-equiv="Content-Type"
 content="text/html; charset=iso-8859-1">
 <title>SIMPLE mysqli SELECT</title>
</head>
<body>
<?php
 # connect to SQL node:
 $link = new mysqli('192.168.0.20', 'root', 'root_password', 'world');
 # parameters for mysqli constructor are:
 # host, user, password, database

 if(mysqli_connect_errno())
 die("Connect failed: " . mysqli_connect_error());

 $query = "SELECT Name, Population
 FROM City
 ORDER BY Population DESC
 LIMIT 5";

 # if no errors...
 if($result = $link->query($query))
 {
?>
<table border="1" width="40%" cellpadding="4" cellspacing ="1">
 <tbody>
 <tr>
 <th width="10%">City</th>
 <th>Population</th>
 </tr>
 </tbody>
</table>
<?
 # then display the results...
 while($row = $result->fetch_object())
 printf("<tr>\n <td align=\"center\">%s</td><td>%d</td>\n</tr>\n",
 $row->Name, $row->Population);
?>
 </tbody>
</table>
<?
 # ...and verify the number of rows that were retrieved
 printf("<p>Affected rows: %d</p>\n", $link->affected_rows);
}
else
 # otherwise, tell us what went wrong
 echo mysqli_error();

 # free the result set and the mysqli connection object
 $result->close();
 $link->close();
?>
</body>
</html>

```

We assume that the process running on the Web server can reach the IP address of the SQL node.

In a similar fashion, you can use the MySQL C API, Perl-DBI, Python-mysql, or MySQL Connectors to perform the tasks of data definition and manipulation just as you would normally with MySQL.

## 17.2.4. Safe Shutdown and Restart of MySQL Cluster

To shut down the cluster, enter the following command in a shell on the machine hosting the management node:

```
shell> ndb_mgm -e shutdown
```

The `-e` option here is used to pass a command to the `ndb_mgm` client from the shell. (See [Section 17.4.23, “Options Common to MySQL Cluster Programs”](#), for more information about this option.) The command causes the `ndb_mgm`, `ndb_mgmd`, and any `ndbd` or `ndbmted` processes to terminate gracefully. Any SQL nodes can be terminated using `mysqladmin shutdown` and other means. On Windows platforms, assuming that you have installed the SQL node as a Windows service, you can use `NET STOP MySQL`.

To restart the cluster on Unix platforms, run these commands:

- On the management host (`192.168.0.10` in our example setup):

```
shell> ndb_mgmd -f /var/lib/mysql-cluster/config.ini
```

- On each of the data node hosts (`192.168.0.30` and `192.168.0.40`):

```
shell> ndbd
```

- Use the `ndb_mgm` client to verify that both data nodes have started successfully.
- On the SQL host (`192.168.0.20`):

```
shell> mysqld_safe &
```

On Windows platforms, assuming that you have installed all MySQL Cluster processes as Windows services using the default service names (see [Section 17.2.2.4, “Installing MySQL Cluster Processes as Windows Services”](#)), you can restart the cluster as follows:

- On the management host (`192.168.0.10` in our example setup), execute the following command:

```
C:\> NET START ndb_mgmd
```

- On each of the data node hosts (`192.168.0.30` and `192.168.0.40`), execute the following command:

```
C:\> NET START ndbd
```

- On the management node host, use the `ndb_mgm` client to verify that the management node and both data nodes have started successfully (see [Section 17.2.2.3, “Initial Startup of MySQL Cluster on Windows”](#)).

- On the SQL node host (`192.168.0.20`), execute the following command:

```
C:\> NET START mysql
```

In a production setting, it is usually not desirable to shut down the cluster completely. In many cases, even when making configuration changes, or performing upgrades to the cluster hardware or software (or both), which require shutting down individual host machines, it is possible to do so without shutting down the cluster as a whole by performing a *rolling restart* of the cluster. For more information about doing this, see [Section 17.2.5.1, “Performing a Rolling Restart of a MySQL Cluster”](#).

## 17.2.5. Upgrading and Downgrading MySQL Cluster

This portion of the MySQL Cluster chapter covers upgrading and downgrading a MySQL Cluster from one MySQL release to another. It discusses different types of Cluster upgrades and downgrades, and provides a Cluster upgrade/downgrade compatibility matrix (see [Section 17.2.5.2, “MySQL Cluster 5.1 and MySQL Cluster NDB 6.x/7.x Upgrade and Downgrade Compatibility”](#)). You are expected already to be familiar with installing and configuring a MySQL Cluster prior to attempting an upgrade or downgrade. See [Section 17.3, “MySQL Cluster Configuration”](#).

For more information about upgrading or downgrading between MySQL Cluster NDB releases, or between MySQL Cluster NDB releases and mainline MySQL releases, see the changelogs relating to the applicable MySQL Cluster versions.

This section remains in development, and continues to be updated and expanded.

### 17.2.5.1. Performing a Rolling Restart of a MySQL Cluster

This section discusses how to perform a *rolling restart* of a MySQL Cluster installation, so called because it involves stopping and starting (or restarting) each node in turn, so that the cluster itself remains operational. This is often done as part of a *rolling upgrade* or *rolling downgrade*, where high availability of the cluster is mandatory and no downtime of the cluster as a whole is permissible. Where we refer to upgrades, the information provided here also generally applies to downgrades as well.

There are a number of reasons why a rolling restart might be desirable:

- **Cluster configuration change.** To make a change in the cluster's configuration, such as adding an SQL node to the cluster, or setting a configuration parameter to a new value.
- **Cluster software upgrade/downgrade.** To upgrade the cluster to a newer version of the MySQL Cluster software (or to downgrade it to an older version). This is usually referred to as a “rolling upgrade” (or “rolling downgrade”, when reverting to an older version of MySQL Cluster).
- **Change on node host.** To make changes in the hardware or operating system on which one or more cluster nodes are running.
- **Cluster reset.** To reset the cluster because it has reached an undesirable state. In such cases it is often desirable to reload the data and metadata of one or more data nodes. This can be done 1 of 3 ways:
  - Start each data node process (`ndbd`, or possibly `ndbmtd` in MySQL Cluster NDB 7.0 and later) with the `--initial` op-

tion, which forces the data node to clear its filesystem and reload data and metadata from the other data nodes.

- Create a backup using the `ndb_mgm` client `BACKUP` command prior to performing the restart. Following the upgrade, restore the node or nodes using `ndb_restore`.

See [Section 17.5.3, “Online Backup of MySQL Cluster”](#), and [Section 17.4.17, “`ndb\_restore` — Restore a MySQL Cluster Backup”](#), for more information.

- Use `mysqldump` (see [Section 4.5.4, “`mysqldump` — A Database Backup Program”](#)) to create a backup prior to the upgrade; afterward, restore the dump using `LOAD DATA INFILE`.
- **Freeing of resources.** To permit memory allocated to a table by successive `INSERT` and `DELETE` operations to be freed for re-use by other MySQL Cluster tables.

The process for performing a rolling restart may be generalized as follows:

1. Stop all cluster management nodes (`ndb_mgmd` processes), reconfigure them, then restart them.
2. Stop, reconfigure, then restart each cluster data node (`ndbd` process) in turn.
3. Stop, reconfigure, then restart each cluster SQL node (`mysqld` process) in turn.

The specifics for implementing a particular rolling upgrade depend upon the actual changes being made. A more detailed view of the process is presented here:

<b>RESTART TYPE:</b>				
<i>Cluster Configuration Change</i>	<i>Cluster Software Upgrade or Downgrade</i>	<i>Change on Node Host</i>	<i>Cluster Reset</i>	
<b>A. Management node (<code>ndb_mgmd</code>) processes...</b>				
1. Stop all <code>ndb_mgmd</code> processes  2. Make changes in global configuration file(s)  3. Start all <code>ndb_mgmd</code> processes	1. Stop all <code>ndb_mgmd</code> processes  2. Replace each <code>ndb_mgmd</code> binary with new version  3. Start <code>ndb_mgmd</code> processes	1. Stop all <code>ndb_mgmd</code> processes  2. Make desired changes in hardware, operating system, or both  3. Start all <code>ndb_mgmd</code> processes	( OR )  1. Stop all <code>ndb_mgmd</code> processes  2. Start all <code>ndb_mgmd</code> processes	Restart all <code>ndb_mgmd</code> processes (optional)
<b>B. For each data node (<code>ndbd</code>) process...</b>				
( OR )  1. Stop <code>ndbd</code> 2. Start <code>ndbd</code>	Restart <code>ndbd</code>	1. Stop <code>ndbd</code>  2. Replace <code>ndbd</code> binary with new version  3. Start <code>ndbd</code>	( OR )  1. Stop <code>ndbd</code>  2. Start <code>ndbd</code>	Restart <code>ndbd</code>
<b>C. For each SQL node (<code>mysqld</code>) process...</b>				
( OR )  1. Stop <code>mysqld</code> 2. Start <code>mysqld</code>	Restart <code>mysqld</code>	1. Stop <code>mysqld</code>  2. Replace <code>mysqld</code> binary with new version  3. Start <code>mysqld</code>	( OR )  1. Stop <code>mysqld</code>  2. Start <code>mysqld</code>	Restart <code>mysqld</code>

In the previous diagram, the **Stop** and **Start** steps indicate that the process must be stopped completely using a shell command (such as `kill` on most Unix systems) or the management client `STOP` command, then started again from a system shell by invoking the `ndbd` or `ndb_mgmd` executable as appropriate. **Restart** indicates the process may be restarted using the `ndb_mgm` management client `RESTART` command.

**Prior to MySQL Cluster NDB 6.3.29 and MySQL Cluster NDB 7.0.10.** When performing an upgrade or downgrade of the cluster software, you *must* upgrade or downgrade the management nodes *first*, then the data nodes, and finally the SQL nodes. Doing so in any other order may leave the cluster in an unusable state.

**MySQL Cluster NDB 6.3.29 and later; MySQL Cluster NDB 7.0.10 and later.** MySQL Cluster supports a more flexible order for upgrading the cluster nodes. When upgrading a cluster running MySQL Cluster NDB 6.3.29 or later, or a cluster that is running MySQL Cluster NDB 7.0.10 or later, you may upgrade API nodes (including SQL nodes) before upgrading the management nodes, data nodes, or both. In other words, you are permitted to upgrade the API and SQL nodes in any order. This is subject to the following provisions:

- This functionality is intended for use as part of an online upgrade only. A mix of node binaries from different MySQL Cluster releases is neither intended nor supported for constant, long-term use in a production setting.
- All management nodes must be upgraded before any data nodes are upgraded. This remains true regardless of the order in which you upgrade the cluster's API and SQL nodes.
- For MySQL Cluster NDB 6.3, the ability to upgrade API nodes in any order relative to upgrading management nodes and data nodes is supported only for MySQL Cluster NDB 6.3.29 and later; for MySQL Cluster NDB 7.0, it supported only for MySQL Cluster NDB 7.0.10 and later. This means that, if you are upgrading from a MySQL Cluster NDB 6.3 release to a MySQL Cluster NDB 7.0 release, the “old” `NDB` engine version must be 6.3.29 or later, and the “new” `NDB` engine version must be 7.0.10 or later.
- When upgrading the cluster from a MySQL Cluster NDB 6.3 release to a MySQL Cluster NDB 7.0 release: Once you have started upgrading the API nodes, you should not perform DDL operations until all management nodes and data nodes have been upgraded. DML operations should be unaffected, and can continue while the upgrade is in progress.

However, it is possible to perform DDL from an “old” (NDB 6.3 version) API node as long as the master data node is also running the “old” version of MySQL Cluster. You should keep in mind that a data node restart could result in the master node running a “new” (NDB 7.0 version) binary while one or more data nodes are still using the “old” (NDB 6.3) version; in this situation, no DDL can be performed from *any* API node, because the master data node is no longer using an NDB 6.3 binary, but the cluster still contains nodes which are not yet using NDB 7.0. For this reason, we recommend that you avoid performing DDL at any time while the upgrade is in progress.

- Features specific to the “new” version must not be used until all management nodes and data nodes have been upgraded.

This also applies to any MySQL Server version change that may apply, in addition to the NDB engine version change, so do not forget to take this into account when planning the upgrade. (This is true for online upgrades of MySQL Cluster in general.)

See also [Bug#48528](#) and [Bug#49163](#).

### 17.2.5.2. MySQL Cluster 5.1 and MySQL Cluster NDB 6.x/7.x Upgrade and Downgrade Compatibility

This section provides information about MySQL Cluster software and table file compatibility between MySQL 5.1.23 and earlier, MySQL Cluster NDB 6.x, and MySQL Cluster NDB 7.x releases with regard to performing upgrades and downgrades.

For information about upgrades and downgrades to, from, and between different releases of MySQL Cluster NDB 7.0 and MySQL Cluster NDB 7.1, see [Upgrade and downgrade compatibility: MySQL Cluster NDB 7.x](#).

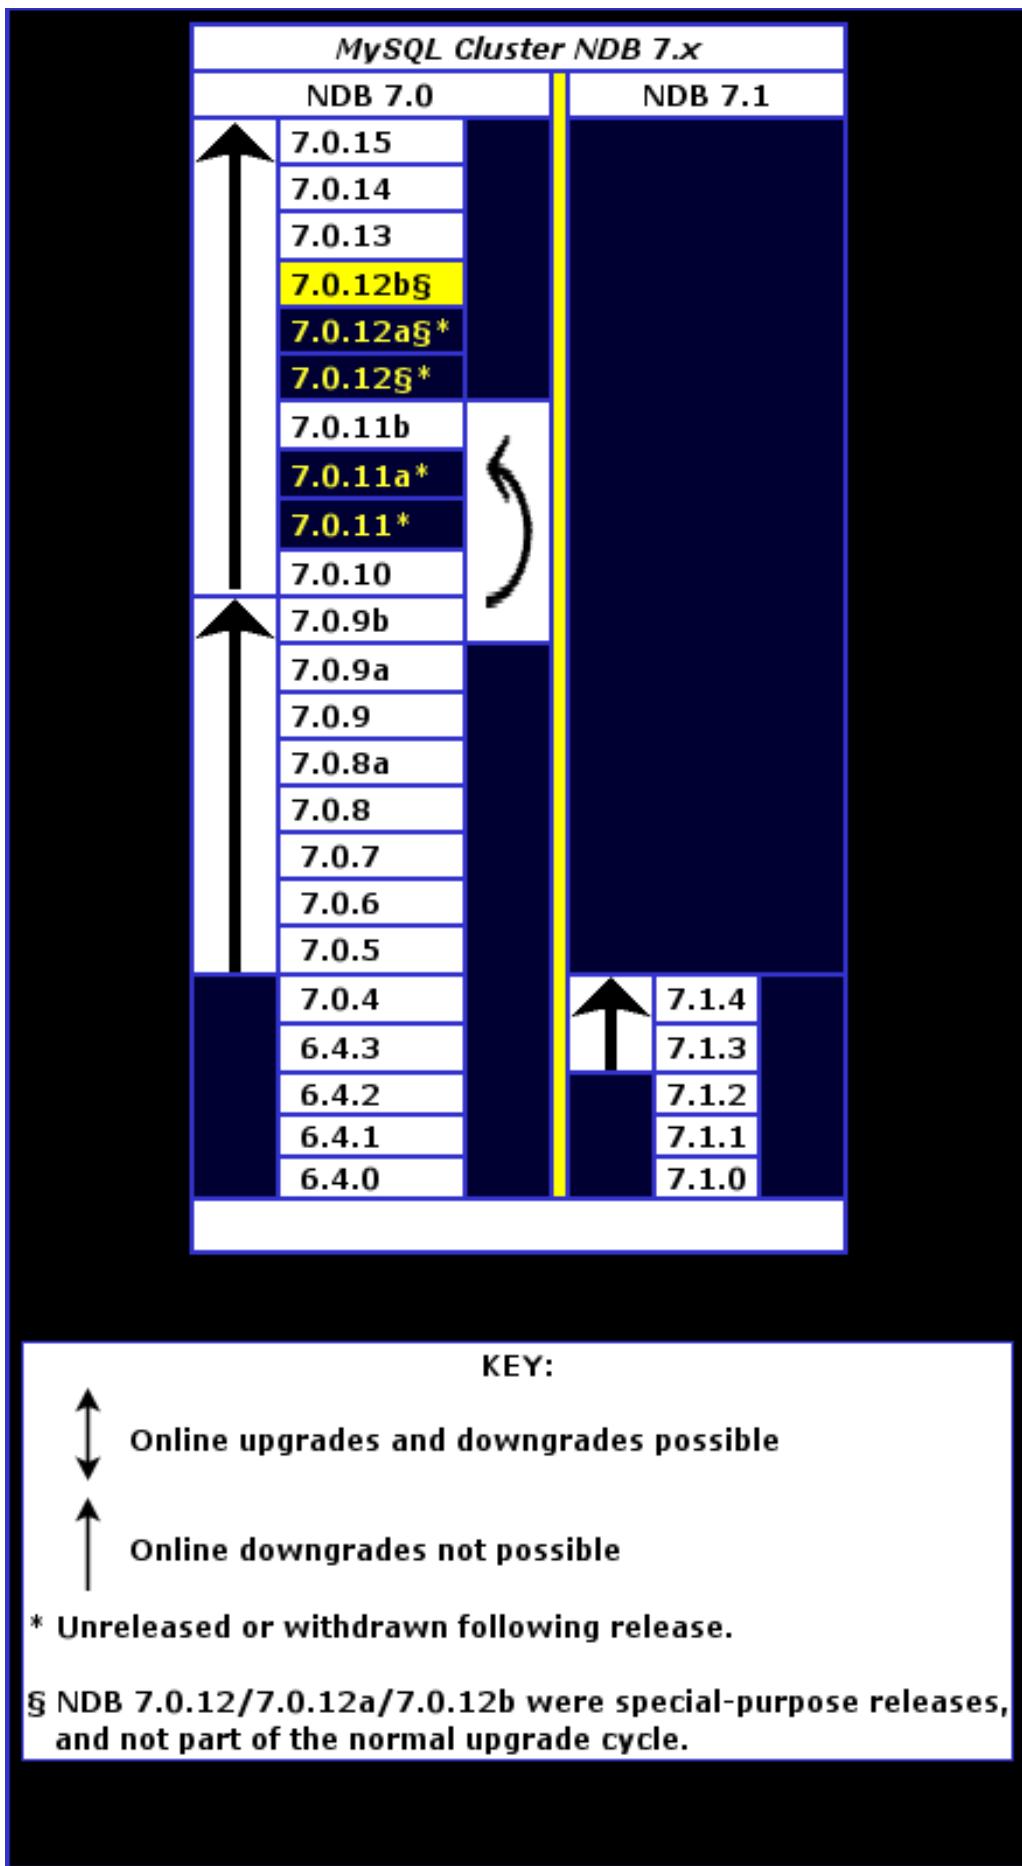

For information about upgrades and downgrades to, from, and between different releases of MySQL Cluster NDB 6.1, MySQL Cluster NDB 6.2, and MySQL Cluster NDB 6.3, see [Upgrade and downgrade compatibility: MySQL Cluster NDB 6.x](#).

For information about upgrades and downgrades to, from, and between different editions of MySQL Cluster as found in standard MySQL 5.1.23 and earlier releases, see [Upgrade and downgrade compatibility: MySQL 5.1](#).

#### Important

Only compatibility between MySQL versions with regard to `NDBCLUSTER` is taken into account in this section, and there are likely other issues to be considered. *As with any other MySQL software upgrade or downgrade, you are strongly encouraged to review the relevant portions of the MySQL Manual for the MySQL versions from which and to which you intend to migrate, before attempting an upgrade or downgrade of the MySQL Cluster software.* See [Section 2.12.1, “Upgrading MySQL”](#).

**Upgrade and downgrade compatibility: MySQL Cluster NDB 7.x.** The table shown here provides information on MySQL Cluster upgrade and downgrade compatibility among different releases of MySQL Cluster NDB 7.0 and 7.1. Additional notes about upgrades and downgrades to, from, or within the MySQL Cluster NDB 7.x release series can be found immediately following the table.

**Notes: MySQL Cluster NDB 6.x:**

- Online upgrades from any MySQL Cluster NDB 7.0 release up to and including MySQL Cluster NDB 7.0.4 (as well as all early releases numbered NDB 6.4.x) to MySQL Cluster NDB 7.0.5 or later are not possible. Upgrades to MySQL Cluster NDB 7.0.6 or later from MySQL Cluster NDB 6.3.8 or a later MySQL Cluster NDB 6.3 release, or from MySQL Cluster NDB 7.0.5 or later, are supported. ([Bug#44294](#))

When upgrading online from a MySQL Cluster NDB 6.3 release to a MySQL Cluster NDB 7.0 release, you should not try to upgrade the data nodes from `ndbd` to `ndbmt`d at the same time. Instead, perform the upgrade using the new `ndbd` executable (from the MySQL Cluster NDB 7.0.x distribution to which you are upgrading) to replace the one in use on the data nodes. Once the version upgrade is complete, you can perform a second (online) upgrade to replace the data node executables with `ndbmt`d from the MySQL Cluster NDB 7.0.x distribution.

- In MySQL Cluster NDB 7.0.4, the default values for a number of MySQL Cluster configuration parameters relating to memory usage and buffering changed (see [Section 17.7.2.25, “Changes in MySQL Cluster NDB 7.0.4 \(5.1.32-ndb-7.0.4\) \(18 March 2008\)](#), for a list of the parameters whose defaults changed). For this reason, you may encounter issues if you try to use a configuration that does not explicitly define each of these buffers (because it was developed for a previous version of MySQL Cluster, `SendBufferMemory` and `ReceiveBufferMemory` in particular).
- Prior to MySQL Cluster NDB 7.0.7, DML statements failed if executed while performing an online upgrade from a MySQL Cluster NDB 6.3 release. ([Bug#45917](#))
- Following an upgrade from any MySQL Cluster NDB 6.3.x release to MySQL Cluster NDB 7.0.6, DDL and backup operations failed. This issue was resolved in MySQL Cluster NDB 7.0.7. ([Bug#46494](#), [Bug#46563](#))
- In some cases, there could be problems with online upgrades from MySQL Cluster NDB 6.3 releases to MySQL Cluster NDB 7.0 releases due to a previous change in the signalling format used between nodes. This issue was corrected in MySQL Cluster NDB 7.0.9.
- Once an `NDB` table had an `ALTER ONLINE TABLE` operation performed on it using a MySQL Cluster NDB 6.3.x release, it could not be upgraded online to MySQL Cluster NDB 7.0. This issue was resolved in MySQL Cluster NDB 7.0.8. (See [Bug#47542](#).)
- Following an upgrade from MySQL Cluster NDB 6.3 to MySQL Cluster NDB 7.0, if there were any tables having unique indexes prior to the upgrade, attempts to create unique indexes failed. This could also occur when performing offline `ALTER TABLE` operations on tables having indexes that were not dropped as a result of the `ALTER TABLE`. This issue was due to a change in the way that `NDB` tracked unique indexes internally, and was resolved in MySQL Cluster NDB 7.0.9. ([Bug#48416](#))

**Workaround.** For upgrades to MySQL Cluster NDB 7.0 releases prior to version 7.0.9, a workaround is available: Following the upgrade, perform a second rolling restart of the cluster before performing any `ALTER TABLE` operations involving indexes.

- Due to an issue discovered after the release of MySQL Cluster NDB 7.0.10 ([Bug#50433](#)), it is not possible to perform an online upgrade from MySQL Cluster NDB 7.0.9b and earlier MySQL Cluster NDB 7.0 releases to MySQL Cluster NDB 7.0.10. Instead, you should upgrade your MySQL Cluster NDB 7.0 cluster directly to MySQL Cluster NDB 7.0.11 or later.

This issue did not appear to affect MySQL Cluster NDB 6.3, and it should be possible to upgrade online from MySQL Cluster NDB 6.3 to MySQL Cluster NDB 7.0.10 without any problems other than those noted previously.

- It was not possible to perform an online upgrade from a MySQL Cluster NDB 6.3 or 7.0 release to MySQL Cluster NDB 7.1.0 or 7.1.1. This issue was fixed in MySQL Cluster NDB 7.1.2. ([Bug#51429](#))
- Following an upgrade to MySQL Cluster NDB 7.0.15 or later (MySQL Cluster NDB 7.0), or to MySQL Cluster NDB 7.1.4 or later (MySQL Cluster NDB 7.1), a table created in a previous version of MySQL Cluster does *not* automatically support `NDB`-native default values. Such a table continues to use default values supplied by the MySQL server until it is upgraded by performing an offline `ALTER TABLE` on it.

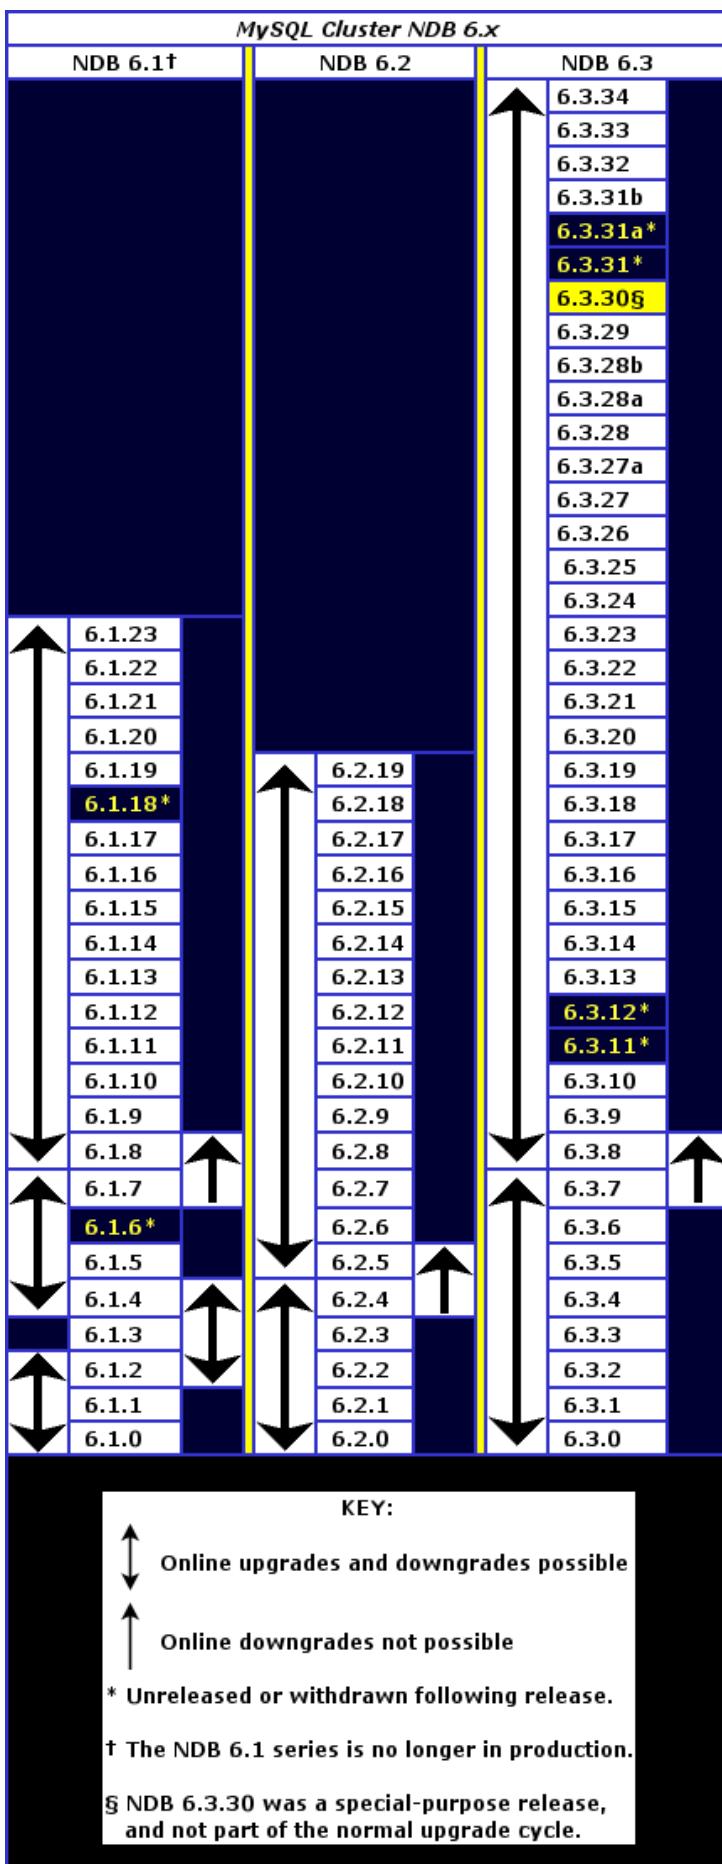

When upgrading to a MySQL Cluster release that supports native default values from a MySQL Cluster release that does not, you should not attempt to create any new tables until all data nodes are using the new `ndbd` or `ndbmt`d binaries. This is because the older binaries do not provide support for native default values.

**Important**

Tables created with native default value support cannot be used with versions of MySQL Cluster that do not support native default values.

**Upgrade and downgrade compatibility: MySQL Cluster NDB 6.x.** The table shown here provides information on MySQL Cluster upgrade and downgrade compatibility among different releases of MySQL Cluster NDB 6.1, 6.2, and 6.3. Additional notes about upgrades and downgrades to, from, or within the MySQL Cluster NDB 6.x release series can be found immediately follow-

ing the table.

**Notes: MySQL Cluster NDB 6.x:**

- MySQL Cluster NDB 6.1 is no longer in production; if you are still using a MySQL Cluster NDB 6.1 release, you should upgrade to the most recent MySQL Cluster NDB 6.3 or 7.0 release as soon as possible.
- It is not possible to upgrade from MySQL Cluster NDB 6.1.2 (or an older 6.1 release) directly to 6.1.4 or a newer NDB 6.1 release, or to downgrade from 6.1.4 (or a newer 6.1 release) directly to 6.1.2 or an older NDB 6.1 release; in either case, you must upgrade or downgrade to MySQL Cluster NDB 6.1.3 first.
- It is not possible to perform an online downgrade from MySQL Cluster NDB 6.1.8 (or a newer 6.1 release) to MySQL Cluster NDB 6.1.7 (or an older 6.1 release).
- MySQL Cluster NDB 6.1.6 and 6.1.18 were not released.
- It is not possible to perform an online upgrade or downgrade between MySQL Cluster NDB 6.2 and any previous release series (including mainline MySQL 5.1 and MySQL Cluster NDB 6.1); it is necessary to perform a dump and reload. However, it should be possible to perform online upgrades or downgrades between any MySQL Cluster NDB 6.2 release and any MySQL Cluster NDB 6.3 release up to and including 6.3.7.
- The internal specifications for columns in [NDB](#) tables changed in MySQL Cluster NDB 6.1.17 and 6.2.1 to enable compatibility with future MySQL Cluster releases that are expected to implement online adding and dropping of columns. This change is not backward-compatible with earlier MySQL or MySQL Cluster NDB 6.x versions.

To make tables created in earlier versions compatible with online adding and dropping of columns in later versions, it is necessary to force MySQL Cluster to convert the tables to the new format by following this procedure following an upgrade:

1. Upgrade the MySQL Cluster software on all data, management, and SQL nodes
2. Back up all [NDB](#) tables
3. Shut down the cluster (all data, management, and SQL nodes)
4. Restart the cluster, starting all data nodes with the `--initial` option (to clear and rebuild the data node file systems)
5. Restore the tables from backup

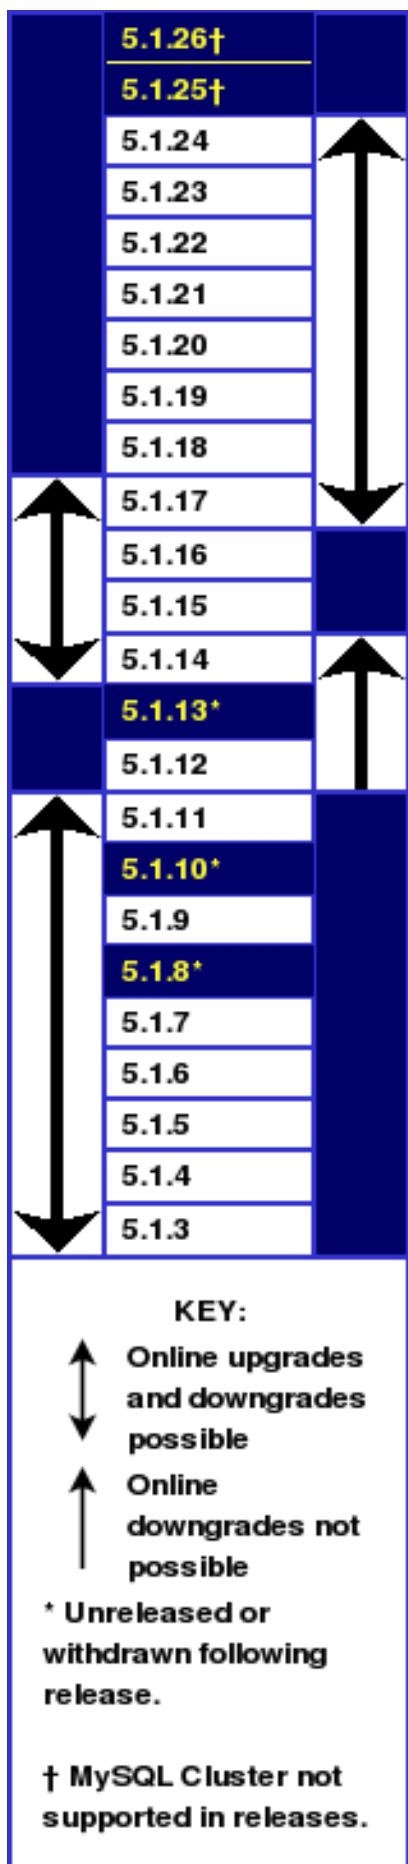

To minimize possible later difficulties, it is strongly advised that the procedure outlined above be followed as soon as possible after to upgrading between the versions indicated. The procedure is *not* necessary for [NDBCLUSTER](#) tables created in any of the following versions:

- MySQL Cluster NDB 6.1.8 or a later MySQL Cluster NDB 6.1 release
- MySQL Cluster 6.2.1 or a later MySQL Cluster NDB 6.2 release
- Any MySQL Cluster NDB 6.3 release

Tables created in the listed versions (or later ones, as indicated) are already compatible with online adding and dropping of columns (as implemented beginning with MySQL Cluster NDB 6.2.5 and MySQL Cluster NDB 6.3.2).

- It was not possible to perform an online upgrade between any MySQL Cluster NDB 6.2 release and MySQL Cluster NDB 6.3.8 and later MySQL Cluster 6.3 releases. This issue was fixed in MySQL Cluster NDB 6.3.21. ([Bug#41435](#))
- Online downgrades between MySQL Cluster NDB 6.2.5 and earlier releases are not supported.
- Online downgrades between MySQL Cluster NDB 6.3.8 and earlier releases are not supported.

**Upgrade and downgrade compatibility: MySQL 5.1.** The table shown here provides information on MySQL Cluster upgrade and downgrade compatibility among different releases of MySQL 5.1 prior to MySQL 5.1.24. Additional notes about upgrades and downgrades to, from, or within the MySQL 5.1 release series can be found immediately following the table.

**Notes: MySQL 5.1:**

- MySQL 5.1.3 was the first public release in this series.
- Direct upgrades or downgrades between MySQL Cluster 5.0 and 5.1 are not supported; you must dump all `NDBCLUSTER` tables using `mysqldump`, install the new version of the software, and then reload the tables from the dump.
- You cannot downgrade a MySQL 5.1.6 or later Cluster using Disk Data tables to MySQL 5.1.5 or earlier unless you convert all such tables to in-memory Cluster tables first.
- MySQL 5.1.8, MySQL 5.1.10, and MySQL 5.1.13 were not released.
- Online cluster upgrades and downgrades between MySQL 5.1.11 (or an earlier version) and 5.1.12 (or a later version) are not possible due to major changes in the cluster file system. In such cases, you must perform a backup or dump, upgrade (or downgrade) the software, start each data node with `--initial`, and then restore from the backup or dump. You can use `NDB` backup/restore or `mysqldump` for this purpose.
- Online downgrades from MySQL 5.1.14 or later to versions previous to 5.1.14 are not supported due to incompatible changes in the cluster system tables.
- Online upgrades from MySQL 5.1.17 and earlier to 5.1.18 and later MySQL 5.1.x releases are not supported for clusters using replication due to incompatible changes in the `mysql.ndb_apply_status` table. (Online upgrades from MySQL 5.1 to MySQL Cluster NDB 6.2 and later are not supported, as discussed elsewhere in this section.) However, it should not be necessary to shut down the cluster entirely, if you follow this modified rolling restart procedure:

**Note**

You should upgrade the MySQL Cluster software on each node using the same method by which it was originally installed. See [Section 17.2.1.1, “MySQL Cluster Multi-Computer Installation”](#), for more information.

1. Stop the management server, update the management server software, then start the management server again. For multiple management servers, repeat this step for each management server in turn.
2. For each data node in turn: Stop the data node, update the data node daemon (in MySQL Cluster NDB 7.0 and later, this can be either `ndbd` or `ndbmt`) with the new version, then restart the data node. It should not be necessary to use `--initial` when restarting any of the data nodes after updating the software.
3. Stop *all* SQL nodes. Upgrade the existing MySQL server installations to the new version on all SQL nodes, then restart them. It is not necessary to start them one at a time after upgrading the MySQL server software, but *there must be a time when none of them is running before starting any of them again using the 5.1.18 (or later) mysqld*. Otherwise—due to the fact that `mysql.ndb_apply_status` uses the `NDB` storage engine and is thus shared between all SQL nodes—there may be conflicts between the old and new versions of the table on different SQL nodes.

You can find more information about the changes to `ndb_apply_status` in [Section 17.6.4, “MySQL Cluster Replication Schema and Tables”](#).

As with any other MySQL Cluster version upgrade, you should also update the MySQL Cluster management client (`ndb_mgm`) and other MySQL Cluster client programs such as `ndb_config` and `ndb_error_reporter`; however, this does not have to be done in any particular order.

- The internal specifications for columns in `NDBCLUSTER` tables changed in MySQL 5.1.18 to enable compatibility with later MySQL Cluster releases that permit online adding and dropping of columns. *This change is not backward-compatible with earlier MySQL versions.*

To make tables created in MySQL 5.1.17 and earlier compatible with online adding and dropping of columns (available beginning with MySQL Cluster NDB 6.2.5 and MySQL Cluster NDB 6.3.3—see [Section 12.1.7, “ALTER TABLE Syntax”](#), for more information), it is necessary to force MySQL 5.1.18 and later to convert the tables to the new format by following this procedure:

1. Back up all `NDBCLUSTER` tables.
2. Upgrade the MySQL Cluster software on all data, management, and SQL nodes.
3. Shut down the cluster completely (this includes all data, management, and API or SQL nodes).
4. Restart the cluster, starting all data nodes with the `--initial` option (to clear and rebuild the data node file systems).
5. Restore the `NDBCLUSTER` tables from backup.

This is not necessary for `NDBCLUSTER` tables created in MySQL 5.1.18 and later; such tables will automatically be compatible

with online adding and dropping of columns (as implemented beginning with MySQL Cluster NDB 6.2.5 and MySQL Cluster NDB 6.3.2).

To minimize possible later difficulties, it is strongly advised that the procedure outlined above be followed as soon as possible after to upgrading from MySQL 5.1.17 or earlier to MySQL 5.1.18 or later.

Information about how this change effects users of MySQL Cluster NDB 6.x and 7.x is provided later in this section.

- MySQL Cluster is not supported in standard MySQL 5.1 releases, beginning with MySQL 5.1.24. If you are using MySQL Cluster in a standard MySQL 5.1 release, you should upgrade to the most recent MySQL Cluster NDB 6.2 or 6.3 release.

## 17.3. MySQL Cluster Configuration

A MySQL server that is part of a MySQL Cluster differs in one chief respect from a normal (nonclustered) MySQL server, in that it employs the `NDBCLUSTER` storage engine. This engine is also referred to simply as `NDB`, and the two forms of the name are synonymous.

To avoid unnecessary allocation of resources, the server is configured by default with the `NDB` storage engine disabled. To enable `NDB`, you must modify the server's `my.cnf` configuration file, or start the server with the `--ndbcluster` option.

For more information about `--ndbcluster` and other MySQL server options specific to MySQL Cluster, see [Section 17.3.4.2, “mysqld Command Options for MySQL Cluster”](#).

The MySQL server is a part of the cluster, so it also must know how to access an MGM node to obtain the cluster configuration data. The default behavior is to look for the MGM node on `localhost`. However, should you need to specify that its location is elsewhere, this can be done in `my.cnf` or on the MySQL server command line. Before the `NDB` storage engine can be used, at least one MGM node must be operational, as well as any desired data nodes.

`NDB`, the MySQL Cluster storage engine, is available in binary distributions for Linux, Mac OS X, Solaris, and Windows. We are working to support MySQL Cluster on all operating systems supported by the MySQL Server. For information about installing MySQL Cluster, see [Section 17.2.1.1, “MySQL Cluster Multi-Computer Installation”](#).

### 17.3.1. Quick Test Setup of MySQL Cluster

To familiarize you with the basics, we will describe the simplest possible configuration for a functional MySQL Cluster. After this, you should be able to design your desired setup from the information provided in the other relevant sections of this chapter.

First, you need to create a configuration directory such as `/var/lib/mysql-cluster`, by executing the following command as the system `root` user:

```
shell> mkdir /var/lib/mysql-cluster
```

In this directory, create a file named `config.ini` that contains the following information. Substitute appropriate values for `HostName` and `DataDir` as necessary for your system.

```
file "config.ini" - showing minimal setup consisting of 1 data node,
1 management server, and 3 MySQL servers.
The empty default sections are not required, and are shown only for
the sake of completeness.
Data nodes must provide a hostname but MySQL Servers are not required
to do so.
If you don't know the hostname for your machine, use localhost.
The DataDir parameter also has a default value, but it is recommended to
set it explicitly.
Note: [db], [api], and [mgm] are aliases for [ndbd], [mysqld], and [ndb_mgmd],
respectively. [db] is deprecated and should not be used in new installations.

[ndbd default]
NoOfReplicas= 1

[mysqld default]
[ndb_mgmd default]
[tcp default]

[ndb_mgmd]
HostName= myhost.example.com

[ndbd]
HostName= myhost.example.com
DataDir= /var/lib/mysql-cluster

[mysqld]
[mysqld]
[mysqld]
```

You can now start the `ndb_mgmd` management server. By default, it attempts to read the `config.ini` file in its current working directory, so change location into the directory where the file is located and then invoke `ndb_mgmd`:

```
shell> cd /var/lib/mysql-cluster
shell> ndb_mgmd
```

Then start a single data node by running `ndbd`:

```
shell> ndbd
```

For command-line options which can be used when starting `ndbd`, see [Section 17.4.23, “Options Common to MySQL Cluster Programs”](#).

By default, `ndbd` looks for the management server at `localhost` on port 1186.

### Note

If you have installed MySQL from a binary tarball, you will need to specify the path of the `ndb_mgmd` and `ndbd` servers explicitly. (Normally, these will be found in `/usr/local/mysql/bin`.)

Finally, change location to the MySQL data directory (usually `/var/lib/mysql` or `/usr/local/mysql/data`), and make sure that the `my.cnf` file contains the option necessary to enable the NDB storage engine:

```
[mysqld]
ndbcluster
```

You can now start the MySQL server as usual:

```
shell> mysqld_safe --user=mysql &
```

Wait a moment to make sure the MySQL server is running properly. If you see the notice `mysql ended`, check the server's `.err` file to find out what went wrong.

If all has gone well so far, you now can start using the cluster. Connect to the server and verify that the `NDBCLUSTER` storage engine is enabled:

```
shell> mysql
Welcome to the MySQL monitor. Commands end with ; or \g.
Your MySQL connection id is 1 to server version: 5.1.52

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SHOW ENGINES\G
...
***** 12. row *****
Engine: NDBCLUSTER
Support: YES
Comment: Clustered, fault-tolerant, memory-based tables
***** 13. row *****
Engine: NDB
Support: YES
Comment: Alias for NDBCLUSTER
...
```

The row numbers shown in the preceding example output may be different from those shown on your system, depending upon how your server is configured.

Try to create an `NDBCLUSTER` table:

```
shell> mysql
mysql> USE test;
Database changed

mysql> CREATE TABLE ctest (i INT) ENGINE=NDBCLUSTER;
Query OK, 0 rows affected (0.09 sec)

mysql> SHOW CREATE TABLE ctest \G
***** 1. row *****
Table: ctest
Create Table: CREATE TABLE `ctest` (
 `i` int(11) default NULL
) ENGINE=ndbcluster DEFAULT CHARSET=latin1
1 row in set (0.00 sec)
```

To check that your nodes were set up properly, start the management client:

```
shell> ndb_mgm
```

Use the `SHOW` command from within the management client to obtain a report on the cluster's status:

```
ndb_mgm> SHOW
Cluster Configuration

[ndbd(NDB)] 1 node(s)
id=2 @127.0.0.1 (Version: 3.5.3, Nodegroup: 0, Master)

[ndb_mgmd(MGM)] 1 node(s)
id=1 @127.0.0.1 (Version: 3.5.3)

[mysqld(API)] 3 node(s)
id=3 @127.0.0.1 (Version: 3.5.3)
id=4 (not connected, accepting connect from any host)
id=5 (not connected, accepting connect from any host)
```

At this point, you have successfully set up a working MySQL Cluster. You can now store data in the cluster by using any table created with `ENGINE=NDBCLUSTER` or its alias `ENGINE=NDB`.

### 17.3.2. MySQL Cluster Configuration Files

Configuring MySQL Cluster requires working with two files:

- **`my.cnf`**: Specifies options for all MySQL Cluster executables. This file, with which you should be familiar with from previous work with MySQL, must be accessible by each executable running in the cluster.
- **`config.ini`**: This file, sometimes known as the *global configuration file*, is read only by the MySQL Cluster management server, which then distributes the information contained therein to all processes participating in the cluster. `config.ini` contains a description of each node involved in the cluster. This includes configuration parameters for data nodes and configuration parameters for connections between all nodes in the cluster. For a quick reference to the sections that can appear in this file, and what sorts of configuration parameters may be placed in each section, see [Sections of the `config.ini` File](#).

**Caching of configuration data.** Beginning with MySQL Cluster NDB 6.4.0, MySQL Cluster uses *stateful configuration*. The global configuration file is no longer read every time the management server is restarted. Instead, the management server caches the configuration the first time it is started, and thereafter, the global configuration file is read only when one of the following items is true:

- **The management server is started using the `--initial` option.** In this case, the global configuration file is re-read, any existing cache files are deleted, and the management server creates a new configuration cache.
- **The management server is started using the `--reload` option.** In this case, the management server compares its cache with the global configuration file. If they differ, the management server creates a new configuration cache; any existing configuration cache is preserved, but not used. If the management server's cache and the global configuration file contain the same configuration data, then the existing cache is used, and no new cache is created.
- **The management server is started using a `--config-cache` option.** Beginning with MySQL Cluster NDB 7.0.15 and MySQL Cluster NDB 7.1.4, this option can be used to force the management server to bypass configuration caching altogether. In this case, the management server ignores any configuration files that may be present, always reading its configuration data from the `config.ini` file instead.
- **No configuration cache is found.** In this case, the management server reads the global configuration file and creates a cache containing the same configuration data as found in the file.

**Configuration cache files.** Beginning with MySQL Cluster 6.4.0, the management server by default creates configuration cache files in a directory named `mysql-cluster` in the MySQL installation directory. (If you build MySQL Cluster from source on a Unix system, the default location is `/usr/local/mysql-cluster`.) This can be overridden at run time by starting the management server with the `--configdir` option. Configuration cache files are binary files named according to the pattern `ndb_node_id_config.bin.seq_id`, where `node_id` is the management server's node ID in the cluster, and `seq_id` is a cache identifier. Cache files are numbered sequentially using `seq_id`, in the order in which they are created. The management server uses the latest cache file as determined by the `seq_id`.

#### Note

It is possible to roll back to a previous configuration by deleting later configuration cache files, or by renaming an earlier cache file so that it has a higher `seq_id`. However, since configuration cache files are written in a binary format, you should not attempt to edit their contents by hand.

For more information about the `--configdir`, `--initial`, and `--reload` options for the MySQL Cluster management serv-

er, see [Section 17.4.4, “`ndb\_mgmd` — The MySQL Cluster Management Server Daemon”](#).

We are continuously making improvements in Cluster configuration and attempting to simplify this process. Although we strive to maintain backward compatibility, there may be times when introduce an incompatible change. In such cases we will try to let Cluster users know in advance if a change is not backward compatible. If you find such a change and we have not documented it, please report it in the MySQL bugs database using the instructions given in [Section 1.7, “How to Report Bugs or Problems”](#).

### 17.3.2.1. MySQL Cluster Configuration: Basic Example

To support MySQL Cluster, you will need to update `my.cnf` as shown in the following example. You may also specify these parameters on the command line when invoking the executables.

#### Note

The options shown here should not be confused with those that are used in `config.ini` global configuration files. Global configuration options are discussed later in this section.

```
my.cnf
example additions to my.cnf for MySQL Cluster
(valid in MySQL 5.1)

enable ndbcluster storage engine, and provide connectstring for
management server host (default port is 1186)
[mysqld]
ndbcluster
ndb-connectstring=ndb_mgmd.mysql.com

provide connectstring for management server host (default port: 1186)
[ndbd]
connect-string=ndb_mgmd.mysql.com

provide connectstring for management server host (default port: 1186)
[ndb_mgm]
connect-string=ndb_mgmd.mysql.com

provide location of cluster configuration file
[ndb_mgmd]
config-file=/etc/config.ini
```

(For more information on connectstrings, see [Section 17.3.2.3, “The MySQL Cluster Connectstring”](#).)

```
my.cnf
example additions to my.cnf for MySQL Cluster
(will work on all versions)

enable ndbcluster storage engine, and provide connectstring for management
server host to the default port 1186
[mysqld]
ndbcluster
ndb-connectstring=ndb_mgmd.mysql.com:1186
```

#### Important

Once you have started a `mysqld` process with the `NDBCLUSTER` and `ndb-connectstring` parameters in the `[mysqld]` in the `my.cnf` file as shown previously, you cannot execute any `CREATE TABLE` or `ALTER TABLE` statements without having actually started the cluster. Otherwise, these statements will fail with an error. *This is by design.*

You may also use a separate `[mysql_cluster]` section in the cluster `my.cnf` file for settings to be read and used by all executables:

```
cluster-specific settings
[mysql_cluster]
ndb-connectstring=ndb_mgmd.mysql.com:1186
```

For additional `NDB` variables that can be set in the `my.cnf` file, see [Section 17.3.4.3, “MySQL Cluster System Variables”](#).

The MySQL Cluster global configuration file is named `config.ini` by default. It is read by `ndb_mgmd` at startup and can be placed anywhere. Its location and name are specified by using `--config-file=path_name` on the `ndb_mgmd` command line. If the configuration file is not specified, `ndb_mgmd` by default tries to read a file named `config.ini` located in the current working directory.

The global configuration file for MySQL Cluster uses INI format, which consists of sections preceded by section headings (surrounded by square brackets), followed by the appropriate parameter names and values. One deviation from the standard INI format is that the parameter name and value can be separated by a colon (“`:`”) as well as the equal sign (“`=`”); however, the equal sign is preferred. Another deviation is that sections are not uniquely identified by section name. Instead, unique sections (such as two different nodes of the same type) are identified by a unique ID specified as a parameter within the section.

Default values are defined for most parameters, and can also be specified in `config.ini`. (Prior to MySQL Cluster NDB 6.3.25 and MySQL Cluster NDB 7.0.6, there was no default value for `NoOfReplicas`, which always had to be specified explicitly in the `[ndbd default]` section. Beginning with versions just stated, the default value is 2, which is the recommended setting in most common usage scenarios.) To create a default value section, simply add the word `default` to the section name. For example, an `[ndbd]` section contains parameters that apply to a particular data node, whereas an `[ndbd default]` section contains parameters that apply to all data nodes. Suppose that all data nodes should use the same data memory size. To configure them all, create an `[ndbd default]` section that contains a `DataMemory` line to specify the data memory size.

The global configuration file must define the computers and nodes involved in the cluster and on which computers these nodes are located. An example of a simple configuration file for a cluster consisting of one management server, two data nodes and two MySQL servers is shown here:

```
file "config.ini" - 2 data nodes and 2 SQL nodes
This file is placed in the startup directory of ndb_mgmd (the
management server)
The first MySQL Server can be started from any host. The second
can be started only on the host mysqld_5.mysql.com

[ndbd default]
NoOfReplicas= 2
DataDir= /var/lib/mysql-cluster

[ndb_mgmd]
Hostname= ndb_mgmd.mysql.com
DataDir= /var/lib/mysql-cluster

[ndbd]
HostName= ndbd_2.mysql.com

[ndbd]
HostName= ndbd_3.mysql.com

[mysqld]
[mysqld]
HostName= mysqld_5.mysql.com
```

### Note

The preceding example is intended as a minimal starting configuration for purposes of familiarization with MySQL Cluster, and is almost certain not to be sufficient for production settings. See [Section 17.3.2.2, “Recommended Starting Configurations for MySQL Cluster NDB 6.2 and Later”](#), which provides more complete example starting configurations for use with MySQL Cluster NDB 6.2 and newer versions of MySQL Cluster.

Each node has its own section in the `config.ini` file. For example, this cluster has two data nodes, so the preceding configuration file contains two `[ndbd]` sections defining these nodes.

### Note

Do not place comments on the same line as a section heading in the `config.ini` file; this causes the management server not to start because it cannot parse the configuration file in such cases.

### Sections of the `config.ini` File

There are six different sections that you can use in the `config.ini` configuration file, as described in the following list:

- `[computer]`: Defines cluster hosts. This is not required to configure a viable MySQL Cluster, but may be used as a convenience when setting up a large cluster. See [Section 17.3.2.4, “Defining Computers in a MySQL Cluster”](#), for more information.
- `[ndbd]`: Defines a cluster data node (`ndbd` process). See [Section 17.3.2.6, “Defining MySQL Cluster Data Nodes”](#), for details.
- `[mysqld]`: Defines the cluster's MySQL server nodes (also called SQL or API nodes). For a discussion of SQL node configuration, see [Section 17.3.2.7, “Defining SQL and Other API Nodes in a MySQL Cluster”](#).
- `[mgm]` or `[ndb_mgmd]`: Defines a cluster management server (MGM) node. For information concerning the configuration of MGM nodes, see [Section 17.3.2.5, “Defining a MySQL Cluster Management Server”](#).
- `[tcp]`: Defines a TCP/IP connection between cluster nodes, with TCP/IP being the default connection protocol. Normally, `[tcp]` or `[tcp default]` sections are not required to set up a MySQL Cluster, as the cluster handles this automatically; however, it may be necessary in some situations to override the defaults provided by the cluster. See [Section 17.3.2.8, “MySQL Cluster TCP/IP Connections”](#), for information about available TCP/IP configuration parameters and how to use them. (You may also find [Section 17.3.2.9, “MySQL Cluster TCP/IP Connections Using Direct Connections”](#) to be of interest in some cases.)
- `[shm]`: Defines shared-memory connections between nodes. In MySQL 5.1, it is enabled by default, but should still be con-

sidered experimental. For a discussion of SHM interconnects, see [Section 17.3.2.10, “MySQL Cluster Shared-Memory Connections”](#).

- [\[sci\]](#):Defines *Scalable Coherent Interface* connections between cluster data nodes. Such connections require software which, while freely available, is not part of the MySQL Cluster distribution, as well as specialized hardware. See [Section 17.3.2.11, “SCI Transport Connections in MySQL Cluster”](#) for detailed information about SCI interconnects.

You can define `default` values for each section. All Cluster parameter names are case-insensitive, which differs from parameters specified in `my.cnf` or `my.ini` files.

## 17.3.2.2. Recommended Starting Configurations for MySQL Cluster NDB 6.2 and Later

Achieving the best performance from a MySQL Cluster depends on a number of factors including the following:

- MySQL Cluster software version
- Numbers of data nodes and SQL nodes
- Hardware
- Operating system
- Amount of data to be stored
- Size and type of load under which the cluster is to operate

Therefore, obtaining an optimum configuration is likely to be an iterative process, the outcome of which can vary widely with the specifics of each MySQL Cluster deployment. Changes in configuration are also likely to be indicated when changes are made in the platform on which the cluster is run, or in applications that use the MySQL Cluster's data. For these reasons, it is not possible to offer a single configuration that is ideal for all usage scenarios. However, in this section, we provide recommended base configurations for MySQL Cluster NDB 6.2 and 6.3 that can serve as reasonable starting points.

**Starting configuration for MySQL Cluster NDB 6.2.** The following is a recommended starting point for configuring a cluster running MySQL Cluster NDB 6.2.

```
TCP PARAMETERS
[tcp default]
SendBufferMemory=2M
ReceiveBufferMemory=2M

Increasing the sizes of these 2 buffers beyond the default values
helps prevent bottlenecks due to slow disk I/O.

MANAGEMENT NODE PARAMETERS
[ndb_mgmd default]
DataDir=path/to/management/server/data/directory

It is possible to use a different data directory for each management
server, but for ease of administration it is preferable to be
consistent.

[ndb_mgmd]
HostName=management-server-1-hostname
Id=management-server-A-id

[ndb_mgmd]
HostName=management-server-2-hostname

Using 2 management servers helps guarantee that there is always an
arbitrator in the event of network partitioning, and so is
recommended for high availability. Each management server must be
identified by a HostName. You may for the sake of convenience specify
a node ID for any management server, although one will be allocated
for it automatically; if you do so, it must be in the range 1-255
inclusive and must be unique among all IDs specified for cluster
nodes.

DATA NODE PARAMETERS
[ndbd default]
NoOfReplicas=2

Using 2 replicas is recommended to guarantee availability of data;
using only 1 replica does not provide any redundancy, which means
that the failure of a single data node causes the entire cluster to
shut down. We do not recommend using more than 2 replicas, since 2 is
sufficient to provide high availability, and we do not currently test
with greater values for this parameter.
```

```

LockPagesInMainMemory=1

On Linux and Solaris systems, setting this parameter locks data node
processes into memory. Doing so prevents them from swapping to disk,
which can severely degrade cluster performance.

DataMemory=3072M
IndexMemory=384M

The values provided for DataMemory and IndexMemory assume 4 GB RAM
per data node. However, for best results, you should first calculate
the memory that would be used based on the data you actually plan to
store (you may find the ndb_size.pl utility helpful in estimating
this), then allow an extra 20% over the calculated values. Naturally,
you should ensure that each data node host has at least as much
physical memory as the sum of these two values.

ODIRECT=1

Enabling this parameter causes NDBCLUSTER to try using O_DIRECT
writes for local checkpoints and redo logs; this can reduce load on
CPUs. We recommend doing so when using MySQL Cluster NDB 6.2.3 or
newer on systems running Linux kernel 2.6 or later.

NoOfFragmentLogFile=300
DataDir=path/to/data/node/data/directory
MaxNoOfConcurrentOperations=100000
TimeBetweenGlobalCheckpoints=1000
TimeBetweenEpochs=200
DiskCheckpointSpeed=10M
DiskCheckpointSpeedInRestart=100M
RedoBuffer=32M
MaxNoOfLocalScans=64
MaxNoOfTables=1024
MaxNoOfOrderedIndexes=256

[ndbd]
HostName=data-node-A-hostname
Id=data-node-A-id

[ndbd]
HostName=data-node-B-hostname
Id=data-node-B-id

You must have an [ndbd] section for every data node in the cluster;
each of these sections must include a HostName. Each section may
optionally include an Id for convenience, but in most cases, it is
sufficient to allow the cluster to allocate node IDs dynamically. If
you do specify the node ID for a data node, it must be in the range 1
to 48 inclusive and must be unique among all IDs specified for
cluster nodes.

SQL NODE / API NODE PARAMETERS

[mysqld]
HostName=SQL-node-1-hostname
Id=sql-node-A-id

[mysqld]

[mysqld]

Each API or SQL node that connects to the cluster requires a [mysqld]
or [api] section of its own. Each such section defines a connection
"slot"; you should have at least as many of these sections in the
config.ini file as the total number of API nodes and SQL nodes that
you wish to have connected to the cluster at any given time. There is
no performance or other penalty for having extra slots available in
case you find later that you want or need more API or SQL nodes to
connect to the cluster at the same time.
If no HostName is specified for a given [mysqld] or [api] section,
then any API or SQL node may use that slot to connect to the
cluster. You may wish to use an explicit HostName for one connection slot
to guarantee that an API or SQL node from that host can always
connect to the cluster. If you wish to prevent API or SQL nodes from
connecting from other than a desired host or hosts, then use a
HostName for every [mysqld] or [api] section in the config.ini file.
You can if you wish define a node ID (Id parameter) for any API or
SQL node, but this is not necessary; if you do so, it must be in the
range 1 to 255 inclusive and must be unique among all IDs specified
for cluster nodes.

```

**Starting configuration for MySQL Cluster NDB 6.3.** The following is a recommended starting point for configuring a cluster running MySQL Cluster NDB 6.3. It is similar to the recommendation for MySQL Cluster NDB 6.2, with the addition of parameters for better control of NDBCLUSTER process threads.

```

TCP PARAMETERS

[tcp_default]
SendBufferMemory=2M
ReceiveBufferMemory=2M

Increasing the sizes of these 2 buffers beyond the default values

```

```

helps prevent bottlenecks due to slow disk I/O.

MANAGEMENT NODE PARAMETERS

[ndb_mgmd default]
DataDir=path/to/management/server/data/directory

It is possible to use a different data directory for each management
server, but for ease of administration it is preferable to be
consistent.

[ndb_mgmd]
HostName=management-server-1-hostname
Id=management-server-A-id

[ndb_mgmd]
HostName=management-server-2-hostname

Using 2 management servers helps guarantee that there is always an
arbitrator in the event of network partitioning, and so is
recommended for high availability. Each management server must be
identified by a HostName. You may for the sake of convenience specify
a node ID for any management server, although one will be allocated
for it automatically; if you do so, it must be in the range 1-255
inclusive and must be unique among all IDs specified for cluster
nodes.

DATA NODE PARAMETERS

[ndbd default]
NoOfReplicas=2

Using 2 replicas is recommended to guarantee availability of data;
using only 1 replica does not provide any redundancy, which means
that the failure of a single data node causes the entire cluster to
shut down. We do not recommend using more than 2 replicas, since 2 is
sufficient to provide high availability, and we do not currently test
with greater values for this parameter.

LockPagesInMainMemory=1

On Linux and Solaris systems, setting this parameter locks data node
processes into memory. Doing so prevents them from swapping to disk,
which can severely degrade cluster performance.

DataMemory=3072M
IndexMemory=384M

The values provided for DataMemory and IndexMemory assume 4 GB RAM
per data node. However, for best results, you should first calculate
the memory that would be used based on the data you actually plan to
store (you may find the ndb_size.pl utility helpful in estimating
this), then allow an extra 20% over the calculated values. Naturally,
you should ensure that each data node host has at least as much
physical memory as the sum of these two values.

ODIRECT=1

Enabling this parameter causes NDBCLUSTER to try using O_DIRECT
writes for local checkpoints and redo logs; this can reduce load on
CPUs. We recommend doing so when using MySQL Cluster NDB 6.2.3 or
newer on systems running Linux kernel 2.6 or later.

NoOfFragmentLogFile=300
DataDir=path/to/data/node/data/directory
MaxNoOfConcurrentOperations=100000

SchedulerSpinTimer=400
SchedulerExecutionTimer=100
RealTimeScheduler=1
Setting these parameters allows you to take advantage of real-time scheduling
of NDBCLUSTER threads (introduced in MySQL Cluster NDB 6.3.4) to get higher
throughput.

TimeBetweenGlobalCheckpoints=1000
TimeBetweenEpochs=200
DiskCheckpointSpeed=10M
DiskCheckpointSpeedInRestart=100M
RedoBuffer=32M

CompressedLCP=1
CompressedBackup=1
Enabling CompressedLCP and CompressedBackup causes, respectively, local
checkpoint files and backup files to be compressed, which can result in a space
savings of up to 50% over noncompressed LCPs and backups.

MaxNoOfLocalScans=64
MaxNoOfTables=1024
MaxNoOfOrderedIndexes=256

[ndbd]
HostName=data-node-A-hostname
Id=data-node-A-id

LockExecuteThreadToCPU=1
LockMaintThreadsToCPU=0
On systems with multiple CPUs, these parameters can be used to lock NDBCLUSTER
threads to specific CPUs

```

```
[ndbd]
HostName=data-node-B-hostname
Id=data-node-B-id

LockExecuteThreadToCPU=1
LockMaintThreadsToCPU=0

You must have an [ndbd] section for every data node in the cluster;
each of these sections must include a HostName. Each section may
optionally include an Id for convenience, but in most cases, it is
sufficient to allow the cluster to allocate node IDs dynamically. If
you do specify the node ID for a data node, it must be in the range 1
to 48 inclusive and must be unique among all IDs specified for
cluster nodes.

SQL NODE / API NODE PARAMETERS

[mysqld]
HostName=SQL-node-1-hostname
Id=mysql-node-A-id

[mysqld]

[mysqld]

Each API or SQL node that connects to the cluster requires a [mysqld]
or [api] section of its own. Each such section defines a connection
"slot"; you should have at least as many of these sections in the
config.ini file as the total number of API nodes and SQL nodes that
you wish to have connected to the cluster at any given time. There is
no performance or other penalty for having extra slots available in
case you find later that you want or need more API or SQL nodes to
connect to the cluster at the same time.
If no HostName is specified for a given [mysqld] or [api] section,
then any API or SQL node may use that slot to connect to the
cluster. You may wish to use an explicit HostName for one connection slot
to guarantee that an API or SQL node from that host can always
connect to the cluster. If you wish to prevent API or SQL nodes from
connecting from other than a desired host or hosts, then use a
HostName for every [mysqld] or [api] section in the config.ini file.
You can if you wish define a node ID (Id parameter) for any API or
SQL node, but this is not necessary; if you do so, it must be in the
range 1 to 255 inclusive and must be unique among all IDs specified
for cluster nodes.
```

**Recommended my.cnf options for SQL nodes.** MySQL Servers acting as MySQL Cluster SQL nodes must always be started with the `--ndbcluster` and `--ndb-connectstring` options, either on the command line or in `my.cnf`. In addition, set the following options for all `mysqld` processes in the cluster, unless your setup requires otherwise:

- `--ndb-use-exact-count=0`
- `--ndb-index-stat-enable=0`
- `--ndb-force-send=1`
- `--engine-condition-pushdown=1`

### 17.3.2.3. The MySQL Cluster Connectstring

With the exception of the MySQL Cluster management server (`ndb_mgmd`), each node that is part of a MySQL Cluster requires a *connectstring* that points to the management server's location. This connectstring is used in establishing a connection to the management server as well as in performing other tasks depending on the node's role in the cluster. The syntax for a connectstring is as follows:

```
[nodeid=node_id,]host-definition[, host-definition[, ...]]
host-definition:
 host_name[:port_number]
```

`node_id` is an integer larger than 1 which identifies a node in `config.ini`. `host_name` is a string representing a valid Internet host name or IP address. `port_number` is an integer referring to a TCP/IP port number.

```
example 1 (long): "nodeid=2,myhost1:1100,myhost2:1100,192.168.0.3:1200"
example 2 (short): "myhost1"
```

`localhost:1186` is used as the default connectstring value if none is provided. If `port_num` is omitted from the connectstring, the default port is 1186. This port should always be available on the network because it has been assigned by IANA for this purpose (see <http://www.iana.org/assignments/port-numbers> for details).

By listing multiple host definitions, it is possible to designate several redundant management servers. A MySQL Cluster data or API node attempts to contact successive management servers on each host in the order specified, until a successful connection has been established.

Beginning with MySQL Cluster NDB 6.3.19, it is also possible in a connectstring to specify one or more bind addresses to be used by nodes having multiple network interfaces for connecting to management servers. A bind address consists of a hostname or network address and an optional port number. This enhanced syntax for connectstrings is shown here:

```
[nodeid=node_id,]
[bind-address=host_definition,]
host_definition[; bind-address=host_definition]
host_definition[; bind-address=host_definition]
[, ...]

host_definition:
host_name[:port_number]
```

If a single bind address is used in the connectstring *prior* to specifying any management hosts, then this address is used as the default for connecting to any of them (unless overridden for a given management server; see later in this section for an example). For example, the following connectstring causes the node to use `192.168.178.242` regardless of the management server to which it connects:

```
bind-address=192.168.178.242, poseidon:1186, perch:1186
```

If a bind address is specified *following* a management host definition, then it is used only for connecting to that management node. Consider the following connectstring:

```
poseidon:1186;bind-address=localhost, perch:1186;bind-address=192.168.178.242
```

In this case, the node uses `localhost` to connect to the management server running on the host named `poseidon` and `192.168.178.242` to connect to the management server running on the host named `perch`.

You can specify a default bind address and then override this default for one or more specific management hosts. In the following example, `localhost` is used for connecting to the management server running on host `poseidon`; since `192.168.178.242` is specified first (before any management server definitions), it is the default bind address and so is used for connecting to the management servers on hosts `perch` and `orca`:

```
bind-address=192.168.178.242,poseidon:1186;bind-address=localhost,perch:1186,orca:2200
```

There are a number of different ways to specify the connectstring:

- Each executable has its own command-line option which enables specifying the management server at startup. (See the documentation for the respective executable.)
- It is also possible to set the connectstring for all nodes in the cluster at once by placing it in a `[mysql_cluster]` section in the management server's `my.cnf` file.
- For backward compatibility, two other options are available, using the same syntax:
  1. Set the `NDB_CONNECTSTRING` environment variable to contain the connectstring.
  2. Write the connectstring for each executable into a text file named `Ndb.cfg` and place this file in the executable's startup directory.

However, these are now deprecated and should not be used for new installations.

The recommended method for specifying the connectstring is to set it on the command line or in the `my.cnf` file for each executable.

Previous to MySQL Cluster NDB 7.0.15 and MySQL Cluster NDB 7.1.4, the maximum length of a connectstring was 1024 characters.

#### 17.3.2.4. Defining Computers in a MySQL Cluster

The `[computer]` section has no real significance other than serving as a way to avoid the need of defining host names for each node in the system. All parameters mentioned here are required.

- `Id`

<b>Restart Type</b>	initial, node
<b>Permitted Values</b>	
<b>Type</b>	string
<b>Default</b>	
<b>Range</b>	-

This is a unique identifier, used to refer to the host computer elsewhere in the configuration file.

### Important

The computer ID is *not* the same as the node ID used for a management, API, or data node. Unlike the case with node IDs, you cannot use `NodeId` in place of `Id` in the `[computer]` section of the `config.ini` file.

- `HostName`

<b>Restart Type</b>	system
<b>Permitted Values</b>	
<b>Type</b>	string
<b>Default</b>	
<b>Range</b>	-

This is the computer's hostname or IP address.

### 17.3.2.5. Defining a MySQL Cluster Management Server

The `[ndb_mgmd]` section is used to configure the behavior of the management server. `[mgm]` can be used as an alias; the two section names are equivalent. All parameters in the following list are optional and assume their default values if omitted.

### Note

If neither the `ExecuteOnComputer` nor the `HostName` parameter is present, the default value `localhost` will be assumed for both.

- `Id`

<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	
<b>Range</b>	1-63

Each node in the cluster has a unique identity. For a management node, this is represented by an integer value in the range 1 to 63 inclusive (previous to MySQL Cluster NDB 6.1.1), or in the range 1 to 255 inclusive (MySQL Cluster NDB 6.1.1 and later). This ID is used by all internal cluster messages for addressing the node, and so must be unique for each MySQL Cluster node, regardless of the type of node.

### Note

Data node IDs must be less than 49, regardless of the MySQL Cluster version used. If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for management nodes (and API nodes) to values greater than 48.

This parameter can also be written as `NodeId`, although the short form is sufficient (and preferred for this reason).

- `ExecuteOnComputer`

<b>Restart Type</b>	system
<b>Permitted Values</b>	
<b>Type</b>	string
<b>Default</b>	
<b>Range</b>	-

This refers to the `Id` set for one of the computers defined in a `[computer]` section of the `config.ini` file.

- [PortNumber](#)

<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	1186
<b>Range</b>	0–64K

This is the port number on which the management server listens for configuration requests and management commands.

- [HostName](#)

<b>Restart Type</b>	system
<b>Permitted Values</b>	
<b>Type</b>	string
<b>Default</b>	
<b>Range</b>	-

Specifying this parameter defines the hostname of the computer on which the management node is to reside. To specify a hostname other than `localhost`, either this parameter or `ExecuteOnComputer` is required.

- [LogDestination](#)

<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	string
<b>Default</b>	<code>FILE:filename=ndb_nodeid_cluster.log,maxsize=1000000,maxfiles=6</code>
<b>Range</b>	-

This parameter specifies where to send cluster logging information. There are three options in this regard—`CONSOLE`, `SYSLOG`, and `FILE`—with `FILE` being the default:

- `CONSOLE` outputs the log to `stdout`:

```
CONSOLE
```

- `SYSLOG` sends the log to a `syslog` facility, possible values being one of `auth`, `authpriv`, `cron`, `daemon`, `ftp`, `kern`, `lpr`, `mail`, `news`, `syslog`, `user`, `uucp`, `local0`, `local1`, `local2`, `local3`, `local4`, `local5`, `local6`, or `local7`.

### Note

Not every facility is necessarily supported by every operating system.

```
SYSLOG:facility=syslog
```

- **FILE** pipes the cluster log output to a regular file on the same machine. The following values can be specified:
  - **filename**: The name of the log file.
  - **maxsize**: The maximum size (in bytes) to which the file can grow before logging rolls over to a new file. When this occurs, the old log file is renamed by appending **.N** to the file name, where **N** is the next number not yet used with this name.
  - **maxfiles**: The maximum number of log files.

```
FILE:filename=cluster.log,maxsize=1000000,maxfiles=6
```

The default value for the **FILE** parameter is

**FILE:filename=ndb\_node\_id\_cluster.log,maxsize=1000000,maxfiles=6**, where **node\_id** is the ID of the node.

It is possible to specify multiple log destinations separated by semicolons as shown here:

```
CONSOLE;SYSLOG:facility=local0;FILE:filename=/var/log/mgmd
```

- **ArbitrationRank**

<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	1
<b>Range</b>	0–2

This parameter is used to define which nodes can act as arbitrators. Only management nodes and SQL nodes can be arbitrators. **ArbitrationRank** can take one of the following values:

- **0**: The node will never be used as an arbitrator.
- **1**: The node has high priority; that is, it will be preferred as an arbitrator over low-priority nodes.
- **2**: Indicates a low-priority node which be used as an arbitrator only if a node with a higher priority is not available for that purpose.

Normally, the management server should be configured as an arbitrator by setting its **ArbitrationRank** to 1 (the default for management nodes) and those for all SQL nodes to 0 (the default for SQL nodes).

Beginning with MySQL 5.1.16 and MySQL Cluster NDB 6.1.3, it is possible to disable arbitration completely by setting **ArbitrationRank** to 0 on all management and SQL nodes. In MySQL Cluster NDB 7.0.7 and later releases, you can also control arbitration by overriding this parameter; to do this, set the **Arbitration** parameter in the **[ndbd default]** section of the **config.ini** global configuration file.

- **ArbitrationDelay**

<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	0
<b>Range</b>	0–4G

An integer value which causes the management server's responses to arbitration requests to be delayed by that number of milliseconds. By default, this value is 0; it is normally not necessary to change it.

**DataDir**

<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	<code>string</code>
<b>Default</b>	.
<b>Range</b>	-

This specifies the directory where output files from the management server will be placed. These files include cluster log files, process output files, and the daemon's process ID (PID) file. (For log files, this location can be overridden by setting the `FILE` parameter for `LogDestination` as discussed previously in this section.)

The default value for this parameter is the directory in which `ndb_mgmd` is located.

- **HeartbeatThreadPriority**

Beginning with MySQL Cluster NDB 6.3.32, MySQL Cluster NDB 7.0.13, and MySQL Cluster NDB 7.1.2, it is possible to use this parameter to set the scheduling policy and priority of heartbeat threads for management and API nodes.

The syntax for setting this parameter is shown here:

```
HeartbeatThreadPriority = policy[, priority]
policy:
 {FIFO | RR}
```

When setting this parameter, you must specify a policy. This is one of `FIFO` (first in, first in) or `RR` (round robin). The policy value is followed optionally by the priority (an integer).

- **TotalSendBufferMemory**

This parameter is available beginning with MySQL Cluster NDB 6.4.0. It is used to determine the total amount of memory to allocate on this node for shared send buffer memory among all configured transporters.

If this parameter is set, its minimum permitted value is 256KB; the maximum is 4294967039. For more detailed information about the behavior and use of `TotalSendBufferMemory` and configuring send buffer memory parameters in MySQL Cluster NDB 6.4.0 and later, see [Section 17.3.2.13, “Configuring MySQL Cluster Send Buffer Parameters”](#).

**Note**

After making changes in a management node's configuration, it is necessary to perform a rolling restart of the cluster for the new configuration to take effect.

To add new management servers to a running MySQL Cluster, it is also necessary to perform a rolling restart of all cluster nodes after modifying any existing `config.ini` files. For more information about issues arising when using multiple management nodes, see [Section 17.1.5.10, “Limitations Relating to Multiple MySQL Cluster Nodes”](#).

### 17.3.2.6. Defining MySQL Cluster Data Nodes

The `[ndbd]` and `[ndbd default]` sections are used to configure the behavior of the cluster's data nodes.

`[ndbd]` and `[ndbd default]` are always used as the section names whether you are using `ndbd` or (in MySQL Cluster NDB 6.4.0 and later) `ndbmttd` binaries for the data node processes.

There are many parameters which control buffer sizes, pool sizes, timeouts, and so forth. The only mandatory parameters are:

- Either `ExecuteOnComputer` or `HostName`, which must be defined in the local `[ndbd]` section.
- The parameter `NoOfReplicas`, which must be defined in the `[ndbd default]` section, as it is common to all Cluster data nodes.

**Note**

It is no longer strictly necessary to set `NoOfReplicas` starting with MySQL Cluster NDB 6.3.25 and MySQL Cluster NDB 7.0.6, where it acquires a default value (2). However, it remains good practice to set it explicitly.

Most data node parameters are set in the `[ndbd default]` section. Only those parameters explicitly stated as being able to set local values are permitted to be changed in the `[ndbd]` section. Where present, `HostName`, `Id` and `ExecuteOnComputer` must be defined in the local `[ndbd]` section, and not in any other section of `config.ini`. In other words, settings for these parameters are specific to one data node.

For those parameters affecting memory usage or buffer sizes, it is possible to use `K`, `M`, or `G` as a suffix to indicate units of 1024, 1024×1024, or 1024×1024×1024. (For example, `100K` means  $100 \times 1024 = 102400$ .) Parameter names and values are currently case-sensitive.

Information about configuration parameters specific to MySQL Cluster Disk Data tables can be found later in this section.

Beginning with MySQL Cluster NDB 6.4.0, all of these parameters also apply to `ndbmttd` (the multi-threaded version of `ndbd`). An additional data node configuration parameter `MaxNoOfExecutionThreads` applies to `ndbmttd` only, and has no effect when used with `ndbd`. For more information, see [Section 17.4.3, “ndbmttd — The MySQL Cluster Data Node Daemon \(Multi-Threaded\)”](#).

**Identifying data nodes.** The `Id` value (that is, the data node identifier) can be allocated on the command line when the node is started or in the configuration file.

- [Id](#)

<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	<code>numeric</code>
<b>Default</b>	
<b>Range</b>	<a href="#">1–48</a>

This is the node ID used as the address of the node for all cluster internal messages. For data nodes, this is an integer in the range 1 to 48 inclusive. Each node in the cluster must have a unique identifier.

This parameter can also be written as `NodeId`, although the short form is sufficient (and preferred for this reason).

- [ExecuteOnComputer](#)

<b>Restart Type</b>	system
<b>Permitted Values</b>	
<b>Type</b>	<code>string</code>
<b>Default</b>	
<b>Range</b>	—

This refers to the `Id` set for one of the computers defined in a `[computer]` section.

- [HostName](#)

<b>Restart Type</b>	system
<b>Permitted Values</b>	
<b>Type</b>	<code>string</code>
<b>Default</b>	<code>localhost</code>
<b>Range</b>	—

Specifying this parameter defines the hostname of the computer on which the data node is to reside. To specify a hostname other than `localhost`, either this parameter or `ExecuteOnComputer` is required.

- [ServerPort](#)

<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	
<b>Range</b>	1–64K

Each node in the cluster uses a port to connect to other nodes. By default, this port is allocated dynamically in such a way as to ensure that no two nodes on the same host computer receive the same port number, so it should normally not be necessary to specify a value for this parameter.

However, if you need to be able to open specific ports in a firewall to permit communication between data nodes and API nodes (including SQL nodes), you can set this parameter to the number of the desired port in an [`ndbd`] section or (if you need to do this for multiple data nodes) the [`ndbd default`] section of the `config.ini` file, and then open the port having that number for incoming connections from SQL nodes, API nodes, or both.

### Note

Connections from data nodes to management nodes is done using the `ndb_mgmd` management port (the management server's `PortNumber`; see [Section 17.3.2.5, “Defining a MySQL Cluster Management Server”](#)) so outgoing connections to that port from any data nodes should always be permitted.

- [`TcpBind\_INADDR\_ANY`](#)

Setting this parameter to `TRUE` or `1` binds `IP_ADDR_ANY` so that connections can be made from anywhere (for autogenerated connections). The default is `FALSE` (`0`).

This parameter was added in MySQL Cluster NDB 6.2.0.

- [`NodeGroup`](#)

<b>Version Introduced</b>	5.1.30-ndb-6.4.0
<b>Restart Type</b>	initial, system
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	
<b>Range</b>	0–64K

This parameter can be used to assign a data node to a specific node group. It is read only when the cluster is started for the first time, and cannot be used to reassign a data node to a different node group online. It is generally not desirable to use this parameter in the [`ndbd default`] section of the `config.ini` file, and care must be taken not to assign nodes to node groups in such a way that an invalid numbers of nodes are assigned to any node groups.

The `NodeGroup` parameter is chiefly intended for use in adding a new node group to a running MySQL Cluster without having to perform a rolling restart. For this purpose, you should set it to 65535 (the maximum value). You are not required to set a `NodeGroup` value for all cluster data nodes, only for those nodes which are to be started and added to the cluster as a new node group at a later time. For more information, see [Section 17.5.11.3, “Adding MySQL Cluster Data Nodes Online: Detailed Example”](#).

This parameter was added in MySQL Cluster NDB 6.4.0.

- [`NoOfReplicas`](#)

<b>Restart Type</b>	initial, system
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	None
<b>Range</b>	1–4

<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	None
<b>Range</b>	1–4
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	2
<b>Range</b>	1–4
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	2
<b>Range</b>	1–4

This global parameter can be set only in the `[ndbd default]` section, and defines the number of replicas for each table stored in the cluster. This parameter also specifies the size of node groups. A node group is a set of nodes all storing the same information.

Node groups are formed implicitly. The first node group is formed by the set of data nodes with the lowest node IDs, the next node group by the set of the next lowest node identities, and so on. By way of example, assume that we have 4 data nodes and that `NoOfReplicas` is set to 2. The four data nodes have node IDs 2, 3, 4 and 5. Then the first node group is formed from nodes 2 and 3, and the second node group by nodes 4 and 5. It is important to configure the cluster in such a manner that nodes in the same node groups are not placed on the same computer because a single hardware failure would cause the entire cluster to fail.

If no node IDs are provided, the order of the data nodes will be the determining factor for the node group. Whether or not explicit assignments are made, they can be viewed in the output of the management client's `SHOW` command.

Prior to MySQL Cluster NDB 6.3.25 and MySQL Cluster NDB 7.0.6, there was no default value for `NoOfReplicas`; beginning with these versions, the default value is 2, which is the recommended setting in most common usage scenarios. ([Bug#44746](#))

The maximum possible value is 4; *currently, only the values 1 and 2 are actually supported.*

### Important

Setting `NoOfReplicas` to 1 means that there is only a single copy of all Cluster data; in this case, the loss of a single data node causes the cluster to fail because there are no additional copies of the data stored by that node.

The value for this parameter must divide evenly into the number of data nodes in the cluster. For example, if there are two data nodes, then `NoOfReplicas` must be equal to either 1 or 2, since 2/3 and 2/4 both yield fractional values; if there are four data nodes, then `NoOfReplicas` must be equal to 1, 2, or 4.

- [DataDir](#)

<b>Restart Type</b>	initial, node
<b>Permitted Values</b>	
<b>Type</b>	string
<b>Default</b>	.
<b>Range</b>	-

This parameter specifies the directory where trace files, log files, pid files and error logs are placed.

The default is the data node process working directory.

- [FileSystemPath](#)

<b>Version Introduced</b>	5.1.15-ndb-6.1.1
<b>Restart Type</b>	initial, node

<b>Permitted Values</b>	
<b>Type</b>	<a href="#">string</a>
<b>Default</b>	<a href="#">DataDir</a>
<b>Range</b>	-

This parameter specifies the directory where all files created for metadata, REDO logs, UNDO logs (for Disk Data tables), and data files are placed. The default is the directory specified by [DataDir](#).

### Note

This directory must exist before the [ndbd](#) process is initiated.

The recommended directory hierarchy for MySQL Cluster includes [/var/lib/mysql-cluster](#), under which a directory for the node's file system is created. The name of this subdirectory contains the node ID. For example, if the node ID is 2, this subdirectory is named [ndb\\_2\\_fs](#).

- [BackupDataDir](#)

<b>Restart Type</b>	initial, node
<b>Permitted Values</b>	
<b>Type</b>	<a href="#">string</a>
<b>Default</b>	<a href="#">FileSystemPath</a>
<b>Range</b>	-

This parameter specifies the directory in which backups are placed.

### Important

The string '[/BACKUP](#)' is always appended to this value. For example, if you set the value of [BackupDataDir](#) to [/var/lib/cluster-data](#), then all backups are stored under [/var/lib/cluster-data/BACKUP](#). This also means that the *effective* default backup location is the directory named [BACKUP](#) under the location specified by the [FileSystemPath](#) parameter.

## Data Memory, Index Memory, and String Memory

[DataMemory](#) and [IndexMemory](#) are [\[ndbd\]](#) parameters specifying the size of memory segments used to store the actual records and their indexes. In setting values for these, it is important to understand how [DataMemory](#) and [IndexMemory](#) are used, as they usually need to be updated to reflect actual usage by the cluster:

- [DataMemory](#)

<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	<a href="#">numeric</a>
<b>Default</b>	<a href="#">80M</a>
<b>Range</b>	<a href="#">1M-1024G</a>

This parameter defines the amount of space (in bytes) available for storing database records. The entire amount specified by this value is allocated in memory, so it is extremely important that the machine has sufficient physical memory to accommodate it.

The memory allocated by [DataMemory](#) is used to store both the actual records and indexes. There is a 16-byte overhead on each record; an additional amount for each record is incurred because it is stored in a 32KB page with 128 byte page overhead (see below). There is also a small amount wasted per page due to the fact that each record is stored in only one page.

For variable-size table attributes in MySQL 5.1, the data is stored on separate datapages, allocated from [DataMemory](#). Variable-length records use a fixed-size part with an extra overhead of 4 bytes to reference the variable-size part. The variable-size

part has 2 bytes overhead plus 2 bytes per attribute.

The maximum record size is currently 8052 bytes.

The memory space defined by [DataMemory](#) is also used to store ordered indexes, which use about 10 bytes per record. Each table row is represented in the ordered index. A common error among users is to assume that all indexes are stored in the memory allocated by [IndexMemory](#), but this is not the case: Only primary key and unique hash indexes use this memory; ordered indexes use the memory allocated by [DataMemory](#). However, creating a primary key or unique hash index also creates an ordered index on the same keys, unless you specify [USING HASH](#) in the index creation statement. This can be verified by running `ndb_desc -d db_name table_name` in the management client.

The memory space allocated by [DataMemory](#) consists of 32KB pages, which are allocated to table fragments. Each table is normally partitioned into the same number of fragments as there are data nodes in the cluster. Thus, for each node, there are the same number of fragments as are set in [NoOfReplicas](#).

In addition, due to the way in which new pages are allocated when the capacity of the current page is exhausted, there is an additional overhead of approximately 18.75%. When more [DataMemory](#) is required, more than one new page is allocated, according to the following formula:

```
number of new pages = FLOOR(number of current pages × 0.1875) + 1
```

For example, if 15 pages are currently allocated to a given table and an insert to this table requires additional storage space, the number of new pages allocated to the table is  $FLOOR(15 \times 0.1875) + 1 = FLOOR(2.8125) + 1 = 2 + 1 = 3$ . Now  $15 + 3 = 18$  memory pages are allocated to the table. When the last of these 18 pages becomes full,  $FLOOR(18 \times 0.1875) + 1 = FLOOR(3.3750) + 1 = 3 + 1 = 4$  new pages are allocated, so the total number of pages allocated to the table is now 22.

### Note

The “18.75% + 1” overhead is no longer required beginning with MySQL Cluster NDB 6.2.3 and MySQL Cluster NDB 6.3.0.

Once a page has been allocated, it is currently not possible to return it to the pool of free pages, except by deleting the table. (This also means that [DataMemory](#) pages, once allocated to a given table, cannot be used by other tables.) Performing a node recovery also compresses the partition because all records are inserted into empty partitions from other live nodes.

The [DataMemory](#) memory space also contains UNDO information: For each update, a copy of the unaltered record is allocated in the [DataMemory](#). There is also a reference to each copy in the ordered table indexes. Unique hash indexes are updated only when the unique index columns are updated, in which case a new entry in the index table is inserted and the old entry is deleted upon commit. For this reason, it is also necessary to allocate enough memory to handle the largest transactions performed by applications using the cluster. In any case, performing a few large transactions holds no advantage over using many smaller ones, for the following reasons:

- Large transactions are not any faster than smaller ones
- Large transactions increase the number of operations that are lost and must be repeated in event of transaction failure
- Large transactions use more memory

The default value for [DataMemory](#) is 80MB; the minimum is 1MB. There is no maximum size, but in reality the maximum size has to be adapted so that the process does not start swapping when the limit is reached. This limit is determined by the amount of physical RAM available on the machine and by the amount of memory that the operating system may commit to any one process. 32-bit operating systems are generally limited to 2–4GB per process; 64-bit operating systems can use more. For large databases, it may be preferable to use a 64-bit operating system for this reason.

### [IndexMemory](#)

<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	18M
<b>Range</b>	1M-1T

This parameter controls the amount of storage used for hash indexes in MySQL Cluster. Hash indexes are always used for primary key indexes, unique indexes, and unique constraints. Note that when defining a primary key and a unique index, two indexes will be created, one of which is a hash index used for all tuple accesses as well as lock handling. It is also used to enforce unique constraints.

The size of the hash index is 25 bytes per record, plus the size of the primary key. For primary keys larger than 32 bytes another 8 bytes is added.

The default value for [IndexMemory](#) is 18MB. The minimum is 1MB.

- [StringMemory](#)

<b>Restart Type</b>	system
<b>Permitted Values (&gt;= 5.1.6)</b>	
<b>Type</b>	<a href="#">numeric</a>
<b>Default</b>	5
<b>Range</b>	0–4G

This parameter determines how much memory is allocated for strings such as table names, and is specified in an [\[ndbd\]](#) or [\[ndbd default\]](#) section of the [config.ini](#) file. A value between 0 and 100 inclusive is interpreted as a percent of the maximum default value, which is calculated based on a number of factors including the number of tables, maximum table name size, maximum size of .FRM files, [MaxNoOfTriggers](#), maximum column name size, and maximum default column value. In general it is safe to assume that the maximum default value is approximately 5 MB for a MySQL Cluster having 1000 tables.

A value greater than 100 is interpreted as a number of bytes.

Beginning with MySQL Cluster NDB 6.2.18, MySQL Cluster NDB 6.3.24, and MySQL Cluster NDB 7.0.5, the default value is 25—that is, 25 percent of the default maximum, or approximately 25 KB. (Previously, the default value was 5 beginning with MySQL 5.1.6; prior to MySQL 5.1.6, the default was 0.)

Under most circumstances, the default value should be sufficient, but when you have a great many Cluster tables (1000 or more), it is possible to get Error 773 OUT OF STRING MEMORY, PLEASE MODIFY STRINGMEMORY CONFIG PARAMETER: PERMANENT ERROR: SCHEMA ERROR, in which case you should increase this value. 25 (25 percent) is not excessive, and should prevent this error from recurring in all but the most extreme conditions.

The following example illustrates how memory is used for a table. Consider this table definition:

```
CREATE TABLE example (
 a INT NOT NULL,
 b INT NOT NULL,
 c INT NOT NULL,
 PRIMARY KEY(a),
 UNIQUE(b)
) ENGINE=NDBCLUSTER;
```

For each record, there are 12 bytes of data plus 12 bytes overhead. Having no nullable columns saves 4 bytes of overhead. In addition, we have two ordered indexes on columns [a](#) and [b](#) consuming roughly 10 bytes each per record. There is a primary key hash index on the base table using roughly 29 bytes per record. The unique constraint is implemented by a separate table with [b](#) as primary key and [a](#) as a column. This other table consumes an additional 29 bytes of index memory per record in the [example](#) table as well 8 bytes of record data plus 12 bytes of overhead.

Thus, for one million records, we need 58MB for index memory to handle the hash indexes for the primary key and the unique constraint. We also need 64MB for the records of the base table and the unique index table, plus the two ordered index tables.

You can see that hash indexes takes up a fair amount of memory space; however, they provide very fast access to the data in return. They are also used in MySQL Cluster to handle uniqueness constraints.

Currently, the only partitioning algorithm is hashing and ordered indexes are local to each node. Thus, ordered indexes cannot be used to handle uniqueness constraints in the general case.

An important point for both [IndexMemory](#) and [DataMemory](#) is that the total database size is the sum of all data memory and all index memory for each node group. Each node group is used to store replicated information, so if there are four nodes with two replicas, there will be two node groups. Thus, the total data memory available is  $2 \times \text{DataMemory}$  for each data node.

It is highly recommended that [DataMemory](#) and [IndexMemory](#) be set to the same values for all nodes. Data distribution is even over all nodes in the cluster, so the maximum amount of space available for any node can be no greater than that of the smallest node in the cluster.

[DataMemory](#) and [IndexMemory](#) can be changed, but decreasing either of these can be risky; doing so can easily lead to a node or even an entire MySQL Cluster that is unable to restart due to there being insufficient memory space. Increasing these values should be acceptable, but it is recommended that such upgrades are performed in the same manner as a software upgrade, begin-

ning with an update of the configuration file, and then restarting the management server followed by restarting each data node in turn.

Updates do not increase the amount of index memory used. Inserts take effect immediately; however, rows are not actually deleted until the transaction is committed.

**Transaction parameters.** The next three [\[ndbd\]](#) parameters that we discuss are important because they affect the number of parallel transactions and the sizes of transactions that can be handled by the system. [MaxNoOfConcurrentTransactions](#) sets the number of parallel transactions possible in a node. [MaxNoOfConcurrentOperations](#) sets the number of records that can be in update phase or locked simultaneously.

Both of these parameters (especially [MaxNoOfConcurrentOperations](#)) are likely targets for users setting specific values and not using the default value. The default value is set for systems using small transactions, to ensure that these do not use excessive memory.

- [MaxNoOfConcurrentTransactions](#)

<b>Restart Type</b>	system
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	4096
<b>Range</b>	32–4G

Each cluster data node requires a transaction record for each active transaction in the cluster. The task of coordinating transactions is distributed among all of the data nodes. The total number of transaction records in the cluster is the number of transactions in any given node times the number of nodes in the cluster.

Transaction records are allocated to individual MySQL servers. Each connection to a MySQL server requires at least one transaction record, plus an additional transaction object per table accessed by that connection. This means that a reasonable minimum for this parameter is

```
MaxNoOfConcurrentTransactions =
 (maximum number of tables accessed in any single transaction + 1)
 * number of cluster SQL nodes
```

Suppose that there are 4 SQL nodes using the cluster. A single join involving 5 tables requires 6 transaction records; if there are 5 such joins in a transaction, then  $5 * 6 = 30$  transaction records are required for this transaction, per MySQL server, or  $30 * 4 = 120$  transaction records total.

This parameter must be set to the same value for all cluster data nodes. This is due to the fact that, when a data node fails, the oldest surviving node re-creates the transaction state of all transactions that were ongoing in the failed node.

Changing the value of [MaxNoOfConcurrentTransactions](#) requires a complete shutdown and restart of the cluster.

The default value is 4096.

- [MaxNoOfConcurrentOperations](#)

<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	32K
<b>Range</b>	32–4G

It is a good idea to adjust the value of this parameter according to the size and number of transactions. When performing transactions of only a few operations each and not involving a great many records, there is no need to set this parameter very high. When performing large transactions involving many records need to set this parameter higher.

Records are kept for each transaction updating cluster data, both in the transaction coordinator and in the nodes where the actual updates are performed. These records contain state information needed to find UNDO records for rollback, lock queues, and other purposes.

This parameter should be set to the number of records to be updated simultaneously in transactions, divided by the number of

cluster data nodes. For example, in a cluster which has four data nodes and which is expected to handle 1,000,000 concurrent updates using transactions, you should set this value to  $1000000 / 4 = 250000$ .

Read queries which set locks also cause operation records to be created. Some extra space is allocated within individual nodes to accommodate cases where the distribution is not perfect over the nodes.

When queries make use of the unique hash index, there are actually two operation records used per record in the transaction. The first record represents the read in the index table and the second handles the operation on the base table.

The default value is 32768.

This parameter actually handles two values that can be configured separately. The first of these specifies how many operation records are to be placed with the transaction coordinator. The second part specifies how many operation records are to be local to the database.

A very large transaction performed on an eight-node cluster requires as many operation records in the transaction coordinator as there are reads, updates, and deletes involved in the transaction. However, the operation records of the are spread over all eight nodes. Thus, if it is necessary to configure the system for one very large transaction, it is a good idea to configure the two parts separately. [MaxNoOfConcurrentOperations](#) will always be used to calculate the number of operation records in the transaction coordinator portion of the node.

It is also important to have an idea of the memory requirements for operation records. These consume about 1KB per record.

- [MaxNoOfLocalOperations](#)

<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	UNDEFINED
<b>Range</b>	32–4G

By default, this parameter is calculated as  $1.1 \times \text{MaxNoOfConcurrentOperations}$ . This fits systems with many simultaneous transactions, none of them being very large. If there is a need to handle one very large transaction at a time and there are many nodes, it is a good idea to override the default value by explicitly specifying this parameter.

**Transaction temporary storage.** The next set of [\[ndbd\]](#) parameters is used to determine temporary storage when executing a statement that is part of a Cluster transaction. All records are released when the statement is completed and the cluster is waiting for the commit or rollback.

The default values for these parameters are adequate for most situations. However, users with a need to support transactions involving large numbers of rows or operations may need to increase these values to enable better parallelism in the system, whereas users whose applications require relatively small transactions can decrease the values to save memory.

- [MaxNoOfConcurrentIndexOperations](#)

<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	8K
<b>Range</b>	0–4G

For queries using a unique hash index, another temporary set of operation records is used during a query's execution phase. This parameter sets the size of that pool of records. Thus, this record is allocated only while executing a part of a query. As soon as this part has been executed, the record is released. The state needed to handle aborts and commits is handled by the normal operation records, where the pool size is set by the parameter [MaxNoOfConcurrentOperations](#).

The default value of this parameter is 8192. Only in rare cases of extremely high parallelism using unique hash indexes should it be necessary to increase this value. Using a smaller value is possible and can save memory if the DBA is certain that a high degree of parallelism is not required for the cluster.

- [MaxNoOfFiredTriggers](#)

<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	4000
<b>Range</b>	0–4G

The default value of [MaxNoOfFiredTriggers](#) is 4000, which is sufficient for most situations. In some cases it can even be decreased if the DBA feels certain the need for parallelism in the cluster is not high.

A record is created when an operation is performed that affects a unique hash index. Inserting or deleting a record in a table with unique hash indexes or updating a column that is part of a unique hash index fires an insert or a delete in the index table. The resulting record is used to represent this index table operation while waiting for the original operation that fired it to complete. This operation is short-lived but can still require a large number of records in its pool for situations with many parallel write operations on a base table containing a set of unique hash indexes.

- [TransactionBufferMemory](#)

<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	1M
<b>Range</b>	1K–4G

The memory affected by this parameter is used for tracking operations fired when updating index tables and reading unique indexes. This memory is used to store the key and column information for these operations. It is only very rarely that the value for this parameter needs to be altered from the default.

The default value for [TransactionBufferMemory](#) is 1MB.

Normal read and write operations use a similar buffer, whose usage is even more short-lived. The compile-time parameter [ZATTRBUF\\_FILESIZE](#) (found in `ndb/src/kernel/blocks/Dbtc/Dbtc.hpp`) set to  $4000 \times 128$  bytes (500KB). A similar buffer for key information, [ZDATABUF\\_FILESIZE](#) (also in `Dbtc.hpp`) contains  $4000 \times 16 = 62.5$ KB of buffer space. `Dbtc` is the module that handles transaction coordination.

**Scans and buffering.** There are additional `[ndbd]` parameters in the `Dblqh` module (in `ndb/src/kernel/blocks/Dblqh/Dblqh.hpp`) that affect reads and updates. These include [ZATTRINBUF\\_FILESIZE](#), set by default to  $10000 \times 128$  bytes (1250KB) and [ZDATABUF\\_FILE\\_SIZE](#), set by default to  $10000 \times 16$  bytes (roughly 156KB) of buffer space. To date, there have been neither any reports from users nor any results from our own extensive tests suggesting that either of these compile-time limits should be increased.

- [MaxNoOfConcurrentScans](#)

<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	256
<b>Range</b>	2–500

This parameter is used to control the number of parallel scans that can be performed in the cluster. Each transaction coordinator can handle the number of parallel scans defined for this parameter. Each scan query is performed by scanning all partitions in parallel. Each partition scan uses a scan record in the node where the partition is located, the number of records being the value of this parameter times the number of nodes. The cluster should be able to sustain [MaxNoOfConcurrentScans](#) scans concurrently from all nodes in the cluster.

Scans are actually performed in two cases. The first of these cases occurs when no hash or ordered indexes exists to handle the query, in which case the query is executed by performing a full table scan. The second case is encountered when there is no hash index to support the query but there is an ordered index. Using the ordered index means executing a parallel range scan. The order is kept on the local partitions only, so it is necessary to perform the index scan on all partitions.

The default value of [MaxNoOfConcurrentScans](#) is 256. The maximum value is 500.

- [MaxNoOfLocalScans](#)

<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	UNDEFINED
<b>Range</b>	32–4G

Specifies the number of local scan records if many scans are not fully parallelized. If the number of local scan records is not provided, it is calculated as the product of [MaxNoOfConcurrentScans](#) and the number of data nodes in the system. The minimum value is 32.

- [BatchSizePerLocalScan](#)

<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	64
<b>Range</b>	1–992

This parameter is used to calculate the number of lock records used to handle concurrent scan operations.

The default value is 64; this value has a strong connection to the [ScanBatchSize](#) defined in the SQL nodes.

- [LongMessageBuffer](#)

<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	1M
<b>Range</b>	512K–4G
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	4M
<b>Range</b>	512K–4G

This is an internal buffer used for passing messages within individual nodes and between nodes. In MySQL Cluster NDB 6.4.3 and earlier, the default is 1MB; beginning with MySQL Cluster NDB 7.0.4, it is 4MB.

This parameter seldom needs to be changed from the default. However, when replicating a MySQL Cluster using [ndbmttd](#) for the data nodes, you may need to increase this value to 8MB (or possibly more) to prevent data node instability, because [ndb-mtd](#) uses much more of this resource than [ndbd](#) does. Beginning with MySQL Cluster NDB 7.0.13 and MySQL Cluster NDB 7.1.2, this should no longer be necessary when using [ndbmttd](#) with MySQL Cluster Replication ([Bug#46914](#)).

## Memory Allocation

- [MaxAllocate](#)

This is the maximum size of the memory unit to use when allocating memory for tables. In cases where `NDB` gives `OUT OF MEMORY` errors, but it is evident by examining the cluster logs or the output of `DUMP 1000` (see `DUMP 1000`) that all available memory has not yet been used, you can increase the value of this parameter (or `MaxNoOfTables`, or both) to cause `NDB` to make sufficient memory available.

This parameter was introduced in MySQL 5.1.20, MySQL Cluster NDB 6.1.12 and MySQL Cluster NDB 6.2.3.

**Logging and checkpointing.** The following `[ndbd]` parameters control log and checkpoint behavior.

- `NoOfFragmentLogFile`

<b>Restart Type</b>	initial, node
<b>Permitted Values (&gt;= 5.1.0)</b>	
<b>Type</b>	numeric
<b>Default</b>	16
<b>Range</b>	3-4G

This parameter sets the number of REDO log files for the node, and thus the amount of space allocated to REDO logging. Because the REDO log files are organized in a ring, it is extremely important that the first and last log files in the set (sometimes referred to as the “head” and “tail” log files, respectively) do not meet. When these approach one another too closely, the node begins aborting all transactions encompassing updates due to a lack of room for new log records.

A `REDO` log record is not removed until the required number of local checkpoints has been completed since that log record was inserted (prior to MySQL Cluster NDB 6.3.8, this was 3 local checkpoints; in later versions of MySQL Cluster, only 2 local checkpoints are necessary). Checkpointing frequency is determined by its own set of configuration parameters discussed elsewhere in this chapter.

How these parameters interact and proposals for how to configure them are discussed in [Section 17.3.2.12, “Configuring MySQL Cluster Parameters for Local Checkpoints”](#).

The default parameter value is 16, which by default means 16 sets of 4 16MB files for a total of 1024MB. Beginning with MySQL Cluster NDB 6.1.1, the size of the individual log files is configurable using the `FragmentLogFileSize` parameter; more information about this parameter can be found [here](#). In scenarios requiring a great many updates, the value for `NoOfFragmentLogFile` may need to be set as high as 300 or even higher to provide sufficient space for REDO logs.

If the checkpointing is slow and there are so many writes to the database that the log files are full and the log tail cannot be cut without jeopardizing recovery, all updating transactions are aborted with internal error code 410 (`Out of log file space temporarily`). This condition prevails until a checkpoint has completed and the log tail can be moved forward.

### Important

This parameter cannot be changed “on the fly”; you must restart the node using `--initial`. If you wish to change this value for all data nodes in a running cluster, you can do so using a rolling node restart (using `--initial` when starting each data node).

- `FragmentLogFileSize`

<b>Version Introduced</b>	5.1.15-ndb-6.1.11
<b>Restart Type</b>	initial, node
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	16M
<b>Range</b>	4M-1G

Setting this parameter enables you to control directly the size of redo log files. This can be useful in situations when MySQL Cluster is operating under a high load and it is unable to close fragment log files quickly enough before attempting to open new ones (only 2 fragment log files can be open at one time); increasing the size of the fragment log files gives the cluster more time before having to open each new fragment log file. The default value for this parameter is 16M. `FragmentLogFileSize` was added in MySQL Cluster NDB 6.1.11.

For more information about fragment log files, see the description of the `NoOfFragmentLogFile` parameter.

- [InitFragmentLogFile](#)

<b>Version Introduced</b>	5.1.29-ndb-6.3.19
<b>Restart Type</b>	initial, node
	<b>Permitted Values</b>
<b>Type</b>	<a href="#">string</a>
<b>Default</b>	
<b>Range</b>	<a href="#">-</a>

By default, fragment log files are created sparsely when performing an initial start of a data node—that is, depending on the operating system and file system in use, not all bytes are necessarily written to disk. Beginning with MySQL Cluster NDB 6.3.19, it is possible to override this behavior and force all bytes to be written regardless of the platform and file system type being used by mean of this parameter.

[InitFragmentLogFile](#) takes one of two values:

- [SPARSE](#). Fragment log files are created sparsely. This is the default value.
- [FULL](#). Force all bytes of the fragment log file to be written to disk.

Depending on your operating system and file system, setting [InitFragmentLogFile=FULL](#) may help eliminate I/O errors on writes to the REDO log.

- [MaxNoOfOpenFiles](#)

<b>Restart Type</b>	node
	<b>Permitted Values (&lt;= 5.1.15)</b>
<b>Type</b>	<a href="#">numeric</a>
<b>Default</b>	<a href="#">40</a>
<b>Range</b>	<a href="#">20-4G</a>
	<b>Permitted Values (&gt;= 5.1.16)</b>
<b>Type</b>	<a href="#">numeric</a>
<b>Default</b>	<a href="#">0</a>
<b>Range</b>	<a href="#">20-4G</a>

This parameter sets a ceiling on how many internal threads to allocate for open files. *Any situation requiring a change in this parameter should be reported as a bug.*

The default value is 0. (Prior to MySQL 5.1.16, the default was 40.) However, the minimum value to which this parameter can be set is 20.

- [InitialNoOfOpenFiles](#)

<b>Version Introduced</b>	5.1.9
<b>Restart Type</b>	node
	<b>Permitted Values (&gt;= 5.1.9)</b>
<b>Type</b>	<a href="#">numeric</a>
<b>Default</b>	<a href="#">27</a>
<b>Range</b>	<a href="#">20-4G</a>

This parameter sets the initial number of internal threads to allocate for open files.

The default value is 27.

- [MaxNoOfSavedMessages](#)

<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	25
<b>Range</b>	0–4G

This parameter sets the maximum number of trace files that are kept before overwriting old ones. Trace files are generated when, for whatever reason, the node crashes.

The default is 25 trace files.

- [MaxLCPStartDelay](#)

<b>Version Introduced</b>	5.1.32-ndb-6.4.3
<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	0
<b>Range</b>	0–600
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	0
<b>Range</b>	0–600

In parallel data node recovery (supported in MySQL Cluster NDB 6.3.8 and later), only table data is actually copied and synchronized in parallel; synchronization of metadata such as dictionary and checkpoint information is done in a serial fashion. In addition, recovery of dictionary and checkpoint information cannot be executed in parallel with performing of local checkpoints. This means that, when starting or restarting many data nodes concurrently, data nodes may be forced to wait while a local checkpoint is performed, which can result in longer node recovery times.

Beginning with MySQL Cluster NDB 6.3.23 and MySQL Cluster NDB 6.4.3, it is possible to force a delay in the local checkpoint to permit more (and possibly all) data nodes to complete metadata synchronization; once each data node's metadata synchronization is complete, all of the data nodes can recover table data in parallel, even while the local checkpoint is being executed.

To force such a delay, you can set [MaxLCPStartDelay](#), which determines the number of seconds the cluster can wait to begin a local checkpoint while data nodes continue to synchronize metadata. This parameter should be set in the [\[ndbd default\]](#) section of the [config.ini](#) file, so that it is the same for all data nodes. The maximum value is 600; the default is 0.

**Metadata objects.** The next set of [\[ndbd\]](#) parameters defines pool sizes for metadata objects, used to define the maximum number of attributes, tables, indexes, and trigger objects used by indexes, events, and replication between clusters. Note that these act merely as “suggestions” to the cluster, and any that are not specified revert to the default values shown.

- [MaxNoOfAttributes](#)

<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	1000
<b>Range</b>	32–4G

Defines the number of attributes that can be defined in the cluster.

The default value is 1000, with the minimum possible value being 32. The maximum is 4294967039. Each attribute consumes

around 200 bytes of storage per node due to the fact that all metadata is fully replicated on the servers.

When setting `MaxNoOfAttributes`, it is important to prepare in advance for any `ALTER TABLE` statements that you might want to perform in the future. This is due to the fact, during the execution of `ALTER TABLE` on a Cluster table, 3 times the number of attributes as in the original table are used, and a good practice is to permit double this amount. For example, if the MySQL Cluster table having the greatest number of attributes (`greatest_number_of_attributes`) has 100 attributes, a good starting point for the value of `MaxNoOfAttributes` would be `6 * greatest_number_of_attributes = 600`.

You should also estimate the average number of attributes per table and multiply this by `MaxNoOfTables`. If this value is larger than the value obtained in the previous paragraph, you should use the larger value instead.

Assuming that you can create all desired tables without any problems, you should also verify that this number is sufficient by trying an actual `ALTER TABLE` after configuring the parameter. If this is not successful, increase `MaxNoOfAttributes` by another multiple of `MaxNoOfTables` and test it again.

- [MaxNoOfTables](#)

<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	128
<b>Range</b>	8–20320

A table object is allocated for each table and for each unique hash index in the cluster. This parameter sets the maximum number of table objects for the cluster as a whole.

For each attribute that has a `BLOB` data type an extra table is used to store most of the `BLOB` data. These tables also must be taken into account when defining the total number of tables.

The default value of this parameter is 128. The minimum is 8 and the maximum is 20320. Each table object consumes approximately 20KB per node.

**Note**

The sum of `MaxNoOfTables`, `MaxNoOfOrderedIndexes`, and `MaxNoOfUniqueHashIndexes` must not exceed  $2^{32} - 2$  (4294967294).

- [MaxNoOfOrderedIndexes](#)

<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	128
<b>Range</b>	0–4G

For each ordered index in the cluster, an object is allocated describing what is being indexed and its storage segments. By default, each index so defined also defines an ordered index. Each unique index and primary key has both an ordered index and a hash index. `MaxNoOfOrderedIndexes` sets the total number of hash indexes that can be in use in the system at any one time.

The default value of this parameter is 128. Each hash index object consumes approximately 10KB of data per node.

**Note**

The sum of `MaxNoOfTables`, `MaxNoOfOrderedIndexes`, and `MaxNoOfUniqueHashIndexes` must not exceed  $2^{32} - 2$  (4294967294).

- [MaxNoOfUniqueHashIndexes](#)

<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	64
<b>Range</b>	0–4G

For each unique index that is not a primary key, a special table is allocated that maps the unique key to the primary key of the indexed table. By default, an ordered index is also defined for each unique index. To prevent this, you must specify the [USING HASH](#) option when defining the unique index.

The default value is 64. Each index consumes approximately 15KB per node.

### Note

The sum of [MaxNoOfTables](#), [MaxNoOfOrderedIndexes](#), and [MaxNoOfUniqueHashIndexes](#) must not exceed  $2^{32} - 2$  (4294967294).

- [MaxNoOfTriggers](#)

<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	768
<b>Range</b>	0–4G

Internal update, insert, and delete triggers are allocated for each unique hash index. (This means that three triggers are created for each unique hash index.) However, an *ordered* index requires only a single trigger object. Backups also use three trigger objects for each normal table in the cluster.

Replication between clusters also makes use of internal triggers.

This parameter sets the maximum number of trigger objects in the cluster.

The default value is 768.

- [MaxNoOfIndexes](#)

This parameter is deprecated in MySQL 5.1; you should use [MaxNoOfOrderedIndexes](#) and [MaxNoOfUniqueHashIndexes](#) instead.

This parameter is used only by unique hash indexes. There needs to be one record in this pool for each unique hash index defined in the cluster.

The default value of this parameter is 128.

- [MaxNoOfSubscriptions](#)

<b>Version Introduced</b>	5.1.23-ndb-6.3.7
<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	0
<b>Range</b>	0–4G
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	0
<b>Range</b>	0–4G

Each `NDB` table in a MySQL Cluster requires a subscription in the NDB kernel. For some NDB API applications, it may be necessary or desirable to change this parameter, which became available in MySQL Cluster NDB 6.2.10 and MySQL Cluster NDB 6.3.7. However, for normal usage with MySQL servers acting as SQL nodes, there is not any need to do so.

The default value for `MaxNoOfSubscriptions` is 0, which is treated as equal to `MaxNoOfTables`.

- [MaxNoOfSubscribers](#)

<b>Version Introduced</b>	5.1.23-ndb-6.3.7						
<b>Restart Type</b>	node						
	<b>Permitted Values</b> <table border="1"> <tr> <td><b>Type</b></td><td>numeric</td></tr> <tr> <td><b>Default</b></td><td>0</td></tr> <tr> <td><b>Range</b></td><td>0–4G</td></tr> </table>	<b>Type</b>	numeric	<b>Default</b>	0	<b>Range</b>	0–4G
<b>Type</b>	numeric						
<b>Default</b>	0						
<b>Range</b>	0–4G						
	<b>Permitted Values</b> <table border="1"> <tr> <td><b>Type</b></td><td>numeric</td></tr> <tr> <td><b>Default</b></td><td>0</td></tr> <tr> <td><b>Range</b></td><td>0–4G</td></tr> </table>	<b>Type</b>	numeric	<b>Default</b>	0	<b>Range</b>	0–4G
<b>Type</b>	numeric						
<b>Default</b>	0						
<b>Range</b>	0–4G						

This parameter, added in MySQL Cluster NDB 6.2.10 and MySQL Cluster NDB 6.3.7, is of interest only when using MySQL Cluster Replication. The default value is 0, which is treated as `2 * MaxNoOfTables`; that is, there is one subscription per `NDB` table for each of two MySQL servers (one acting as the replication master and the other as the slave).

When using circular replication, multi-master replication, and other replication setups involving more than 2 MySQL servers, you should increase this parameter to the number of `mysqld` processes included in replication (this is often, but not always, the same as the number of clusters). For example, if you have a circular replication setup using three MySQL Clusters, with one `mysqld` attached to each cluster, and each of these `mysqld` processes acts as a master and as a slave, you should set `MaxNoOfSubscribers` equal to `3 * MaxNoOfTables`.

For more information, see [Section 17.6, “MySQL Cluster Replication”](#).

- [MaxNoOfConcurrentSubOperations](#)

<b>Version Introduced</b>	5.1.23-ndb-6.3.7						
<b>Restart Type</b>	node						
	<b>Permitted Values</b> <table border="1"> <tr> <td><b>Type</b></td><td>numeric</td></tr> <tr> <td><b>Default</b></td><td>256</td></tr> <tr> <td><b>Range</b></td><td>0–4G</td></tr> </table>	<b>Type</b>	numeric	<b>Default</b>	256	<b>Range</b>	0–4G
<b>Type</b>	numeric						
<b>Default</b>	256						
<b>Range</b>	0–4G						
	<b>Permitted Values</b> <table border="1"> <tr> <td><b>Type</b></td><td>numeric</td></tr> <tr> <td><b>Default</b></td><td>256</td></tr> <tr> <td><b>Range</b></td><td>0–4G</td></tr> </table>	<b>Type</b>	numeric	<b>Default</b>	256	<b>Range</b>	0–4G
<b>Type</b>	numeric						
<b>Default</b>	256						
<b>Range</b>	0–4G						

This parameter sets a ceiling on the number of operations that can be performed by all API nodes in the cluster at one time. The default value (256) is sufficient for normal operations, and might need to be adjusted only in scenarios where there are a great many API nodes each performing a high volume of operations concurrently.

This parameter was added in MySQL Cluster NDB 6.2.10 and MySQL Cluster NDB 6.3.7.

**Boolean parameters.** The behavior of data nodes is also affected by a set of `[ndbd]` parameters taking on boolean values. These parameters can each be specified as `TRUE` by setting them equal to `1` or `Y`, and as `FALSE` by setting them equal to `0` or `N`.

- [LockPagesInMainMemory](#)

<b>Restart Type</b>	node
<b>Permitted Values (&gt;= 5.1.0, &lt;= 5.1.14)</b>	
<b>Type</b>	boolean
<b>Default</b>	0
<b>Range</b>	0–1
<b>Permitted Values (&gt;= 5.1.15)</b>	
<b>Type</b>	numeric
<b>Default</b>	0
<b>Range</b>	0–2

For a number of operating systems, including Solaris and Linux, it is possible to lock a process into memory and so avoid any swapping to disk. This can be used to help guarantee the cluster's real-time characteristics.

Beginning with MySQL 5.1.15 and MySQL Cluster NDB 6.1.1, this parameter takes one of the integer values [0](#), [1](#), or [2](#), which act as follows:

- [0](#): Disables locking. This is the default value.
- [1](#): Performs the lock after allocating memory for the process.
- [2](#): Performs the lock before memory for the process is allocated.

Previously, this parameter was a Boolean. [0](#) or [false](#) was the default setting, and disabled locking. [1](#) or [true](#) enabled locking of the process after its memory was allocated.

### Important

Beginning with MySQL 5.1.15 and MySQL Cluster NDB 6.1.1, it is no longer possible to use [true](#) or [false](#) for the value of this parameter; when upgrading from a previous version, you must change the value to [0](#), [1](#), or [2](#).

Prior to MySQL Cluster NDB 6.3.31 and MySQL Cluster NDB 7.0.11, setting this parameter did not cause the stated memory to be allocated when the node was started, but rather only when the memory was used by the data node process for other reasons. ([Bug#37430](#))

### Note

If the operating system is not configured to permit unprivileged users to lock pages, then the data node process making use of this parameter may have to be run as system root. ([LockPagesInMainMemory](#) uses the [mlockall](#) function. From Linux kernel 2.6.9, unprivileged users can lock memory as limited by [max locked memory](#). For more information, see [ulimit -l](#) and <http://linux.die.net/man/2/mlock>).

- [StopOnError](#)

<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	boolean
<b>Default</b>	true
<b>Range</b>	-

This parameter specifies whether an [ndbd](#) process should exit or perform an automatic restart when an error condition is encountered.

This feature is enabled by default.

- [Diskless](#)

<b>Restart Type</b>	initial, system
---------------------	-----------------

<b>Permitted Values</b>	
<b>Type</b>	<code>boolean</code>
<b>Default</b>	<code>0</code>
<b>Range</b>	<code>0-1</code>

It is possible to specify MySQL Cluster tables as *diskless*, meaning that tables are not checkpointed to disk and that no logging occurs. Such tables exist only in main memory. A consequence of using diskless tables is that neither the tables nor the records in those tables survive a crash. However, when operating in diskless mode, it is possible to run `ndbd` on a diskless computer.

### Important

This feature causes the *entire* cluster to operate in diskless mode.

When this feature is enabled, Cluster online backup is disabled. In addition, a partial start of the cluster is not possible.

`Diskless` is disabled by default.

- `ODirect`

<b>Version Introduced</b>	5.1.19-ndb-6.3.0
<b>Restart Type</b>	node
	<b>Permitted Values</b>
	<b>Type</b> <code>numeric</code>
	<b>Default</b> <code>0</code>
	<b>Range</b> <code>0-1</code>
	<b>Permitted Values</b>
	<b>Type</b> <code>numeric</code>
	<b>Default</b> <code>0</code>
	<b>Range</b> <code>0-1</code>
	<b>Permitted Values</b>
	<b>Type</b> <code>numeric</code>
	<b>Default</b> <code>0</code>
	<b>Range</b> <code>0-1</code>

Enabling this parameter causes `NDB` to attempt using `O_DIRECT` writes for LCP, backups, and redo logs, often lowering `kswapd` and CPU usage. When using MySQL Cluster on Linux, enable `ODirect` if you are using a 2.6 or kernel.

This parameter was added in the following releases:

- MySQL 5.1.20
- MySQL Cluster NDB 6.1.11
- MySQL Cluster NDB 6.2.3
- MySQL Cluster NDB 6.3.0

`ODirect` is disabled by default.

- `RestartOnErrorInsert`

<b>Restart Type</b>	node
	<b>Permitted Values</b>
	<b>Type</b> <code>numeric</code>
	<b>Default</b> <code>2</code>
	<b>Range</b> <code>0-4</code>

This feature is accessible only when building the debug version where it is possible to insert errors in the execution of individual blocks of code as part of testing.

This feature is disabled by default.

- [CompressedBackup](#)

<b>Version Introduced</b>	5.1.23-ndb-6.3.7
<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	<a href="#">boolean</a>
<b>Default</b>	<a href="#">false</a>
<b>Range</b>	-

Setting this parameter to [1](#) causes backup files to be compressed. The compression used is equivalent to [gzip --fast](#), and can save 50% or more of the space required on the data node to store uncompressed backup files. Compressed backups can be enabled for individual data nodes, or for all data nodes (by setting this parameter in the [\[ndbd default\]](#) section of the [config.ini](#) file).

**Important**

You cannot restore a compressed backup to a cluster running a MySQL version that does not support this feature.

The default value is [0](#) (disabled).

This parameter was introduced in MySQL Cluster NDB 6.3.7.

- [CompressedLCP](#)

<b>Version Introduced</b>	5.1.23-ndb-6.3.7
<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	<a href="#">boolean</a>
<b>Default</b>	<a href="#">false</a>
<b>Range</b>	-

Setting this parameter to [1](#) causes local checkpoint files to be compressed. The compression used is equivalent to [gzip -fast](#), and can save 50% or more of the space required on the data node to store uncompressed checkpoint files. Compressed LCPs can be enabled for individual data nodes, or for all data nodes (by setting this parameter in the [\[ndbd default\]](#) section of the [config.ini](#) file).

**Important**

You cannot restore a compressed local checkpoint to a cluster running a MySQL version that does not support this feature.

The default value is [0](#) (disabled).

This parameter was introduced in MySQL Cluster NDB 6.3.7.

### Controlling Timeouts, Intervals, and Disk Paging

There are a number of [\[ndbd\]](#) parameters specifying timeouts and intervals between various actions in Cluster data nodes. Most of the timeout values are specified in milliseconds. Any exceptions to this are mentioned where applicable.

- [TimeBetweenWatchDogCheck](#)

<b>Restart Type</b>	node
---------------------	------

<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	6000
<b>Range</b>	70–4G

To prevent the main thread from getting stuck in an endless loop at some point, a “watchdog” thread checks the main thread. This parameter specifies the number of milliseconds between checks. If the process remains in the same state after three checks, the watchdog thread terminates it.

This parameter can easily be changed for purposes of experimentation or to adapt to local conditions. It can be specified on a per-node basis although there seems to be little reason for doing so.

The default timeout is 6000 milliseconds (6 seconds).

- [TimeBetweenWatchDogCheckInitial](#)

<b>Version Introduced</b>	5.1.20
<b>Restart Type</b>	node
<b>Permitted Values (&gt;= 5.1.20)</b>	
<b>Type</b>	numeric
<b>Default</b>	6000
<b>Range</b>	70–4G

This is similar to the [TimeBetweenWatchDogCheck](#) parameter, except that [TimeBetweenWatchDogCheckInitial](#) controls the amount of time that passes between execution checks inside a database node in the early start phases during which memory is allocated.

The default timeout is 6000 milliseconds (6 seconds).

This parameter was added in MySQL 5.1.20.

- [StartPartialTimeout](#)

<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	30000
<b>Range</b>	0–4G

This parameter specifies how long the Cluster waits for all data nodes to come up before the cluster initialization routine is invoked. This timeout is used to avoid a partial Cluster startup whenever possible.

This parameter is overridden when performing an initial start or initial restart of the cluster.

The default value is 30000 milliseconds (30 seconds). 0 disables the timeout, in which case the cluster may start only if all nodes are available.

- [StartPartitionedTimeout](#)

<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	60000
<b>Range</b>	0–4G

If the cluster is ready to start after waiting for `StartPartialTimeout` milliseconds but is still possibly in a partitioned state, the cluster waits until this timeout has also passed. If `StartPartitionedTimeout` is set to 0, the cluster waits indefinitely.

This parameter is overridden when performing an initial start or initial restart of the cluster.

The default timeout is 60000 milliseconds (60 seconds).

- [StartFailureTimeout](#)

<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	0
<b>Range</b>	0–4G

If a data node has not completed its startup sequence within the time specified by this parameter, the node startup fails. Setting this parameter to 0 (the default value) means that no data node timeout is applied.

For nonzero values, this parameter is measured in milliseconds. For data nodes containing extremely large amounts of data, this parameter should be increased. For example, in the case of a data node containing several gigabytes of data, a period as long as 10–15 minutes (that is, 600000 to 1000000 milliseconds) might be required to perform a node restart.

- [HeartbeatIntervalDbDb](#)

<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	1500
<b>Range</b>	10–4G

One of the primary methods of discovering failed nodes is by the use of heartbeats. This parameter states how often heartbeat signals are sent and how often to expect to receive them. After missing three heartbeat intervals in a row, the node is declared dead. Thus, the maximum time for discovering a failure through the heartbeat mechanism is four times the heartbeat interval.

The default heartbeat interval is 1500 milliseconds (1.5 seconds). This parameter must not be changed drastically and should not vary widely between nodes. If one node uses 5000 milliseconds and the node watching it uses 1000 milliseconds, obviously the node will be declared dead very quickly. This parameter can be changed during an online software upgrade, but only in small increments.

- [HeartbeatIntervalDbApi](#)

<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	1500
<b>Range</b>	100–4G

Each data node sends heartbeat signals to each MySQL server (SQL node) to ensure that it remains in contact. If a MySQL server fails to send a heartbeat in time it is declared “dead,” in which case all ongoing transactions are completed and all resources released. The SQL node cannot reconnect until all activities initiated by the previous MySQL instance have been completed. The three-heartbeat criteria for this determination are the same as described for [HeartbeatIntervalDbDb](#).

The default interval is 1500 milliseconds (1.5 seconds). This interval can vary between individual data nodes because each data node watches the MySQL servers connected to it, independently of all other data nodes.

**HeartbeatOrder**

<b>Version Introduced</b>	5.1.47-ndb-7.1.5
<b>Restart Type</b>	system
	<b>Permitted Values</b>
	<b>Type</b> numeric
	<b>Default</b> 0
	<b>Range</b> 0–65535

Data nodes send heartbeats to one another in a circular fashion whereby each data node monitors the previous one. If a heartbeat is not detected by a given data node, this node declares the previous data node in the circle “dead” (that is, no longer accessible by the cluster). The determination that a data node is dead is done globally; in other words; once a data node is declared dead, it is regarded as such by all nodes in the cluster.

It is possible for heartbeats between data nodes residing on different hosts to be too slow compared to heartbeats between other pairs of nodes (for example, due to a very low heartbeat interval or temporary connection problem), such that a data node is declared dead, even though the node can still function as part of the cluster. .

In this type of situation, it may be that the order in which heartbeats are transmitted between data nodes makes a difference as to whether or not a particular data node is declared dead. If this declaration occurs unnecessarily, this can in turn lead to the unnecessary loss of a node group and as thus to a failure of the cluster.

Consider a setup where there are 4 data nodes A, B, C, and D running on 2 host computers `host1` and `host2`, and that these data nodes make up 2 node groups, as shown in the following table:

	<code>host1</code>	<code>host2</code>
<i>Node Group 0:</i>	Node A	Node B
<i>Node Group 1:</i>	Node C	Node D

Suppose the heartbeats are transmitted in the order A->B->C->D->A. In this case, the loss of the heartbeat between the hosts causes node B to declare node A dead and node C to declare node B dead. This results in loss of Node Group 0, and so the cluster fails. On the other hand, if the order of transmission is A->B->D->C->A (and all other conditions remain as previously stated), the loss of the heartbeat causes nodes A and D to be declared dead; in this case, each node group has one surviving node, and the cluster survives.

Prior to MySQL Cluster NDB 6.3.35, MySQL Cluster NDB 7.0.16, and MySQL Cluster NDB 7.1.5, the order of heartbeat transmission between data nodes was always automatically determined by `NDB`. However, beginning with these versions, the `HeartbeatOrder` configuration parameter makes the order of heartbeat transmission user-configurable.

The default value for `HeartbeatOrder` is zero; allowing the default value to be used on all data nodes causes the order of heartbeat transmission to be determined by `NDB`. If this parameter is used, it must be set to a nonzero value (maximum 65535) for every data node in the cluster, and this value must be unique for each data node; this causes the heartbeat transmission to proceed from data node to data node in the order of their `HeartbeatOrder` values from lowest to highest (and then directly from the data node having the highest `HeartbeatOrder` to the data node having the lowest value, to complete the circle). The values need not be consecutive; for example, to force the heartbeat transmission order A->B->D->C->A in the scenario outlined previously, you could set the `HeartbeatOrder` values as shown here:

Node	<code>HeartbeatOrder</code>
A	10
B	20
C	30
D	25

To use this parameter to change the heartbeat transmission order in a running MySQL Cluster, you must first set `HeartbeatOrder` for each data node in the cluster in the global configuration (`config.ini`) file (or files). To cause the change to take effect, you must perform either of the following:

- A complete shutdown and restart of the entire cluster.
- 2 rolling restarts of the cluster in succession. *All nodes must be restarted in the same order in both rolling restarts.*

You can use `DUMP 908` to observe the effect of this parameter in the data node logs.

- [TimeBetweenLocalCheckpoints](#)

<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	20
<b>Range</b>	0-31

This parameter is an exception in that it does not specify a time to wait before starting a new local checkpoint; rather, it is used to ensure that local checkpoints are not performed in a cluster where relatively few updates are taking place. In most clusters with high update rates, it is likely that a new local checkpoint is started immediately after the previous one has been completed.

The size of all write operations executed since the start of the previous local checkpoints is added. This parameter is also exceptional in that it is specified as the base-2 logarithm of the number of 4-byte words, so that the default value 20 means 4MB ( $4 \times 2^{20}$ ) of write operations, 21 would mean 8MB, and so on up to a maximum value of 31, which equates to 8GB of write operations.

All the write operations in the cluster are added together. Setting `TimeBetweenLocalCheckpoints` to 6 or less means that local checkpoints will be executed continuously without pause, independent of the cluster's workload.

- [TimeBetweenGlobalCheckpoints](#)

<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	2000
<b>Range</b>	10-32000

When a transaction is committed, it is committed in main memory in all nodes on which the data is mirrored. However, transaction log records are not flushed to disk as part of the commit. The reasoning behind this behavior is that having the transaction safely committed on at least two autonomous host machines should meet reasonable standards for durability.

It is also important to ensure that even the worst of cases—a complete crash of the cluster—is handled properly. To guarantee that this happens, all transactions taking place within a given interval are put into a global checkpoint, which can be thought of as a set of committed transactions that has been flushed to disk. In other words, as part of the commit process, a transaction is placed in a global checkpoint group. Later, this group's log records are flushed to disk, and then the entire group of transactions is safely committed to disk on all computers in the cluster.

This parameter defines the interval between global checkpoints. The default is 2000 milliseconds.

- [TimeBetweenEpochs](#)

<b>Version Introduced</b>	5.1.22-ndb-6.3.2
<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	100
<b>Range</b>	0-32000
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	100
<b>Range</b>	0-32000

This parameter defines the interval between synchronisation epochs for MySQL Cluster Replication. The default value is 100 milliseconds.

[TimeBetweenEpochs](#) is part of the implementation of “micro-GCPs”, which can be used to improve the performance of MySQL Cluster Replication. This parameter was introduced in MySQL Cluster NDB 6.2.5 and MySQL Cluster NDB 6.3.2.

- [TimeBetweenEpochsTimeout](#)

<b>Version Introduced</b>	5.1.22-ndb-6.3.4
<b>Restart Type</b>	node
	<b>Permitted Values</b>
<b>Type</b>	numeric
<b>Default</b>	4000
<b>Range</b>	0–32000
	<b>Permitted Values</b>
<b>Type</b>	numeric
<b>Default</b>	4000
<b>Range</b>	0–32000

This parameter defines a timeout for synchronisation epochs for MySQL Cluster Replication. If a node fails to participate in a global checkpoint within the time determined by this parameter, the node is shut down. The default value is 4000 milliseconds.

[TimeBetweenEpochsTimeout](#) is part of the implementation of “micro-GCPs”, which can be used to improve the performance of MySQL Cluster Replication. This parameter was introduced in MySQL Cluster NDB 6.2.7 and MySQL Cluster NDB 6.3.4.

- [MaxBufferedEpochs](#)

<b>Version Introduced</b>	5.1.23-ndb-6.2.14
<b>Restart Type</b>	node
	<b>Permitted Values</b>
<b>Type</b>	numeric
<b>Default</b>	100
<b>Range</b>	0–100000

The number of unprocessed epochs by which a subscribing node can lag behind. Exceeding this number causes a lagging subscriber to be disconnected.

The default value of 100 is sufficient for most normal operations. If a subscribing node does lag enough to cause disconnections, it is usually due to network or scheduling issues with regard to processes or threads. (In rare circumstances, the problem may be due to a bug in the [NDB](#) client.) It may be desirable to set the value lower than the default when epochs are longer.

Disconnection prevents client issues from affecting the data node service, running out of memory to buffer data, and eventually shutting down. Instead, only the client is affected as a result of the disconnect (by, for example gap events in the binlog), forcing the client to reconnect or restart the process.

- [TimeBetweenInactiveTransactionAbortCheck](#)

<b>Restart Type</b>	node
	<b>Permitted Values</b>
<b>Type</b>	numeric
<b>Default</b>	1000
<b>Range</b>	1000–4G

Timeout handling is performed by checking a timer on each transaction once for every interval specified by this parameter.

Thus, if this parameter is set to 1000 milliseconds, every transaction will be checked for timing out once per second.

The default value is 1000 milliseconds (1 second).

- [TransactionInactiveTimeout](#)

<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	4G
<b>Range</b>	0–4G

This parameter states the maximum time that is permitted to lapse between operations in the same transaction before the transaction is aborted.

The default for this parameter is zero (no timeout). For a real-time database that needs to ensure that no transaction keeps locks for too long, this parameter should be set to a relatively small value. The unit is milliseconds.

- [TransactionDeadlockDetectionTimeout](#)

<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	1200
<b>Range</b>	50–4G

When a node executes a query involving a transaction, the node waits for the other nodes in the cluster to respond before continuing. A failure to respond can occur for any of the following reasons:

- The node is “dead”
- The operation has entered a lock queue
- The node requested to perform the action could be heavily overloaded.

This timeout parameter states how long the transaction coordinator waits for query execution by another node before aborting the transaction, and is important for both node failure handling and deadlock detection. In MySQL 5.1.10 and earlier versions, setting it too high could cause undesirable behavior in situations involving deadlocks and node failure. Beginning with MySQL 5.1.11, active transactions occurring during node failures are actively aborted by the MySQL Cluster Transaction Coordinator, and so high settings are no longer an issue with this parameter.

The default timeout value is 1200 milliseconds (1.2 seconds).

Prior to MySQL Cluster NDB versions 6.2.18, 6.3.24, and 7.0.5, the effective minimum for this parameter was 100 milliseconds. ([Bug#44099](#)) Beginning with these versions, the actual minimum is 50 milliseconds.

- [DiskSyncSize](#)

<b>Version Introduced</b>	5.1.12
<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	4M
<b>Range</b>	32K–4G

This is the maximum number of bytes to store before flushing data to a local checkpoint file. This is done to prevent write buffering, which can impede performance significantly. This parameter is *not* intended to take the place of [TimeBetweenLoc-](#)

`alCheckpoints`.

### Note

When `ODirect` is enabled, it is not necessary to set `DiskSyncSize`; in fact, in such cases its value is simply ignored.

The default value is 4M (4 megabytes).

This parameter was added in MySQL 5.1.12.

- `DiskCheckpointSpeed`

<b>Version Introduced</b>	5.1.12
<b>Restart Type</b>	node
	<b>Permitted Values</b>
<b>Type</b>	numeric
<b>Default</b>	10M
<b>Range</b>	1M-4G

The amount of data,in bytes per second, that is sent to disk during a local checkpoint. This allocation is shared by DML operations and backups (but not backup logging), which means that backups started during times of intensive DML may be impaired by flooding of the redo log buffer and may fail altogether if the contention is sufficiently severe.

The default value is 10M (10 megabytes per second).

This parameter was added in MySQL 5.1.12.

- `DiskCheckpointSpeedInRestart`

<b>Version Introduced</b>	5.1.12
<b>Restart Type</b>	node
	<b>Permitted Values</b>
<b>Type</b>	numeric
<b>Default</b>	100M
<b>Range</b>	1M-4G

The amount of data,in bytes per second, that is sent to disk during a local checkpoint as part of a restart operation.

The default value is 100M (100 megabytes per second).

This parameter was added in MySQL 5.1.12.

- `NoOfDiskPagesToDiskAfterRestartTUP`

<b>Version Removed</b>	5.1.6
<b>Restart Type</b>	node
	<b>Permitted Values (&lt;= 5.1.6)</b>
<b>Type</b>	numeric
<b>Default</b>	40
<b>Range</b>	1-4G

When executing a local checkpoint, the algorithm flushes all data pages to disk. Merely doing so as quickly as possible without any moderation is likely to impose excessive loads on processors, networks, and disks. To control the write speed, this parameter specifies how many pages per 100 milliseconds are to be written. In this context, a “page” is defined as 8KB. This parameter is specified in units of 80KB per second, so setting `NoOfDiskPagesToDiskAfterRestartTUP` to a value of 20 entails writing 1.6MB in data pages to disk each second during a local checkpoint. This value includes the writing of UNDO log re-

cords for data pages. That is, this parameter handles the limitation of writes from data memory. (See the entry for [IndexMemory](#) for information about index pages.)

In short, this parameter specifies how quickly to execute local checkpoints. It operates in conjunction with [NoOfFragmentLogFiles](#), [DataMemory](#), and [IndexMemory](#).

For more information about the interaction between these parameters and possible strategies for choosing appropriate values for them, see [Section 17.3.2.12, “Configuring MySQL Cluster Parameters for Local Checkpoints”](#).

The default value is 40 (3.2MB of data pages per second).

### Note

This parameter is deprecated as of MySQL 5.1.6. For MySQL 5.1.12 and later versions, use [DiskCheckpointSpeed](#) and [DiskSyncSize](#) instead.

- [NoOfDiskPagesToDiskAfterRestartACC](#)

<b>Version Removed</b>	5.1.6
<b>Restart Type</b>	node
<b>Permitted Values (&lt;= 5.1.6)</b>	
<b>Type</b>	numeric
<b>Default</b>	20
<b>Range</b>	1–4G

This parameter uses the same units as [NoOfDiskPagesToDiskAfterRestartTUP](#) and acts in a similar fashion, but limits the speed of writing index pages from index memory.

The default value of this parameter is 20 (1.6MB of index memory pages per second).

### Note

This parameter is deprecated as of MySQL 5.1.6. For MySQL 5.1.12 and later versions, use [DiskCheckpointSpeed](#) and [DiskSyncSize](#).

- [NoOfDiskPagesToDiskDuringRestartTUP](#)

<b>Version Removed</b>	5.1.6
<b>Restart Type</b>	node
<b>Permitted Values (&lt;= 5.1.6)</b>	
<b>Type</b>	numeric
<b>Default</b>	40
<b>Range</b>	1–4G

This parameter is used in a fashion similar to [NoOfDiskPagesToDiskAfterRestartTUP](#) and [NoOfDiskPagesToDiskAfterRestartACC](#), only it does so with regard to local checkpoints executed in the node when a node is restarting. A local checkpoint is always performed as part of all node restarts. During a node restart it is possible to write to disk at a higher speed than at other times, because fewer activities are being performed in the node.

This parameter covers pages written from data memory.

The default value is 40 (3.2MB per second).

### Note

This parameter is deprecated as of MySQL 5.1.6. For MySQL 5.1.12 and later versions, use [DiskCheckpointSpeedInRestart](#) and [DiskSyncSize](#).

- [NoOfDiskPagesToDiskDuringRestartACC](#)

<b>Version Removed</b>	5.1.6
------------------------	-------

<b>Restart Type</b>	node
<b>Permitted Values (&lt;= 5.1.6)</b>	
<b>Type</b>	numeric
<b>Default</b>	20
<b>Range</b>	1–4G

Controls the number of index memory pages that can be written to disk during the local checkpoint phase of a node restart.

As with [NoDiskPagesToDiskAfterRestartTUP](#) and [NoDiskPagesToDiskAfterRestartACC](#), values for this parameter are expressed in terms of 8KB pages written per 100 milliseconds (80KB/second).

The default value is 20 (1.6MB per second).

### Note

This parameter is deprecated as of MySQL 5.1.6. For MySQL 5.1.12 and later versions, use [DiskCheckpointSpeedInRestart](#) and [DiskSyncSize](#).

- [ArbitrationTimeout](#)

<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	1000
<b>Range</b>	10–4G

This parameter specifies how long data nodes wait for a response from the arbitrator to an arbitration message. If this is exceeded, the network is assumed to have split.

The default value is 1000 milliseconds (1 second).

- [Arbitration](#)

<b>Version Introduced</b>	5.1.35-ndb-7.0.7
<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	enumeration
<b>Default</b>	Default
<b>Valid Values</b>	Default, Disabled, WaitExternal

The [Arbitration](#) parameter, added in MySQL Cluster NDB 7.0.7, enables a choice of arbitration schemes, corresponding to one of 3 possible values for this parameter:

- **Default**. This enables arbitration to proceed normally, as determined by the [ArbitrationRank](#) settings for the management and API nodes. This is the default value.
- **Disabled**. Previously, it was possible to disable arbitration only by setting [ArbitrationRank](#) to 0 on all management and API nodes. Now, you can now use [Arbitration = Disabled](#) in the [\[ndbd default\]](#) section of the [config.ini](#) file to accomplish this task. In this case, any [ArbitrationRank](#) settings are ignored.
- **WaitExternal**. The [Arbitration](#) parameter also makes it possible to configure arbitration in such a way that the cluster waits until after the time determined by [ArbitrationTimeout](#) has passed for an external cluster manager application to perform arbitration instead of handling arbitration internally. This can be done by setting [Arbitration = WaitExternal](#) in the [\[ndbd default\]](#) section of the [config.ini](#) file. For best results with the [WaitExternal](#) setting, it is recommended that [ArbitrationTimeout](#) be 2 times as long as the interval required by the external cluster manager to perform arbitration.

**Important**

This parameter should be used only in the `[ndbd default]` section of the cluster configuration file. The behavior of the cluster is unspecified when `Arbitration` is set to different values for individual data nodes.

**Buffering and logging.** Several `[ndbd]` configuration parameters enable the advanced user to have more control over the resources used by node processes and to adjust various buffer sizes at need.

These buffers are used as front ends to the file system when writing log records to disk. If the node is running in diskless mode, these parameters can be set to their minimum values without penalty due to the fact that disk writes are “faked” by the `NDB` storage engine’s file system abstraction layer.

- [UndoIndexBuffer](#)

<b>Restart Type</b>	node	
<b>Permitted Values</b>		
<b>Type</b>	<code>numeric</code>	
<b>Default</b>	<code>2M</code>	
<b>Range</b>	<code>1M-4G</code>	

The UNDO index buffer, whose size is set by this parameter, is used during local checkpoints. The `NDB` storage engine uses a recovery scheme based on checkpoint consistency in conjunction with an operational REDO log. To produce a consistent checkpoint without blocking the entire system for writes, UNDO logging is done while performing the local checkpoint. UNDO logging is activated on a single table fragment at a time. This optimization is possible because tables are stored entirely in main memory.

The UNDO index buffer is used for the updates on the primary key hash index. Inserts and deletes rearrange the hash index; the `NDB` storage engine writes UNDO log records that map all physical changes to an index page so that they can be undone at system restart. It also logs all active insert operations for each fragment at the start of a local checkpoint.

Reads and updates set lock bits and update a header in the hash index entry. These changes are handled by the page-writing algorithm to ensure that these operations need no UNDO logging.

This buffer is 2MB by default. The minimum value is 1MB, which is sufficient for most applications. For applications doing extremely large or numerous inserts and deletes together with large transactions and large primary keys, it may be necessary to increase the size of this buffer. If this buffer is too small, the `NDB` storage engine issues internal error code 677 ([Index UNDO buffers overloaded](#)).

**Important**

It is not safe to decrease the value of this parameter during a rolling restart.

- [UndoDataBuffer](#)

<b>Restart Type</b>	node	
<b>Permitted Values</b>		
<b>Type</b>	<code>numeric</code>	
<b>Default</b>	<code>16M</code>	
<b>Range</b>	<code>1M-4G</code>	

This parameter sets the size of the UNDO data buffer, which performs a function similar to that of the UNDO index buffer, except the UNDO data buffer is used with regard to data memory rather than index memory. This buffer is used during the local checkpoint phase of a fragment for inserts, deletes, and updates.

Because UNDO log entries tend to grow larger as more operations are logged, this buffer is also larger than its index memory counterpart, with a default value of 16MB.

This amount of memory may be unnecessarily large for some applications. In such cases, it is possible to decrease this size to a minimum of 1MB.

It is rarely necessary to increase the size of this buffer. If there is such a need, it is a good idea to check whether the disks can actually handle the load caused by database update activity. A lack of sufficient disk space cannot be overcome by increasing the size of this buffer.

If this buffer is too small and gets congested, the NDB storage engine issues internal error code 891 (`DATA UNDO BUFFERS OVERLOADED`).

### Important

It is not safe to decrease the value of this parameter during a rolling restart.

- [RedoBuffer](#)

<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	8M
<b>Range</b>	1M–4G

All update activities also need to be logged. The REDO log makes it possible to replay these updates whenever the system is restarted. The NDB recovery algorithm uses a “fuzzy” checkpoint of the data together with the UNDO log, and then applies the REDO log to play back all changes up to the restoration point.

[RedoBuffer](#) sets the size of the buffer in which the REDO log is written. In MySQL Cluster NDB 6.4.3 and earlier, the default value is 8MB; beginning with MySQL Cluster NDB 7.0.4, the default is 32MB. The minimum value is 1MB.

If this buffer is too small, the NDB storage engine issues error code 1221 (`REDO log buffers overloaded`).

### Important

It is not safe to decrease the value of this parameter during a rolling restart.

**Controlling log messages.** In managing the cluster, it is very important to be able to control the number of log messages sent for various event types to `stdout`. For each event category, there are 16 possible event levels (numbered 0 through 15). Setting event reporting for a given event category to level 15 means all event reports in that category are sent to `stdout`; setting it to 0 means that there will be no event reports made in that category.

By default, only the startup message is sent to `stdout`, with the remaining event reporting level defaults being set to 0. The reason for this is that these messages are also sent to the management server's cluster log.

An analogous set of levels can be set for the management client to determine which event levels to record in the cluster log.

- [LogLevelStartup](#)

<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	1
<b>Range</b>	0–15

The reporting level for events generated during startup of the process.

The default level is 1.

- [LogLevelShutdown](#)

<b>Restart Type</b>	node
---------------------	------

<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	0
<b>Range</b>	0-15

The reporting level for events generated as part of graceful shutdown of a node.

The default level is 0.

- [LogLevelStatistic](#)

<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	0
<b>Range</b>	0-15

The reporting level for statistical events such as number of primary key reads, number of updates, number of inserts, information relating to buffer usage, and so on.

The default level is 0.

- [LogLevelCheckpoint](#)

<b>Restart Type</b>	initial, node
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	0
<b>Range</b>	0-15

The reporting level for events generated by local and global checkpoints.

The default level is 0.

- [LogLevelNodeRestart](#)

<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	0
<b>Range</b>	0-15

The reporting level for events generated during node restart.

The default level is 0.

- [LogLevelConnection](#)

<b>Restart Type</b>	node
<b>Permitted Values</b>	

<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	0
<b>Range</b>	0-15

The reporting level for events generated by connections between cluster nodes.

The default level is 0.

- [LogLevelError](#)

<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	0
<b>Range</b>	0-15

The reporting level for events generated by errors and warnings by the cluster as a whole. These errors do not cause any node failure but are still considered worth reporting.

The default level is 0.

- [LogLevelCongestion](#)

<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	0
<b>Range</b>	0-15

The reporting level for events generated by congestion. These errors do not cause node failure but are still considered worth reporting.

The default level is 0.

- [LogLevelInfo](#)

<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	0
<b>Range</b>	0-15

The reporting level for events generated for information about the general state of the cluster.

The default level is 0.

- [MemReportFrequency](#)

<b>Version Introduced</b>	5.1.16
<b>Restart Type</b>	node

Permitted Values (>= 5.1.16)	
Type	numeric
Default	0
Range	0–4G

This parameter controls how often data node memory usage reports are recorded in the cluster log; it is an integer value representing the number of seconds between reports.

Each data node's data memory and index memory usage is logged as both a percentage and a number of 32 KB pages of the [DataMemory](#) and [IndexMemory](#), respectively, set in the [config.ini](#) file. For example, if [DataMemory](#) is equal to 100 MB, and a given data node is using 50 MB for data memory storage, the corresponding line in the cluster log might look like this:

```
2006-12-24 01:18:16 [MgmSrvr] INFO -- Node 2: Data usage is 50%(1280 32K pages of total 2560)
```

[MemReportFrequency](#) is not a required parameter. If used, it can be set for all cluster data nodes in the [\[ndbd default\]](#) section of [config.ini](#), and can also be set or overridden for individual data nodes in the corresponding [\[ndbd\]](#) sections of the configuration file. The minimum value—which is also the default value—is 0, in which case memory reports are logged only when memory usage reaches certain percentages (80%, 90%, and 100%), as mentioned in the discussion of statistics events in [Section 17.5.4.2, “MySQL Cluster Log Events”](#).

This parameter was added in MySQL Cluster 5.1.16 and MySQL Cluster NDB 6.1.0.

- [StartupStatusReportFrequency](#)

Version Introduced	5.1.30-ndb-6.4.0
Restart Type	node
Permitted Values	
Type	numeric

When a data node is started with the [--initial](#), it initializes the redo log file during Start Phase 4 (see [Section 17.5.1, “Summary of MySQL Cluster Start Phases”](#)). When very large values are set for [NoOfFragmentLogFile](#), [FragmentLogFileSize](#), or both, this initialization can take a long time. Previous to MySQL Cluster NDB 6.4.0, only the beginning and end of the redo log file initialization process were logged. Beginning with this version, it is possible to force reports on the progress of this process to be logged periodically, by means of the [StartupStatusReportFrequency](#) configuration parameter. In this case, progress is reported in the cluster log, in terms of both the number of files and the amount of space that have been initialized, as shown here:

```
2009-06-20 16:39:23 [MgmSrvr] INFO -- Node 1: Local redo log file initialization status:
#Total files: 80, Completed: 60
#Total MBytes: 20480, Completed: 15557
2009-06-20 16:39:23 [MgmSrvr] INFO -- Node 2: Local redo log file initialization status:
#Total files: 80, Completed: 60
#Total MBytes: 20480, Completed: 15570
```

These reports are logged each [StartupStatusReportFrequency](#) seconds during Start Phase 4. If [StartupStatusReportFrequency](#) is 0 (the default), then reports are written to the cluster log only when at the beginning and at the completion of the redo log file initialization process.

**Debugging Parameters.** Beginning with MySQL Cluster NDB 6.3.36, MySQL Cluster NDB 7.0.17, and MySQL Cluster NDB 7.1.6, it is possible to cause logging of traces for events generated by creating and dropping tables using [DictTrace](#). This parameter is useful only in debugging NDB kernel code. [DictTrace](#) takes an integer value; currently, 0 (default - no logging) and 1 (logging enabled) are the only supported values.

**Backup parameters.** The [\[ndbd\]](#) parameters discussed in this section define memory buffers set aside for execution of online backups.

- [BackupDataBufferSize](#)

Restart Type	node
--------------	------

<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	2M
<b>Range</b>	0–4G

In creating a backup, there are two buffers used for sending data to the disk. The backup data buffer is used to fill in data recorded by scanning a node's tables. Once this buffer has been filled to the level specified as [BackupWriteSize](#) (see below), the pages are sent to disk. While flushing data to disk, the backup process can continue filling this buffer until it runs out of space. When this happens, the backup process pauses the scan and waits until some disk writes have completed freed up memory so that scanning may continue.

In MySQL Cluster NDB 6.4.3 and earlier, the default value is 2MB; in MySQL Cluster NDB 7.0.4 and later, it is 16MB.

- [BackupLogBufferSize](#)

<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	2M
<b>Range</b>	0–4G

The backup log buffer fulfills a role similar to that played by the backup data buffer, except that it is used for generating a log of all table writes made during execution of the backup. The same principles apply for writing these pages as with the backup data buffer, except that when there is no more space in the backup log buffer, the backup fails. For that reason, the size of the backup log buffer must be large enough to handle the load caused by write activities while the backup is being made. See [Section 17.5.3.3, “Configuration for MySQL Cluster Backups”](#).

The default value for this parameter should be sufficient for most applications. In fact, it is more likely for a backup failure to be caused by insufficient disk write speed than it is for the backup log buffer to become full. If the disk subsystem is not configured for the write load caused by applications, the cluster is unlikely to be able to perform the desired operations.

It is preferable to configure cluster nodes in such a manner that the processor becomes the bottleneck rather than the disks or the network connections.

In MySQL Cluster NDB 6.4.3 and earlier, the default value is 2MB; in MySQL Cluster NDB 7.0.4 and later, it is 16MB.

- [BackupMemory](#)

<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	4M
<b>Range</b>	0–4G

This parameter is simply the sum of [BackupDataBufferSize](#) and [BackupLogBufferSize](#).

In MySQL Cluster NDB 6.4.3 and earlier, the default value was 2MB + 2MB = 4MB; in MySQL Cluster NDB 7.0.4 and later, it is 16MB + 16MB = 32MB.

**Important**

If [BackupDataBufferSize](#) and [BackupLogBufferSize](#) taken together exceed the default value for [BackupMemory](#), then this parameter must be set explicitly in the `config.ini` file to their sum.

- [BackupReportFrequency](#)

<b>Version Introduced</b>	5.1.19-ndb-6.2.3
---------------------------	------------------

<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	0
<b>Range</b>	0–4G

This parameter controls how often backup status reports are issued in the management client during a backup, as well as how often such reports are written to the cluster log (provided cluster event logging is configured to permit it—see [Logging and checkpointing](#)). `BackupReportFrequency` represents the time in seconds between backup status reports.

The default value is 0.

This parameter was added in MySQL Cluster NDB 6.2.3.

- [BackupWriteSize](#)

<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	32K
<b>Range</b>	2K–4G

This parameter specifies the default size of messages written to disk by the backup log and backup data buffers.

In MySQL Cluster 6.4.3 and earlier, the default value for this parameter was 32KB; beginning with MySQL Cluster NDB 7.0.4, it is 256KB.

- [BackupMaxWriteSize](#)

<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	256K
<b>Range</b>	2K–4G

This parameter specifies the maximum size of messages written to disk by the backup log and backup data buffers.

In MySQL Cluster 6.4.3 and earlier, the default value for this parameter was 256KB; beginning with MySQL Cluster NDB 7.0.4, it is 1MB.

### Important

When specifying these parameters, the following relationships must hold true. Otherwise, the data node will be unable to start.

- `BackupDataBufferSize >= BackupWriteSize + 188KB`
- `BackupLogBufferSize >= BackupWriteSize + 16KB`
- `BackupMaxWriteSize >= BackupWriteSize`

### Realtime Performance Parameters

The `[ndbd]` parameters discussed in this section are used in scheduling and locking of threads to specific CPUs on multiprocessor data node hosts. They were introduced in MySQL Cluster NDB 6.3.4.

**Note**

To make use of these parameters, the data node process must be run as system root.

- [LockExecuteThreadToCPU](#)

<b>Version Introduced</b>	5.1.19-ndb-6.3.4
<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	64K
<b>Range</b>	0–64K

**Previous to MySQL Cluster NDB 7.0.** This parameter specifies the ID of the CPU assigned to handle the `NDBCLUSTER` execution thread. The value of this parameter is an integer in the range 0 to 65535 (inclusive). The default is 65535.

**MySQL Cluster NDB 7.0 and later (beginning with MySQL Cluster NDB 6.4.0).** When used with `ndbd`, this parameter (now a string) specifies the ID of the CPU assigned to handle the `NDBCLUSTER` execution thread. When used with `ndbmtd`, the value of this parameter is a comma-separated list of CPU IDs assigned to handle execution threads. Each CPU ID in the list should be an integer in the range 0 to 65535 (inclusive). The number of IDs specified should match the number of execution threads determined by `MaxNoOfExecutionThreads`. There is no default value.

Prior to MySQL Cluster NDB 7.0.18 and MySQL Cluster NDB 7.1.7, the effective maximum value recognized by this parameter as a valid CPU ID was 255; using a greater value caused thread locking to be disabled. ([Bug#56185](#))

- [LockMaintThreadsToCPU](#)

<b>Version Introduced</b>	5.1.19-ndb-6.3.4
<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	64K
<b>Range</b>	0–64K

This parameter specifies the ID of the CPU assigned to handle `NDBCLUSTER` maintenance threads.

The value of this parameter is an integer in the range 0 to 65535 (inclusive). This parameter was added in MySQL Cluster NDB 6.3.4. Prior to MySQL Cluster NDB 6.4.0, the default is 65535; in MySQL Cluster NDB 7.0 and later MySQL Cluster release series, there is no default value.

- [RealtimeScheduler](#)

<b>Version Introduced</b>	5.1.19-ndb-6.3.4
<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	boolean
<b>Default</b>	false
<b>Range</b>	-

Setting this parameter to 1 enables real-time scheduling of `NDBCLUSTER` threads.

The default is 0 (scheduling disabled).

- [SchedulerExecutionTimer](#)

<b>Version Introduced</b>	5.1.22-ndb-6.3.4
<b>Restart Type</b>	node
	<b>Permitted Values</b>
<b>Type</b>	numeric
<b>Default</b>	50
<b>Range</b>	0–11000

This parameter specifies the time in microseconds for threads to be executed in the scheduler before being sent. Setting it to 0 minimizes the response time; to achieve higher throughput, you can increase the value at the expense of longer response times.

The default is 50  $\mu$ sec, which our testing shows to increase throughput slightly in high-load cases without materially delaying requests.

This parameter was added in MySQL Cluster NDB 6.3.4.

- [SchedulerSpinTimer](#)

<b>Version Introduced</b>	5.1.22-ndb-6.3.4
<b>Restart Type</b>	node
	<b>Permitted Values</b>
<b>Type</b>	numeric
<b>Default</b>	0
<b>Range</b>	0–500

This parameter specifies the time in microseconds for threads to be executed in the scheduler before sleeping.

The default value is 0.

- [BuildIndexThreads](#)

<b>Version Introduced</b>	5.1.39-ndb-7.0.11
<b>Restart Type</b>	
	<b>Permitted Values</b>
<b>Type</b>	numeric
<b>Default</b>	0
<b>Range</b>	0–128

This parameter determines the number of threads to create when rebuilding indexes during a system or node start. It is supported only when there is more than one fragment for the table per data node (for example, when the `MAX_ROWS` option has been used with `CREATE TABLE`).

Setting this parameter to 0 (which is also the default value) disables multi-threaded building of ordered indexes. The maximum allowed value is 128.

This parameter was added in MySQL Cluster NDB 6.3.30 and MySQL Cluster NDB 7.0.11. Prior to MySQL Cluster NDB 7.0.16 and MySQL Cluster NDB 7.1.5, it was supported only when using `ndbd`; in these and later MySQL Cluster releases, `BuildIndexThreads` is also supported for data nodes running `ndbmttd` (see Bug#54521).

**Disk Data Configuration Parameters.** Configuration parameters affecting Disk Data behavior include the following:

- [DiskPageBufferMemory](#)

This determines the amount of space used for caching pages on disk, and is set in the `[ndbd]` or `[ndbd default]` section of the `config.ini` file. It is measured in bytes. Each page takes up 32 KB. This means that Cluster Disk Data storage always

uses  $N * 32$  KB memory where  $N$  is some nonnegative integer.

The default value for this parameter is `64M` (2000 pages of 32 KB each).

This parameter was added in MySQL 5.1.6.

- **`SharedGlobalMemory`**

This determines the amount of memory that is used for log buffers, disk operations (such as page requests and wait queues), and metadata for tablespaces, log file groups, `UNDO` files, and data files. It can be set in the `[ndbd]` or `[ndbd default]` section of the `config.ini` configuration file, and is measured in bytes.

The default value is `20M`.

This parameter was added in MySQL 5.1.6.

- **`DiskIOThreadPool`**

This parameter determines the number of unbound threads used for Disk Data file access. Before `DiskIOThreadPool` was introduced, exactly one thread was spawned for each Disk Data file, which could lead to performance issues, particularly when using very large data files. With `DiskIOThreadPool`, you can—for example—access a single large data file using several threads working in parallel.

Currently, this parameter applies to Disk Data I/O threads only, but we plan in the future to make the number of such threads configurable for in-memory data as well.

The optimum value for this parameter depends on your hardware and configuration, and includes these factors:

- **Physical distribution of Disk Data files.** You can obtain better performance by placing data files, undo log files, and the data node filesystem on separate physical disks. If you do this with some or all of these sets of files, then you can set `DiskIOThreadPool` higher to enable separate threads to handle the files on each disk.
- **Disk performance and types.** The number of threads that can be accommodated for Disk Data file handling is also dependent on the speed and throughput of the disks. Faster disks and higher throughput allow for more disk I/O threads. Our test results indicate that solid-state disk drives can handle many more disk I/O threads than conventional disks, and thus higher values for `DiskIOThreadPool`.

This parameter was added in MySQL Cluster NDB 6.4.0. Previous to MySQL Cluster NDB 6.4.3, it was named `ThreadPool`. Previous to MySQL Cluster NDB 7.0.7, the default value was 8. Beginning with MySQL Cluster NDB 7.0.7 and MySQL Cluster NDB 7.1.0, the default is 2.

- **Disk Data filesystem parameters.** The parameters in the following list were added in MySQL Cluster NDB 6.2.17, 6.3.22, and 6.4.3 to make it possible to place MySQL Cluster Disk Data files in specific directories without the need for using symbolic links.

- **`FileSystemPathDD`**

If this parameter is specified, then MySQL Cluster Disk Data data files and undo log files are placed in the indicated directory. This can be overridden for data files, undo log files, or both, by specifying values for `FileSystemPathDataFiles`, `FileSystemPathUndoFiles`, or both, as explained for these parameters. It can also be overridden for data files by specifying a path in the `ADD DATAFILE` clause of a `CREATE TABLESPACE` or `ALTER TABLESPACE` statement, and for undo log files by specifying a path in the `ADD UNDOFILE` clause of a `CREATE LOGFILE GROUP` or `ALTER LOGFILE GROUP` statement. If `FileSystemPathDD` is not specified, then `FileSystemPath` is used.

If a `FileSystemPathDD` directory is specified for a given data node (including the case where the parameter is specified in the `[ndbd default]` section of the `config.ini` file), then starting that data node with `--initial` causes all files in the directory to be deleted.

- **`FileSystemPathDataFiles`**

If this parameter is specified, then MySQL Cluster Disk Data data files are placed in the indicated directory. This overrides any value set for `FileSystemPathDD`. This parameter can be overridden for a given data file by specifying a path in the `ADD DATAFILE` clause of a `CREATE TABLESPACE` or `ALTER TABLESPACE` statement used to create that data file. If `FileSystemPathDataFiles` is not specified, then `FileSystemPathDD` is used (or `FileSystemPath`, if `FileSystemPathDD` has also not been set).

If a `FileSystemPathDataFiles` directory is specified for a given data node (including the case where the parameter

is specified in the `[ndbd default]` section of the `config.ini` file), then starting that data node with `--initial` causes all files in the directory to be deleted.

- **`FileSystemPathUndoFiles`**

If this parameter is specified, then MySQL Cluster Disk Data undo log files are placed in the indicated directory. This overrides any value set for `FileSystemPathDD`. This parameter can be overridden for a given data file by specifying a path in the `ADD UNDO` clause of a `CREATE LOGFILE GROUP` or `CREATE LOGFILE GROUP` statement used to create that data file. If `FileSystemPathUndoFiles` is not specified, then `FileSystemPathDD` is used (or `FileSystemPath`, if `FileSystemPathDD` has also not been set).

If a `FileSystemPathUndoFiles` directory is specified for a given data node (including the case where the parameter is specified in the `[ndbd default]` section of the `config.ini` file), then starting that data node with `--initial` causes all files in the directory to be deleted.

For more information, see [Section 17.5.10.1, “MySQL Cluster Disk Data Objects”](#).

- **Disk Data object creation parameters.** The next two parameters enable you—when starting the cluster for the first time—to cause a Disk Data log file group, tablespace, or both, to be created without the use of SQL statements.

- **`InitialLogFileGroup`**

This parameter can be used to specify a log file group that is created when performing an initial start of the cluster. `InitialLogFileGroup` is specified as shown here:

```
InitialLogFileGroup = [name=name;] [undo_buffer_size=size;] file-specification-list
file-specification-list:
 file-specification[; file-specification[; ...]]
file-specification:
 filename:size
```

The `name` of the log file group is optional and defaults to `DEFAULT-LG`. The `undo_buffer_size` is also optional; if omitted, it defaults to `64M`. Each `file-specification` corresponds to an undo log file, and at least one must be specified in the `file-specification-list`. Undo log files are placed according to any values that have been set for `FileSystemPath`, `FileSystemPathDD`, and `FileSystemPathUndoFiles`, just as if they had been created as the result of a `CREATE LOGFILE GROUP` or `ALTER LOGFILE GROUP` statement.

Consider the following example:

```
InitialLogFileGroup = name=LG1; undo_buffer_size=128M; undo1.log:250M; undo2.log:150M
```

This is equivalent to the following SQL statements:

```
CREATE LOGFILE GROUP LG1
 ADD UNDOFILE 'undo1.log'
 INITIAL_SIZE 250M
 UNDO_BUFFER_SIZE 128M
 ENGINE NDBCLUSTER;

ALTER LOGFILE GROUP LG1
 ADD UNDOFILE 'undo2.log'
 INITIAL_SIZE 150M
 ENGINE NDBCLUSTER;
```

This logfile group is created when the data nodes are started with `--initial`.

This parameter, if used, should always be set in the `[ndbd default]` section of the `config.ini` file. The behavior of a MySQL Cluster when different values are set on different data nodes is not defined.

- **`InitialTablespace`**

This parameter can be used to specify a MySQL Cluster Disk Data tablespace that is created when performing an initial start of the cluster. `InitialTablespace` is specified as shown here:

```
InitialTablespace = [name=name;] [extent_size=size;] file-specification-list
```

The `name` of the tablespace is optional and defaults to `DEFAULT-TS`. The `extent_size` is also optional; it defaults to

**1M.** The *file-specification-list* uses the same syntax as shown with the `InitialLogfileGroup` parameter, the only difference being that each *file-specification* used with `InitialTablespace` corresponds to a data file. At least one must be specified in the *file-specification-list*. Data files are placed according to any values that have been set for `FileSystemPath`, `FileSystemPathDD`, and `FileSystemPathDataFiles`, just as if they had been created as the result of a `CREATE TABLESPACE` or `ALTER TABLESPACE` statement.

For example, consider the following line specifying `InitialTablespace` in the `[ndbd default]` section of the `config.ini` file (as with `InitialLogfileGroup`, this parameter should always be set in the `[ndbd default]` section, as the behavior of a MySQL Cluster when different values are set on different data nodes is not defined):

```
InitialTablespace = name=TS1; extent_size=8M; data1.dat:2G; data2.dat:4G
```

This is equivalent to the following SQL statements:

```
CREATE TABLESPACE TS1
 ADD DATAFILE 'data1.dat'
 EXTENT_SIZE 8M
 INITIAL_SIZE 2G
 ENGINE NDBCCLUSTER;

ALTER TABLESPACE TS1
 ADD UNDOFILE 'data2.dat'
 INITIAL_SIZE 4G
 ENGINE NDBCCLUSTER;
```

This tablespace is created when the data nodes are started with `--initial`, and can be used whenever creating MySQL Cluster Disk Data tables thereafter.

**Disk Data and GCP Stop errors.** Errors encountered when using Disk Data tables such as `NODE NODEID KILLED THIS NODE BECAUSE GCP STOP WAS DETECTED` (error 2303) are often referred to as “GCP stop errors”. Such errors occur when the redo log is not flushed to disk quickly enough; this is usually due to slow disks and insufficient disk throughput.

You can help prevent these errors from occurring by using faster disks, and by placing Disk Data files on a separate disk from the data node filesystem. Reducing the value of `TimeBetweenGlobalCheckpoints` tends to decrease the amount of data to be written for each global checkpoint, and so may provide some protection against redo log buffer overflows when trying to write a global checkpoint; however, reducing this value also permits less time in which to write the GCP, so this must be done with caution.

In addition, adjusting the cluster configuration as discussed here can also help:

- **MySQL Cluster NDB 6.2 and 6.3.** When working with large amounts of data on disk under high load, the default value for `DiskPageBufferMemory` may not be large enough. In such cases, you should increase its value to include most of the memory available to the data nodes after accounting for index memory, data memory, internal buffers, and memory needed by the data node host operating system.

You can use this formula as a guide:

```
DiskPageBufferMemory
 = 0.8
 x (
 [total memory]
 - ([operating system memory] + [buffer memory] + DataMemory + IndexMemory)
)
```

Once you have established that sufficient memory is reserved for `DataMemory`, `IndexMemory`, NDB internal buffers, and operating system overhead, it is possible (and sometimes desirable) to allocate more than the above amount of the remainder to `DiskPageBufferMemory`.

- **MySQL Cluster NDB 7.X.** In addition to the considerations given for `DiskPageBufferMemory` as explained in the previous item, it is also very important that the `DiskIOThreadPool` configuration parameter be set correctly; having `DiskIOThreadPool` set too high is very likely to cause GCP stop errors ([Bug#37227](#)).

**Parameters for configuring send buffer memory allocation (MySQL Cluster NDB 7.0).** Beginning with MySQL Cluster NDB 6.4.0, send buffer memory is allocated dynamically from a memory pool shared between all transporters, which means that the size of the send buffer can be adjusted as necessary. (Previously, the NDB kernel used a fixed-size send buffer for every node in the cluster, which was allocated when the node started and could not be changed while the node was running.) The following data node configuration parameters were added in MySQL Cluster NDB 6.4.0 to permit the setting of limits on this memory allocation; this change is reflected by the addition of the configuration parameters `TotalSendBufferMemory` and `OverLoadLimit`, as well as a change in how the existing `SendBufferMemory` configuration parameter is used. For more information, see [Section 10.1.1, “Send Buffer Memory Allocation”](#).

tion 17.3.2.13, “Configuring MySQL Cluster Send Buffer Parameters”.

- **TotalSendBufferMemory**

This parameter is available beginning with MySQL Cluster NDB 6.4.0. It is used to determine the total amount of memory to allocate on this node for shared send buffer memory among all configured transporters.

If this parameter is set, its minimum permitted value is 256KB; the maximum is 4294967039.

- **ReservedSendBufferMemory**

This parameter is present in `NDBCLUSTER` source code beginning with MySQL Cluster NDB 6.4.0. However, it is not currently enabled.

For more detailed information about the behavior and use of `TotalSendBufferMemory` and about configuring send buffer memory parameters in MySQL Cluster NDB 6.4.0 and later, see [Section 17.3.2.13, “Configuring MySQL Cluster Send Buffer Parameters”](#).

**Note**

Previous to MySQL Cluster NDB 7.0, to add new data nodes to a MySQL Cluster, it is necessary to shut down the cluster completely, update the `config.ini` file, and then restart the cluster (that is, you must perform a system restart). All data node processes must be started with the `--initial` option.

Beginning with MySQL Cluster NDB 7.0, it is possible to add new data node groups to a running cluster online. See [Section 17.5.11, “Adding MySQL Cluster Data Nodes Online”](#), for more information.

**Controlling restart attempts.** Beginning in MySQL Cluster NDB 6.2.19, MySQL Cluster NDB 6.3.37, MySQL Cluster NDB 7.0.18, and MySQL Cluster NDB 7.1.7, it is possible to exercise more finely-grained control over restart attempts by data nodes when they fail to start using two data node configuration parameters added in these releases. `MaxStartFailRetries` limits the total number of retries made before giving up on starting the data node; `StartFailRetryDelay` sets the number of seconds between retry attempts, as described in the following list:

- **StartFailRetryDelay**

<b>Version Introduced</b>	5.1.47-ndb-7.1.7						
<b>Restart Type</b>	node						
	<b>Permitted Values</b> <table border="1"> <tr> <td><b>Type</b></td><td>numeric</td></tr> <tr> <td><b>Default</b></td><td>0</td></tr> <tr> <td><b>Range</b></td><td>0-4G</td></tr> </table>	<b>Type</b>	numeric	<b>Default</b>	0	<b>Range</b>	0-4G
<b>Type</b>	numeric						
<b>Default</b>	0						
<b>Range</b>	0-4G						
	<b>Permitted Values</b> <table border="1"> <tr> <td><b>Type</b></td><td>numeric</td></tr> <tr> <td><b>Default</b></td><td>0</td></tr> <tr> <td><b>Range</b></td><td>0-4G</td></tr> </table>	<b>Type</b>	numeric	<b>Default</b>	0	<b>Range</b>	0-4G
<b>Type</b>	numeric						
<b>Default</b>	0						
<b>Range</b>	0-4G						
	<b>Permitted Values</b> <table border="1"> <tr> <td><b>Type</b></td><td>numeric</td></tr> <tr> <td><b>Default</b></td><td>0</td></tr> <tr> <td><b>Range</b></td><td>0-4G</td></tr> </table>	<b>Type</b>	numeric	<b>Default</b>	0	<b>Range</b>	0-4G
<b>Type</b>	numeric						
<b>Default</b>	0						
<b>Range</b>	0-4G						
	<b>Permitted Values</b> <table border="1"> <tr> <td><b>Type</b></td><td>numeric</td></tr> <tr> <td><b>Default</b></td><td>0</td></tr> <tr> <td><b>Range</b></td><td>0-4G</td></tr> </table>	<b>Type</b>	numeric	<b>Default</b>	0	<b>Range</b>	0-4G
<b>Type</b>	numeric						
<b>Default</b>	0						
<b>Range</b>	0-4G						

Beginning in MySQL Cluster NDB 6.2.19, MySQL Cluster NDB 6.3.37, MySQL Cluster NDB 7.0.18, and MySQL Cluster NDB 7.1.7, it is possible to set the number of seconds between restart attempts by the data node in the event of failure on startup. The default is 0 (no delay).

**Note**

This parameter is ignored unless `StartOnError` is equal to 0.

- `MaxStartFailRetries`

<b>Version Introduced</b>	5.1.47-ndb-7.1.7
<b>Restart Type</b>	node
	<b>Permitted Values</b>
	<b>Type</b> numeric
	<b>Default</b> 3
	<b>Range</b> 0–4G
	<b>Permitted Values</b>
	<b>Type</b> numeric
	<b>Default</b> 3
	<b>Range</b> 0–4G
	<b>Permitted Values</b>
	<b>Type</b> numeric
	<b>Default</b> 3
	<b>Range</b> 0–4G
	<b>Permitted Values</b>
	<b>Type</b> numeric
	<b>Default</b> 3
	<b>Range</b> 0–4G

Beginning in MySQL Cluster NDB 6.2.19, MySQL Cluster NDB 6.3.37, MySQL Cluster NDB 7.0.18, and MySQL Cluster NDB 7.1.7, it is possible to limit the number restart attempts made by the data node in the event that it fails on startup. The default is 3 attempts.

**Note**

This parameter is ignored unless `StartOnError` is equal to 0.

### 17.3.2.7. Defining SQL and Other API Nodes in a MySQL Cluster

The `[mysqld]` and `[api]` sections in the `config.ini` file define the behavior of the MySQL servers (SQL nodes) and other applications (API nodes) used to access cluster data. None of the parameters shown is required. If no computer or host name is provided, any host can use this SQL or API node.

Generally speaking, a `[mysqld]` section is used to indicate a MySQL server providing an SQL interface to the cluster, and an `[api]` section is used for applications other than `mysqld` processes accessing cluster data, but the two designations are actually synonymous; you can, for instance, list parameters for a MySQL server acting as an SQL node in an `[api]` section.

**Note**

For a discussion of MySQL server options for MySQL Cluster, see [Section 17.3.4.2, “mysqld Command Options for MySQL Cluster”](#); for information about MySQL server system variables relating to MySQL Cluster, see [Section 17.3.4.3, “MySQL Cluster System Variables”](#).

- `Id`

<b>Restart Type</b>	node
---------------------	------

<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	
<b>Range</b>	1–63

The `Id` is an integer value used to identify the node in all cluster internal messages. Prior to MySQL Cluster NDB 6.1.1, the permitted range of values for this parameter was 1 to 63 inclusive. Beginning with MySQL Cluster NDB 6.1.1, the permitted range is 1 to 255 inclusive. This value must be unique for each node in the cluster, regardless of the type of node.

### Note

Data node IDs must be less than 49, regardless of the MySQL Cluster version used. If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for API nodes (and management nodes) to values greater than 48.

This parameter can also be written as `NodeId`, although the short form is sufficient (and preferred for this reason).

- [ExecuteOnComputer](#)

<b>Restart Type</b>	system
<b>Permitted Values</b>	
<b>Type</b>	string
<b>Default</b>	
<b>Range</b>	–

This refers to the `Id` set for one of the computers (hosts) defined in a `[computer]` section of the configuration file.

- [HostName](#)

<b>Restart Type</b>	system
<b>Permitted Values</b>	
<b>Type</b>	string
<b>Default</b>	
<b>Range</b>	–

Specifying this parameter defines the hostname of the computer on which the SQL node (API node) is to reside. To specify a hostname, either this parameter or `ExecuteOnComputer` is required.

If no `HostName` or `ExecuteOnComputer` is specified in a given `[mysql]` or `[api]` section of the `config.ini` file, then an SQL or API node may connect using the corresponding “slot” from any host which can establish a network connection to the management server host machine. *This differs from the default behavior for data nodes, where `localhost` is assumed for `HostName` unless otherwise specified.*

- [ArbitrationRank](#)

<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	0
<b>Range</b>	0–2

This parameter defines which nodes can act as arbitrators. Both MGM nodes and SQL nodes can be arbitrators. A value of 0 means that the given node is never used as an arbitrator, a value of 1 gives the node high priority as an arbitrator, and a value of 2 gives it low priority. A normal configuration uses the management server as arbitrator, setting its `ArbitrationRank` to 1

(the default for management nodes) and those for all SQL nodes to 0 (the default for SQL nodes).

Beginning with MySQL 5.1.16 and MySQL Cluster NDB 6.1.3, it is possible to disable arbitration completely by setting [ArbitrationRank](#) to 0 on all management and SQL nodes. In MySQL Cluster NDB 7.0.7 and later releases, you can also control arbitration by overriding this parameter; to do this, set the [Arbitration](#) parameter in the [\[ndbd default\]](#) section of the [config.ini](#) global configuration file.

- [ArbitrationDelay](#)

<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	0
<b>Range</b>	0–4G

Setting this parameter to any other value than 0 (the default) means that responses by the arbitrator to arbitration requests will be delayed by the stated number of milliseconds. It is usually not necessary to change this value.

- [BatchByteSize](#)

<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	32K
<b>Range</b>	1024–1M

For queries that are translated into full table scans or range scans on indexes, it is important for best performance to fetch records in properly sized batches. It is possible to set the proper size both in terms of number of records ([BatchSize](#)) and in terms of bytes ([BatchByteSize](#)). The actual batch size is limited by both parameters.

The speed at which queries are performed can vary by more than 40% depending upon how this parameter is set. In future releases, MySQL Server will make educated guesses on how to set parameters relating to batch size, based on the query type.

This parameter is measured in bytes and by default is equal to 32KB.

- [BatchSize](#)

<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	64
<b>Range</b>	1–992

This parameter is measured in number of records and is by default set to 64. The maximum size is 992.

- [HeartbeatThreadPriority](#)

Beginning with MySQL Cluster NDB 6.3.32, MySQL Cluster NDB 7.0.13, and MySQL Cluster NDB 7.1.2, it is possible to use this parameter to set the scheduling policy and priority of heartbeat threads for management and API nodes.

The syntax for setting this parameter is shown here:

```
HeartbeatThreadPriority = policy[, priority]
policy:
 {FIFO | RR}
```

When setting this parameter, you must specify a policy. This is one of [FIFO](#) (first in, first in) or [RR](#) (round robin). This fol-

lowed optionally by the priority (an integer).

- [MaxScanBatchSize](#)

<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	<a href="#">numeric</a>
<b>Default</b>	<a href="#">256K</a>
<b>Range</b>	<a href="#">32K-16M</a>

The batch size is the size of each batch sent from each data node. Most scans are performed in parallel to protect the MySQL Server from receiving too much data from many nodes in parallel; this parameter sets a limit to the total batch size over all nodes.

The default value of this parameter is set to 256KB. Its maximum size is 16MB.

- [TotalSendBufferMemory](#)

<b>Version Introduced</b>	5.1.30-ndb-6.4.0
<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	<a href="#">numeric</a>
<b>Default</b>	<a href="#">256K</a>
<b>Range</b>	<a href="#">0-4G</a>

This parameter is available beginning with MySQL Cluster NDB 6.4.0. It is used to determine the total amount of memory to allocate on this node for shared send buffer memory among all configured transporters.

If this parameter is set, its minimum permitted value is 256KB; the maximum is 4294967039. For more detailed information about the behavior and use of [TotalSendBufferMemory](#) and configuring send buffer memory parameters in MySQL Cluster NDB 6.4.0 and later, see [Section 17.3.2.13, “Configuring MySQL Cluster Send Buffer Parameters”](#).

- [AutoReconnect](#)

<b>Version Introduced</b>	5.1.35-ndb-7.0.7
<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	<a href="#">boolean</a>
<b>Default</b>	<a href="#">false</a>
<b>Range</b>	<a href="#">false-true</a>

This parameter is available beginning with MySQL Cluster NDB 6.3.26 and MySQL Cluster NDB 7.0.7. By default, its value is [false](#), which forces disconnected API nodes (including MySQL Servers acting as SQL nodes) to use a new connection to the cluster rather than attempting to re-use an existing one, which can cause problems when using dynamically-allocated node IDs. ([Bug#45921](#))

### Note

This parameter can be overridden using the NDB API. For more information, see [Ndb\\_cluster\\_connection::set\\_auto\\_reconnect\(\)](#), and [Ndb\\_cluster\\_connection::get\\_auto\\_reconnect\(\)](#).

You can obtain some information from a MySQL server running as a Cluster SQL node using [SHOW STATUS](#) in the [mysql](#) client, as shown here:

```
mysql> SHOW STATUS LIKE 'ndb%';
+-----+-----+
```

Variable_name	Value
Ndb_cluster_node_id	5
Ndb_config_from_host	192.168.0.112
Ndb_config_from_port	1186
Ndb_number_of_storage_nodes	4

4 rows in set (0.02 sec)

For information about these Cluster system status variables, see [Section 5.1.6, “Server Status Variables”](#).

#### Note

To add new SQL or API nodes to the configuration of a running MySQL Cluster, it is necessary to perform a rolling restart of all cluster nodes after adding new `[mysqld]` or `[api]` sections to the `config.ini` file (or files, if you are using more than one management server). This must be done before the new SQL or API nodes can connect to the cluster.

It is *not* necessary to perform any restart of the cluster if new SQL or API nodes can employ previously unused API slots in the cluster configuration to connect to the cluster.

### 17.3.2.8. MySQL Cluster TCP/IP Connections

TCP/IP is the default transport mechanism for all connections between nodes in a MySQL Cluster. Normally it is not necessary to define TCP/IP connections; MySQL Cluster automatically sets up such connections for all data nodes, management nodes, and SQL or API nodes.

#### Note

For an exception to this rule, see [Section 17.3.2.9, “MySQL Cluster TCP/IP Connections Using Direct Connections”](#).

To override the default connection parameters, it is necessary to define a connection using one or more `[tcp]` sections in the `config.ini` file. Each `[tcp]` section explicitly defines a TCP/IP connection between two MySQL Cluster nodes, and must contain at a minimum the parameters `NodeId1` and `NodeId2`, as well as any connection parameters to override.

It is also possible to change the default values for these parameters by setting them in the `[tcp default]` section.

#### Important

Any `[tcp]` sections in the `config.ini` file should be listed *last*, following all other sections in the file. However, this is not required for a `[tcp default]` section. This requirement is a known issue with the way in which the `config.ini` file is read by the MySQL Cluster management server.

Connection parameters which can be set in `[tcp]` and `[tcp default]` sections of the `config.ini` file are listed here:

- `NodeId1`, `NodeId2`

To identify a connection between two nodes it is necessary to provide their node IDs in the `[tcp]` section of the configuration file. These are the same unique `Id` values for each of these nodes as described in [Section 17.3.2.7, “Defining SQL and Other API Nodes in a MySQL Cluster”](#).

- `OverloadLimit`

Beginning in MySQL Cluster NDB 6.4.0, this parameter can be used to determine the amount of unsent data that must be present in the send buffer before the connection is considered overloaded. See [Section 17.3.2.13, “Configuring MySQL Cluster Send Buffer Parameters”](#), for more information.

- `SendBufferMemory`

<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	256K
<b>Range</b>	64K–4G

TCP transporters use a buffer to store all messages before performing the send call to the operating system. When this buffer

reaches 64KB its contents are sent; these are also sent when a round of messages have been executed. To handle temporary overload situations it is also possible to define a bigger send buffer.

Prior to MySQL Cluster NDB 7.0, this parameter determines a fixed amount of memory allocated at startup for each configured TCP connection. Beginning with MySQL Cluster NDB 6.4.0, if this parameter is set explicitly, then the memory is not dedicated to each transporter; instead, the value used denotes the hard limit for how much memory (out of the total available memory—that is, [TotalSendBufferMemory](#)) that may be used by a single transporter. For more information about configuring dynamic transporter send buffer memory allocation in MySQL Cluster NDB 7.0 and later, see [Section 17.3.2.13, “Configuring MySQL Cluster Send Buffer Parameters”](#).

In MySQL Cluster NDB 6.4.3 and earlier, the default size of the send buffer was 256 KB; in MySQL Cluster NDB 7.0.4 and later, it is 2MB, which is the size recommended in most situations. The minimum size is 64 KB; the theoretical maximum is 4 GB.

- [SendSignalId](#)

<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	<a href="#">boolean</a>
<b>Default</b>	<a href="#">false (debug builds: true)</a>
<b>Range</b>	—

To be able to retrace a distributed message datagram, it is necessary to identify each message. When this parameter is set to [Y](#), message IDs are transported over the network. This feature is disabled by default in production builds, and enabled in [-debug](#) builds.

- [Checksum](#)

<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	<a href="#">boolean</a>
<b>Default</b>	<a href="#">false</a>
<b>Range</b>	—

This parameter is a boolean parameter (enabled by setting it to [Y](#) or [1](#), disabled by setting it to [N](#) or [0](#)). It is disabled by default. When it is enabled, checksums for all messages are calculated before they placed in the send buffer. This feature ensures that messages are not corrupted while waiting in the send buffer, or by the transport mechanism.

- [PortNumber \(OBSOLETE\)](#)

This formerly specified the port number to be used for listening for connections from other nodes. This parameter should no longer be used.

- [ReceiveBufferMemory](#)

<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	<a href="#">numeric</a>
<b>Default</b>	<a href="#">64K</a>
<b>Range</b>	<a href="#">16K-4G</a>

Specifies the size of the buffer used when receiving data from the TCP/IP socket.

In MySQL Cluster NDB 6.4.3 and earlier, the default value of this parameter was 64 KB; beginning with MySQL Cluster NDB 7.0.4, 2MB is the default. The minimum possible value is 16KB; the theoretical maximum is 4GB.

### 17.3.2.9. MySQL Cluster TCP/IP Connections Using Direct Connections

Setting up a cluster using direct connections between data nodes requires specifying explicitly the crossover IP addresses of the data nodes so connected in the `[tcp]` section of the cluster `config.ini` file.

In the following example, we envision a cluster with at least four hosts, one each for a management server, an SQL node, and two data nodes. The cluster as a whole resides on the `172.23.72.*` subnet of a LAN. In addition to the usual network connections, the two data nodes are connected directly using a standard crossover cable, and communicate with one another directly using IP addresses in the `1.1.0.*` address range as shown:

```
Management Server
[ndb_mgmd]
Id=1
HostName=172.23.72.20

SQL Node
[mysqld]
Id=2
HostName=172.23.72.21

Data Nodes
[ndbd]
Id=3
HostName=172.23.72.22

[ndbd]
Id=4
HostName=172.23.72.23

TCP/IP Connections
[tcp]
NodeId1=3
NodeId2=4
HostName1=1.1.0.1
HostName2=1.1.0.2
```

The `HostNameN` parameter, where `N` is an integer, is used only when specifying direct TCP/IP connections.

The use of direct connections between data nodes can improve the cluster's overall efficiency by enabling the data nodes to bypass an Ethernet device such as a switch, hub, or router, thus cutting down on the cluster's latency. It is important to note that to take the best advantage of direct connections in this fashion with more than two data nodes, you must have a direct connection between each data node and every other data node in the same node group.

### 17.3.2.10. MySQL Cluster Shared-Memory Connections

MySQL Cluster attempts to use the shared memory transporter and configure it automatically where possible. `[shm]` sections in the `config.ini` file explicitly define shared-memory connections between nodes in the cluster. When explicitly defining shared memory as the connection method, it is necessary to define at least `NodeId1`, `NodeId2` and `ShmKey`. All other parameters have default values that should work well in most cases.

#### Important

*SHM functionality is considered experimental only.* It is not officially supported in any current MySQL Cluster release, and testing results indicate that SHM performance is not appreciably greater than when using TCP/IP for the transporter.

For these reasons, you must determine for yourself or by using our free resources (forums, mailing lists) whether SHM can be made to work correctly in your specific case.

- `NodeId1`, `NodeId2`

To identify a connection between two nodes it is necessary to provide node identifiers for each of them, as `NodeId1` and `NodeId2`.

- `ShmKey`

<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	
<b>Range</b>	0-4G

When setting up shared memory segments, a node ID, expressed as an integer, is used to identify uniquely the shared memory segment to use for the communication. There is no default value.

- [ShmSize](#)

<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	1M
<b>Range</b>	64K–4G

Each SHM connection has a shared memory segment where messages between nodes are placed by the sender and read by the reader. The size of this segment is defined by [ShmSize](#). The default value is 1MB.

- [SendSignalId](#)

<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	boolean
<b>Default</b>	false
<b>Range</b>	-

To retrace the path of a distributed message, it is necessary to provide each message with a unique identifier. Setting this parameter to [Y](#) causes these message IDs to be transported over the network as well. This feature is disabled by default in production builds, and enabled in [-debug](#) builds.

- [Checksum](#)

<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	boolean
<b>Default</b>	true
<b>Range</b>	-

This parameter is a boolean ([Y/N](#)) parameter which is disabled by default. When it is enabled, checksums for all messages are calculated before being placed in the send buffer.

This feature prevents messages from being corrupted while waiting in the send buffer. It also serves as a check against data being corrupted during transport.

- [SigNum](#)

<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	
<b>Range</b>	0–4G

When using the shared memory transporter, a process sends an operating system signal to the other process when there is new data available in the shared memory. Should that signal conflict with an existing signal, this parameter can be used to change it. This is a possibility when using SHM due to the fact that different operating systems use different signal numbers.

The default value of [SigNum](#) is 0; therefore, it must be set to avoid errors in the cluster log when using the shared memory

transporter. Typically, this parameter is set to 10 in the [shm default] section of the config.ini file.

### 17.3.2.11. SCI Transport Connections in MySQL Cluster

[sci] sections in the config.ini file explicitly define SCI (Scalable Coherent Interface) connections between cluster nodes. Using SCI transporters in MySQL Cluster is supported only when the MySQL binaries are built using --with-ndb-sci=/your/path/to/SCI. The path should point to a directory that contains at a minimum lib and include directories containing SISCI libraries and header files. (See Section 17.3.5, “Using High-Speed Interconnects with MySQL Cluster” for more information about SCI.)

In addition, SCI requires specialized hardware.

It is strongly recommended to use SCI Transporters only for communication between ndbd processes. Note also that using SCI Transporters means that the ndbd processes never sleep. For this reason, SCI Transporters should be used only on machines having at least two CPUs dedicated for use by ndbd processes. There should be at least one CPU per ndbd process, with at least one CPU left in reserve to handle operating system activities.

- `NodeId1,NodeId2`

To identify a connection between two nodes it is necessary to provide node identifiers for each of them, as `NodeId1` and `NodeId2`.

- `Host1SciId0`

<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	
<b>Range</b>	0–4G

This identifies the SCI node ID on the first Cluster node (identified by `NodeId1`).

- `Host1SciId1`

<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	0
<b>Range</b>	0–4G

It is possible to set up SCI Transporters for failover between two SCI cards which then should use separate networks between the nodes. This identifies the node ID and the second SCI card to be used on the first node.

- `Host2SciId0`

<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	
<b>Range</b>	0–4G

This identifies the SCI node ID on the second Cluster node (identified by `NodeId2`).

- `Host2SciId1`

<b>Restart Type</b>	node
<b>Permitted Values</b>	

<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	0
<b>Range</b>	0–4G

When using two SCI cards to provide failover, this parameter identifies the second SCI card to be used on the second node.

- [SharedBufferSize](#)

<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	10M
<b>Range</b>	64K–4G

Each SCI transporter has a shared memory segment used for communication between the two nodes. Setting the size of this segment to the default value of 1MB should be sufficient for most applications. Using a smaller value can lead to problems when performing many parallel inserts; if the shared buffer is too small, this can also result in a crash of the `ndbd` process.

- [SendLimit](#)

<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	8K
<b>Range</b>	128–32K

A small buffer in front of the SCI media stores messages before transmitting them over the SCI network. By default, this is set to 8KB. Our benchmarks show that performance is best at 64KB but 16KB reaches within a few percent of this, and there was little if any advantage to increasing it beyond 8KB.

- [SendSignalId](#)

<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	boolean
<b>Default</b>	true
<b>Range</b>	–

To trace a distributed message it is necessary to identify each message uniquely. When this parameter is set to `Y`, message IDs are transported over the network. This feature is disabled by default in production builds, and enabled in `-debug` builds.

- [Checksum](#)

<b>Restart Type</b>	node
<b>Permitted Values</b>	
<b>Type</b>	boolean
<b>Default</b>	false
<b>Range</b>	–

This parameter is a boolean value, and is disabled by default. When `Checksum` is enabled, checksums are calculated for all messages before they are placed in the send buffer. This feature prevents messages from being corrupted while waiting in the send buffer. It also serves as a check against data being corrupted during transport.

### 17.3.2.12. Configuring MySQL Cluster Parameters for Local Checkpoints

The parameters discussed in [Logging and Checkpointing](#) and in [Data Memory, Index Memory, and String Memory](#) that are used to configure local checkpoints for a MySQL Cluster do not exist in isolation, but rather are very much interdependent on each other. In this section, we illustrate how these parameters—including `DataMemory`, `IndexMemory`, `NoOfDiskPagesToDiskAfterRestartTUP`, `NoOfDiskPagesToDiskAfterRestartACC`, and `NoOfFragmentLogFile`s—relate to one another in a working Cluster.

#### Important

The parameters `NoOfDiskPagesToDiskAfterRestartTUP` and `NoOfDiskPagesToDiskAfterRestartACC` were deprecated in MySQL 5.1.6. From MySQL 5.1.6 through 5.1.11, disk writes during LCPs took place at the maximum speed possible. Beginning with MySQL 5.1.12, the speed and throughput for LCPs are controlled using the parameters `DiskSyncSize`, `DiskCheckpointSpeed`, and `DiskCheckpointSpeedInRestart`. See [Section 17.3.2.6, “Defining MySQL Cluster Data Nodes”](#).

In this example, we assume that our application performs the following numbers of types of operations per hour:

- 50000 selects
- 15000 inserts
- 15000 updates
- 15000 deletes

We also make the following assumptions about the data used in the application:

- We are working with a single table having 40 columns.
- Each column can hold up to 32 bytes of data.
- A typical `UPDATE` run by the application affects the values of 5 columns.
- No `NULL` values are inserted by the application.

A good starting point is to determine the amount of time that should elapse between local checkpoints (LCPs). It is worth noting that, in the event of a system restart, it takes 40-60 percent of this interval to execute the REDO log—for example, if the time between LCPs is 5 minutes (300 seconds), then it should take 2 to 3 minutes (120 to 180 seconds) for the REDO log to be read.

The maximum amount of data per node can be assumed to be the size of the `DataMemory` parameter. In this example, we assume that this is 2 GB. The `NoOfDiskPagesToDiskAfterRestartTUP` parameter represents the amount of data to be checkpointed per unit time—however, this parameter is actually expressed as the number of 8K memory pages to be checkpointed per 100 milliseconds. 2 GB per 300 seconds is approximately 6.8 MB per second, or 700 KB per 100 milliseconds, which works out to roughly 85 pages per 100 milliseconds.

Similarly, we can calculate `NoOfDiskPagesToDiskAfterRestartACC` in terms of the time for local checkpoints and the amount of memory required for indexes—that is, the `IndexMemory`. Assuming that we permit 512 MB for indexes, this works out to approximately 20 8-KB pages per 100 milliseconds for this parameter.

Next, we need to determine the number of REDO log files required—that is, fragment log files—the corresponding parameter being `NoOfFragmentLogFile`s. We need to make sure that there are sufficient REDO log files for keeping records for at least 3 local checkpoints (in MySQL Cluster NDB 6.3.8 and later, we need only allow for 2 local checkpoints). In a production setting, there are always uncertainties—for instance, we cannot be sure that disks always operate at top speed or with maximum throughput. For this reason, it is best to err on the side of caution, so we double our requirement and calculate a number of fragment log files which should be enough to keep records covering 6 local checkpoints (in MySQL Cluster NDB 6.3.8 and later, a number of fragment log files accommodating 4 local checkpoints should be sufficient).

It is also important to remember that the disk also handles writes to the REDO log, so if you find that the amount of data being written to disk as determined by the values of `NoOfDiskPagesToDiskAfterRestartACC` and `NoOfDiskPagesToDiskAfterRestartTUP` is approaching the amount of disk bandwidth available, you may wish to increase the

time between local checkpoints.

Given 5 minutes (300 seconds) per local checkpoint, this means that we need to support writing log records at maximum speed for  $6 * 300 = 1800$  seconds (*MySQL Cluster NDB 6.3.8 and later*:  $4 * 300 = 1200$  seconds). The size of a REDO log record is 72 bytes plus 4 bytes per updated column value plus the maximum size of the updated column, and there is one REDO log record for each table record updated in a transaction, on each node where the data reside. Using the numbers of operations set out previously in this section, we derive the following:

- 50000 `SELECT` statements per hour yields 0 log records (and thus 0 bytes), since `SELECT` statements are not recorded in the REDO log.
- 15000 `DELETE` statements per hour is approximately 5 delete operations per second. (Since we wish to be conservative in our estimate, we round up here and in the following calculations.) No columns are updated by deletes, so these statements consume only 5 operations \* 72 bytes per operation = 360 bytes per second.
- 15000 `UPDATE` statements per hour is roughly the same as 5 updates per second. Each update uses 72 bytes, plus 4 bytes per column \* 5 columns updated, plus 32 bytes per column \* 5 columns—this works out to  $72 + 20 + 160 = 252$  bytes per operation, and multiplying this by 5 operation per second yields 1260 bytes per second.
- 15000 `INSERT` statements per hour is equivalent to 5 insert operations per second. Each insert requires REDO log space of 72 bytes, plus 4 bytes per record \* 40 columns, plus 32 bytes per column \* 40 columns, which is  $72 + 160 + 1280 = 1512$  bytes per operation. This times 5 operations per second yields 7560 bytes per second.

So the total number of REDO log bytes being written per second is approximately  $0 + 360 + 1260 + 7560 = 9180$  bytes. Multiplied by 1800 seconds, this yields 16524000 bytes required for REDO logging, or approximately 15.75 MB. The unit used for `NoOfFragmentLogFile`s represents a set of 4 16-MB log files—that is, 64 MB. Thus, the minimum value (3) for this parameter is sufficient for the scenario envisioned in this example, since  $3 \times 64 = 192$  MB, or about 12 times what is required; the default value of 8 (or 512 MB) is more than ample in this case.

### 17.3.2.13. Configuring MySQL Cluster Send Buffer Parameters

Formerly, the NDB kernel used a send buffer whose size was fixed at 2MB for every node in the cluster, which was allocated when the node started. Because the size of this buffer could not be changed after the cluster was started, it was necessary to make it large enough in advance to accomodate the maximum possible load on any transporter socket. However, this was an inefficient use of memory, since much of it often went unused, and could result in large amounts of resources being wasted when scaling up to many API nodes.

Beginning with MySQL Cluster NDB 7.0, this problem is solved by employing a unified send buffer whose memory is allocated dynamically from a pool shared by all transporters. This means that the size of the send buffer can be adjusted as necessary. Configuration of the unified send buffer can accomplished by setting the following parameters:

- **TotalSendBufferMemory**. This parameter can be set for all types of MySQL Cluster nodes—that is, it can be set in the `[ndbd]`, `[mgm]`, and `[api]` (or `[mysql]`) sections of the `config.ini` file. It represents the total amount of memory (in bytes) to be allocated by each node for which it is set for use among all configured transporters. If set, its minimum is 256KB; the maximum is 4294967039.

To be backward-compatible with existing configurations, this parameter takes as its default value the sum of the maximum send buffer sizes of all configured transporters, plus an additional 32KB (one page) per transporter. The maximum depends on the type of transporter, as shown in the following table:

Transporter	Maxmimum Send Buffer Size (bytes)
TCP	<code>SendBufferMemory</code> (default = 2M)
SCI	<code>SendLimit</code> (default = 8K) plus 16K
SHM	20K

This enables existing configurations to function in close to the same way as they did with MySQL Cluster NDB 6.3 and earlier, with the same amount of memory and send buffer space available to each transporter. However, memory that is unused by one transporter is not available to other transporters.

- **OverloadLimit**. This parameter is used in the `config.ini` file `[tcp]` section, and denotes the amount of unsent data (in bytes) that must be present in the send buffer before the connection is considered overloaded. When such an overload condition occurs, transactions that affect the overloaded connection fail with NDB API Error 1218 (`SEND BUFFERS OVERLOADED IN NDB KERNEL`) until the overload status passes. The default value is 0, in which case the effective overload limit is calculated as `SendBufferMemory * 0.8` for a given connection. The maximum value for this parameter is 4G.

- **SendBufferMemory.** In MySQL Cluster NDB 6.3 and earlier, this TCP configuration parameter represented the amount of memory allocated at startup for each configured TCP connection. Beginning with MySQL Cluster NDB 7.0, this value denotes a hard limit for the amount of memory that may be used by a single transporter out of the entire pool specified by **TotalSendBufferMemory**. However, the sum of **SendBufferMemory** for all configured transporters may be greater than the **TotalSendBufferMemory** that is set for a given node. This is a way to save memory when many nodes are in use, as long as the maximum amount of memory is never required by all transporters at the same time.

### 17.3.3. Overview of MySQL Cluster Configuration Parameters

The next four sections provide summary tables of MySQL Cluster configuration parameters used in the `config.ini` file to govern the cluster's functioning. Each table lists the parameters for one of the Cluster node process types (`ndbd`, `ndb_mgmd`, and `mysqlld`), and includes the parameter's type as well as its default, minimum, and maximum values as applicable.

These tables also indicate what type of restart is required (node restart or system restart)—and whether the restart must be done with `--initial`—to change the value of a given configuration parameter.

When performing a node restart or an initial node restart, all of the cluster's data nodes must be restarted in turn (also referred to as a *rolling restart*). It is possible to update cluster configuration parameters marked as `node` online—that is, without shutting down the cluster—in this fashion. An initial node restart requires restarting each `ndbd` process with the `--initial` option.

A system restart requires a complete shutdown and restart of the entire cluster. An initial system restart requires taking a backup of the cluster, wiping the cluster file system after shutdown, and then restoring from the backup following the restart.

In any cluster restart, all of the cluster's management servers must be restarted for them to read the updated configuration parameter values.

#### Important

Values for numeric cluster parameters can generally be increased without any problems, although it is advisable to do so progressively, making such adjustments in relatively small increments. Many of these can be increased online, using a rolling restart.

However, decreasing the values of such parameters—whether this is done using a node restart, node initial restart, or even a complete system restart of the cluster—is not to be undertaken lightly; it is recommended that you do so only after careful planning and testing. This is especially true with regard to those parameters that relate to memory usage and disk space, such as `MaxNoOfTables`, `MaxNoOfOrderedIndexes`, and `MaxNoOfUniqueHashIndexes`. In addition, it is the generally the case that configuration parameters relating to memory and disk usage can be raised using a simple node restart, but they require an initial node restart to be lowered.

Because some of these parameters can be used for configuring more than one type of cluster node, they may appear in more than one of the tables.

#### Note

`4294967039`—which often appears as a maximum value in these tables—is defined in the `NDBCLUSTER` sources as `MAX_INT_RNIL` and is equal to `0xFFFFFFFF`, or  $2^{32} - 2^8 - 1$ .

#### 17.3.3.1. MySQL Cluster Data Node Configuration Parameters

The summary table in this section provides information about parameters used in the `[ndbd]` or `[ndbd default]` sections of a `config.ini` file for configuring MySQL Cluster data nodes. For detailed descriptions and other additional information about each of these parameters, see [Section 17.3.2.6, “Defining MySQL Cluster Data Nodes”](#).

Beginning with MySQL Cluster NDB 6.4.0, these parameters also apply to `ndbmttd`, which is a multi-threaded version of `ndbd`. For more information, see [Section 17.4.3, “ndbmttd — The MySQL Cluster Data Node Daemon \(Multi-Threaded\)”](#).

**Restart types.** Changes in MySQL Cluster configuration parameters do not take effect until the cluster is restarted. The type of restart required to change a given parameter is indicated in the summary table as follows:

- **N**—Node restart: The parameter can be updated using a rolling restart (see [Section 17.2.5.1, “Performing a Rolling Restart of a MySQL Cluster”](#)).
- **S**—System restart: The cluster must be shut down completely, then restarted, to effect a change in this parameter.
- **I**—Initial restart: Data nodes must be restarted using the `--initial` option.

For more information about restart types, see [Section 17.3.3, “Overview of MySQL Cluster Configuration Parameters”](#).

**Table 17.1. Data Node Configuration Parameters**

Name	Type/Units	Default	Min Value	Max Value	Restart Type
Arbitration	{Disabled Default WaitExternal}	Default			N

UndoIndexBuffer	unsigned	2M	1M	4G	N

### Note

Prior to MySQL Cluster NDB 7.0, to add new data nodes to a MySQL Cluster, it is necessary to shut down the cluster completely, update the `config.ini` file, and then restart the cluster, starting all data node processes using the `-initial` option—that is, you must perform a system restart.

Beginning in MySQL Cluster NDB 7.0, it is possible to add new data node groups to a running cluster online. For more information, see [Section 17.5.11, “Adding MySQL Cluster Data Nodes Online”](#).

### 17.3.3.2. MySQL Cluster Management Node Configuration Parameters

The summary table in this section provides information about parameters used in the `[ndb_mgmd]` or `[mgm]` sections of a `config.ini` file for configuring MySQL Cluster management nodes. For detailed descriptions and other additional information about each of these parameters, see [Section 17.3.2.5, “Defining a MySQL Cluster Management Server”](#).

**Restart types.** Changes in MySQL Cluster configuration parameters do not take effect until the cluster is restarted. The type of restart required to change a given parameter is indicated in the summary table as follows:

- **N**—Node restart: The parameter can be updated using a rolling restart (see [Section 17.2.5.1, “Performing a Rolling Restart of a MySQL Cluster”](#)).
- **S**—System restart: The cluster must be shut down completely, then restarted, to effect a change in this parameter.
- **I**—Initial restart: Data nodes must be restarted using the `--initial` option.

For more information about restart types, see [Section 17.3.3, “Overview of MySQL Cluster Configuration Parameters”](#).

**Table 17.2. Management Node Configuration Parameters**

Name	Type/Units	Default	Min Value	Max Value	Restart Type
<code>ArbitrationDelay</code>	milliseconds			4G	N
<code>ArbitrationRank</code>	0-2	1		2	N
<code>DataDir</code>	path	.			N
<code>ExecuteOnComputer</code>	name				S
<code>HeartbeatThreadPriority</code>		none			
<code>HostName</code>	name or IP				S
<code>Id</code>	unsigned		1	63	N
<code>LogDestination</code>	{CONSOLE SYSLOG FILE}	FILE:filename=ndb_nodeid_cluster.log,maxsize=100000,maxfiles=6			N
<code>MaxNoOfSavedEvents</code>	unsigned	100		4G	N
<code>PortNumber</code>	unsigned	1186		64K	N
<code>PortNumberStats</code>	unsigned			64K	N
wan		false			N

#### Note

After making changes in a management node's configuration, it is necessary to perform a rolling restart of the cluster for the new configuration to take effect. See [Section 17.3.2.5, “Defining a MySQL Cluster Management Server”](#), for more information.

To add new management servers to a running MySQL Cluster, it is also necessary perform a rolling restart of all cluster nodes after modifying any existing `config.ini` files. For more information about issues arising when using multiple management nodes, see [Section 17.1.5.10, “Limitations Relating to Multiple MySQL Cluster Nodes”](#).

### 17.3.3.3. MySQL Cluster SQL Node and API Node Configuration Parameters

The summary table in this section provides information about parameters used in the `[SQL]` and `[api]` sections of a `config.ini` file for configuring MySQL Cluster SQL nodes and API nodes. For detailed descriptions and other additional information about each of these parameters, see [Section 17.3.2.7, “Defining SQL and Other API Nodes in a MySQL Cluster”](#).

#### Note

For a discussion of MySQL server options for MySQL Cluster, see [Section 17.3.4.2, “mysql Command Options for MySQL Cluster”](#); for information about MySQL server system variables relating to MySQL Cluster, see [Section 17.3.4.3, “MySQL Cluster System Variables”](#).

**Restart types.** Changes in MySQL Cluster configuration parameters do not take effect until the cluster is restarted. The type of re-

start required to change a given parameter is indicated in the summary table as follows:

- **N**—Node restart: The parameter can be updated using a rolling restart (see [Section 17.2.5.1, “Performing a Rolling Restart of a MySQL Cluster”](#)).
- **S**—System restart: The cluster must be shut down completely, then restarted, to effect a change in this parameter.
- **I**—Initial restart: Data nodes must be restarted using the `--initial` option.

For more information about restart types, see [Section 17.3.3, “Overview of MySQL Cluster Configuration Parameters”](#).

**Table 17.3. API Node Configuration Parameters**

Name	Type/Units	Default	Min Value	Max Value	Restart Type
<code>ArbitrationDelay</code>	milliseconds			4G	N
<code>ArbitrationRank</code>	0-2			2	N
<code>AutoReconnect</code>		false	false	true	N
<code>BatchByteSize</code>	bytes	32K	1024	1M	N
<code>BatchSize</code>	records	64	1	992	N
<code>ConnectionMap</code>					N
<code>ExecuteOnComputer</code>	name				S
<code>HeartbeatThreadPriority</code>		none			
<code>HostName</code>	name or IP				S
<code>Id</code>	unsigned		1	63	N
<code>MaxScanBatchSize</code>	bytes	256K	32K	16M	N
<code>TotalSendBufferMemory</code>	bytes	256K		4G	N
wan		false			N

#### Note

To add new SQL or API nodes to the configuration of a running MySQL Cluster, it is necessary to perform a rolling restart of all cluster nodes after adding new `[mysqld]` or `[api]` sections to the `config.ini` file (or files, if you are using more than one management server). This must be done before the new SQL or API nodes can connect to the cluster.

It is *not* necessary to perform any restart of the cluster if new SQL or API nodes can employ previously unused API slots in the cluster configuration to connect to the cluster.

#### 17.3.3.4. Other MySQL Cluster Configuration Parameters

The summary tables in this section provide information about parameters used in the `[computer]`, `[tcp]`, `[shm]`, and `[sci]` sections of a `config.ini` file for configuring MySQL Cluster management nodes. For detailed descriptions and other additional information about individual parameters, see [Section 17.3.2.8, “MySQL Cluster TCP/IP Connections”](#), [Section 17.3.2.10, “MySQL Cluster Shared-Memory Connections”](#), or [Section 17.3.2.11, “SCI Transport Connections in MySQL Cluster”](#), as appropriate.

**Restart types.** Changes in MySQL Cluster configuration parameters do not take effect until the cluster is restarted. The type of restart required to change a given parameter is indicated in the summary tables as follows:

- **N**—Node restart: The parameter can be updated using a rolling restart (see [Section 17.2.5.1, “Performing a Rolling Restart of a MySQL Cluster”](#)).
- **S**—System restart: The cluster must be shut down completely, then restarted, to effect a change in this parameter.
- **I**—Initial restart: Data nodes must be restarted using the `--initial` option.

For more information about restart types, see [Section 17.3.3, “Overview of MySQL Cluster Configuration Parameters”](#).

## 17.3.4. MySQL Server Options and Variables for MySQL Cluster

This section provides information about MySQL server options, server and status variables that are specific to MySQL Cluster. For general information on using these, and for other options and variables not specific to MySQL Cluster, see [Section 5.1, “The MySQL Server”](#).

For MySQL Cluster configuration parameters used in the cluster configuration file (usually named `config.ini`), see [Section 17.3, “MySQL Cluster Configuration”](#).

### 17.3.4.1. MySQL Cluster Server Option and Variable Reference

The following table provides a list of the command-line options, server and status variables applicable within `mysqld` when it is running as an SQL node in a MySQL Cluster. For a table showing *all* command-line options, server and status variables available for use with `mysqld`, see [Section 5.1.1, “Server Option and Variable Reference”](#).

**Table 17.8. Command Options for MySQL Cluster**

Name	Cmd-Line	Option file	System Var	Status Var	Var Scope	Dynamic
<code>Handler_discover</code>				Yes	Both	No
<code>have_ndbcluster</code>			Yes		Global	No
<code>ndb_autoincrement_prefetch_sz</code>	Yes	Yes	Yes		Both	Yes

#### 17.3.4.2. `mysqld` Command Options for MySQL Cluster

This section provides descriptions of `mysqld` server options relating to MySQL Cluster. For information about `mysqld` options not specific to MySQL Cluster, and for general information about the use of options with `mysqld`, see [Section 5.1.2, “Server Command Options”](#).

For information about command-line options used with other MySQL Cluster processes (`ndbd`, `ndb_mgmd`, and `ndb_mgm`), see [Section 17.4.23, “Options Common to MySQL Cluster Programs”](#). For information about command-line options used with `NDB` utility programs (such as `ndb_desc`, `ndb_size.pl`, and `ndb_show_tables`), see [Section 17.4, “MySQL Cluster Programs”](#).

- `--ndb-batch-size=#`

<b>Version Introduced</b>	5.1.23-ndb-6.3.8
<b>Command-Line Format</b>	<code>--ndb-batch-size</code>
<b>Config-File Format</b>	<code>ndb-batch-size</code>
<b>Variable Name</b>	<code>ndb_batch_size</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	
<b>Type</b>	<code>numeric</code>
<b>Default</b>	<code>32768</code>
<b>Range</b>	<code>0-31536000</code>

This sets the size in bytes that is used for NDB transaction batches.

- `--ndb-cluster-connection-pool=#`

<b>Version Introduced</b>	5.1.19-ndb-6.2.2
<b>Command-Line Format</b>	<code>--ndb-cluster-connection-pool</code>
<b>Config-File Format</b>	<code>ndb-cluster-connection-pool</code>
<b>Variable Name</b>	<code>Ndb_cluster_connection_pool</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	
<b>Type</b>	<code>numeric</code>
<b>Default</b>	<code>1</code>
<b>Range</b>	<code>1-63</code>

By setting this option to a value greater than 1 (the default), a `mysqld` process can use multiple connections to the cluster, effectively mimicking several SQL nodes. Each connection requires its own `[api]` or `[mysqld]` section in the cluster configuration (`config.ini`) file, and counts against the maximum number of API connections supported by the cluster.

Suppose that you have 2 cluster host computers, each running an SQL node whose `mysqld` process was started with `--ndb-cluster-connection-pool=4`; this means that the cluster must have 8 API slots available for these connections (instead of 2). All of these connections are set up when the SQL node connects to the cluster, and are allocated to threads in a round-robin fashion.

This option is useful only when running `mysqld` on host machines having multiple CPUs, multiple cores, or both. For best results, the value should be smaller than the total number of cores available on the host machine. Setting it to a value greater than this is likely to degrade performance severely.

### Important

Because each SQL node using connection pooling occupies multiple API node slots—each slot having its own node ID in the cluster—you must *not* use a node ID as part of the cluster connect string when starting any `mysqld` process that employs connection pooling.

Setting a node ID in the connect string when using the `--ndb-cluster-connection-pool` option causes node ID allocation errors when the SQL node attempts to connect to the cluster.

This option was introduced in MySQL Cluster NDB 6.2.2. Beginning with MySQL Cluster NDB 6.2.16 and MySQL Cluster NDB 6.3.13, the value used for this option is available as a global status variable ([Bug#35573](#)).

- `--ndb-connectstring=connect_string`

<b>Command-Line Format</b>	--ndb-connectstring
<b>Config-File Format</b>	ndb-connectstring
	<b>Permitted Values</b>
<b>Type</b>	string

When using the `NDBCLUSTER` storage engine, this option specifies the management server that distributes cluster configuration data. See [Section 17.3.2.3, “The MySQL Cluster Connectstring”](#), for syntax.

- `--ndbcluster`

<b>Command-Line Format</b>	--ndbcluster
<b>Config-File Format</b>	ndbcluster
<b>Option Sets Variable</b>	Yes, <code>have_ndbcluster</code>
<b>Disabled by</b>	<code>skip-ndbcluster</code>
	<b>Permitted Values</b>
	<b>Type</b> boolean
	<b>Default</b> FALSE

The `NDBCLUSTER` storage engine is necessary for using MySQL Cluster. If a `mysqld` binary includes support for the `NDBCLUSTER` storage engine, the engine is disabled by default. Use the `--ndbcluster` option to enable it. Use `--skip-ndbcluster` to explicitly disable the engine.

- `--ndb-nodeid=#`

<b>Version Introduced</b>	5.1.15
<b>Command-Line Format</b>	--ndb-nodeid=#
<b>Config-File Format</b>	ndb-nodeid
<b>Variable Name</b>	<code>Ndb_cluster_node_id</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No
	<b>Permitted Values (&gt;= 5.1.5)</b>
	<b>Type</b> numeric
	<b>Range</b> 1-255

Set this MySQL server's node ID in a MySQL Cluster.

Prior to MySQL Cluster NDB 7.0.15 and MySQL Cluster NDB 7.1.4, this option can be used *instead* of specifying the node ID as part of the connectstring or in the `config.ini` file, or permitting the cluster to determine an arbitrary node ID. If you use this option, then `--ndb-nodeid` must be specified *before* `--ndb-connectstring`. If `--ndb-nodeid` is used *and* a node ID is specified in the connectstring, then the MySQL server cannot connect to the cluster.

Beginning with MySQL Cluster NDB 7.0.15 and MySQL Cluster NDB 7.1.4, the `--ndb-nodeid` option *overrides* any node ID set with `--ndb-connectstring`, regardless of the order in which the two options are used.

In addition (regardless of the MySQL Cluster version), if `--ndb-nodeid` is used, then either a matching node ID must be found in a `[mysqld]` or `[api]` section of `config.ini`, or there must be an “open” `[mysqld]` or `[api]` section in the file (that is, a section without an `Id` parameter specified). This is also true if the node ID is specified as part of the connectstring.

Regardless of how the node ID is determined, its is shown as the value of the global status variable `Ndb_cluster_node_id` in the output of `SHOW STATUS`, and as `cluster_node_id` in the `connection` row of the output of `SHOW ENGINE NDBCLUSTER STATUS`.

For more information about node IDs for MySQL Cluster SQL nodes, see [Section 17.3.2.7, “Defining SQL and Other API Nodes in a MySQL Cluster”](#).

- `--server-id-bits=#`

<b>Version Introduced</b>	5.1.47-ndb-7.1.6
<b>Command-Line Format</b>	<code>--server-id-bits=#</code>
<b>Config-File Format</b>	<code>server_id_bits</code>
<b>Option Sets Variable</b>	Yes, <code>server_id_bits</code>
<b>Variable Name</b>	<code>server_id_bits</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No
	<b>Permitted Values</b>
	Type      numeric
	Default    32
	Range     7-32

This option indicates the number of least significant bits within the 32-bit `server_id` which actually identify the server. Indicating that the server is actually identified by fewer than 32 bits makes it possible for some of the remaining bits to be used for other purposes, such as storing user data generated by applications using the NDB API's Event API within the `AnyValue` of an `OperationOptions` structure (MySQL Cluster uses the `AnyValue` to store the server ID).

When extracting the effective server ID from `server_id` for purposes such as detection of replication loops, the server ignores the remaining bits. The `--server-id-bits` option is used to mask out any irrelevant bits of `server_id` in the IO and SQL threads when deciding whether an event should be ignored based on the server ID.

This data can be read from the binary log by `mysqlbinlog`, provided that it is run with its own `--server-id-bits` option set to 32 (the default).

The value of `server_id` must be less than  $2^{\text{server\_id\_bits}}$ ; otherwise, `mysqld` refuses to start.

This system variable was added in MySQL Cluster NDB 7.0.17 and MySQL Cluster NDB 7.1.6; it is supported only in these and later releases of MySQL Cluster. It is not supported by the standard MySQL Server.

- `--skip-ndbcluster`

<b>Command-Line Format</b>	<code>--skip-ndbcluster</code>
<b>Config-File Format</b>	<code>skip-ndbcluster</code>

Disable the `NDBCLUSTER` storage engine. This is the default for binaries that were built with `NDBCLUSTER` storage engine support; the server allocates memory and other resources for this storage engine only if the `--ndbcluster` option is given explicitly. See [Section 17.3.1, “Quick Test Setup of MySQL Cluster”](#), for an example.

#### 17.3.4.3. MySQL Cluster System Variables

This section provides detailed information about MySQL server system variables that are specific to MySQL Cluster and the `NDB` storage engine. For system variables not specific to MySQL Cluster, see [Section 5.1.4, “Server System Variables”](#). For general information on using system variables, see [Section 5.1.5, “Using System Variables”](#).

- `have_ndbcluster`

<b>Variable Name</b>	<code>have_ndbcluster</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No
	<b>Permitted Values</b>
	Type      boolean

`YES` if `mysqld` supports `NDBCLUSTER` tables. `DISABLED` if `--skip-ndbcluster` is used.

- `multi_range_count`

<b>Command-Line Format</b>	<code>--multi_range_count=#</code>
----------------------------	------------------------------------

<b>Config-File Format</b>	<code>multi_range_count</code>
<b>Option Sets Variable</b>	Yes, <code>multi_range_count</code>
<b>Variable Name</b>	<code>multi_range_count</code>
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
	<b>Type</b> <code>numeric</code>
	<b>Default</b> <code>256</code>
	<b>Range</b> <code>1-4294967295</code>

The maximum number of ranges to send to a table handler at once during range selects. The default value is 256. Sending multiple ranges to a handler at once can improve the performance of certain selects dramatically. This is especially true for the `ND-BCLUSTER` table handler, which needs to send the range requests to all nodes. Sending a batch of those requests at once reduces communication costs significantly.

This variable is deprecated in MySQL 5.1, and is no longer supported in MySQL 5.5, in which arbitrarily long lists of ranges can be processed.

- `ndb_autoincrement_prefetch_sz`

<b>Command-Line Format</b>	<code>--ndb_autoincrement_prefetch_sz</code>
<b>Config-File Format</b>	<code>ndb_autoincrement_prefetch_sz</code>
<b>Option Sets Variable</b>	Yes, <code>ndb_autoincrement_prefetch_sz</code>
<b>Variable Name</b>	<code>ndb_autoincrement_prefetch_sz</code>
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values (&lt;= 5.1.22)</b>
	<b>Type</b> <code>numeric</code>
	<b>Default</b> <code>32</code>
	<b>Range</b> <code>1-256</code>
	<b>Permitted Values (&gt;= 5.1.23)</b>
	<b>Type</b> <code>numeric</code>
	<b>Default</b> <code>1</code>
	<b>Range</b> <code>1-256</code>

Determines the probability of gaps in an autoincremented column. Set it to `1` to minimize this. Setting it to a high value for optimization—makes inserts faster, but decreases the likelihood that consecutive autoincrement numbers will be used in a batch of inserts. Default value: `32`. Minimum value: `1`.

Beginning with MySQL Cluster NDB 6.2.10, MySQL Cluster NDB 6.3.7, and MySQL 5.1.23, this variable affects the number of `AUTO_INCREMENT` IDs that are fetched between statements only. Within a statement, at least 32 IDs are now obtained at a time. The default value for `ndb_autoincrement_prefetch_sz` is now `1`, to increase the speed of statements inserting single rows. ([Bug#31956](#))

Beginning with MySQL Cluster NDB 6.3.31 and MySQL CLuster NDB 7.0.11, the maximum value for `ndb_autoincrement_prefetch_sz` is increased, from 256 to 65536. ([Bug#50621](#))

- `ndb_cache_check_time`

<b>Command-Line Format</b>	<code>--ndb_cache_check_time</code>
<b>Config-File Format</b>	<code>ndb_cache_check_time</code>
<b>Option Sets Variable</b>	Yes, <code>ndb_cache_check_time</code>
<b>Variable Name</b>	<code>ndb_cache_check_time</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes

<b>Permitted Values</b>	
Type	numeric
Default	0

The number of milliseconds that elapse between checks of MySQL Cluster SQL nodes by the MySQL query cache. Setting this to 0 (the default and minimum value) means that the query cache checks for validation on every query.

The recommended maximum value for this variable is 1000, which means that the check is performed once per second. A larger value means that the check is performed and possibly invalidated due to updates on different SQL nodes less often. It is generally not desirable to set this to a value greater than 2000.

- [ndb\\_extra\\_logging](#)

<b>Version Introduced</b>	5.1.6
<b>Command-Line Format</b>	<code>ndb_extra_logging=#</code>
<b>Config-File Format</b>	<code>ndb_extra_logging</code>
<b>Variable Name</b>	<code>ndb_extra_logging</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	
Type	numeric
Default	0

This variable can be used to enable recording in the MySQL error log of information specific to the [NDB](#) storage engine. It is normally of interest only when debugging [NDB](#) storage engine code.

The default value is 0, which means that the only [NDB](#)-specific information written to the MySQL error log relates to transaction handling. If the value is greater than 0 but less than 10, [NDB](#) table schema and connection events are also logged, as well as whether or not conflict resolution is in use, and other [NDB](#) errors and information. If the value is set to 10 or more, information about [NDB](#) internals, such as the progress of data distribution among cluster nodes, is also written to the MySQL error log.

This variable was added in MySQL 5.1.6.

- [ndb\\_force\\_send](#)

<b>Command-Line Format</b>	<code>--ndb-force-send</code>
<b>Config-File Format</b>	<code>ndb_force_send</code>
<b>Option Sets Variable</b>	Yes, <code>ndb_force_send</code>
<b>Variable Name</b>	<code>ndb_force_send</code>
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	
Type	boolean
Default	TRUE

Forces sending of buffers to [NDB](#) immediately, without waiting for other threads. Defaults to [ON](#).

- [ndb\\_index\\_stat\\_cache\\_entries](#)

<b>Version Removed</b>	5.1.14
<b>Command-Line Format</b>	<code>--ndb_index_stat_cache_entries</code>
<b>Config-File Format</b>	<code>ndb_index_stat_cache_entries</code>

<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	32
<b>Range</b>	0–4294967295

Sets the granularity of the statistics by determining the number of starting and ending keys to store in the statistics memory cache. Zero means no caching takes place; in this case, the data nodes are always queried directly. Default value: 32.

### Note

If `ndb_index_stat_enable` is OFF, then setting this variable has no effect.

- `ndb_index_stat_enable`

<b>Version Removed</b>	5.1.19
<b>Command-Line Format</b>	<code>--ndb_index_stat_enable</code>
<b>Config-File Format</b>	<code>ndb_index_stat_enable</code>
<b>Permitted Values</b>	
<b>Type</b>	boolean
<b>Default</b>	OFF

Use NDB index statistics in query optimization. Defaults to ON.

- `ndb_index_stat_update_freq`

<b>Version Removed</b>	5.1.14
<b>Command-Line Format</b>	<code>--ndb_index_stat_update_freq</code>
<b>Config-File Format</b>	<code>ndb_index_stat_update_freq</code>
<b>Permitted Values</b>	
<b>Type</b>	numeric
<b>Default</b>	20
<b>Range</b>	0–4294967295

How often to query data nodes instead of the statistics cache. For example, a value of 20 (the default) means to direct every 20th query to the data nodes.

### Note

If `ndb_index_stat_cache_entries` is 0, then setting this variable has no effect; in this case, every query is sent directly to the data nodes.

- `ndb_log_bin`

<b>Version Introduced</b>	5.1.6
<b>Command-Line Format</b>	<code>--ndb-log-bin={1 0}</code>
<b>Option Sets Variable</b>	Yes, <code>ndb_log_bin</code>
<b>Variable Name</b>	<code>ndb_log_bin</code>
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	
<b>Type</b>	boolean
<b>Default</b>	ON

Causes updates to NDB tables to be written to the binary log. Setting this variable has no effect if binary logging is not already

enabled for the server using `log_bin.ndb_log_bin` defaults to 1 (ON); normally, there is never any need to change this value in a production environment.

This variable was added in MySQL 5.1.6.

- [ndb\\_log\\_binlog\\_index](#)

<b>Version Introduced</b>	5.1.6				
<b>Command-Line Format</b>	<code>--ndb-log-binlog-index={1 0}</code>				
<b>Option Sets Variable</b>	Yes, <code>ndb_log_binlog_index</code>				
<b>Variable Name</b>	<code>ndb_log_binlog_index</code>				
<b>Variable Scope</b>	Global				
<b>Dynamic Variable</b>	Yes				
	<b>Permitted Values</b>				
	<table border="1"> <tr> <td><b>Type</b></td><td><code>boolean</code></td></tr> <tr> <td><b>Default</b></td><td><code>ON</code></td></tr> </table>	<b>Type</b>	<code>boolean</code>	<b>Default</b>	<code>ON</code>
<b>Type</b>	<code>boolean</code>				
<b>Default</b>	<code>ON</code>				

Causes a mapping of epochs to positions in the binary log to be inserted into the `ndb_binlog_index` table. Setting this variable has no effect if binary logging is not already enabled for the server using `log_bin`. (In addition, `ndb_log_bin` must not be disabled.) `ndb_log_binlog_index` defaults to 1 (ON); normally, there is never any need to change this value in a production environment.

This variable was added in MySQL 5.1.6.

- [ndb\\_optimized\\_node\\_selection](#)

<b>Command-Line Format</b>	<code>-</code> <code>-</code> <code>ndb-</code> <code>optimized-</code> <code>node-</code> <code>selec-</code> <code>tion</code>	4.1.9-5.1. 22-ndb-6. 33	
	<code>--ndb-optimized-node-selection=#</code>		
<b>Config-File Format</b>	<code>ndb_optimized_node_selection</code>		
	<b>Permitted Values (&lt;= 5.1.22-ndb-6.33)</b>		
	<b>Type</b>	<code>boolean</code>	
	<b>Default</b>	<code>ON</code>	

**Prior to MySQL Cluster NDB 6.3.4.** Causes an SQL node to use the “closest” data node as transaction coordinator. Enabled by default. Set to 0 or OFF to disable, in which case the SQL node uses each data node in the cluster in succession. When this option is disabled each SQL thread attempts to use a given data node 8 times before proceeding to the next one.

**Beginning with MySQL Cluster NDB 6.3.4.** There are two forms of optimized node selection:

1. The SQL node uses *proximity* to determine the transaction coordinator; that is, the “closest” data node to the SQL node is chosen as the transaction coordinator. For this purpose, a data node having a shared memory connection with the SQL node is considered to be “closest” to the SQL node; the next closest (in order of decreasing proximity) are: TCP connection to `localhost`; SCI connection; TCP connection from a host other than `localhost`.
2. The SQL thread uses *distribution awareness* to select the data node. That is, the data node housing the cluster partition accessed by the first statement of a given transaction is used as the transaction coordinator for the entire transaction. (This is effective only if the first statement of the transaction accesses no more than one cluster partition.)

This option takes one of the integer values 0, 1, 2, or 3. 3 is the default. These values affect node selection as follows:

- 0: Node selection is not optimized. Each data node is employed as the transaction coordinator 8 times before the SQL thread proceeds to the next data node. (This is the same “round-robin” behavior as caused by setting this option to 0 or OFF in previous versions of MySQL Cluster.)
- 1: Proximity to the SQL node is used to determine the transaction coordinator. (This is the same behavior as caused by setting this option to 1 or ON in previous MySQL versions.)

- 2: Distribution awareness is used to select the transaction coordinator. However, if the first statement of the transaction accesses more than one cluster partition, the SQL node reverts to the round-robin behavior seen when this option is set to 0.
- 3: If distribution awareness can be employed to determine the transaction coordinator, then it is used; otherwise proximity is used to select the transaction coordinator. (This is the default behavior in MySQL Cluster NDB 6.3.4 and later.)

### Important

Beginning with MySQL Cluster NDB 6.3.4, it is no longer possible to set `--ndb_optimized_node_selection` to ON or OFF; attempting to do so causes `mysqld` to abort with an error.

- `ndb_report_thresh_binlog_epoch_slip`

<b>Command-Line Format</b>	<code>--ndb_report_thresh_binlog_epoch_slip</code>
<b>Config-File Format</b>	<code>ndb_report_thresh_binlog_epoch_slip</code>
<b>Permitted Values</b>	
<b>Type</b>	<code>numeric</code>
<b>Default</b>	3
<b>Range</b>	0–256

This is a threshold on the number of epochs to be behind before reporting binlog status. For example, a value of 3 (the default) means that if the difference between which epoch has been received from the storage nodes and which epoch has been applied to the binlog is 3 or more, a status message will be sent to the cluster log.

- `ndb_report_thresh_binlog_mem_usage`

<b>Command-Line Format</b>	<code>--ndb_report_thresh_binlog_mem_usage</code>
<b>Config-File Format</b>	<code>ndb_report_thresh_binlog_mem_usage</code>
<b>Permitted Values</b>	
<b>Type</b>	<code>numeric</code>
<b>Default</b>	10
<b>Range</b>	0–10

This is a threshold on the percentage of free memory remaining before reporting binlog status. For example, a value of 10 (the default) means that if the amount of available memory for receiving binlog data from the data nodes falls below 10%, a status message will be sent to the cluster log.

- `ndb_table_no_logging`

<b>Version Introduced</b>	5.1.23-ndb-6.3.8
<b>Variable Name</b>	<code>ndb_table_no_logging</code>
<b>Variable Scope</b>	Session
<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	
<b>Type</b>	<code>boolean</code>
<b>Default</b>	<code>FALSE</code>

When this variable is set to `ON` or 1, it causes NDB tables not to be checkpointed to disk. More specifically, this setting applies to tables which are created or altered using `ENGINE NDB` when `ndb_table_no_logging` is enabled, and continues to apply for the lifetime of the table, even if `ndb_table_no_logging` is later changed. Suppose that A, B, C, and D are tables that we create (and perhaps also alter), and that we also change the setting for `ndb_table_no_logging` as shown here:

```
SET @@ndb_table_no_logging = 1;
CREATE TABLE A ... ENGINE NDB;
CREATE TABLE B ... ENGINE MYISAM;
CREATE TABLE C ... ENGINE MYISAM;
ALTER TABLE B ENGINE NDB;
```

```
SET @@ndb_table_no_logging = 0;
CREATE TABLE D ... ENGINE NDB;
ALTER TABLE C ENGINE NDB;
SET @@ndb_table_no_logging = 1;
```

After the previous sequence of events, tables A and B are not checkpointed; A was created with `ENGINE NDB` and B was altered to use `NDB`, both while `ndb_table_no_logging` was enabled. However, tables C and D are logged; C was altered to use `NDB` and D was created using `ENGINE NDB`, both while `ndb_table_no_logging` was disabled. Setting `ndb_table_no_logging` back to 1 or ON does *not* cause table C or D to be checkpointed.

### Note

`ndb_table_no_logging` has no effect on the creation of `NDB` table schema files; to suppress these, use `ndb_table_temporary` instead.

- `ndb_table_temporary`

<b>Version Introduced</b>	5.1.23-ndb-6.3.8
<b>Variable Name</b>	<code>ndb_table_temporary</code>
<b>Variable Scope</b>	Session
<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	
<b>Type</b>	<code>boolean</code>
<b>Default</b>	<code>FALSE</code>

When set to `ON` or 1, this variable causes `NDB` tables not to be written to disk: This means that no table schema files are created, and that the tables are not logged.

### Note

Setting this variable currently has no effect in MySQL Cluster NDB 7.0 and later. This is a known issue; see [Bug#34036](#).

- `ndb_use_copying_alter_table`

<b>Version Introduced</b>	5.1.12
<b>Variable Name</b>	<code>ndb_use_copying_alter_table</code>
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	No

Forces `NDB` to use copying of tables in the event of problems with online `ALTER TABLE` operations. The default value is `OFF`.

This variable was added in MySQL 5.1.12.

- `ndb_use_exact_count`

<b>Variable Name</b>	<code>ndb_use_exact_count</code>
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	
<b>Type</b>	<code>boolean</code>
<b>Default</b>	<code>ON</code>

Forces `NDB` to use a count of records during `SELECT COUNT(*)` query planning to speed up this type of query. The default value is `ON`. For faster queries overall, disable this feature by setting the value of `ndb_use_exact_count` to `OFF`.

- `ndb_use_transactions`

<b>Command-Line Format</b>	--ndb_use_transactions
<b>Config-File Format</b>	ndb_use_transactions
<b>Variable Name</b>	ndb_use_transactions
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
	<b>Type</b> boolean
	<b>Default</b> ON

You can disable NDB transaction support by setting this variable's values to OFF (not recommended). The default is ON.

### Note

The setting for this variable was not honored in MySQL Cluster NDB 6.4.3 and MySQL Cluster NDB 7.0.4.  
[\(Bug#43236\)](#)

- [ndb\\_wait\\_connected](#)

<b>Version Introduced</b>	5.1.16-ndb-6.2.0
<b>Command-Line Format</b>	ndb_wait_connected
<b>Config-File Format</b>	ndb_wait_connected
<b>Option Sets Variable</b>	Yes, ndb_wait_connected
<b>Variable Name</b>	ndb_wait_connected
<b>Variable Scope</b>	
<b>Dynamic Variable</b>	No
	<b>Permitted Values</b>
	<b>Type</b> numeric
	<b>Default</b> 0
	<b>Range</b> 0-31536000

This variable shows the period of time that the MySQL server waits for connections to MySQL Cluster management and data nodes to be established before accepting MySQL client connections. The time is specified in seconds. The default value is 0.

- [ndb\\_wait\\_setup](#)

This variable shows the period of time that the MySQL server waits for the NDB storage engine to complete setup before timing out and treating NDB as unavailable. The time is specified in seconds. The default value is 15.

The system variables in the following list all relate to the [ndbinfo](#) information database (see [Section 17.5.8, “The ndbinfo MySQL Cluster Information Database”](#)). They were added in MySQL Cluster NDB 7.1.1.

- [ndbinfo\\_database](#)

<b>Version Introduced</b>	5.1.41-ndb-7.1.1
<b>Variable Name</b>	ndbinfo_database
<b>Variable Scope</b>	
<b>Dynamic Variable</b>	No
	<b>Permitted Values</b>
	<b>Type</b> string
	<b>Default</b> ndbinfo

Shows the name used for the NDB information database; the default is [ndbinfo](#). This is a read-only variable whose value is determined at compile time; you can set it by starting the server using [--ndbinfo-database=name](#), which sets the value

shown for this variable but does not actually change the name used for the NDB information database.

- [ndbinfo\\_max\\_bytes](#)

<b>Version Introduced</b>	5.1.41-ndb-7.1.1
<b>Command-Line Format</b>	<code>--ndbinfo-max-bytes=#</code>
<b>Option Sets Variable</b>	Yes, <a href="#">ndbinfo_max_bytes</a>
<b>Variable Name</b>	<a href="#">ndbinfo_max_bytes</a>
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
	Type <a href="#">numeric</a>
	Default <a href="#">0</a>

Used in testing and debugging only.

- [ndbinfo\\_max\\_rows](#)

<b>Version Introduced</b>	5.1.41-ndb-7.1.1
<b>Command-Line Format</b>	<code>--ndbinfo-max-rows=#</code>
<b>Option Sets Variable</b>	Yes, <a href="#">ndbinfo_max_rows</a>
<b>Variable Name</b>	<a href="#">ndbinfo_max_rows</a>
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
	Type <a href="#">numeric</a>
	Default <a href="#">10</a>

Used in testing and debugging only.

- [ndbinfo\\_show\\_hidden](#)

<b>Version Introduced</b>	5.1.41-ndb-7.1.1
<b>Command-Line Format</b>	<code>--ndbinfo-show-hidden={0 1}</code>
<b>Option Sets Variable</b>	Yes, <a href="#">ndbinfo_show_hidden</a>
<b>Variable Name</b>	<a href="#">ndbinfo_show_hidden</a>
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes
	<b>Permitted Values</b>
	Type <a href="#">boolean</a>
	Default <a href="#">no</a>

Whether or not the `ndbinfo` database's underlying internal tables are shown in the `mysql` client. The default is `OFF`.

- [ndbinfo\\_table\\_prefix](#)

<b>Version Introduced</b>	5.1.41-ndb-7.1.1
<b>Command-Line Format</b>	<code>--ndbinfo-table-prefix=name</code>
<b>Option Sets Variable</b>	Yes, <a href="#">ndbinfo_table_prefix</a>
<b>Variable Name</b>	<a href="#">ndbinfo_table_prefix</a>
<b>Variable Scope</b>	Both
<b>Dynamic Variable</b>	Yes

<b>Permitted Values</b>	
Type	string
Default	ndb\$

The prefix used in naming the `ndbinfo` database's base tables (normally hidden, unless exposed by setting `ndbinfo_show_hidden`). This is a read-only variable whose default value is “`ndb$`”. You can start the server with the `--ndbinfo-table-prefix` option, but this merely sets the variable and does not change the actual prefix used to name the hidden base tables; the prefix itself is determined at compile time.

- `ndbinfo_version`

<b>Version Introduced</b>	5.1.41-ndb-7.1.1
<b>Variable Name</b>	<code>ndbinfo_version</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	
Type	string
Default	

Shows the version of the `ndbinfo` engine in use; read-only.

- `server_id_bits`

<b>Version Introduced</b>	5.1.47-ndb-7.1.6
<b>Command-Line Format</b>	<code>--server-id-bits=#</code>
<b>Config-File Format</b>	<code>server-id-bits</code>
<b>Option Sets Variable</b>	Yes, <code>server_id_bits</code>
<b>Variable Name</b>	<code>server_id_bits</code>
<b>Variable Scope</b>	Global
<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	
Type	numeric
Default	32
Range	7–32

The effective value of `server_id` if the server was started with the `--server-id-bits` option set to a non-default value.

If the value of `server_id` greater than or equal to 2 to the power of `server_id_bits`, `mysqld` refuses to start.

This system variable was added in MySQL Cluster NDB 7.0.17 and MySQL Cluster NDB 7.1.6; it is supported only in these and later releases of MySQL Cluster. It is not supported by the standard MySQL Server.

#### 17.3.4.4. MySQL Cluster Status Variables

This section provides detailed information about MySQL server status variables that relate to MySQL Cluster and the `NDB` storage engine. For status variables not specific to MySQL Cluster, and for general information on using status variables, see [Section 5.1.6, “Server Status Variables”](#).

- `Handler_discover`

The MySQL server can ask the `NDBCLUSTER` storage engine if it knows about a table with a given name. This is called discovery. `Handler_discover` indicates the number of times that tables have been discovered using this mechanism.

- `Ndb_cluster_node_id`

If the server is acting as a MySQL Cluster node, then the value of this variable its node ID in the cluster.

If the server is not part of a MySQL Cluster, then the value of this variable is 0.

- [Ndb\\_config\\_from\\_host](#)

If the server is part of a MySQL Cluster, the value of this variable is the host name or IP address of the Cluster management server from which it gets its configuration data.

If the server is not part of a MySQL Cluster, then the value of this variable is an empty string.

Prior to MySQL 5.1.12, this variable was named [Ndb\\_connected\\_host](#).

- [Ndb\\_config\\_from\\_port](#)

If the server is part of a MySQL Cluster, the value of this variable is the number of the port through which it is connected to the Cluster management server from which it gets its configuration data.

If the server is not part of a MySQL Cluster, then the value of this variable is 0.

Prior to MySQL 5.1.12, this variable was named [Ndb\\_connected\\_port](#).

- [Ndb\\_execute\\_count](#)

Provides the number of round trips to the [NDB](#) kernel made by operations. Added in MySQL Cluster NDB 6.3.6.

- [Ndb\\_number\\_of\\_data\\_nodes](#)

If the server is part of a MySQL Cluster, the value of this variable is the number of data nodes in the cluster.

If the server is not part of a MySQL Cluster, then the value of this variable is 0.

Prior to MySQL 5.1.12, this variable was named [Ndb\\_number\\_of\\_storage\\_nodes](#).

- [Slave\\_heartbeat\\_period](#)

Shows the replication heartbeat interval (in seconds) on a replication slave.

This variable was added in MySQL Cluster NDB 6.3.4.

- [Slave\\_received\\_heartbeats](#)

This counter increments with each replication heartbeat received by a replication slave since the last time that the slave was re-started or reset, or a [CHANGE MASTER TO](#) statement was issued.

This variable was added in MySQL Cluster NDB 6.3.4.

- [Ndb\\_pruned\\_scan\\_count](#)

This variable holds a count of the number of scans executed by [NDBCLUSTER](#) since the MySQL Cluster was last started where [NDBCLUSTER](#) was able to use partition pruning.

Using this variable together with [Ndb\\_scan\\_count](#) can be helpful in schema design to maximize the ability of the server to prune scans to a single table partition, thereby involving only a single data node.

This variable was added in MySQL Cluster NDB 6.3.25 and MySQL Cluster NDB 7.0.5.

- [Ndb\\_scan\\_count](#)

This variable holds a count of the total number of scans executed by [NDBCLUSTER](#) since the MySQL Cluster was last started.

This variable was added in MySQL Cluster NDB 6.3.25 and MySQL Cluster NDB 7.0.5.

## 17.3.5. Using High-Speed Interconnects with MySQL Cluster

Even before design of [NDBCLUSTER](#) began in 1996, it was evident that one of the major problems to be encountered in building parallel databases would be communication between the nodes in the network. For this reason, [NDBCLUSTER](#) was designed from the very beginning to permit the use of a number of different data transport mechanisms. In this Manual, we use the term *transporter* for these.

The MySQL Cluster codebase provides for four different transporters:

- *TCP/IP using 100 Mbps or gigabit Ethernet*, as discussed in [Section 17.3.2.8, “MySQL Cluster TCP/IP Connections”](#).
- *Direct (machine-to-machine) TCP/IP*; although this transporter uses the same TCP/IP protocol as mentioned in the previous item, it requires setting up the hardware differently and is configured differently as well. For this reason, it is considered a separate transport mechanism for MySQL Cluster. See [Section 17.3.2.9, “MySQL Cluster TCP/IP Connections Using Direct Connections”](#), for details.
- *Shared memory (SHM)*. For more information about SHM, see [Section 17.3.2.10, “MySQL Cluster Shared-Memory Connections”](#).

#### Note

SHM is considered experimental only, and is not officially supported.

- *Scalable Coherent Interface (SCI)*, as described in the next section of this chapter, [Section 17.3.2.11, “SCI Transport Connections in MySQL Cluster”](#).

Most users today employ TCP/IP over Ethernet because it is ubiquitous. TCP/IP is also by far the best-tested transporter for use with MySQL Cluster.

We are working to make sure that communication with the `ndbd` process is made in “chunks” that are as large as possible because this benefits all types of data transmission.

For users who desire it, it is also possible to use cluster interconnects to enhance performance even further. There are two ways to achieve this: Either a custom transporter can be designed to handle this case, or you can use socket implementations that bypass the TCP/IP stack to one extent or another. We have experimented with both of these techniques using the SCI (Scalable Coherent Interface) technology developed by [Dolphin Interconnect Solutions](#).

### 17.3.5.1. Configuring MySQL Cluster to use SCI Sockets

It is possible employing Scalable Coherent Interface (SCI) technology to achieve a significant increase in connection speeds and throughput between MySQL Cluster data and SQL nodes. To use SCI, it is necessary to obtain and install Dolphin SCI network cards and to use the drivers and other software supplied by Dolphin. You can get information on obtaining these, from [Dolphin Interconnect Solutions](#). SCI SuperSocket or SCI Transporter support is available for 32-bit and 64-bit Linux, Solaris, Windows, and other platforms. See the Dolphin documentation referenced later in this section for more detailed information regarding platforms supported for SCI.

#### Note

Prior to MySQL 5.1.20, there were issues with building MySQL Cluster with SCI support (see [Bug#25470](#)), but these have been resolved due to work contributed by Dolphin. SCI Sockets are now correctly supported for MySQL Cluster hosts running recent versions of Linux using the `-max` builds, and versions of MySQL Cluster with SCI Transporter support can be built using either of `compile-amd64-max-sci` or `compile-pentium64-max-sci`. Both of these build scripts can be found in the `BUILD` directory of the MySQL Cluster source trees; it should not be difficult to adapt them for other platforms. Generally, all that is necessary is to compile MySQL Cluster with SCI Transporter support is to configure the MySQL Cluster build using `--with-ndb-sci=/opt/DIS`.

Once you have acquired the required Dolphin hardware and software, you can obtain detailed information on how to adapt a MySQL Cluster configured for normal TCP/IP communication to use SCI from the *Dolphin Express for MySQL Installation and Reference Guide*, available for download at [http://docsrva.mysql.com/public/DIS\\_install\\_guide\\_book.pdf](http://docsrva.mysql.com/public/DIS_install_guide_book.pdf) (PDF file, 94 pages, 753 KB). This document provides instructions for installing the SCI hardware and software, as well as information concerning network topology and configuration.

### 17.3.5.2. MySQL Cluster Interconnects and Performance

The `ndbd` process has a number of simple constructs which are used to access the data in a MySQL Cluster. We have created a very simple benchmark to check the performance of each of these and the effects which various interconnects have on their performance.

There are four access methods:

- **Primary key access.** This is access of a record through its primary key. In the simplest case, only one record is accessed at a time, which means that the full cost of setting up a number of TCP/IP messages and a number of costs for context switching are borne by this single request. In the case where multiple primary key accesses are sent in one batch, those accesses share the cost of setting up the necessary TCP/IP messages and context switches. If the TCP/IP messages are for different destinations, addi-

tional TCP/IP messages need to be set up.

- **Unique key access.** Unique key accesses are similar to primary key accesses, except that a unique key access is executed as a read on an index table followed by a primary key access on the table. However, only one request is sent from the MySQL Server, and the read of the index table is handled by `ndbd`. Such requests also benefit from batching.
- **Full table scan.** When no indexes exist for a lookup on a table, a full table scan is performed. This is sent as a single request to the `ndbd` process, which then divides the table scan into a set of parallel scans on all cluster `ndbd` processes. In future versions of MySQL Cluster, an SQL node will be able to filter some of these scans.
- **Range scan using ordered index**

When an ordered index is used, it performs a scan in the same manner as the full table scan, except that it scans only those records which are in the range used by the query transmitted by the MySQL server (SQL node). All partitions are scanned in parallel when all bound index attributes include all attributes in the partitioning key.

With benchmarks developed internally by MySQL for testing simple and batched primary and unique key accesses, we have found that using SCI sockets improves performance by approximately 100% over TCP/IP, except in rare instances when communication performance is not an issue. This can occur when scan filters make up most of processing time or when very large batches of primary key accesses are achieved. In that case, the CPU processing in the `ndbd` processes becomes a fairly large part of the overhead.

Using the SCI transporter instead of SCI Sockets is only of interest in communicating between `ndbd` processes. Using the SCI transporter is also only of interest if a CPU can be dedicated to the `ndbd` process because the SCI transporter ensures that this process will never go to sleep. It is also important to ensure that the `ndbd` process priority is set in such a way that the process does not lose priority due to running for an extended period of time, as can be done by locking processes to CPUs in Linux 2.6. If such a configuration is possible, the `ndbd` process will benefit by 10–70% as compared with using SCI sockets. (The larger figures will be seen when performing updates and probably on parallel scan operations as well.)

There are several other optimized socket implementations for computer clusters, including Myrinet, Gigabit Ethernet, Infiniband and the VIA interface. However, we have tested MySQL Cluster so far only with SCI sockets. See [Section 17.3.5.1, “Configuring MySQL Cluster to use SCI Sockets”](#), for information on how to set up SCI sockets using ordinary TCP/IP for MySQL Cluster.

## 17.4. MySQL Cluster Programs

Using and managing a MySQL Cluster requires several specialized programs, which we describe in this chapter. We discuss the purposes of these programs in a MySQL Cluster, how to use the programs, and what startup options are available for each of them.

These programs include the MySQL Cluster data, management, and SQL node processes (`ndbd`, `ndbmttd`, `ndb_mgmd`, and `mysqld`) and the management client (`ndb_mgm`).

Other NDB utility, diagnostic, and example programs are included with the MySQL Cluster distribution. These include `ndb_restore`, `ndb_show_tables`, and `ndb_config`. These programs are covered later in this chapter.

The last two sections of this chapter contain tables of options used, respectively, with `mysqld` and with the various NDB programs.

### 17.4.1. MySQL Server Usage for MySQL Cluster

`mysqld` is the traditional MySQL server process. To be used with MySQL Cluster, `mysqld` needs to be built with support for the `NDBCLUSTER` storage engine, as it is in the precompiled binaries available from <http://dev.mysql.com/downloads/>. If you build MySQL from source, you must invoke `configure` with one of the options to enable `NDBCLUSTER` storage engine support:

- `--with-plugins=ndbcluster`
- `--with-plugins=max`
- `--with-plugins=max-no-innodb`

(`--with-ndbcluster` also works to enable `NDBCLUSTER` support, but is deprecated and so produces a `configure` warning as of MySQL 5.1.9.)

For information about other MySQL server options and variables relevant to MySQL Cluster in addition to those discussed in this section, see [Section 17.3.4, “MySQL Server Options and Variables for MySQL Cluster”](#).

If the `mysqld` binary has been built with Cluster support, the `NDBCLUSTER` storage engine is still disabled by default. You can use either of two possible options to enable this engine:

- Use `--ndbcluster` as a startup option on the command line when starting `mysqld`.
- Insert a line containing `NDBCLUSTER` in the `[mysqld]` section of your `my.cnf` file.

An easy way to verify that your server is running with the `NDBCLUSTER` storage engine enabled is to issue the `SHOW ENGINES` statement in the MySQL Monitor (`mysql`). You should see the value `YES` as the `Support` value in the row for `NDBCLUSTER`. If you see `NO` in this row or if there is no such row displayed in the output, you are not running an `NDB`-enabled version of MySQL. If you see `DISABLED` in this row, you need to enable it in either one of the two ways just described.

To read cluster configuration data, the MySQL server requires at a minimum three pieces of information:

- The MySQL server's own cluster node ID
- The host name or IP address for the management server (MGM node)
- The number of the TCP/IP port on which it can connect to the management server

Node IDs can be allocated dynamically, so it is not strictly necessary to specify them explicitly.

The `mysqld` parameter `ndb-connectstring` is used to specify the connectstring either on the command line when starting `mysqld` or in `my.cnf`. The connectstring contains the host name or IP address where the management server can be found, as well as the TCP/IP port it uses.

In the following example, `ndb_mgmd.mysql.com` is the host where the management server resides, and the management server listens for cluster messages on port 1186:

```
shell> mysqld --ndbcluster --ndb-connectstring=ndb_mgmd.mysql.com:1186
```

See [Section 17.3.2.3, “The MySQL Cluster Connectstring”](#), for more information on connectstrings.

Given this information, the MySQL server will be a full participant in the cluster. (We often refer to a `mysqld` process running in this manner as an SQL node.) It will be fully aware of all cluster data nodes as well as their status, and will establish connections to all data nodes. In this case, it is able to use any data node as a transaction coordinator and to read and update node data.

You can see in the `mysql` client whether a MySQL server is connected to the cluster using `SHOW PROCESSLIST`. If the MySQL server is connected to the cluster, and you have the `PROCESS` privilege, then the first row of the output is as shown here:

```
mysql> SHOW PROCESSLIST \G
***** 1. row *****
Id: 1
User: system user
Host:
db:
Command: Daemon
Time: 1
State: Waiting for event from ndbcluster
Info: NULL
```

### Important

To participate in a MySQL Cluster, the `mysqld` process must be started with *both* the options `--ndbcluster` and `--ndb-connectstring` (or their equivalents in `my.cnf`). If `mysqld` is started with only the `--ndbcluster` option, or if it is unable to contact the cluster, it is not possible to work with `NDB` tables, *nor is it possible to create any new tables regardless of storage engine*. The latter restriction is a safety measure intended to prevent the creation of tables having the same names as `NDB` tables while the SQL node is not connected to the cluster. If you wish to create tables using a different storage engine while the `mysqld` process is not participating in a MySQL Cluster, you must restart the server *without* the `--ndbcluster` option.

## 17.4.2. `ndbd` — The MySQL Cluster Data Node Daemon

`ndbd` is the process that is used to handle all the data in tables using the NDB Cluster storage engine. This is the process that empowers a data node to accomplish distributed transaction handling, node recovery, checkpointing to disk, online backup, and related tasks.

In a MySQL Cluster, a set of `ndbd` processes cooperate in handling data. These processes can execute on the same computer (host) or on different computers. The correspondences between data nodes and Cluster hosts is completely configurable.

The following table includes command options specific to the MySQL Cluster data node program `ndbd`. Additional descriptions follow the table. For options common to all MySQL Cluster programs, see [Section 17.4.23, “Options Common to MySQL Cluster”](#).

Programs”.

**Table 17.9. `ndbd` Command Line Options**

Format	Description	Introduction	Deprecated	Removed
<code>--bind-address=name</code>	Local bind address	5.1.12		
<code>--daemon</code>	Start ndbd as daemon (default); override with <code>--nodaemon</code>			
<code>--foreground</code>	Run ndbd in foreground, provided for debugging purposes (implies <code>--nodaemon</code> )			
<code>--initial</code>	Perform initial start of ndbd, including cleaning the file system. Consult the documentation before using this option			
<code>--initial-start</code>	Perform partial initial start (requires <code>--nowait-nodes</code> )	5.1.11		
<code>--install[=name]</code>	Used to install the data node process as a Windows service. Does not apply on non-Windows platforms.	5.1.47-ndb-7.1.5		
<code>--nodaemon</code>	Do not start ndbd as daemon; provided for testing purposes			
<code>--nostart</code>	Don't start ndbd immediately; ndbd waits for command to start from <code>ndb_mgmd</code>			
<code>--nowait-nodes=list</code>	Do not wait for these data nodes to start (takes comma-separated list of node IDs). Also requires <code>--ndb-nodeid</code> to be used.	5.1.9		
<code>--remove[=name]</code>	Used to remove a data node process that was previously installed as a Windows service. Does not apply on non-Windows platforms.	5.1.47-ndb-7.1.5		

### Note

All of these options also apply to the multi-threaded version of this program—`ndbmt`, which is available in MySQL Cluster NDB 7.0—and you may substitute “`ndbmt`” for “`ndbd`” wherever the latter occurs in this section.

For options common to all `NDBCLUSTER` programs, see [Section 17.4.23, “Options Common to MySQL Cluster Programs”](#).

- `--bind-address`

<b>Version Introduced</b>	5.1.12
<b>Command-Line Format</b>	<code>--bind-address=name</code>
	<b>Permitted Values</b>
	Type <code>string</code>
	Default

Causes `ndbd` to bind to a specific network interface (host name or IP address). This option has no default value.

This option was added in MySQL 5.1.12.

- `--daemon, -d`

<b>Command-Line Format</b>	<code>--daemon</code>
	<code>-d</code>
	<b>Permitted Values</b>
	Type <code>boolean</code>
	Default <code>TRUE</code>

Instructs `ndbd` to execute as a daemon process. This is the default behavior. `--nodaemon` can be used to prevent the process from running as a daemon.

This option has no effect when running `ndbd` or `ndbmt` on Windows platforms.

- `--initial`

<b>Command-Line Format</b>	--initial
<b>Permitted Values</b>	
<b>Type</b>	boolean
<b>Default</b>	FALSE

Instructs `ndbd` to perform an initial start. An initial start erases any files created for recovery purposes by earlier instances of `ndbd`. It also re-creates recovery log files. Note that on some operating systems this process can take a substantial amount of time.

An `--initial` start is to be used *only* when starting the `ndbd` process under very special circumstances; this is because this option causes all files to be removed from the Cluster file system and all redo log files to be re-created. These circumstances are listed here:

- When performing a software upgrade which has changed the contents of any files.
- When restarting the node with a new version of `ndbd`.
- As a measure of last resort when for some reason the node restart or system restart repeatedly fails. In this case, be aware that this node can no longer be used to restore data due to the destruction of the data files.

Use of this option prevents the `StartPartialTimeout` and `StartPartitionedTimeout` configuration parameters from having any effect.

### Important

This option does *not* affect either of the following:

- Backup files that have already been created by the affected node
- MySQL Cluster Disk Data files (see [Section 17.5.10, “MySQL Cluster Disk Data Tables”](#)).

This option also has no effect on recovery of data by a data node that is just starting (or restarting) from data nodes that are already running. This recovery of data occurs automatically, and requires no user intervention in a MySQL Cluster that is running normally.

It is permissible to use this option when starting the cluster for the very first time (that is, before any data node files have been created); however, it is *not* necessary to do so.

- `--initial-start`

<b>Version Introduced</b>	5.1.11
<b>Command-Line Format</b>	--initial-start
<b>Permitted Values</b>	
<b>Type</b>	boolean
<b>Default</b>	FALSE

This option is used when performing a partial initial start of the cluster. Each node should be started with this option, as well as `--nowait-nodes`.

Suppose that you have a 4-node cluster whose data nodes have the IDs 2, 3, 4, and 5, and you wish to perform a partial initial start using only nodes 2, 4, and 5—that is, omitting node 3:

```
shell> ndbd --ndb-nodeid=2 --nowait-nodes=3 --initial-start
shell> ndbd --ndb-nodeid=4 --nowait-nodes=3 --initial-start
shell> ndbd --ndb-nodeid=5 --nowait-nodes=3 --initial-start
```

Prior to MySQL 5.1.19, it was not possible to perform DDL operations involving Disk Data tables on a partially started cluster. (See [Bug#24631](#).)

When using this option, you must also specify the node ID for the data node being started with the `--ndb-nodeid` option.

This option was added in MySQL 5.1.11.

## Important

Do not confuse this option with the `--nowait-nodes` option added for `ndb_mgmd` in MySQL Cluster NDB 7.0.10, which can be used to enable a cluster configured with multiple management servers to be started without all management servers being online.

- `--nowait-nodes=node_id_1[, node_id_2[, ...]]`

<b>Version Introduced</b>	5.1.9
<b>Command-Line Format</b>	<code>--nowait-nodes=list</code>
<b>Permitted Values</b>	
Type	<code>string</code>
Default	

This option takes a list of data nodes which for which the cluster will not wait for before starting.

This can be used to start the cluster in a partitioned state. For example, to start the cluster with only half of the data nodes (nodes 2, 3, 4, and 5) running in a 4-node cluster, you can start each `ndbd` process with `--nowait-nodes=3,5`. In this case, the cluster starts as soon as nodes 2 and 4 connect, and does *not* wait `StartPartitionedTimeout` milliseconds for nodes 3 and 5 to connect as it would otherwise.

If you wanted to start up the same cluster as in the previous example without one `ndbd`—say, for example, that the host machine for node 3 has suffered a hardware failure—then start nodes 2, 4, and 5 with `--nowait-nodes=3`. Then the cluster will start as soon as nodes 2, 4, and 5 connect and will not wait for node 3 to start.

This option was added in MySQL 5.1.9.

- `--nodaemon`

<b>Command-Line Format</b>	<code>--nodaemon</code>
<b>Permitted Values</b>	
Type	<code>boolean</code>
Default	<code>FALSE</code>
<b>Permitted Values</b>	
Type (windows)	<code>boolean</code>
Default	<code>TRUE</code>

Instructs `ndbd` not to start as a daemon process. This is useful when `ndbd` is being debugged and you want output to be redirected to the screen.

As of MySQL Cluster NDB 7.0.8, the default behavior for `ndbd` and `ndbmt` on Windows is to run in the foreground, making this option unnecessary on Windows platforms. ([Bug#45588](#))

- `--nostart, -n`

<b>Command-Line Format</b>	<code>--nostart</code>
	<code>-n</code>
<b>Permitted Values</b>	
Type	<code>boolean</code>
Default	<code>FALSE</code>

Instructs `ndbd` not to start automatically. When this option is used, `ndbd` connects to the management server, obtains configuration data from it, and initializes communication objects. However, it does not actually start the execution engine until specifically requested to do so by the management server. This can be accomplished by issuing the proper `START` command in the management client (see [Section 17.5.2, “Commands in the MySQL Cluster Management Client”](#)).

- `--install[=name]`

<b>Version Introduced</b>	5.1.47-ndb-7.1.5
<b>Command-Line Format</b>	<code>--install[=name]</code>
<b>Permitted Values</b>	
<b>Type</b> (windows)	<code>string</code>
<b>Default</b>	<code>ndbd</code>

Causes `ndbd` to be installed as a Windows service. Optionally, you can specify a name for the service; if not set, the service name defaults to `ndbd`. Although it is preferable to specify other `ndbd` program options in a `my.ini` or `my.cnf` configuration file, it is possible to use together with `--install`. However, in such cases, the `--install` option must be specified first, before any other options are given, for the Windows service installation to succeed.

It is generally not advisable to use this option together with the `--initial` option, since this causes the data node filesystem to be wiped and rebuilt every time the service is stopped and started. Extreme care should also be taken if you intend to use any of the other `ndbd` options that affect the starting of data nodes—including `--initial-start`, `--nostart`, and `--nowait-nodes`—together with `--install`, and you should make absolutely certain you fully understand and allow for any possible consequences of doing so.

The `--install` option has no effect on non-Windows platforms.

This option became available in MySQL Cluster NDB 7.0.16 and MySQL Cluster NDB 7.1.5.

- `--remove[=name]`

<b>Version Introduced</b>	5.1.47-ndb-7.1.5
<b>Command-Line Format</b>	<code>--remove[=name]</code>
<b>Permitted Values</b>	
<b>Type</b> (windows)	<code>string</code>
<b>Default</b>	<code>ndbd</code>

Causes an `ndbd` process that was previously installed as a Windows service to be removed. Optionally, you can specify a name for the service to be uninstalled; if not set, the service name defaults to `ndbd`.

The `--remove` option has no effect on non-Windows platforms.

This option became available in MySQL Cluster NDB 7.0.16 and MySQL Cluster NDB 7.1.5.

`ndbd` generates a set of log files which are placed in the directory specified by `DataDir` in the `config.ini` configuration file.

These log files are listed below. `node_id` is the node's unique identifier. Note that `node_id` represents the node's unique identifier. For example, `ndb_2_error.log` is the error log generated by the data node whose node ID is `2`.

- `ndb_node_id_error.log` is a file containing records of all crashes which the referenced `ndbd` process has encountered. Each record in this file contains a brief error string and a reference to a trace file for this crash. A typical entry in this file might appear as shown here:

```
Date/Time: Saturday 30 July 2004 - 00:20:01
Type of error: error
Message: Internal program error (failed ndbrequire)
Fault ID: 2341
Problem data: DbtupFixAlloc.cpp
Object of reference: DBTUP (Line: 173)
ProgramName: NDB Kernel
ProcessID: 14909
TraceFile: ndb_2_trace.log.2
EOM
```

Listings of possible `ndbd` exit codes and messages generated when a data node process shuts down prematurely can be found in [ndbd Error Messages](#).

**Important**

*The last entry in the error log file is not necessarily the newest one* (nor is it likely to be). Entries in the error log are not listed in chronological order; rather, they correspond to the order of the trace files as determined in the `ndb_node_id_trace.log.next` file (see below). Error log entries are thus overwritten in a cyclical and not sequential fashion.

- `ndb_node_id_trace.log.trace_id` is a trace file describing exactly what happened just before the error occurred. This information is useful for analysis by the MySQL Cluster development team.

It is possible to configure the number of these trace files that will be created before old files are overwritten. `trace_id` is a number which is incremented for each successive trace file.

- `ndb_node_id_trace.log.next` is the file that keeps track of the next trace file number to be assigned.
- `ndb_node_id_out.log` is a file containing any data output by the `ndbd` process. This file is created only if `ndbd` is started as a daemon, which is the default behavior.
- `ndb_node_id.pid` is a file containing the process ID of the `ndbd` process when started as a daemon. It also functions as a lock file to avoid the starting of nodes with the same identifier.
- `ndb_node_id_signal.log` is a file used only in debug versions of `ndbd`, where it is possible to trace all incoming, outgoing, and internal messages with their data in the `ndbd` process.

It is recommended not to use a directory mounted through NFS because in some environments this can cause problems whereby the lock on the `.pid` file remains in effect even after the process has terminated.

To start `ndbd`, it may also be necessary to specify the host name of the management server and the port on which it is listening. Optionally, one may also specify the node ID that the process is to use.

```
shell> ndbd --connect-string="nodeid=2;host=ndb_mgmd.mysql.com:1186"
```

See [Section 17.3.2.3, “The MySQL Cluster Connectstring”](#), for additional information about this issue. [Section 17.4.2, “ndbd — The MySQL Cluster Data Node Daemon”](#), describes other options for `ndbd`.

When `ndbd` starts, it actually initiates two processes. The first of these is called the “angel process”; its only job is to discover when the execution process has been completed, and then to restart the `ndbd` process if it is configured to do so. Thus, if you attempt to kill `ndbd` using the Unix `kill` command, it is necessary to kill both processes, beginning with the angel process. The preferred method of terminating an `ndbd` process is to use the management client and stop the process from there.

The execution process uses one thread for reading, writing, and scanning data, as well as all other activities. This thread is implemented asynchronously so that it can easily handle thousands of concurrent actions. In addition, a watch-dog thread supervises the execution thread to make sure that it does not hang in an endless loop. A pool of threads handles file I/O, with each thread able to handle one open file. Threads can also be used for transporter connections by the transporters in the `ndbd` process. In a multi-processor system performing a large number of operations (including updates), the `ndbd` process can consume up to 2 CPUs if permitted to do so.

For a machine with many CPUs it is possible to use several `ndbd` processes which belong to different node groups; however, such a configuration is still considered experimental and is not supported for MySQL 5.1 in a production setting. See [Section 17.1.5, “Known Limitations of MySQL Cluster”](#).

### 17.4.3. `ndbmttd` — The MySQL Cluster Data Node Daemon (Multi-Threaded)

`ndbmttd` is a multi-threaded version of `ndbd`, the process that is used to handle all the data in tables using the `NDBCLUSTER` storage engine. `ndbmttd` is intended for use on host computers having multiple CPU cores. Except where otherwise noted, `ndbmttd` functions in the same way as `ndbd`; therefore, in this section, we concentrate on the ways in which `ndbmttd` differs from `ndbd`, and you should consult [Section 17.4.2, “ndbd — The MySQL Cluster Data Node Daemon”](#), for additional information about running MySQL Cluster data nodes that apply to both the single-threaded and multi-threaded versions of the data node process.

Command-line options and configuration parameters used with `ndbd` also apply to `ndbmttd`. For more information about these options and parameters, see [Section 17.4.2, “ndbd — The MySQL Cluster Data Node Daemon”](#), and [Section 17.3.2.6, “Defining MySQL Cluster Data Nodes”](#), respectively.

`ndbmttd` is also file system-compatible with `ndbd`. In other words, a data node running `ndbd` can be stopped, the binary replaced with `ndbmttd`, and then restarted without any loss of data. (However, when doing this, you must make sure that `MaxNoOfExecutionThreads` is set to an appropriate value before restarting the node if you wish for `ndbmttd` to run in multi-threaded fashion.) Similarly, an `ndbmttd` binary can be replaced with `ndbd` simply by stopping the node and then starting `ndbd` in place of the multi-

threaded binary. It is not necessary when switching between the two to start the data node binary using `--initial`.

Prior to MySQL Cluster NDB 7.0.6, there were known issues when using `ndbmtd` with MySQL Cluster Disk Data tables. If you wish to use multi-threaded data nodes with disk-based `NDB` tables, you should ensure that you are running MySQL Cluster NDB 7.0.6 or later. ([Bug#41915](#), [Bug#44915](#))

Using `ndbmtd` differs from using `ndbd` in two key respects:

1. You must set an appropriate value for the `MaxNoOfExecutionThreads` configuration parameter in the `config.ini` file. If you do not do so, `ndbmtd` runs in single-threaded mode—that is, it behaves like `ndbd`.
2. Trace files are generated by critical errors in `ndbmtd` processes in a somewhat different fashion from how these are generated by `ndbd` failures.

These differences are discussed in more detail in the next few paragraphs.

**Number of execution threads.** The `MaxNoOfExecutionThreads` configuration parameter is used to determine the number of local query handler (LQH) threads spawned by `ndbmtd`. Although this parameter is set in `[ndbd]` or `[ndbd default]` sections of the `config.ini` file, it is exclusive to `ndbmtd` and does not apply to `ndbd`.

This parameter takes an integer value from 2 to 8 inclusive. Generally, you should set this parameter equal to the number of CPU cores on the data node host, as shown in the following table:

Number of Cores	Recommended <code>MaxNoOfExecutionThreads</code> Value
2	2
4	4
8 or more	8

(It is possible to set this parameter to other values within the permitted range, but these are automatically rounded as shown in the `Value Used` column of the next table in this section.)

The multi-threaded data node process always spawns at least 4 threads:

- 1 local query handler (LQH) thread
- 1 transaction coordinator (TC) thread
- 1 transporter thread
- 1 subscription manager (SUMA) thread

Setting this parameter to a value between 4 and 8 inclusive causes additional LQH threads to be used by `ndbmtd` (up to a maximum of 4 LQH threads), as shown in the following table:

<code>config.ini</code> Value	Value Used	Number of LQH Threads Used
3	2	1
5 or 6	4	2
7	8	4

Setting this parameter outside the permitted range of values causes the management server to abort on startup with the error `ERROR LINE NUMBER: ILLEGAL VALUE VALUE FOR PARAMETER MAXNOOFEVENTS`.

### Note

In MySQL Cluster NDB 6.4.0, it is not possible to set `MaxNoOfExecutionThreads` to 2. You can safely use the value 3 instead (it is treated as 2 internally). This issue is resolved in MySQL Cluster NDB 6.4.1.

In MySQL Cluster NDB 6.4.0 through 6.4.3, the default value for this parameter was undefined, although the default behavior for `ndbmtd` was to use 1 LQH thread, as though `MaxNoOfExecutionThreads` had been set to 2. Beginning with MySQL Cluster NDB 7.0.4, this parameter has an explicit default value of 2, thus guaranteeing this default behavior.

In MySQL Cluster NDB 7.0, it is not possible to cause `ndbmtd` to use more than 1 TC thread, although we plan to introduce this capability in a future MySQL Cluster release series.

Like `ndbd`, `ndbmtd` generates a set of log files which are placed in the directory specified by `DataDir` in the `config.ini` configuration file. Except for trace files, these are generated in the same way and have the same names as those generated by `ndbd`.

In the event of a critical error, `ndbmtd` generates trace files describing what happened just prior to the error's occurrence. These files, which can be found in the data node's `DataDir`, are useful for analysis of problems by the MySQL Cluster Development and Support teams. One trace file is generated for each `ndbmtd` thread. The names of these files follow the pattern `ndb_node_id_trace.log.trace_id_tthread_id`, where `node_id` is the data node's unique node ID in the cluster, `trace_id` is a trace sequence number, and `tthread_id` is the thread ID. For example, in the event of the failure of an `ndbmtd` process running as a MySQL Cluster data node having the node ID 3 and with `MaxNoOfExecutionThreads` equal to 4, four trace files are generated in the data node's data directory; if this is the first time this node has failed, then these files are named `ndb_3_trace.log.1_t1`, `ndb_3_trace.log.1_t2`, `ndb_3_trace.log.1_t3`, and `ndb_3_trace.log.1_t4`. Internally, these trace files follow the same format as `ndbd` trace files.

The `ndbd` exit codes and messages that are generated when a data node process shuts down prematurely are also used by `ndbmtd`. See [ndbd Error Messages](#), for a listing of these.

#### Note

It is possible to use `ndbd` and `ndbmtd` concurrently on different data nodes in the same MySQL Cluster. However, such configurations have not been tested extensively; thus, we cannot recommend doing so in a production setting at this time.

### 17.4.4. `ndb_mgmd` — The MySQL Cluster Management Server Daemon

The management server is the process that reads the cluster configuration file and distributes this information to all nodes in the cluster that request it. It also maintains a log of cluster activities. Management clients can connect to the management server and check the cluster's status.

The following table includes options that are specific to the MySQL Cluster management server program `ndb_mgmd`. Additional descriptions follow the table. For options common to all MySQL Cluster programs, see [Section 17.4.23, “Options Common to MySQL Cluster Programs”](#).

**Table 17.10. `ndb_mgmd` Command Line Options**

Format	Description	Introduction	Deprecated	Removed
<code>--bind-address</code>	Local bind address	5.1.22-ndb-6.3.2		
<code>--config-cache=value</code>	Enable the management server configuration cache; ON by default.	5.1.44-ndb-7.1.4		
<code>-c</code>	Specify the cluster configuration file; in NDB-6.4.0 and later, needs <code>--reload</code> or <code>--initial</code> to override configuration cache if present			
<code>--configdir=directory</code>	Specify the cluster management server's configuration cache directory	5.1.30-ndb-6.4.0		
<code>--daemon</code>	Run <code>ndb_mgmd</code> in daemon mode (default)			
<code>--initial</code>	Causes the management server reload its configuration data from the configuration file, bypassing the configuration cache	5.1.30-ndb-6.4.0		
<code>--install[=name]</code>	Used to install the management server process as a Windows service. Does not apply on non-Windows platforms.	5.1.47-ndb-7.1.5		
<code>--interactive</code>	Run <code>ndb_mgmd</code> in interactive mode (not officially supported in production; for testing purposes only)			
<code>--log-name=</code>	A name to use when writing messages applying to this node in the cluster log.	5.1.37-ndb-7.0.8		
<code>--mycnf</code>	Read cluster configuration data from the <code>my.cnf</code> file			
<code>--no-nodeid-checks</code>	Do not provide any node id checks			
<code>--nodaemon</code>	Do not run <code>ndb_mgmd</code> as a daemon			
<code>--nowait-nodes=list</code>	Do not wait for these management nodes when starting this management server. Also requires <code>--ndb-nodeid</code> to be used.	5.1.39-ndb-7.1.0		
<code>--print-full-config</code>	Print full configuration and exit			
<code>--reload</code>	Causes the management server to compare the configuration file	5.1.30-ndb-		

Format	Description	Introduction	Deprecated	Removed
	with its configuration cache	6.4.0		
--remove[=name]	Used to remove a management server process that was previously installed as a Windows service, optionally specifying the name of the service to be removed. Does not apply on non-Windows platforms.	5.1.47-ndb-7.1.5		

- `--bind-address=host[:port]`

<b>Version Introduced</b>	5.1.22-ndb-6.3.2				
<b>Command-Line Format</b>	<code>--bind-address</code>				
	<b>Permitted Values</b>				
	<table border="1"> <tr> <td>Type</td> <td><code>string</code></td> </tr> <tr> <td>Default</td> <td><code>[none]</code></td> </tr> </table>	Type	<code>string</code>	Default	<code>[none]</code>
Type	<code>string</code>				
Default	<code>[none]</code>				

When specified, this option limits management server connections by management clients to clients at the specified host name or IP address (and possibly port, if this is also specified). In such cases, a management client attempting to connect to the management server from any other address fails with the error `UNABLE TO SETUP PORT: HOST:PORT!`

If the `port` is not specified, the management client attempts to use port 1186.

This option was added in MySQL Cluster NDB 6.2.5 and MySQL Cluster NDB 6.3.2.

- `--configdir=directory`

<b>Version Introduced</b>	5.1.30-ndb-6.4.0				
<b>Command-Line Format</b>	<code>--configdir=directory</code>				
	<table border="1"> <tr> <td>-</td> <td>5.1.37-ndb-7.0.8</td> </tr> <tr> <td>- config-dir=directory</td> <td></td> </tr> </table>	-	5.1.37-ndb-7.0.8	- config-dir=directory	
-	5.1.37-ndb-7.0.8				
- config-dir=directory					
	<b>Permitted Values</b>				
	<table border="1"> <tr> <td>Type</td> <td><code>filename</code></td> </tr> <tr> <td>Default</td> <td><code>\$INSTALLDIR/mysql-cluster</code></td> </tr> </table>	Type	<code>filename</code>	Default	<code>\$INSTALLDIR/mysql-cluster</code>
Type	<code>filename</code>				
Default	<code>\$INSTALLDIR/mysql-cluster</code>				

Beginning with MySQL Cluster NDB 6.4.0, configuration data is cached internally rather than being read from the cluster global configuration file each time the management server is started (see [Section 17.3.2, “MySQL Cluster Configuration Files”](#)).

This option instructs the management server to its configuration cache in the `directory` indicated. By default, this is a directory named `mysql-cluster` in the MySQL installation directory—for example, if you compile and install MySQL Cluster on a Unix system using the default location, this is `/usr/local/mysql-cluster`.

This behavior can be overridden using the `--initial` or `--reload` option for `ndb_mgmd`. Beginning with MySQL Cluster NDB 7.0.15 and MySQL Cluster NDB 7.1.4, it can also be overridden using the `--config-cache` option. Each of these options is described elsewhere in this section.

This option is available beginning with MySQL Cluster NDB 6.4.0.

Beginning with MySQL Cluster NDB 7.0.8, `--config-dir` is accepted as an alias for `--configdir`.

- This option, whose default value is `1` (or `TRUE`, or `ON`), can be used to disable the management server's configuration cache, so that it reads its configuration from `config.ini` every time it starts (see [Section 17.3.2, “MySQL Cluster Configuration Files”](#)). You can do this by starting the `ndb_mgmd` process with any one of the following options:

- `--config-cache=0`
- `--config-cache=FALSE`

- `--config-cache=OFF`
- `--skip-config-cache`

Using one of the options just listed is effective only if the management server has no stored configuration at the time it is started. If the management server finds any configuration cache files, then the `--config-cache` option or the `--skip-config-cache` option is ignored. Therefore, to disable configuration caching, the option should be used the *first* time that the management server is started. Otherwise—that is, if you wish to disable configuration caching for a management server that has *already* created a configuration cache—you must stop the management server, delete any existing configuration cache files manually, then restart the management server with `--skip-config-cache` (or with `--config-cache` set equal to 0, `OFF`, or `FALSE`).

Configuration cache files are normally created in a directory named `mysql-cluster` under the installation directory (unless this location has been overridden using the `--configdir` option). Each time the management server updates its configuration data, it writes a new cache file. The files are named sequentially in order of creation using the following format:

```
ndb_node-id_config.bin.seq-number
```

`node-id` is the management server's node ID; `seq-number` is a sequence number, beginning with 1. For example, if the management server's node ID is 5, then the first three configuration cache files would, when they are created, be named `ndb_5_config.bin.1`, `ndb_5_config.bin.2`, and `ndb_5_config.bin.3`.

If your intent is to purge or reload the configuration cache without actually disabling caching, you should start `ndb_mgmd` with one of the options `--reload` or `--initial` instead of `--skip-config-cache`.

To re-enable the configuration cache, simply restart the management server, but without the `--config-cache` or `--skip-config-cache` option that was used previously to disable the configuration cache.

This option was added in MySQL Cluster NDB 7.0.15 and MySQL Cluster NDB 7.1.4.

- `--config-file=filename, -f filename`

<b>Command-Line Format</b>	<code>--config-file</code>				
	<code>-f</code>				
	<code>-c</code>				
	<b>Permitted Values</b>				
	<table border="1"> <thead> <tr> <th>Type</th><th>filename</th></tr> </thead> <tbody> <tr> <td><b>Default</b></td><td><code>./config.ini</code></td></tr> </tbody> </table>	Type	filename	<b>Default</b>	<code>./config.ini</code>
Type	filename				
<b>Default</b>	<code>./config.ini</code>				

Instructs the management server as to which file it should use for its configuration file. By default, the management server looks for a file named `config.ini` in the same directory as the `ndb_mgmd` executable; otherwise the file name and location must be specified explicitly.

Beginning with MySQL Cluster NDB 6.4.0, this option is ignored unless the management server is forced to read the configuration file, either because `ndb_mgmd` was started with the `--reload` or `--initial` option, or because the management server could not find any configuration cache. Beginning with MySQL Cluster NDB 7.0.15 and MySQL Cluster NDB 7.1.4, this option is also read if `ndb_mgmd` was started with `--config-cache=OFF`. See [Section 17.3.2, “MySQL Cluster Configuration Files”](#), for more information.

- `--daemon, -d`

<b>Command-Line Format</b>	<code>--daemon</code>				
	<code>-d</code>				
	<b>Permitted Values</b>				
	<table border="1"> <thead> <tr> <th>Type</th><th>boolean</th></tr> </thead> <tbody> <tr> <td><b>Default</b></td><td><code>TRUE</code></td></tr> </tbody> </table>	Type	boolean	<b>Default</b>	<code>TRUE</code>
Type	boolean				
<b>Default</b>	<code>TRUE</code>				

Instructs `ndb_mgmd` to start as a daemon process. This is the default behavior.

This option has no effect when running `ndb_mgmd` on Windows platforms.

- `--initial`

<b>Version Introduced</b>	5.1.30-ndb-6.4.0
<b>Command-Line Format</b>	<code>--initial</code>
<b>Permitted Values</b>	
<b>Type</b>	<code>boolean</code>
<b>Default</b>	<code>FALSE</code>

Beginning with MySQL Cluster NDB 6.4.0, configuration data is cached internally rather than being read from the cluster global configuration file each time the management server is started (see [Section 17.3.2, “MySQL Cluster Configuration Files”](#)). Using this option overrides this behavior, by forcing the management server to delete any existing cache files, and then to re-read the configuration data from the cluster configuration file and to build a new cache.

This differs in two ways from the `--reload` option. First, `--reload` forces the server to check the configuration file against the cache and reload its data only if the contents of the file are different from the cache. Second, `--reload` does not delete any existing cache files.

If `ndb_mgmd` is invoked with `--initial` but cannot find a global configuration file, the management server cannot start.

This option was introduced in MySQL Cluster NDB 6.4.0.

- `--log-name=name`

<b>Version Introduced</b>	5.1.37-ndb-7.0.8
<b>Command-Line Format</b>	<code>--log-name=</code>
<b>Permitted Values</b>	
<b>Type</b>	<code>string</code>
<b>Default</b>	<code>MgmtSrvr</code>

Provides a name to be used for this node in the cluster log.

This option was added in MySQL Cluster NDB 7.0.8.

- `--nodaemon`

<b>Command-Line Format</b>	<code>--nodaemon</code>
<b>Permitted Values</b>	
<b>Type</b>	<code>boolean</code>
<b>Default</b>	<code>FALSE</code>
<b>Permitted Values</b>	
<b>Type (windows)</b>	<code>boolean</code>
<b>Default</b>	<code>TRUE</code>

Instructs `ndb_mgmd` not to start as a daemon process.

As of MySQL Cluster NDB 7.0.8, the default behavior for `ndb_mgmd` on Windows is to run in the foreground, making this option unnecessary on Windows platforms. ([Bug#45588](#))

- `--print-full-config, -P`

<b>Command-Line Format</b>	<code>--print-full-config</code>
	<code>-P</code>

<b>Permitted Values</b>	
<b>Type</b>	<code>boolean</code>
<b>Default</b>	<code>FALSE</code>

Shows extended information regarding the configuration of the cluster. With this option on the command line the `ndb_mgmd` process prints information about the cluster setup including an extensive list of the cluster configuration sections as well as parameters and their values. Normally used together with the `--config-file (-f)` option.

- `--reload`

<b>Version Introduced</b>	5.1.30-ndb-6.4.0
<b>Command-Line Format</b>	<code>--reload</code>
<b>Permitted Values</b>	
<b>Type</b>	<code>boolean</code>
<b>Default</b>	<code>FALSE</code>

Beginning with MySQL Cluster NDB 6.4.0, configuration data is stored internally rather than being read from the cluster global configuration file each time the management server is started (see [Section 17.3.2, “MySQL Cluster Configuration Files”](#)). Using this option forces the management server to check its internal data store against the cluster configuration file and to reload the configuration if it finds that the configuration file does not match the cache. Existing configuration cache files are preserved, but not used.

This differs in two ways from the `--initial` option. First, `--initial` causes all cache files to be deleted. Second, `--initial` forces the management server to re-read the global configuration file and construct a new cache.

If the management server cannot find a global configuration file, then the `--reload` option is ignored.

This option was introduced in MySQL Cluster NDB 6.4.0.

- `--nowait-nodes`

<b>Version Introduced</b>	5.1.39-ndb-7.1.0
<b>Command-Line Format</b>	<code>--nowait-nodes=list</code>
<b>Permitted Values</b>	
<b>Type</b>	<code>numeric</code>
<b>Default</b>	
<b>Range</b>	<code>1-255</code>

When starting a MySQL Cluster is configured with two management nodes and running MySQL Cluster NDB 7.0 and later, each management server normally checks to see whether the other `ndb_mgmd` is also operational and whether the other management server's configuration is identical to its own. However, it is sometimes desirable to start the cluster with only one management node (and perhaps to allow the other `ndb_mgmd` to be started later). This option causes the management node to bypass any checks for any other management nodes whose node IDs are passed to this option, permitting the cluster to start as though configured to use only the management node that was started.

For purposes of illustration, consider the following portion of a `config.ini` file (where we have omitted most of the configuration parameters that are not relevant to this example):

```
[ndbd]
NodeId = 1
HostName = 192.168.0.101

[ndbd]
NodeId = 2
HostName = 192.168.0.102

[ndbd]
NodeId = 3
HostName = 192.168.0.103

[ndbd]
NodeId = 4
HostName = 192.168.0.104
```

```
[ndb_mgmd]
NodeId = 10
HostName = 192.168.0.150

[ndb_mgmd]
NodeId = 11
HostName = 192.168.0.151

[api]
NodeId = 20
HostName = 192.168.0.200

[api]
NodeId = 21
HostName = 192.168.0.201
```

Assume that you wish to start this cluster using only the management server having node ID 10 and running on the host having the IP address 192.168.0.150. (Suppose, for example, that the host computer on which you intend to the other management server is temporarily unavailable due to a hardware failure, and you are waiting for it to be repaired.) To start the cluster in this way, use a command line on the machine at 192.168.0.150 to enter the following command:

```
shell> ndb_mgmd --ndb-nodeid=10 --nowait-nodes=11
```

As shown in the preceding example, when using `--nowait-nodes`, you must also use the `--ndb-nodeid` option to specify the node ID of this `ndb_mgmd` process.

You can then start each of the cluster's data nodes in the usual way. If you wish to start and use the second management server in addition to the first management server at a later time without restarting the data nodes, you must start each data node with a connectstring that references both management servers, like this:

```
shell> ndbd -c 192.168.0.150,192.168.0.151
```

The same is true with regard to the connectstring used with any `mysqld` processes that you wish to start as MySQL Cluster SQL nodes connected to this cluster. See [Section 17.3.2.3, “The MySQL Cluster Connectstring”](#), for more information.

When used with `ndb_mgmd`, this option affects the behavior of the management node with regard to other management nodes only. Do not confuse it with the `--nowait-nodes` option used with `ndbd` (or `ndbmt`) in MySQL Cluster NDB 7.0 and later) to permit a cluster to start with fewer than its full complement of data nodes; when used with data nodes, this option affects their behavior only with regard to other data nodes.

Multiple management node IDs may be passed to this option as a comma-separated list. Each node ID must be no less than 1 and no greater than 255. In practice, it is quite rare to use more than two management servers for the same MySQL Cluster (or to have any need for doing so); in most cases you need to pass to this option only the single node ID for the one management server that you do not wish to use when starting the cluster.

### Note

When you later start the “missing” management server, its configuration must match that of the management server that is already in use by the cluster. Otherwise, it fails the configuration check performed by the existing management server, and does not start.

This option was introduced in MySQL Cluster NDB 7.0.10 and MySQL Cluster NDB 7.1.0.

It is not strictly necessary to specify a connectstring when starting the management server. However, if you are using more than one management server, a connectstring should be provided and each node in the cluster should specify its node ID explicitly.

See [Section 17.3.2.3, “The MySQL Cluster Connectstring”](#), for information about using connectstrings. [Section 17.4.4, “`ndb\_mgmd` — The MySQL Cluster Management Server Daemon”](#), describes other options for `ndb_mgmd`.

The following files are created or used by `ndb_mgmd` in its starting directory, and are placed in the `DataDir` as specified in the `config.ini` configuration file. In the list that follows, `node_id` is the unique node identifier.

- `config.ini` is the configuration file for the cluster as a whole. This file is created by the user and read by the management server. [Section 17.3, “MySQL Cluster Configuration”](#), discusses how to set up this file.
- `ndb_node_id_cluster.log` is the cluster events log file. Examples of such events include checkpoint startup and completion, node startup events, node failures, and levels of memory usage. A complete listing of cluster events with descriptions may be found in [Section 17.5, “Management of MySQL Cluster”](#).

When the size of the cluster log reaches one million bytes, the file is renamed to `ndb_node_id_cluster.log.seq_id`, where `seq_id` is the sequence number of the cluster log file. (For example: If files with the sequence numbers 1, 2, and 3 already exist, the next log file is named using the number 4.)

- `ndb_node_id_out.log` is the file used for `stdout` and `stderr` when running the management server as a daemon.
- `ndb_node_id.pid` is the process ID file used when running the management server as a daemon.
- `--install[=name]`

<b>Version Introduced</b>	5.1.47-ndb-7.1.5
<b>Command-Line Format</b>	<code>--install[=name]</code>
	<b>Permitted Values</b>
	<b>Type</b> <code>string</code> (windows)
	<b>Default</b> <code>ndb_mgmd</code>

Causes `ndb_mgmd` to be installed as a Windows service. Optionally, you can specify a name for the service; if not set, the service name defaults to `ndb_mgmd`. Although it is preferable to specify other `ndb_mgmd` program options in a `my.ini` or `my.cnf` configuration file, it is possible to use them together with `--install`. However, in such cases, the `--install` option must be specified first, before any other options are given, for the Windows service installation to succeed.

It is generally not advisable to use this option together with the `--initial` option, since this causes the configuration cache to be wiped and rebuilt every time the service is stopped and started. Care should also be taken if you intend to use any other `ndb_mgmd` options that affect the starting of the management server, and you should make absolutely certain you fully understand and allow for any possible consequences of doing so.

The `--install` option has no effect on non-Windows platforms.

This option became available in MySQL Cluster NDB 7.0.16 and MySQL Cluster NDB 7.1.5.

- `--remove[=name]`

<b>Version Introduced</b>	5.1.47-ndb-7.1.5
<b>Command-Line Format</b>	<code>--remove[=name]</code>
	<b>Permitted Values</b>
	<b>Type</b> <code>string</code> (windows)
	<b>Default</b> <code>ndb_mgmd</code>

Causes an `ndb_mgmd` process that was previously installed as a Windows service to be removed. Optionally, you can specify a name for the service to be uninstalled; if not set, the service name defaults to `ndb_mgmd`.

The `--remove` option has no effect on non-Windows platforms.

This option became available in MySQL Cluster NDB 7.0.16 and MySQL Cluster NDB 7.1.5.

## 17.4.5. `ndb_mgm` — The MySQL Cluster Management Client

The `ndb_mgm` management client process is actually not needed to run the cluster. Its value lies in providing a set of commands for checking the cluster's status, starting backups, and performing other administrative functions. The management client accesses the management server using a C API. Advanced users can also employ this API for programming dedicated management processes to perform tasks similar to those performed by `ndb_mgm`.

To start the management client, it is necessary to supply the host name and port number of the management server:

```
shell> ndb_mgm [host_name [port_num]]
```

For example:

```
shell> ndb_mgm ndb_mgmd.mysql.com 1186
```

The default host name and port number are `localhost` and 1186, respectively.

The following table includes options that are specific to the MySQL Cluster management client program `ndb_mgm`. Additional descriptions follow the table. For options common to all MySQL Cluster programs, see [Section 17.4.23, “Options Common to MySQL Cluster Programs”](#).

**Table 17.11. `ndb_mgm` Command Line Options**

Format	Description	Introduction	Deprecated	Removed
<code>--execute=name</code>	Execute command and exit			
<code>--try-reconnect=#</code>	Specify number of tries for connecting to <code>ndb_mgmd</code> (0 = infinite)			

- `--execute=command`, `-e command`

<b>Command-Line Format</b>	<code>--execute=name</code>
	<code>-e</code>

This option can be used to send a command to the MySQL Cluster management client from the system shell. For example, either of the following:

```
shell> ndb_mgm -e "SHOW"
```

or

```
shell> ndb_mgm --execute="SHOW"
```

is equivalent to

```
ndb_mgm> SHOW
```

This is analogous to how the `--execute` or `-e` option works with the `mysql` command-line client. See [Section 4.2.3.1, “Using Options on the Command Line”](#).

### Note

If the management client command to be passed using this option contains any space characters, then the command *must* be enclosed in quotation marks. Either single or double quotation marks may be used. If the management client command contains no space characters, the quotation marks are optional.

- `--try-reconnect=number`

<b>Command-Line Format</b>	<code>--try-reconnect=#</code>
	<code>-t</code>
	<b>Permitted Values</b>
	Type <code>boolean</code>
	Default <code>TRUE</code>

If the connection to the management server is broken, the node tries to reconnect to it every 5 seconds until it succeeds. By using this option, it is possible to limit the number of attempts to `number` before giving up and reporting an error instead.

Additional information about using `ndb_mgm` can be found in [Section 17.5.2, “Commands in the MySQL Cluster Management Client”](#).

## 17.4.6. `ndb_config` — Extract MySQL Cluster Configuration Information

This tool extracts current configuration information for data nodes, SQL nodes, and API nodes from a cluster management node (and possibly its `config.ini` file). Beginning with MySQL Cluster NDB 6.3.25 and MySQL Cluster NDB 7.0.6, it can also provide an offline dump (in text or XML format) of all configuration parameters which can be used, along with their default, maximum, and minimum values and other information (see the discussion of the `--configinfo` and `--xml` options later in this section).

The following table includes options that are specific to `ndb_config`. Additional descriptions follow the table. For options common to all MySQL Cluster programs, see [Section 17.4.23, “Options Common to MySQL Cluster Programs”](#).

**Table 17.12. `ndb_config` Command Line Options**

Format	Description	Introduction	Deprecated	Removed
<code>--configinfo</code>	Dumps information about all NDB configuration parameters in text format with default, maximum, and minimum values. Use with <code>--xml</code> to obtain XML output.	5.1.34-ndb-7.0.6		
<code>--connections</code>	Print connection information only			
<code>--fields=string</code>	Field separator			
<code>--host=name</code>	Specify host			
<code>--mycnf</code>	Read configuration data from my.cnf file			
<code>--nodeid</code>	Get configuration of node with this ID			
<code>--nodes</code>	Print node information only			
	Short form for <code>--ndb-connectstring</code>	5.1.12		
<code>--config-file=path</code>	Set the path to config.ini file			
<code>--query=string</code>	One or more query options (attributes)			
<code>--rows=string</code>	Row separator			
<code>--type=name</code>	Specify node type			
<code>--configinfo --xml</code>	Use with <code>--configinfo</code> to obtain a dump of all NDB configuration parameters in XML format with default, maximum, and minimum values.	5.1.34-ndb-7.0.6		

- `--usage`, `--help`, or `-?`

Command-Line Format	<code>--help</code>
	<code>--usage</code>
	<code>-?</code>

Causes `ndb_config` to print a list of available options, and then exit.

- `--version`, `-V`

Command-Line Format	<code>-V</code>
	<code>--version</code>

Causes `ndb_config` to print a version information string, and then exit.

- `--ndb-connectstring=connect_string`

Command-Line Format	<code>--ndb-connectstring=name</code>
	<code>--connect-string=name</code>
	<code>-C</code>
<b>Permitted Values</b>	
Type	<code>string</code>
Default	<code>localhost:1186</code>

Specifies the connectstring to use in connecting to the management server. The format for the connectstring is the same as described in [Section 17.3.2.3, “The MySQL Cluster Connectstring”](#), and defaults to `localhost:1186`.

The use of `-c` as a short version for this option is supported for `ndb_config` beginning with MySQL 5.1.12.

- `--config-file=path-to-file`

Gives the path to the management server's configuration file (`config.ini`). This may be a relative or absolute path. If the management node resides on a different host from the one on which `ndb_config` is invoked, then an absolute path must be used.

- `--query=query-options, -q query-options`

<b>Command-Line Format</b>	<code>--query=string</code>
	<code>-q</code>
	<b>Permitted Values</b>
	Type <code>string</code>
	<b>Default</b>

This is a comma-delimited list of *query options*—that is, a list of one or more node attributes to be returned. These include `id` (node ID), type (node type—that is, `ndbd`, `mysqld`, or `ndb_mgmd`), and any configuration parameters whose values are to be obtained.

For example, `--query=id,type,indexmemory,datamemory` would return the node ID, node type, `DataMemory`, and `IndexMemory` for each node.

### Note

If a given parameter is not applicable to a certain type of node, than an empty string is returned for the corresponding value. See the examples later in this section for more information.

- `--host=hostname`

<b>Command-Line Format</b>	<code>--host=name</code>
	<b>Permitted Values</b>
	Type <code>string</code>
	<b>Default</b>

Specifies the host name of the node for which configuration information is to be obtained.

### Note

While the hostname `localhost` usually resolves to the IP address `127.0.0.1`, this may not necessarily be true for all operating platforms and configurations. This means that it is possible, when `localhost` is used in `config.ini`, for `ndb_config --host=localhost` to fail if `ndb_config` is run on a different host where `localhost` resolves to a different address (for example, on some versions of SUSE Linux, this is `127.0.0.2`). In general, for best results, you should use numeric IP addresses for all MySQL Cluster configuration values relating to hosts, or verify that all MySQL Cluster hosts handle `localhost` in the same fashion.

- `--id=node_id, --nodeid=node_id`

Used to specify the node ID of the node for which configuration information is to be obtained.

- `--nodes`

<b>Command-Line Format</b>	<code>--nodes</code>
	<b>Permitted Values</b>
	Type <code>boolean</code>
	<b>Default</b> <code>FALSE</code>

(Tells `ndb_config` to print information from parameters defined in `[ndbd]` sections only. Currently, using this option has

no affect, since these are the only values checked, but it may become possible in future to query parameters set in [tcp] and other sections of cluster configuration files.)

- `--type=node_type`

<b>Command-Line Format</b>	<code>--type=name</code>
<b>Permitted Values</b>	
<b>Type</b>	<code>enumeration</code>
<b>Default</b>	
<b>Valid Values</b>	<code>ndbd, mysqld, ndb_mgmd</code>

Filters results so that only configuration values applying to nodes of the specified `node_type` (`ndbd`, `mysqld`, or `ndb_mgmd`) are returned.

- `--fields=delimiter, -f delimiter`

<b>Command-Line Format</b>	<code>--fields=string</code>
	<code>-f</code>
<b>Permitted Values</b>	
<b>Type</b>	<code>string</code>
<b>Default</b>	

Specifies a `delimiter` string used to separate the fields in the result. The default is “,” (the comma character).

### Note

If the `delimiter` contains spaces or escapes (such as `\n` for the linefeed character), then it must be quoted.

- `--rows=separator, -r separator`

<b>Command-Line Format</b>	<code>--rows=string</code>
	<code>-r</code>
<b>Permitted Values</b>	
<b>Type</b>	<code>string</code>
<b>Default</b>	

Specifies a `separator` string used to separate the rows in the result. The default is a space character.

### Note

If the `separator` contains spaces or escapes (such as `\n` for the linefeed character), then it must be quoted.

- `--configinfo`

The `--configinfo` option, added in MySQL Cluster NDB 6.3.25 and MySQL Cluster NDB 7.0.6, causes `ndb_config` to dump a list of each MySQL Cluster configuration parameter supported by the MySQL Cluster distribution of which `ndb_config` is a part, including the following information:

- A brief description of each parameter's purpose, effects, and usage
- The section of the `config.ini` file where the parameter may be used
- The parameter's data type or unit of measurement
- Where applicable, the parameter's default, minimum, and maximum values
- A brief description of the parameter's purpose, effects, and usage
- MySQL Cluster release version and build information

By default, this output is in text format. Part of this output is shown here:

```
shell> ndb_config --configinfo

** SYSTEM ****
Name (String)
Name of system (NDB Cluster)
MANDATORY

PrimaryMGMNode (Non-negative Integer)
Node id of Primary ndb_mgmd(MGM) node
Default: 0 (Min: 0, Max: 4294967039)

ConfigGenerationNumber (Non-negative Integer)
Configuration generation number
Default: 0 (Min: 0, Max: 4294967039)

** DB ****
MaxNoOfSubscriptions (Non-negative Integer)
Max no of subscriptions (default 0 == MaxNoOfTables)
Default: 0 (Min: 0, Max: 4294967039)

MaxNoOfSubscribers (Non-negative Integer)
Max no of subscribers (default 0 == 2 * MaxNoOfTables)
Default: 0 (Min: 0, Max: 4294967039)

...

```

--configinfo --xml

<b>Version Introduced</b>	5.1.34-ndb-7.0.6
<b>Command-Line Format</b>	--configinfo --xml
	<b>Permitted Values</b>
	<b>Type</b> boolean
	<b>Default</b> false

You can obtain the output of `ndb_config --configinfo` as XML by adding the `--xml` option (like the `--configinfo` option, available beginning with MySQL Cluster NDB 6.3.25 and MySQL Cluster NDB 7.0.6). A portion of the resulting output is shown in this example:

```
shell> ndb_config --configinfo --xml
<configvariables protocolversion="1" ndbversionstring="mysql-5.1.34 ndb-7.0.6"
 ndbversion="458758" ndbversionmajor="7" ndbversionminor="0"
 ndbversionbuild="6">
 <section name="SYSTEM">
 <param name="Name" comment="Name of system (NDB Cluster)" type="string"
 mandatory="true"/>
 <param name="PrimaryMGMNode" comment="Node id of Primary ndb_mgmd(MGM) node"
 type="unsigned" default="0" min="0" max="4294967039"/>
 <param name="ConfigGenerationNumber" comment="Configuration generation number"
 type="unsigned" default="0" min="0" max="4294967039"/>
 </section>
 <section name="NDBD">
 <param name="MaxNoOfSubscriptions" comment="Max no of subscriptions (default 0 == MaxNoOfTables)"
 type="unsigned" default="0" min="0" max="4294967039"/>
 <param name="MaxNoOfSubscribers" comment="Max no of subscribers (default 0 == 2 * MaxNoOfTables)"
 type="unsigned" default="0" min="0" max="4294967039"/>
 ...
 </section>
 ...
</configvariables>
```

### Note

Normally, the XML output produced by `ndb_config --configinfo --xml` is formatted using one line per element; we have added extra whitespace in the previous example, as well as the next one, for reasons of legibility. This should not make any difference to applications using this output, since most XML processors either ignore nonessential whitespace as a matter of course, or can be instructed to do so.

Beginning with MySQL Cluster NDB 6.3.29 and MySQL Cluster NDB 7.0.10, the XML output also indicates when changing a given parameter requires that nodes be restarted using the `--initial` option. This is shown by the presence of an `initial="true"` attribute in the corresponding `<param>` element. In addition (also beginning with MySQL Cluster NDB

6.3.29 and MySQL Cluster NDB 7.0.10), the restart type (`system` or `node`) is also shown; if a given parameter requires a system restart, this is indicated by the presence of a `restart="system"` attribute in the corresponding `<param>` element. For example, the `Diskless` parameter requires a system initial restart, as shown here (with the `restart` and `initial` attributes highlighted for visibility):

```
<param name="Diskless" comment="Run wo/ disk" type="bool" default="false"
 restart="system" initial="true"/>
```

Currently, no `initial` attribute is included in the XML output for `<param>` elements corresponding to parameters which do not require initial restarts; in other words, `initial="false"` is the default, and the value `false` should be assumed if the attribute is not present. Similarly, the default restart type is `node` (that is, an online or “rolling” restart of the cluster), but the `restart` attribute is included only if the restart type is `system` (meaning that all cluster nodes must be shut down at the same time, then restarted).

### Important

The `--xml` option can be used only with the `--configinfo` option. Using `--xml` without `--configinfo` fails with an error.

Unlike the options used with this program to obtain current configuration data, `--configinfo` and `--xml` use information obtained from the MySQL Cluster sources when `ndb_config` was compiled. For this reason, no connection to a running MySQL Cluster or access to a `config.ini` or `my.cnf` file is required for these two options.

Combining other `ndb_config` options (such as `--query` or `--type`) with `--configinfo` or `--xml` is not supported. If you attempt to do so, the usual (current) result is that all other options besides `--configinfo` or `--xml` are simply ignored. However, this behavior is not guaranteed and is subject to change at any time. In addition, since `ndb_config` when used with the `--configinfo` option does not access the MySQL Cluster or read any files, trying to specify additional options such as `-ndb-connectstring` or `--config-file` with `--configinfo` serves no purpose.

### Examples:

- To obtain the node ID and type of each node in the cluster:

```
shell> ./ndb_config --query=id,type --fields=':' --rows='\n'
1:ndbd
2:ndbd
3:ndbd
4:ndbd
5:ndb_mgmd
6:mysqld
7:mysqld
8:mysqld
9:mysqld
```

In this example, we used the `--fields` options to separate the ID and type of each node with a colon character (:), and the `--rows` options to place the values for each node on a new line in the output.

- To produce a connectstring that can be used by data, SQL, and API nodes to connect to the management server:

```
shell> ./ndb_config --config-file=usr/local/mysql/cluster-data/config.ini --query=hostname,portnumber --fields=-
192.168.0.179:1186
```

- This invocation of `ndb_config` checks only data nodes (using the `--type` option), and shows the values for each node's ID and host name, and its `DataMemory`, `IndexMemory`, and `DataDir` parameters:

```
shell> ./ndb_config --type=ndbd --query=id,host,datamemory,indexmemory,datadir -f ' : ' -r '\n'
1 : 192.168.0.193 : 83886080 : 18874368 : /usr/local/mysql/cluster-data
2 : 192.168.0.112 : 83886080 : 18874368 : /usr/local/mysql/cluster-data
3 : 192.168.0.176 : 83886080 : 18874368 : /usr/local/mysql/cluster-data
4 : 192.168.0.119 : 83886080 : 18874368 : /usr/local/mysql/cluster-data
```

In this example, we used the short options `-f` and `-r` for setting the field delimiter and row separator, respectively.

- To exclude results from any host except one in particular, use the `--host` option:

```
shell> ./ndb_config --host=192.168.0.176 -f ' : ' -r '\n' -q id,type
3:ndbd
5:ndb_mgmd
```

In this example, we also used the short form `-q` to determine the attributes to be queried.

Similarly, you can limit results to a node with a specific ID using the `--id` or `--nodeid` option.

## 17.4.7. `ndb_cpcd` — Automate Testing for NDB Development

This utility is found in the `libexec` directory. It is part of an internal automated test framework used in testing and debugging MySQL Cluster. Because it can control processes on remote systems, it is not advisable to use `ndb_cpcd` in a production cluster.

The source files for `ndb_cpcd` may be found in the directory `storage/ndb/src/cw/cpcd`, in the MySQL Cluster source tree.

## 17.4.8. `ndb_delete_all` — Delete All Rows from an NDB Table

`ndb_delete_all` deletes all rows from the given NDB table. In some cases, this can be much faster than `DELETE` or even `TRUNCATE TABLE`.

**Usage:**

```
ndb_delete_all -c connect_string tbl_name -d db_name
```

This deletes all rows from the table named `tbl_name` in the database named `db_name`. It is exactly equivalent to executing `TRUNCATE db_name.tbl_name` in MySQL.

**Additional Options:**

- `--transactional, -t`

Use of this option causes the delete operation to be performed as a single transaction.

### Warning

With very large tables, using this option may cause the number of operations available to the cluster to be exceeded.

## 17.4.9. `ndb_desc` — Describe NDB Tables

`ndb_desc` provides a detailed description of one or more NDB tables.

**Usage:**

```
ndb_desc -c connect_string tbl_name -d db_name [-p]
```

**Sample Output:**

MySQL table creation and population statements:

```
USE test;
CREATE TABLE fish (
 id INT(11) NOT NULL AUTO_INCREMENT,
 name VARCHAR(20) NOT NULL,
 length_mm INT(11) NOT NULL,
 weight_gm INT(11) NOT NULL,
 PRIMARY KEY pk (id),
 UNIQUE KEY uk (name)
) ENGINE=NDB;
INSERT INTO fish VALUES
 ('','guppy', 35, 2), ('','tuna', 2500, 150000),
 ('','shark', 3000, 110000), ('','manta ray', 1500, 50000),
 ('','grouper', 900, 125000), ('','puffer', 250, 2500);
```

Output from `ndb_desc`:

```
shell> ./ndb_desc -c localhost fish -d test -p
-- fish --
Version: 2
Fragment type: 9
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: no
```

```

Number of attributes: 4
Number of primary keys: 1
Length of frm data: 311
Row Checksum: 1
Row GCI: 1
SingleUserMode: 0
ForceVarPart: 1
FragmentCount: 2
TableStatus: Retrieved
-- Attributes --
id Int PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY AUTO_INCR
name Varchar(20;latin1_swedish_ci) NOT NULL AT=SHORT_VAR ST=MEMORY
length_mm Int NOT NULL AT=FIXED ST=MEMORY
weight_gm Int NOT NULL AT=FIXED ST=MEMORY

-- Indexes --
PRIMARY KEY(id) - UniqueHashIndex
PRIMARY(id) - OrderedIndex
uk$unique(name) - UniqueHashIndex
uk(name) - OrderedIndex

-- Per partition info --
Partition Row count Commit count Frag fixed memory Frag varsized memory Extent_space Free extent_space
0 2 2 32768 32768 0 0
1 4 4 32768 32768 0 0

NDBT_ProgramExit: 0 - OK

```

Information about multiple tables can be obtained in a single invocation of `ndb_desc` by using their names, separated by spaces. All of the tables must be in the same database.

The `Extent_space` and `Free extent_space` columns were added in MySQL Cluster NDB 6.3.27 and MySQL Cluster NDB 7.0.8. They are applicable only to NDB tables having columns on disk; for tables having only in-memory columns, these columns always contain the value 0.

To illustrate their use, we modify the previous example. First, we must create the necessary Disk Data objects, as shown here:

```

CREATE LOGFILE GROUP lg_1
 ADD UNDOFILE 'undo_1.log'
 INITIAL_SIZE 16M
 UNDO_BUFFER_SIZE 2M
 ENGINE NDB;

ALTER LOGFILE GROUP lg_1
 ADD UNDOFILE 'undo_2.log'
 INITIAL_SIZE 12M
 ENGINE NDB;

CREATE TABLESPACE ts_1
 ADD DATAFILE 'data_1.dat'
 USE LOGFILE GROUP lg_1
 INITIAL_SIZE 32M
 ENGINE NDB;

ALTER TABLESPACE ts_1
 ADD DATAFILE 'data_2.dat'
 INITIAL_SIZE 48M
 ENGINE NDB;

```

(For more information on the statements just shown and the objects created by them, see [Section 17.5.10.1, “MySQL Cluster Disk Data Objects”](#), as well as [Section 12.1.14, “CREATE LOGFILE GROUP Syntax”](#), and [Section 12.1.18, “CREATE TABLESPACE Syntax”](#).)

Now we can create and populate a version of the `fish` table that stores 2 of its columns on disk (deleting the previous version of the table first, if it already exists):

```

CREATE TABLE fish (
 id INT(11) NOT NULL AUTO_INCREMENT,
 name VARCHAR(20) NOT NULL,
 length_mm INT(11) NOT NULL,
 weight_gm INT(11) NOT NULL,

 PRIMARY KEY pk (id),
 UNIQUE KEY uk (name)
) TABLESPACE ts_1 STORAGE DISK
ENGINE=NDB;

INSERT INTO fish VALUES
 ('','guppy', 35, 2), ('','tuna', 2500, 150000),
 ('','shark', 3000, 110000), ('','manta ray', 1500, 50000),
 ('','grouper', 900, 125000), ('','puffer', 250, 2500);

```

When run against this version of the table, `ndb_desc` displays the following output:

```

shell> ./ndb_desc -c localhost fish -d test -p
-- fish --
Version: 3

```

```

Fragment type: 9
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: no
Number of attributes: 4
Number of primary keys: 1
Length of frm data: 321
Row Checksum: 1
Row GCI: 1
SingleUserMode: 0
ForceVarPart: 1
FragmentCount: 2
TableStatus: Retrieved
-- Attributes --
id Int PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY AUTO_INCR
name Varchar(20;latin1_swedish_ci) NOT NULL AT=SHORT_VAR ST=MEMORY
length_mm Int NOT NULL AT=FIXED ST=DISK
weight_gm Int NOT NULL AT=FIXED ST=DISK

-- Indexes --
PRIMARY KEY(id) - UniqueHashIndex
PRIMARY(id) - OrderedIndex
uk$unique(name) - UniqueHashIndex
uk(name) - OrderedIndex

-- Per partition info --
Partition Row count Commit count Frag fixed memory Frag varsized memory Extent_space Free extent_space
0 2 2 32768 32768 1048576 1044440
1 4 4 32768 32768 1048576 1044400

NDBT_ProgramExit: 0 - OK

```

This means that 1048576 bytes are allocated from the tablespace for this table on each partition, of which 1044440 bytes remain free for additional storage. In other words,  $1048576 - 1044440 = 4136$  bytes per partition is currently being used to store the data from this table's disk-based columns. The number of bytes shown as `Free extent_space` is available for storing on-disk column data from the `fish` table only; for this reason, it is not visible when selecting from the `INFORMATION_SCHEMA.FILES` table.

#### Additional Options:

- `--extra-partition-info, -p`

Print additional information about the table's partitions.

- `--blob-info, -b`

Include information about subordinate `BLOB` and `TEXT` columns.

Use of this option also requires the use of the `--extra-partition-info (-p)` option.

This option was added in MySQL Cluster NDB 6.3.32, MySQL Cluster NDB 7.0.13, and MySQL Cluster NDB 7.1.2.

- `--extra-node-info, -n`

Include information about the mappings between table partitions and the data nodes upon which they reside. This information can be useful for verifying distribution awareness mechanisms and supporting more efficient application access to the data stored in MySQL Cluster.

Use of this option also requires the use of the `--extra-partition-info (-p)` option.

This option was added in MySQL Cluster NDB 6.2.19, MySQL Cluster NDB 6.3.33, MySQL Cluster NDB 7.0.14, and MySQL Cluster NDB 7.1.2.

## 17.4.10. `ndb_drop_index` — Drop Index from an NDB Table

`ndb_drop_index` drops the specified index from an `NDB` table. *It is recommended that you use this utility only as an example for writing NDB API applications—see the Warning later in this section for details.*

#### Usage:

```
ndb_drop_index -c connect_string table_name index -d db_name
```

The statement shown above drops the index named `index` from the `table` in the `database`.

**Additional Options:** None that are specific to this application.

## Warning

*Operations performed on Cluster table indexes using the NDB API are not visible to MySQL and make the table unusable by a MySQL server.* If you use this program to drop an index, then try to access the table from an SQL node, an error results, as shown here:

```
shell> ./ndb_drop_index -c localhost dogs ix -d ctest1
Dropping index dogs/idx...OK
NDBT_ProgramExit: 0 - OK

shell> ./mysql -u jon -p ctest1
Enter password: *****
Reading table information for completion of table and column names
You can turn off this feature to get a quicker startup with -A

Welcome to the MySQL monitor. Commands end with ; or \g.
Your MySQL connection id is 7 to server version: 5.1.47-ndb-7.1.8

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SHOW TABLES;
+-----+
| Tables_in_ctest1 |
+-----+
| a
 bt1
 bt2
 dogs
 employees
 fish
+-----+
6 rows in set (0.00 sec)

mysql> SELECT * FROM dogs;
ERROR 1296 (HY000): GOT ERROR 4243 'INDEX NOT FOUND' FROM NDBCLOUD
```

In such a case, your *only* option for making the table available to MySQL again is to drop the table and re-create it. You can use either the SQL statement `DROP TABLE` or the `ndb_drop_table` utility (see [Section 17.4.11, “`ndb\_drop\_table` — Drop an NDB Table”](#)) to drop the table.

### 17.4.11. `ndb_drop_table` — Drop an NDB Table

`ndb_drop_table` drops the specified NDB table. (If you try to use this on a table created with a storage engine other than NDB, it fails with the error `723: NO SUCH TABLE EXISTS`.) This operation is extremely fast—in some cases, it can be an order of magnitude faster than using `DROP TABLE` on an NDB table from MySQL.

**Usage:**

```
ndb_drop_table -c connect_string tbl_name -d db_name
```

**Additional Options:** None.

### 17.4.12. `ndb_error_reporter` — NDB Error-Reporting Utility

`ndb_error_reporter` creates an archive from data node and management node log files that can be used to help diagnose bugs or other problems with a cluster. *It is highly recommended that you make use of this utility when filing reports of bugs in MySQL Cluster.*

**Usage:**

```
ndb_error_reporter path/to/config-file [username] [--fs]
```

This utility is intended for use on a management node host, and requires the path to the management host configuration file (`config.ini`). Optionally, you can supply the name of a user that is able to access the cluster's data nodes using SSH, to copy the data node log files. `ndb_error_reporter` then includes all of these files in archive that is created in the same directory in which it is run. The archive is named `ndb_error_report_YYYYMMDDHHMMSS.tar.bz2`, where `YYYYMMDDHHMMSS` is a datetime string.

If the `--fs` is used, then the data node file systems are also copied to the management host and included in the archive that is produced by this script. As data node file systems can be extremely large even after being compressed, we ask that you please do *not* send archives created using this option to Oracle unless you are specifically requested to do so.

Command-Line Format	<code>--fs</code>
---------------------	-------------------

Permitted Values	
Type	boolean
Default	FALSE

### 17.4.13. `ndb_print_backup_file` — Print NDB Backup File Contents

`ndb_print_backup_file` obtains diagnostic information from a cluster backup file.

**Usage:**

```
ndb_print_backup_file file_name
```

*file\_name* is the name of a cluster backup file. This can be any of the files (.Data, .ctl, or .log file) found in a cluster backup directory. These files are found in the data node's backup directory under the subdirectory BACKUP-#, where # is the sequence number for the backup. For more information about cluster backup files and their contents, see [Section 17.5.3.1, “MySQL Cluster Backup Concepts”](#).

Like `ndb_print_schema_file` and `ndb_print_sys_file` (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server) `ndb_print_backup_file` must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

**Additional Options:** None.

### 17.4.14. `ndb_print_schema_file` — Print NDB Schema File Contents

`ndb_print_schema_file` obtains diagnostic information from a cluster schema file.

**Usage:**

```
ndb_print_schema_file file_name
```

*file\_name* is the name of a cluster schema file. For more information about cluster schema files, see [Cluster Data Node FileSystemDir Files](#).

Like `ndb_print_backup_file` and `ndb_print_sys_file` (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server) `ndb_schema_backup_file` must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

**Additional Options:** None.

### 17.4.15. `ndb_print_sys_file` — Print NDB System File Contents

`ndb_print_sys_file` obtains diagnostic information from a MySQL Cluster system file.

**Usage:**

```
ndb_print_sys_file file_name
```

*file\_name* is the name of a cluster system file (sysfile). Cluster system files are located in a data node's data directory (DataDir); the path under this directory to system files matches the pattern `ndb_#_fs/D#/DBDIH/P#.sysfile`. In each case, the # represents a number (not necessarily the same number). For more information, see [Cluster Data Node FileSystemDir Files](#).

Like `ndb_print_backup_file` and `ndb_print_schema_file` (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server) `ndb_print_backup_file` must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

**Additional Options:** None.

### 17.4.16. `ndbd_redo_log_reader` — Check and Print Content of Cluster Redo Log

Reads a redo log file, checking it for errors, printing its contents in a human-readable format, or both. `ndb_redo_log_reader` is intended for use primarily by MySQL developers and support personnel in debugging and diagnosing problems.

This utility was made available as part of default builds beginning with MySQL Cluster NDB 6.1.3. It remains under development, and its syntax and behavior are subject to change in future releases. For this reason, it should be considered experimental at this time.

The C++ source files for `ndbd_redo_log_reader` can be found in the directory `/storage/ndb/src/kernel/blocks/dblqh/redoLogReader`.

The following table includes options that are specific to the MySQL Cluster program `ndbd_redo_log_reader`. Additional descriptions follow the table. For options common to all MySQL Cluster programs, see [Section 17.4.23, “Options Common to MySQL Cluster Programs”](#).

**Table 17.13. `ndbd_redo_log_reader` Command Line Options**

Format	Description	Introduction	Deprecated	Removed
<code>-nocheck</code>	Do not check records for errors			
<code>-noprint</code>	Do not print records			

**Usage:**

```
ndbd_redo_log_reader file_name [options]
```

*file\_name* is the name of a cluster REDO log file. REDO log files are located in the numbered directories under the data node's data directory (`DataDir`); the path under this directory to the REDO log files matches the pattern `ndb_#_fs/D#/LCP#/T#F#.Data`. In each case, the # represents a number (not necessarily the same number). For more information, see [Cluster Data Node FileSystemDir Files](#).

The name of the file to be read may be followed by one or more of the options listed here:

- |                            |                       |
|----------------------------|-----------------------|
| <b>Command-Line Format</b> | <code>-noprint</code> |
| <b>Permitted Values</b>    |                       |
| <b>Type</b>                | <code>boolean</code>  |
| <b>Default</b>             | <code>FALSE</code>    |

`-noprint`: Do not print the contents of the log file.

- |                            |                       |
|----------------------------|-----------------------|
| <b>Command-Line Format</b> | <code>-nocheck</code> |
| <b>Permitted Values</b>    |                       |
| <b>Type</b>                | <code>boolean</code>  |
| <b>Default</b>             | <code>FALSE</code>    |

`-nocheck`: Do not check the log file for errors.

Like `ndb_print_backup_file` and `ndb_print_schema_file` (and unlike most of the NDB utilities that are intended to be run on a management server host or to connect to a management server) `ndbd_redo_log_reader` must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

## 17.4.17. `ndb_restore` — Restore a MySQL Cluster Backup

The cluster restoration program is implemented as a separate command-line utility `ndb_restore`, which can normally be found in the MySQL `bin` directory. This program reads the files created as a result of the backup and inserts the stored information into the database.

`ndb_restore` must be executed once for each of the backup files that were created by the `START BACKUP` command used to create the backup (see [Section 17.5.3.2, “Using The MySQL Cluster Management Client to Create a Backup”](#)). This is equal to the number of data nodes in the cluster at the time that the backup was created.

### Note

Before using `ndb_restore`, it is recommended that the cluster be running in single user mode, unless you are restoring multiple data nodes in parallel. See [Section 17.5.6, “MySQL Cluster Single User Mode”](#), for more information about single user mode.

The following table includes options that are specific to the MySQL Cluster native backup restoration program `ndb_restore`. Additional descriptions follow the table. For options common to all MySQL Cluster programs, see [Section 17.4.23, “Options Common to MySQL Cluster Programs”](#).

**Table 17.14. `ndb_restore` Command Line Options**

Format	Description	Introduction	Deprecated	Removed
<code>--append</code>	Append data to a tab-delimited file	5.1.18		
<code>--backup_path=path</code>	Path to backup files directory	5.1.17		
<code>--backupid=#</code>	Restore from the backup with the given ID			
<code>--connect</code>	Same as connectstring			
<code>--restore_data</code>	Restore table data and logs into NDB Cluster using the NDB API			
<code>--disable-indexes</code>	Causes indexes from a backup to be ignored; may decrease time needed to restore data.	5.1.41-ndb-7.1.2		
<code>--dont_ignore_systab_0</code>	Do not ignore system table during restore. Experimental only; not for production use			
<code>- -ex- clude-databases=db-list</code>	List of one or more databases to exclude (includes those not named)	5.1.32-ndb-6.4.3		
<code>- -ex- clude-missing-columns</code>	Causes columns from the backup version of a table that are missing from the version of the table in the database to be ignored.	5.1.35-ndb-7.0.7		
<code>- -ex- clude-tables=table-list</code>	List of one or more tables to exclude (includes those in same database that are not named); each table reference must include the database name	5.1.32-ndb-6.4.3		
<code>- -fields-enclosed-by=char</code>	Fields are enclosed with the indicated character	5.1.18		
<code>- - fields-option- ally-enclosed-by</code>	Fields are optionally enclosed with the indicated character	5.1.18		
<code>- - fields-termin- ated-by=char</code>	Fields are terminated by the indicated character	5.1.18		
<code>--hex</code>	Print binary types in hexadecimal format	5.1.18		
<code>- -in- clude-databases=db-list</code>	List of one or more databases to restore (excludes those not named)	5.1.32-ndb-6.4.3		
<code>- -include-tables=table-list</code>	List of one or more tables to restore (excludes those in same database that are not named); each table reference must include the database name	5.1.32-ndb-6.4.3		
<code>- -lines-termin- ated-by=char</code>	Lines are terminated by the indicated character	5.1.18		
<code>--restore_meta</code>	Restore metadata to NDB Cluster using the NDB API			
<code>- -</code>	Nodegroup map for NDBCLUSTER storage engine. Syntax: list of (source_nodegroup, destination_nodegroup)			

Format	Description	Introduction	Deprecated	Removed
ndb-node-group-map=map				
--no-binlog	If a mysqld is connected and using binary logging, do not log the restored data	5.1.24-ndb-6.3.16		
--no-restore-disk-objects	Do not restore Disk Data objects such as tablespaces and log file groups			
--no-upgrade	Do not upgrade array type for varsize attributes which do not already resize VAR data, and do not change column attributes	5.1.19		
--nodeid=#	Back up files from node with this ID			
--parallelism=#	Number of parallel transactions during restoration of data			
- -preserve-trailing-spaces	Allow preservation of trailing spaces (including padding) when CHAR is promoted to VARCHAR or BINARY is promoted to VARBINARY	5.1.23-ndb-6.3.8		
--print	Print metadata, data and log to stdout (equivalent to --print_meta --print_data --print_log)			
--print_data	Print data to stdout			
--print_log	Print to stdout			
--print_metadata	Print metadata to stdout			
--progress-frequency=#	Print status of restoration each given number of seconds			
--promote-attributes	Allow attributes to be promoted when restoring data from backup	5.1.23-ndb-6.3.8		
--rebuild-indexes	Causes multi-threaded ordered index rebuilding of indexes found in the backup.	5.1.41-ndb-7.1.2		
--restore_epoch	Restore epoch info into the status table. Convenient on a MySQL Cluster replication slave for starting replication. The row in mysql.ndb_apply_status with id 0 will be updated/inserted.			
--skip-table-check	Skip table structure check during restoring of data	5.1.17		
--skip-unknown-objects	Causes schema objects not recognised by ndb_restore to be ignored when restoring a backup made from a newer MySQL Cluster version to an older version.	5.1.41-ndb-7.1.4		
--tab=path	Creates a tab-separated .txt file for each table in the given path	5.1.18		
--verbose=#	Control level of verbosity in output			

Typical options for this utility are shown here:

```
ndb_restore [-c connectstring] -n node_id [-m] -b backup_id \
 -r --backup_path=/path/to/backup/files
```

The `-c` option is used to specify a connectstring which tells `ndb_restore` where to locate the cluster management server. (See Section 17.3.2.3, “The MySQL Cluster Connectstring”, for information on connectstrings.) If this option is not used, then `ndb_restore` attempts to connect to a management server on `localhost:1186`. This utility acts as a cluster API node, and so requires a free connection “slot” to connect to the cluster management server. This means that there must be at least one `[api]` or `[mysqld]` section that can be used by it in the cluster `config.ini` file. It is a good idea to keep at least one empty `[api]` or `[mysqld]` section in `config.ini` that is not being used for a MySQL server or other application for this reason (see Section 17.3.2.7, “Defining SQL and Other API Nodes in a MySQL Cluster”).

You can verify that `ndb_restore` is connected to the cluster by using the `SHOW` command in the `ndb_mgm` management client. You can also accomplish this from a system shell, as shown here:

```
shell> ndb_mgm -e "SHOW"
```

`-n` is used to specify the node ID of the data node on which the backups were taken.

The first time you run the `ndb_restore` restoration program, you also need to restore the metadata. In other words, you must re-create the database tables—this can be done by running it with the `-m` option. Note that the cluster should have an empty database when starting to restore a backup. (In other words, you should start `ndbd` with `--initial` prior to performing the restore. You should also remove manually any Disk Data files present in the data node's `DataDir`.)

It is possible to restore data without restoring table metadata. Prior to MySQL 5.1.17, `ndb_restore` did not perform any checks of table schemas; if a table was altered between the time the backup was taken and when `ndb_restore` was run, `ndb_restore` would still attempt to restore the data to the altered table.

Beginning with MySQL 5.1.17, the default behavior is for `ndb_restore` to fail with an error if table data do not match the table schema; this can be overridden using the `--skip-table-check` or `-s` option. Prior to MySQL 5.1.21, if this option is used, then `ndb_restore` attempts to fit data into the existing table schema, but the result of restoring a backup to a table schema that does not match the original is unspecified.

Beginning with MySQL Cluster NDB 6.3.35, MySQL Cluster NDB 7.0.16, and MySQL Cluster NDB 7.1.5, some of the restrictions on mismatches in column definitions when restoring data using `ndb_restore` are relaxed; when one of these types of mismatches is encountered, `ndb_restore` does not stop with an error as it did previously, but rather accepts the data and inserts it into the target table while issuing a warning to the user that this is being done. This behavior occurs whether or not either of the options `--skip-table-check` or `--promote-attributes` is in use. These differences in column definitions are of the following types:

- Different `COLUMN_FORMAT` settings (`FIXED`, `DYNAMIC`, `DEFAULT`)
- Different `STORAGE` settings (`MEMORY`, `DISK`)
- Different default values
- Different distribution key settings

Beginning with MySQL Cluster NDB 6.3.8, `ndb_restore` supports limited *attribute promotion* in much the same way that it is supported by MySQL replication; that is, data backed up from a column of a given type can generally be restored to a column using a “larger, similar” type. For example, data from a `CHAR(20)` column can be restored to a column declared as `VARCHAR(20)`, `VARCHAR(30)`, or `CHAR(30)`; data from a `MEDIUMINT` column can be restored to a column of type `INT` or `BIGINT`. See [Section 16.4.1.7.2, “Replication of Columns Having Different Data Types”](#), for a table of type conversions currently supported by attribute promotion.

Attribute promotion by `ndb_restore` must be enabled explicitly, as follows:

1. Prepare the table to which the backup is to be restored. `ndb_restore` cannot be used to re-create the table with a different definition from the original; this means that you must either create the table manually, or alter the columns which you wish to promote using `ALTER TABLE` after restoring the table metadata but before restoring the data.
2. Invoke `ndb_restore` with the `--promote-attributes` option (short form `-A`) when restoring the table data. Attribute promotion does not occur if this option is not used; instead, the restore operation fails with an error.

In addition to `--promote-attributes`, a `--preserve-trailing-spaces` option is also available for use with `ndb_restore` beginning with MySQL Cluster NDB 6.3.8. This option (short form `-R`) causes trailing spaces to be preserved when promoting a `CHAR` column to `VARCHAR` or a `BINARY` column to `VARBINARY`. Otherwise, any trailing spaces are dropped from column values when they are inserted into the new columns.

### Note

Although you can promote `CHAR` columns to `VARCHAR` and `BINARY` columns to `VARBINARY`, you cannot promote `VARCHAR` columns to `CHAR` or `VARBINARY` columns to `BINARY`.

The `-b` option is used to specify the ID or sequence number of the backup, and is the same number shown by the management client in the `Backup backup_id completed` message displayed upon completion of a backup. (See [Section 17.5.3.2, “Using The MySQL Cluster Management Client to Create a Backup”](#).)

### Important

When restoring cluster backups, you must be sure to restore all data nodes from backups having the same backup ID. Using files from different backups will at best result in restoring the cluster to an inconsistent state, and may fail altogether.

`--restore_epoch` (short form: `-e`) adds (or restores) epoch information to the cluster replication status table. This is useful for starting replication on a MySQL Cluster replication slave. When this option is used, the row in the `mysql.ndb_apply_status` having `0` in the `id` column is updated if it already exists; such a row is inserted if it does not already exist. (See [Section 17.6.9, “MySQL Cluster Backups With MySQL Cluster Replication”](#).)

The path to the backup directory is required; this is supplied to `ndb_restore` using the `--backup_path` option, and must include the subdirectory corresponding to the ID backup of the backup to be restored. For example, if the data node's `DataDir` is `/`

`/var/lib/mysql-cluster`, then the backup directory is `/var/lib/mysql-cluster/BACKUP`, and the backup files for the backup with the ID 3 can be found in `/var/lib/mysql-cluster/BACKUP/BACKUP-3`. The path may be absolute or relative to the directory in which the `ndb_restore` executable is located, and may be optionally prefixed with `backup_path=`.

### Note

Previous to MySQL 5.1.17 and MySQL Cluster NDB 6.1.5, the path to the backup directory was specified as shown here, with `backup_path=` being optional:

```
[backup_path=/path/to/backup/files]
```

Beginning with MySQL 5.1.17 and MySQL Cluster NDB 6.1.5, this syntax changed to `--backup_path=/path/to/backup/files`, to conform more closely with options used by other MySQL programs; `--backup_id` is required, and there is no short form for this option.

It is possible to restore a backup to a database with a different configuration than it was created from. For example, suppose that a backup with backup ID 12, created in a cluster with two database nodes having the node IDs 2 and 3, is to be restored to a cluster with four nodes. Then `ndb_restore` must be run twice—once for each database node in the cluster where the backup was taken. However, `ndb_restore` cannot always restore backups made from a cluster running one version of MySQL to a cluster running a different MySQL version. See [Section 17.2.5.2, “MySQL Cluster 5.1 and MySQL Cluster NDB 6.x/7.x Upgrade and Downgrade Compatibility”](#), for more information.

### Important

It is not possible to restore a backup made from a newer version of MySQL Cluster using an older version of `ndb_restore`. You can restore a backup made from a newer version of MySQL to an older cluster, but you must use a copy of `ndb_restore` from the newer MySQL Cluster version to do so.

For example, to restore a cluster backup taken from a cluster running MySQL Cluster NDB 6.2.15 to a cluster running MySQL 5.1.20, you must use a copy of `ndb_restore` from the MySQL Cluster NDB 6.2.15 distribution.

For more rapid restoration, the data may be restored in parallel, provided that there is a sufficient number of cluster connections available. That is, when restoring to multiple nodes in parallel, you must have an `[api]` or `[mysqld]` section in the cluster `config.ini` file available for each concurrent `ndb_restore` process. However, the data files must always be applied before the logs.

Formerly, when using `ndb_restore` to restore a backup made from a MySQL 5.0 cluster to a 5.1 cluster, `VARCHAR` columns were not resized and were recreated using the 5.0 fixed format. Beginning with MySQL 5.1.19, `ndb_restore` recreates such `VARCHAR` columns using MySQL Cluster 5.1's variable-width format. Also beginning with MySQL 5.1.19, this behavior can be overridden using the `--no-upgrade` option (short form: `-u`) when running `ndb_restore`.

The `--print_data` option causes `ndb_restore` to direct its output to `stdout`.

`TEXT` and `BLOB` column values are always truncated to the first 256 bytes in the output; this cannot currently be overridden when using `--print_data`.

Beginning with MySQL 5.1.18, several additional options are available for use with the `--print_data` option in generating data dumps, either to `stdout`, or to a file. These are similar to some of the options used with `mysqldump`, and are shown in the following list:

- `--tab`, `-T`

<b>Version Introduced</b>	5.1.18
<b>Command-Line Format</b>	<code>--tab=path</code>
	<code>-T</code>

This option causes `--print_data` to create dump files, one per table, each named `tbl_name.txt`. It requires as its argument the path to the directory where the files should be saved; use `.` for the current directory.

- `--fields-enclosed-by=string`

<b>Version Introduced</b>	5.1.18
<b>Command-Line Format</b>	<code>--fields-enclosed-by=char</code>
	<b>Permitted Values</b>
	<b>Type</b> <code>string</code>
	<b>Default</b>

Each column values are enclosed by the string passed to this option (regardless of data type; see next item).

- `--fields-optionally-enclosed-by=string`

<b>Version Introduced</b>	5.1.18
<b>Command-Line Format</b>	<code>--fields-optionally-enclosed-by</code>
	<b>Permitted Values</b>
	Type <code>string</code>
	Default <code>\t (tab)</code>

The string passed to this option is used to enclose column values containing character data (such as `CHAR`, `VARCHAR`, `BINARY`, `TEXT`, or `ENUM`).

- `--fields-terminated-by=string`

<b>Version Introduced</b>	5.1.18
<b>Command-Line Format</b>	<code>--fields-terminated-by=char</code>
	<b>Permitted Values</b>
	Type <code>string</code>
	Default <code>\t (tab)</code>

The string passed to this option is used to separate column values. The default value is a tab character (`\t`).

- `--hex`

<b>Version Introduced</b>	5.1.18
<b>Command-Line Format</b>	<code>--hex</code>

If this option is used, all binary values are output in hexadecimal format.

- `--fields-terminated-by=string`

<b>Version Introduced</b>	5.1.18
<b>Command-Line Format</b>	<code>--fields-terminated-by=char</code>
	<b>Permitted Values</b>
	Type <code>string</code>
	Default <code>\t (tab)</code>

This option specifies the string used to end each line of output. The default is a linefeed character (`\n`).

- `--append`

<b>Version Introduced</b>	5.1.18
<b>Command-Line Format</b>	<code>--append</code>

When used with the `--tab` and `--print_data` options, this causes the data to be appended to any existing files having the same names.

### Note

If a table has no explicit primary key, then the output generated when using the `--print_data` option includes the table's hidden primary key.

Beginning with MySQL 5.1.18, it is possible to restore selected databases, or to restore selected tables from a given database using the syntax shown here:

```
ndb_restore other_options db_name[,...] | tbl_name[,tbl_name][,...]
```

In other words, you can specify either of the following to be restored:

- All tables from one or more databases
- One or more tables from a single database

```
--include-databases=db_name[,db_name][,...]
```

<b>Version Introduced</b>	5.1.32-ndb-6.4.3
<b>Command-Line Format</b>	<code>--include-databases=db-list</code>
<b>Permitted Values</b>	
Type	<code>string</code>
Default	

```
--include-tables=db_name.tbl_name[,db_name.tbl_name][,...]
```

<b>Version Introduced</b>	5.1.32-ndb-6.4.3
<b>Command-Line Format</b>	<code>--include-tables=table-list</code>
<b>Permitted Values</b>	
Type	<code>string</code>
Default	

Beginning with MySQL Cluster NDB 6.3.22 and MySQL Cluster NDB 6.4.3, you can (and should) use instead the `--include-databases` option or the `--include-tables` option for restoring only specific databases or tables, respectively. `--include-databases` takes a comma-delimited list of databases to be restored. `--include-tables` takes a comma-delimited list of tables (in `database.table` format) to be restored.

When `--include-databases` or `--include-tables` is used, only those databases or tables named by the option are restored; all other databases and tables are excluded by `ndb_restore`, and are not restored.

The following table shows several invocations of `ndb_restore` using `--include-*` options (other options possibly required have been omitted for clarity), and the effects these have on restoring from a MySQL Cluster backup:

Option Used	Result
<code>--include-databases=db1</code>	Only tables in database <code>db1</code> are restored; all tables in all other databases are ignored
<code>--include-databases=db1,db2</code> (or <code>--include-databases=db1 -include-databases=db2</code> )	Only tables in databases <code>db1</code> and <code>db2</code> are restored; all tables in all other databases are ignored
<code>--include-tables=db1.t1</code>	Only table <code>t1</code> in database <code>db1</code> is restored; no other tables in <code>db1</code> or in any other database are restored
<code>--include-tables=db1.t2,db2.t1</code> (or <code>--include-tables=db1.t2 -include-tables=db2.t1</code> )	Only the table <code>t2</code> in database <code>db1</code> and the table <code>t1</code> in database <code>db2</code> are restored; no other tables in <code>db1</code> , <code>db2</code> , or any other database are restored

Beginning with MySQL Cluster NDB 6.3.29 and MySQL Cluster NDB 7.0.10, you can use these two options together. For example, the following causes all tables in databases `db1` and `db2`, together with the tables `t1` and `t2` in database `db3`, to be restored (and no other databases or tables):

```
shell> ndb_restore [...] --include-databases=db1,db2 --include-tables=db3.t1,db3.t2
```

(Again we have omitted other, possibly required, options in the example just shown.)

### Note

Prior to MySQL Cluster NDB 6.3.29 and MySQL Cluster NDB 7.0.10, multiple `--include-*` options were not

handled correctly, and the result of the options shown in the previous example was that only the tables `db3.t1` and `db3.t2` were actually restored. ([Bug#48907](#))

```
--exclude-databases=db_name[,db_name][,...]
```

<b>Version Introduced</b>	5.1.32-ndb-6.4.3
<b>Command-Line Format</b>	<code>--exclude-databases=db-list</code>
	<b>Permitted Values</b>
	Type <code>string</code>
	<b>Default</b>

```
--exclude-tables=db_name.tbl_name[,db_name.tbl_name][,...]
```

<b>Version Introduced</b>	5.1.32-ndb-6.4.3
<b>Command-Line Format</b>	<code>--exclude-tables=table-list</code>
	<b>Permitted Values</b>
	Type <code>string</code>
	<b>Default</b>

Also beginning with MySQL Cluster NDB 6.3.22 and MySQL Cluster NDB 6.4.3, it is possible to exclude from being restored one or more databases or tables using the `ndb_restore` options `--exclude-databases` and `--exclude-tables`.   
`--exclude-databases` takes a comma-delimited list of one or more databases which should not be restored.   
`--exclude-tables` takes a comma-delimited list of one or more tables (using `database.table` format) which should not be restored.

When `--exclude-databases` or `--exclude-tables` is used, only those databases or tables named by the option are excluded; all other databases and tables are restored by `ndb_restore`.

This table shows several invocations of `ndb_restore` usng `--exclude-*` options (other options possibly required have been omitted for clarity), and the effects these options have on restoring from a MySQL Cluster backup:

Option Used	Result
<code>--exclude-databases=db1</code>	All tables in all databases except <code>db1</code> are restored; no tables in <code>db1</code> are restored
<code>--exclude-databases=db1,db2</code> (or <code>--exclude-databases=db1 -</code> <code>--exclude-databases=db2)</code>	All tables in all databases except <code>db1</code> and <code>db2</code> are restored; no tables in <code>db1</code> or <code>db2</code> are restored
<code>--exclude-tables=db1.t1</code>	All tables except <code>t1</code> in database <code>db1</code> are restored; all other tables in <code>db1</code> are restored; all tables in all other databases are restored
<code>--exclude-tables=db1.t2,db2.t1</code> (or <code>--exclude-tables=db1.t2 -</code> <code>--exclude-tables=db2.t1)</code>	All tables in database <code>db1</code> except for <code>t2</code> and all tables in database <code>db2</code> except for table <code>t1</code> are restored; no other tables in <code>db1</code> or <code>db2</code> are restored; all tables in all other databases are restored

Beginning with MySQL Cluster NDB 6.3.29 and MySQL Cluster NDB 7.0.10, you can use these two options together. For example, the following causes all tables in all databases *except for* databases `db1` and `db2`, along with the tables `t1` and `t2` in database `db3`, *not* to be restored:

```
shell> ndb_restore [...] --exclude-databases=db1,db2 --exclude-tables=db3.t1,db3.t2
```

(Again, we have omitted other possibly necessary options in the interest of clarity and brevity from the example just shown.)

### Note

Prior to MySQL Cluster NDB 6.3.29 and MySQL Cluster NDB 7.0.10, multiple `--exclude-*` options were not handled correctly, with the result that the options shown in the previous example caused `ndb_restore` to exclude only the tables `db3.t1` and `db3.t2`. ([Bug#48907](#))

Beginning with MySQL Cluster NDB 6.3.29 and MySQL Cluster NDB 7.0.10, you can use `--include-*` and `--exclude-*` options together, subject to the following rules:

- The actions of all `--include-*` and `--exclude-*` options are cumulative.
- All `--include-*` and `--exclude-*` options are evaluated in the order passed to `ndb_restore`, from right to left.
- In the event of conflicting options, the first (rightmost) option takes precedence. In other words, the first option (going from right to left) that matches against a given database or table “wins”.

For example, the following set of options causes `ndb_restore` to restore all tables from database `db1` except `db1.t1`, while restoring no other tables from any other databases:

```
--include-databases=db1 --exclude-tables=db1.t1
```

However, reversing the order of the options just given simply causes all tables from database `db1` to be restored (including `db1.t1`, but no tables from any other database), because the `--include-databases` option, being farthest to the right, is the first match against database `db1` and thus takes precedence over any other option that matches `db1` or any tables in `db1`:

```
--exclude-tables=db1.t1 --include-databases=db1
```

### Note

Prior to MySQL Cluster NDB 6.3.29 and MySQL Cluster NDB 7.0.10, it was not possible to use `--include-databases` or `--include-tables` together with `--exclude-databases` or `--exclude-tables`, as these combinations were evaluated inconsistently. ([Bug#48907](#))

`--exclude-missing-columns`

<b>Version Introduced</b>	5.1.35-ndb-7.0.7
<b>Command-Line Format</b>	<code>--exclude-missing-columns</code>

Beginning with MySQL Cluster NDB 6.3.26 and MySQL Cluster NDB 7.0.7, it is also possible to restore only selected table columns using the `--exclude-missing-columns` option. When this option is used, `ndb_restore` ignores any columns missing from tables being restored as compared to the versions of those tables found in the backup. This option applies to all tables being restored. If you wish to apply this option only to selected tables or databases, you can use it in combination with one or more of the options described in the previous paragraph to do so, then restore data to the remaining tables using a complementary set of these options.

`--disable-indexes`

<b>Version Introduced</b>	5.1.41-ndb-7.1.2
<b>Command-Line Format</b>	<code>--disable-indexes</code>

Beginning with MySQL Cluster NDB 6.3.31, MySQL Cluster NDB 7.0.11, and MySQL Cluster NDB 7.1.2, you can use this option with `ndb_restore` to disable restoration of indexes during restoration of the data from a native NDB backup. Afterwards, you can restore indexes for all tables at once with multi-threaded building of indexes using `--rebuild-indexes`, which should be faster than rebuilding indexes concurrently for very large tables.

`--rebuild-indexes`

<b>Version Introduced</b>	5.1.41-ndb-7.1.2
<b>Command-Line Format</b>	<code>--rebuild-indexes</code>

Beginning with MySQL Cluster NDB 6.3.31, MySQL Cluster NDB 7.0.11, and MySQL Cluster NDB 7.1.2, you can use this option with `ndb_restore` to cause multi-threaded rebuilding of the ordered indexes while restoring a native `NDB` backup.

`--skip-unknown-objects`

<b>Version Introduced</b>	5.1.41-ndb-7.1.4
<b>Command-Line Format</b>	<code>--skip-unknown-objects</code>

This option causes `ndb_restore` to ignore any schema objects it does not recognize while reading a native `NDB` backup. This can

be used for restoring a backup made from a cluster running MySQL Cluster NDB 7.0 to a cluster running MySQL Cluster NDB 6.3.

This option was added in MySQL Cluster NDB 6.3.34, MySQL Cluster NDB 7.0.15, and MySQL CLuster NDB 7.1.4.

**Error reporting.** `ndb_restore` reports both temporary and permanent errors. In the case of temporary errors, it may able to recover from them. Beginning with MySQL 5.1.12, it reports `Restore successful, but encountered temporary error, please look at configuration` in such cases.

### Important

After using `ndb_restore` to initialize a MySQL Cluster for use in circular replication, binary logs on the SQL node acting as the replication slave are not automatically created, and you must cause them to be created manually. To cause the binary logs to be created, issue a `SHOW TABLES` statement on that SQL node before running `START SLAVE`.

This is a known issue with MySQL Cluster management, which we intend to address in a future release.

## 17.4.18. `ndb_select_all` — Print Rows from an NDB Table

`ndb_select_all` prints all rows from an NDB table to `stdout`.

### Usage:

```
ndb_select_all -c connect_string tbl_name -d db_name [> file_name]
```

### Additional Options:

- `--lock=lock_type, -l lock_type`

Employs a lock when reading the table. Possible values for `lock_type` are:

- `0`: Read lock
- `1`: Read lock with hold
- `2`: Exclusive read lock

There is no default value for this option.

- `--order=index_name, -o index_name`

Orders the output according to the index named `index_name`. Note that this is the name of an index, not of a column, and that the index must have been explicitly named when created.

- `--descending, -z`

Sorts the output in descending order. This option can be used only in conjunction with the `-o (--order)` option.

- `--header=FALSE`

Excludes column headers from the output.

- `--useHexFormat -x`

Causes all numeric values to be displayed in hexadecimal format. This does not affect the output of numerals contained in strings or datetime values.

- `--delimiter=character, -D character`

Causes the `character` to be used as a column delimiter. Only table data columns are separated by this delimiter.

The default delimiter is the tab character.

- `--disk`

Adds a disk reference column to the output. The column is nonempty only for Disk Data tables having nonindexed columns.

- `--rowid`

Adds a `ROWID` column providing information about the fragments in which rows are stored.

- **--gci**

Adds a column to the output showing the global checkpoint at which each row was last updated. See [Section 17.1, “MySQL Cluster Overview”](#), and [Section 17.5.4.2, “MySQL Cluster Log Events”](#), for more information about checkpoints.

- **--tupscan, -t**

Scan the table in the order of the tuples.

- **--nodata**

Causes any table data to be omitted.

### Sample Output:

Output from a MySQL `SELECT` statement:

```
mysql> SELECT * FROM ctest1.fish;
+---+-----+
| id | name |
+---+-----+
| 3 | shark |
| 6 | puffer |
| 2 | tuna |
| 4 | manta ray|
| 5 | grouper|
| 1 | guppy |
+---+-----+
6 rows in set (0.04 sec)
```

Output from the equivalent invocation of `ndb_select_all`:

```
shell> ./ndb_select_all -c localhost fish -d ctest1
id name
3 [shark]
6 [puffer]
2 [tuna]
4 [manta ray]
5 [grouper]
1 [guppy]
6 rows returned

NDBT_ProgramExit: 0 - OK
```

Note that all string values are enclosed by square brackets (“[ ... ]”) in the output of `ndb_select_all`. For a further example, consider the table created and populated as shown here:

```
CREATE TABLE dogs (
 id INT(11) NOT NULL AUTO_INCREMENT,
 name VARCHAR(25) NOT NULL,
 breed VARCHAR(50) NOT NULL,
 PRIMARY KEY pk (id),
 KEY ix (name)
)
TABLESPACE ts STORAGE DISK
ENGINE=NDBCLUSTER;

INSERT INTO dogs VALUES
 ('', 'Lassie', 'collie'),
 ('', 'Scooby-Doo', 'Great Dane'),
 ('', 'Rin-Tin-Tin', 'Alsatian'),
 ('', 'Rosscoe', 'Mutt');
```

This demonstrates the use of several additional `ndb_select_all` options:

```
shell> ./ndb_select_all -d ctest1 dogs -o ix -z --gci --disk
GCI id name breed DISK_REF
834461 2 [Scooby-Doo] [Great Dane] [m_file_no: 0 m_page: 98 m_page_idx: 0]
834878 4 [Rosscoe] [Mutt] [m_file_no: 0 m_page: 98 m_page_idx: 16]
834463 3 [Rin-Tin-Tin] [Alsatian] [m_file_no: 0 m_page: 34 m_page_idx: 0]
835657 1 [Lassie] [Collie] [m_file_no: 0 m_page: 66 m_page_idx: 0]
4 rows returned

NDBT_ProgramExit: 0 - OK
```

## 17.4.19. `ndb_select_count` — Print Row Counts for NDB Tables

`ndb_select_count` prints the number of rows in one or more NDB tables. With a single table, the result is equivalent to that obtained by using the MySQL statement `SELECT COUNT(*) FROM tbl_name`.

**Usage:**

```
ndb_select_count [-c connect_string] -ddb_name tbl_name[, tbl_name2[, ...]]
```

**Additional Options:** None that are specific to this application. However, you can obtain row counts from multiple tables in the same database by listing the table names separated by spaces when invoking this command, as shown under **Sample Output**.

**Sample Output:**

```
shell> ./ndb_select_count -c localhost -d ctest1 fish dogs
6 records in table fish
4 records in table dogs
NDBT_ProgramExit: 0 - OK
```

## 17.4.20. `ndb_show_tables` — Display List of NDB Tables

`ndb_show_tables` displays a list of all `NDB` database objects in the cluster. By default, this includes not only both user-created tables and `NDB` system tables, but `NDB`-specific indexes, internal triggers, and MySQL Cluster Disk Data objects as well.

The following table includes options that are specific to the MySQL Cluster program `ndb_show_tables`. Additional descriptions follow the table. For options common to all MySQL Cluster programs, see [Section 17.4.23, “Options Common to MySQL Cluster Programs”](#).

**Table 17.15. `ndb_show_tables` Command Line Options**

Format	Description	Introduction	Deprecated	Removed
<code>--database=string</code>	Specifies the database in which the table is found			
<code>--loops=#</code>	Number of times to repeat output			
<code>--parsable</code>	Return output suitable for MySQL LOAD DATA INFILE statement			
<code>--show-temp-status</code>	Show table temporary flag			
<code>--type=#</code>	Limit output to objects of this type			
<code>--unqualified</code>	Do not qualify table names			

**Usage:**

```
ndb_show_tables [-c connect_string]
```

- `--database, -d`

Specifies the name of the database in which the tables are found.

- `--loops, -l`

Specifies the number of times the utility should execute. This is 1 when this option is not specified, but if you do use the option, you must supply an integer argument for it.

- `--parsable, -p`

Using this option causes the output to be in a format suitable for use with `LOAD DATA INFILE`.

- `--show-temp-status`

If specified, this causes temporary tables to be displayed.

- `--type, -t`

Can be used to restrict the output to one type of object, specified by an integer type code as shown here:

- 1: System table
- 2: User-created table

- **3:** Unique hash index

Any other value causes all **NDB** database objects to be listed (the default).

- **--unqualified, -u**

If specified, this causes unqualified object names to be displayed.

#### Note

Only user-created Cluster tables may be accessed from MySQL; system tables such as **SYSTAB\_0** are not visible to **mysqld**. However, you can examine the contents of system tables using **NDB** API applications such as **ndb\_select\_all** (see [Section 17.4.18, “ndb\\_select\\_all — Print Rows from an NDB Table”](#)).

## 17.4.21. **ndb\_size.pl** — NDBCLUSTER Size Requirement Estimator

This is a Perl script that can be used to estimate the amount of space that would be required by a MySQL database if it were converted to use the **NDBCLUSTER** storage engine. Unlike the other utilities discussed in this section, it does not require access to a MySQL Cluster (in fact, there is no reason for it to do so). However, it does need to access the MySQL server on which the database to be tested resides.

#### Requirements:

- A running MySQL server. The server instance does not have to provide support for MySQL Cluster.
- A working installation of Perl.
- The **DBI** module, which can be obtained from CPAN if it is not already part of your Perl installation. (Many Linux and other operating system distributions provide their own packages for this library.)
- Previous to MySQL 5.1.18, **ndb\_size.pl** also required the **HTML::Template** module and an associated template file **share/mysql/ndb\_size tmpl**. Beginning with MySQL 5.1.18, **ndb\_size tmpl** is no longer needed (or included).
- A MySQL user account having the necessary privileges. If you do not wish to use an existing account, then creating one using **GRANT USAGE ON db\_name.\***—where **db\_name** is the name of the database to be examined—is sufficient for this purpose.

**ndb\_size.pl** can also be found in the MySQL sources in **storage/ndb/tools**. If this file is not present in your MySQL installation, you can obtain it from the [MySQL Forge project page](#).

The following table includes options that are specific to the MySQL Cluster program **ndb\_size.pl**. Additional descriptions follow the table. For options common to all MySQL Cluster programs, see [Section 17.4.23, “Options Common to MySQL Cluster Programs”](#).

**Table 17.16. **ndb\_size.pl** Command Line Options**

Format	Description	Introduction	Deprecated	Removed
<b>--database=dbname</b>	The database or databases to examine; accepts a comma-delimited list; the default is ALL (use all databases found on the server)			
<b>--excludedbs=db-list</b>	Skip any databases in a comma-separated list of databases			
<b>--excludetables=tbl-list</b>	Skip any tables in a comma-separated list of tables			
<b>--format=string</b>	Set output format (text or HTML)			
<b>--hostname[:port]</b>	Specify host and optional port as host[:port]			
<b>--loadqueries=file</b>	Loads all queries from the file specified; does not connect to a database			
<b>--password=string</b>	Specify a MySQL user password			
<b>--real_table_name=table</b>	Designates a table to handle unique index size calculations	5.1.22-ndb-6.2.5		
<b>--savequeries=file</b>	Saves all queries to the database into the file specified			

Format	Description	Introduction	Deprecated	Removed
--socket=file	Specify a socket to connect to	5.1.22-ndb-6.2.5		
--user=string	Specify a MySQL user name			

**Usage:**

```
perl ndb_size.pl db_name|ALL] [--hostname=host[:port]] [--socket=socket] [--user=user] \
 [--password=password] [--help|-h] [--format=(html|text)] [--loadqueries=file_name] [--savequeries=file_name]
```

By default, this utility attempts to analyze all databases on the server. You can specify a single database using the `--database` option; the default behavior can be made explicit by using `ALL` for the name of the database. You can also exclude one or more databases by using the `--excludedbs` with a comma-separated list of the names of the databases to be skipped. Similarly, you can cause specific tables to be skipped by listing their names, separated by commas, following the optional `--excludetables` option. A host name (and possibly a port as well) can be specified using `--hostname`; the default is `localhost:3306`. If necessary, you can specify a socket; the default is `/var/lib/mysql.sock`. A MySQL user name and password can be specified the corresponding options shown. It also possible to control the format of the output using the `--format` option; this can take either of the values `html` or `text`, with `text` being the default. An example of the text output is shown here:

```
shell> ndb_size.pl --database=test --socket=/tmp/mysql.sock
ndb_size.pl report for database: 'test' (1 tables)

Connected to: DBI:mysql:host=localhost:mysq_socket=/tmp/mysql.sock

Including information for versions: 4.1, 5.0, 5.1

test.t1

DataMemory for Columns (* means varsized DataMemory):
 Column Name Type Varsized Key 4.1 5.0 5.1
 HIDDEN_NDB_PKEY bigint PRI 8 8 8
 c2 varchar(50) Y 52 52 4*
 c1 int(11) - 4 4 4
 -- -- --
Fixed Size Columns DM/Row
Varsize Columns DM/Row 64 64 12
 0 0 4

DataMemory for Indexes:
 Index Name Type 4.1 5.0 5.1
 PRIMARY BTREE 16 16 16
 -- -- --
 Total Index DM/Row 16 16 16

IndexMemory for Indexes:
 Index Name 4.1 5.0 5.1
 PRIMARY 33 16 16
 -- -- -- --
 Indexes IM/Row 33 16 16

Summary (for THIS table):
 4.1 5.0 5.1
 Fixed Overhead DM/Row 12 12 16
 NULL Bytes/Row 4 4 4
 DataMemory/Row 96 96 48 (Includes overhead, bitmap and indexes)

 Varsize Overhead DM/Row 0 0 8
 Varsize NULL Bytes/Row 0 0 4
 Avg Varside DM/Row 0 0 16

 No. Rows 0 0 0

 Rows/32kb DM Page 340 340 680
 Fixedsize DataMemory (KB) 0 0 0

 Rows/32kb Varsize DM Page 0 0 2040
 Varsize DataMemory (KB) 0 0 0

 Rows/8kb IM Page 248 512 512
 IndexMemory (KB) 0 0 0

Parameter Minimum Requirements

* indicates greater than default

 Parameter Default 4.1 5.0 5.1
 DataMemory (KB) 81920 0 0 0
 NoOfOrderedIndexes 128 1 1 1
 NoOfTables 128 1 1 1
 IndexMemory (KB) 18432 0 0 0
 NoOfUniqueHashIndexes 64 0 0 0
 NoOfAttributes 1000 3 3 3
 NoOfTriggers 768 5 5 5
```

For debugging purposes, the Perl arrays containing the queries run by this script can be read from the file specified using `--savequeries`; a file containing such arrays to be read in during script execution can be specified using `-loadqueries`. Neither of these options has a default value.

To produce output in HTML format, use the `--format` option and redirect the output to a file, as shown in this example:

```
shell> ndb_size.pl --database=test --socket=/tmp/mysql.sock --format=html > ndb_size.html
```

(Without the redirection, the output is sent to `stdout`.) This figure shows a portion of the generated `ndb_size.html` output file, as viewed in a Web browser:

## MySQL Cluster analysis for world

This is an automated analysis of the DBI:mysql:database=world;host=192.168.0.176 database for migration into MySQL Cluster. No warranty is made to the accuracy of the information.

This information should be valid for MySQL 4.1 and 5.0. Since 5.1 is not a final release yet, the numbers should be used as a guide only.

### Parameter Settings

**NOTE** the configuration parameters below do not take into account system tables and other requirements.

Parameter	4.1	5.0	5.1
DataMemory (kb)	544	544	544
IndexMemory (kb)	192	136	136
MaxNoOfTables	3	3	3
MaxNoOfAttributes	24	24	24
MaxNoOfOrderedIndexes	3	3	3
MaxNoOfUniqueHashIndexes	3	3	3
MaxNoOfTriggers	12	12	12

### Memory usage because of parameters

Usage is in kilobytes. Actual usage will vary as you should set the parameters larger than those listed in the table above.

Parameter	4.1	5.0	5.1
Attributes	5	5	5
Tables	60	60	60
OrderedIndexes	30	30	30
UniqueHashIndexes	45	45	45

### Table List

- [City](#)
- [Country](#)
- [CountryLanguage](#)

### City

Column	Type	Size	Key	4.1 NDB Size	5.0 NDB Size	5.1 NDB Size
ID	int	11	PRI	4	4	4
District	char	20		20	20	20
Name	char	35		36	36	36
Population	int	11		4	4	4
CountryCode	char	3		4	4	4

### Indexes

We assume that indexes are ORDERED (not created USING HASH). If order is not required, 10 bytes of data memory can be saved per row if the index is created USING HASH

Index	Type	Columns	4.1 IdxMem	5.0 IdxMem	5.1 IdxMem	4.1 DatMem	5.0 DatMem	5.1 DatMem
PRIMARY	BTREE	ID	29	25	25	10	10	10

### DataMemory Usage

	4.1	5.0	5.1
Row Overhead	16	16	16
Column DataMemory/Row	68	68	68
Index DataMemory/Row	10	10	10
Total DataMemory/Row	94	94	94
Rows per 32.kb page	347	347	347
Current number of rows	4079	4079	4079
Total DataMemory (kb)	384	384	384

### IndexMemory Usage

	4.1	5.0	5.1
IndexMemory/Row	29	25	25
Rows per 8kb page	282	327	327
Current number of rows	4079	4079	4079
Total IndexMemory (kb)	120	104	104

The output from this script includes:

- Minimum values for the `DataMemory`, `IndexMemory`, `MaxNoOfTables`, `MaxNoOfAttributes`, `MaxNoOfOrderedIndexes`, `MaxNoOfUniqueHashIndexes`, and `MaxNoOfTriggers` configuration parameters required to accommodate the tables analyzed.
- Memory requirements for all of the tables, attributes, ordered indexes, and unique hash indexes defined in the database.
- The `IndexMemory` and `DataMemory` required per table and table row.

### Note

Prior to MySQL 5.1.23, MySQL Cluster NDB 6.2.5, and MySQL Cluster NDB 6.3.7, `ndb_size.pl` was invoked as shown here:

```
perl ndb_size.pl db_name hostname username password > file_name.html
```

For more information about this change, see [Bug#28683](#) and [Bug#28253](#).

## 17.4.22. `ndb_waiter` — Wait for MySQL Cluster to Reach a Given Status

`ndb_waiter` repeatedly (each 100 milliseconds) prints out the status of all cluster data nodes until either the cluster reaches a given status or the `--timeout` limit is exceeded, then exits. By default, it waits for the cluster to achieve `STARTED` status, in which all nodes have started and connected to the cluster. This can be overridden using the `--no-contact` and `--not-started` options (see [Additional Options](#)).

The node states reported by this utility are as follows:

- `NO_CONTACT`: The node cannot be contacted.
- `UNKNOWN`: The node can be contacted, but its status is not yet known. Usually, this means that the node has received a `START` or `RESTART` command from the management server, but has not yet acted on it.
- `NOT_STARTED`: The node has stopped, but remains in contact with the cluster. This is seen when restarting the node using the management client's `RESTART` command.
- `STARTING`: The node's `ndbd` process has started, but the node has not yet joined the cluster.
- `STARTED`: The node is operational, and has joined the cluster.
- `SHUTTING_DOWN`: The node is shutting down.
- `SINGLE_USER_MODE`: This is shown for all cluster data nodes when the cluster is in single user mode.

**Usage:**

```
ndb_waiter [-c connect_string]
```

**Additional Options:**

- `--no-contact`, `-n`

Instead of waiting for the `STARTED` state, `ndb_waiter` continues running until the cluster reaches `NO_CONTACT` status before exiting.

- `--not-started`

Instead of waiting for the `STARTED` state, `ndb_waiter` continues running until the cluster reaches `NOT_STARTED` status before exiting.

- `--timeout=seconds`, `-t seconds`

Time to wait. The program exits if the desired state is not achieved within this number of seconds. The default is 120 seconds (1200 reporting cycles).

- `--single-user`

The program waits for the cluster to enter single user mode.

- `--nowait-nodes=list`

When this option is used, `ndb_waiter` does not wait for the nodes whose IDs are listed. The list is comma-delimited; ranges can be indicated by dashes, as shown here:

```
shell> ndb_waiter --nowait-nodes=1,3,7-9
```

### Important

*Do not use this option together with the `--wait-nodes` option.*

This option was added in MySQL Cluster NDB 6.2.1.

- `--wait-nodes=list,-w list`

When this option is used, `ndb_waiter` waits only for the nodes whose IDs are listed. The list is comma-delimited; ranges can be indicated by dashes, as shown here:

```
shell> ndb_waiter --wait-nodes=2,4-6,10
```

### Important

*Do not use this option together with the `--nowait-nodes` option.*

This option was added in MySQL Cluster NDB 6.3.34, 7.0.15, and 7.1.4.

**Sample Output.** Shown here is the output from `ndb_waiter` when run against a 4-node cluster in which two nodes have been shut down and then started again manually. Duplicate reports (indicated by “`...`”) are omitted.

```
shell> ./ndb_waiter -c localhost
Connecting to mgmsrv at (localhost)
State node 1 STARTED
State node 2 NO_CONTACT
State node 3 STARTED
State node 4 NO_CONTACT
Waiting for cluster enter state STARTED
...
State node 1 STARTED
State node 2 UNKNOWN
State node 3 STARTED
State node 4 NO_CONTACT
Waiting for cluster enter state STARTED
...
State node 1 STARTED
State node 2 STARTING
State node 3 STARTED
State node 4 NO_CONTACT
Waiting for cluster enter state STARTED
...
State node 1 STARTED
State node 2 STARTING
State node 3 STARTED
State node 4 UNKNOWN
Waiting for cluster enter state STARTED
...
State node 1 STARTED
State node 2 STARTED
State node 3 STARTED
State node 4 STARTING
Waiting for cluster enter state STARTED
...
State node 1 STARTED
State node 2 STARTED
State node 3 STARTED
State node 4 STARTING
Waiting for cluster enter state STARTED
...
```

```

State node 1 STARTED
State node 2 STARTED
State node 3 STARTED
State node 4 STARTED
Waiting for cluster enter state STARTED
NDBT_ProgramExit: 0 - OK

```

**Note**

If no connectstring is specified, then `ndb_waiter` tries to connect to a management on `localhost`, and reports `Connecting to mgmsrv at (null)`.

## 17.4.23. Options Common to MySQL Cluster Programs

All MySQL Cluster programs (except for `mysqld`) take the options described in this section. Users of earlier MySQL Cluster versions should note that some of these options have been changed to make them consistent with one another as well as with `mysqld`. You can use the `--help` option with any MySQL Cluster program to view a list of the options which it supports.

The options in the following table are common to all MySQL Cluster executables.

**Table 17.17. Common MySQL Cluster Command Line Options**

Format	Description	Introduction	Deprecated	Removed
<code>-c character-sets-dir=name</code>	Directory where character sets are			
<code>-c ndb-connectstring=name</code>	Set connect string for connecting to <code>ndb_mgmd</code> . Syntax: <code>[nodeid=&lt;id&gt;;][host=&lt;hostname&gt;[:&lt;port&gt;]</code> . Overrides specifying entries in <code>NDB_CONNECTSTRING</code> and <code>my.cnf</code>			
<code>--core-file</code>	Write core on errors (defaults to TRUE in debug builds)			
<code>--debug=options</code>	Enable output from debug calls. Can be used only for versions compiled with debugging enabled			
<code>--help</code>	Display help message and exit			
<code>--ndb-mgmd-host=name</code>	Set host and port for connecting to <code>ndb_mgmd</code> . Syntax: <code>&lt;hostname&gt;[:&lt;port&gt;]</code> . Overrides specifying entries in <code>NDB_CONNECTSTRING</code> and <code>my.cnf</code>			
<code>--ndb-nodeid=#</code>	Set node id for this node			
<code>-c ndb-optimized-node-selection</code>	Select nodes for transactions in a more optimal way			
<code>--ndb-shm</code>	Allow optimizing using shared memory connections when available (was EXPERIMENTAL; REMOVED in later versions)			5.1.47-ndb-7.1.5
<code>-V</code>	Output version information and exit			

For options specific to individual MySQL Cluster programs, see [Section 17.4, “MySQL Cluster Programs”](#).

See [Section 17.3.4.2, “mysqld Command Options for MySQL Cluster”](#), for `mysqld` options relating to MySQL Cluster.

- `--help --usage, -?`

<b>Command-Line Format</b>	<code>--help</code>
	<code>--usage</code>
	<code>-?</code>

Prints a short list with descriptions of the available command options.

- `--character-sets-dir=name`

<b>Command-Line Format</b>	<code>--character-sets-dir=name</code>
<b>Permitted Values</b>	
<b>Type</b>	<code>filename</code>
<b>Default</b>	

Tells the program where to find character set information.

- `--connect-string=connect_string, -c connect_string`

<b>Command-Line Format</b>	<code>--ndb-connectstring=name</code>
	<code>--connect-string=name</code>
	<code>-c</code>
<b>Permitted Values</b>	
<b>Type</b>	<code>string</code>
<b>Default</b>	<code>localhost:1186</code>

`connect_string` sets the connectstring to the management server as a command option.

```
shell> ndbd --connect-string="nodeid=2;host=ndb_mgmd.mysql.com:1186"
```

For more information, see [Section 17.3.2.3, “The MySQL Cluster Connectstring”](#).

- `--core-file`

<b>Command-Line Format</b>	<code>--core-file</code>
<b>Permitted Values</b>	
<b>Type</b>	<code>boolean</code>
<b>Default</b>	<code>FALSE</code>

Write a core file if the program dies. The name and location of the core file are system-dependent. (For MySQL Cluster programs nodes running on Linux, the default location is the program's working directory—for a data node, this is the node's `DataDir`.) For some systems, there may be restrictions or limitations; for example, it might be necessary to execute `ulimit -c unlimited` before starting the server. Consult your system documentation for detailed information.

If MySQL Cluster was built using the `--debug` option for `configure`, then `--core-file` is enabled by default. For regular builds, `--core-file` is disabled by default.

- `--debug[=options]`

<b>Command-Line Format</b>	<code>--debug=options</code>
<b>Permitted Values</b>	
<b>Type</b>	<code>string</code>
<b>Default</b>	<code>d:t:O,/tmp/ndb_restore.trace</code>

This option can be used only for versions compiled with debugging enabled. It is used to enable output from debug calls in the same manner as for the `mysqld` process.

- `--ndb-mgmd-host=host[:port]`

Can be used to set the host and port number of the management server to connect to.

- `--ndb-nodeid=#`

<b>Command-Line Format</b>	<code>--ndb-nodeid=#</code>
----------------------------	-----------------------------

<b>Permitted Values</b>	
Type	numeric
Default	0

Sets this node's MySQL Cluster node ID. *The range of permitted values depends on the type of the node (data, management, or API) and the version of the MySQL Cluster software which is running on it.* See [Section 17.1.5.2, “Limits and Differences of MySQL Cluster from Standard MySQL Limits”](#), for more information.

- `--ndb-optimized-node-selection`

Command-Line Format	<code>--ndb-optimized-node-selection</code>
<b>Permitted Values</b>	
Type	boolean
Default	TRUE

Optimize selection of nodes for transactions. Enabled by default.

- `--version, -V`

Command-Line Format	<code>-V</code>
	<code>--version</code>

Prints the MySQL Cluster version number of the executable. The version number is relevant because not all versions can be used together, and the MySQL Cluster startup process verifies that the versions of the binaries being used can co-exist in the same cluster. This is also important when performing an online (rolling) software upgrade or downgrade of MySQL Cluster. (See [Section 17.2.5.1, “Performing a Rolling Restart of a MySQL Cluster”](#)).

## 17.5. Management of MySQL Cluster

Managing a MySQL Cluster involves a number of tasks, the first of which is to configure and start MySQL Cluster. This is covered in [Section 17.3, “MySQL Cluster Configuration”](#), and [Section 17.4, “MySQL Cluster Programs”](#).

The next few sections cover the management of a running MySQL Cluster.

For information about security issues relating to management and deployment of a MySQL Cluster, see [Section 17.5.9, “MySQL Cluster Security Issues”](#).

There are essentially two methods of actively managing a running MySQL Cluster. The first of these is through the use of commands entered into the management client whereby cluster status can be checked, log levels changed, backups started and stopped, and nodes stopped and started. The second method involves studying the contents of the cluster log `ndb_node_id_cluster.log`; this is usually found in the management server's `DataDir` directory, but this location can be overridden using the `LogDestination` option—see [Section 17.3.2.5, “Defining a MySQL Cluster Management Server”](#), for details. (Recall that `node_id` represents the unique identifier of the node whose activity is being logged.) The cluster log contains event reports generated by `ndbd`. It is also possible to send cluster log entries to a Unix system log.

Some aspects of the cluster's operation can be also be monitored from an SQL node using the `SHOW ENGINE NDB STATUS` statement. See [Section 12.4.5.16, “SHOW ENGINE Syntax”](#), for more information.

In MySQL Cluster NDB 7.1.1 and later, detailed information about cluster operations is available in real time through an SQL interface using the `ndbinfo` database. For more information, see [Section 17.5.8, “The ndbinfo MySQL Cluster Information Database”](#).

### 17.5.1. Summary of MySQL Cluster Start Phases

This section provides a simplified outline of the steps involved when MySQL Cluster data nodes are started. More complete information can be found in [MySQL Cluster Start Phases](#).

These phases are the same as those reported in the output from the `node_id STATUS` command in the management client (see [Section 17.5.2, “Commands in the MySQL Cluster Management Client”](#)). In MySQL Cluster NDB 7.1.1 and later, these start

phases are also reported in the `start_phase` column of the `ndbinfo.nodes` table (see [Section 17.5.8.7, “The ndbinfo nodes Table”](#)).

**Start types.** There are several different startup types and modes, as shown here:

- **Initial Start.** The cluster starts with a clean file system on all data nodes. This occurs either when the cluster started for the very first time, or when all data nodes are restarted using the `--initial` option.

#### Note

Disk Data files are not removed when restarting a node using `--initial`.

- **System Restart.** The cluster starts and reads data stored in the data nodes. This occurs when the cluster has been shut down after having been in use, when it is desired for the cluster to resume operations from the point where it left off.
- **Node Restart.** This is the online restart of a cluster node while the cluster itself is running.
- **Initial Node Restart.** This is the same as a node restart, except that the node is reinitialized and started with a clean file system.

**Setup and initialization (Phase -1).** Prior to startup, each data node (`ndbd` process) must be initialized. Initialization consists of the following steps:

1. Obtain a node ID
2. Fetch configuration data
3. Allocate ports to be used for inter-node communications
4. Allocate memory according to settings obtained from the configuration file

When a data node or SQL node first connects to the management node, it reserves a cluster node ID. To make sure that no other node allocates the same node ID, this ID is retained until the node has managed to connect to the cluster and at least one `ndbd` reports that this node is connected. This retention of the node ID is guarded by the connection between the node in question and `ndb_mgmd`.

Normally, in the event of a problem with the node, the node disconnects from the management server, the socket used for the connection is closed, and the reserved node ID is freed. However, if a node is disconnected abruptly—for example, due to a hardware failure in one of the cluster hosts, or because of network issues—the normal closing of the socket by the operating system may not take place. In this case, the node ID continues to be reserved and not released until a TCP timeout occurs 10 or so minutes later.

To take care of this problem, you can use `PURGE STALE SESSIONS`. Running this statement forces all reserved node IDs to be checked; any that are not being used by nodes actually connected to the cluster are then freed.

Beginning with MySQL 5.1.11, timeout handling of node ID assignments is implemented. This performs the ID usage checks automatically after approximately 20 seconds, so that `PURGE STALE SESSIONS` should no longer be necessary in a normal Cluster start.

After each data node has been initialized, the cluster startup process can proceed. The stages which the cluster goes through during this process are listed here:

- **Phase 0.** The `NDBFS` and `NDBCNTR` blocks start (see [NDB Kernel Blocks](#)). The cluster file system is cleared, if the cluster was started with the `--initial` option.
- **Phase 1.** In this stage, all remaining `NDB` kernel blocks are started. Cluster connections are set up, inter-block communications are established, and Cluster heartbeats are started. In the case of a node restart, API node connections are also checked.

#### Note

When one or more nodes hang in Phase 1 while the remaining node or nodes hang in Phase 2, this often indicates network problems. One possible cause of such issues is one or more cluster hosts having multiple network interfaces. Another common source of problems causing this condition is the blocking of TCP/IP ports needed for communications between cluster nodes. In the latter case, this is often due to a misconfigured firewall.

- **Phase 2.** The `NDBCNTR` kernel block checks the states of all existing nodes. The master node is chosen, and the cluster schema file is initialized.

- **Phase 3.** The `DBLQH` and `DBTC` kernel blocks set up communications between them. The startup type is determined; if this is a restart, the `DBDIH` block obtains permission to perform the restart.
- **Phase 4.** For an initial start or initial node restart, the redo log files are created. The number of these files is equal to `NoOf-FragmentLogFiles`.

For a system restart:

- Read schema or schemas.
- Read data from the local checkpoint.
- Apply all redo information until the latest restorable global checkpoint has been reached.

For a node restart, find the tail of the redo log.

- **Phase 5.** Most of the database-related portion of a data node start is performed during this phase. For an initial start or system restart, a local checkpoint is executed, followed by a global checkpoint. Periodic checks of memory usage begin during this phase, and any required node takeovers are performed.
- **Phase 6.** In this phase, node groups are defined and set up.
- **Phase 7.** The arbitrator node is selected and begins to function. The next backup ID is set, as is the backup disk write speed. Nodes reaching this start phase are marked as `Started`. It is now possible for API nodes (including SQL nodes) to connect to the cluster. `connect`.
- **Phase 8.** If this is a system restart, all indexes are rebuilt (by `DBDIH`).
- **Phase 9.** The node internal startup variables are reset.
- **Phase 100 (OBSOLETE).** Formerly, it was at this point during a node restart or initial node restart that API nodes could connect to the node and begin to receive events. Currently, this phase is empty.
- **Phase 101.** At this point in a node restart or initial node restart, event delivery is handed over to the node joining the cluster. The newly-joined node takes over responsibility for delivering its primary data to subscribers. This phase is also referred to as `SUMA handover phase`.

After this process is completed for an initial start or system restart, transaction handling is enabled. For a node restart or initial node restart, completion of the startup process means that the node may now act as a transaction coordinator.

## 17.5.2. Commands in the MySQL Cluster Management Client

In addition to the central configuration file, a cluster may also be controlled through a command-line interface available through the management client `ndb_mgm`. This is the primary administrative interface to a running cluster.

Commands for the event logs are given in [Section 17.5.4, “Event Reports Generated in MySQL Cluster”](#); commands for creating backups and restoring from them are provided in [Section 17.5.3, “Online Backup of MySQL Cluster”](#).

The management client has the following basic commands. In the listing that follows, `node_id` denotes either a database node ID or the keyword `ALL`, which indicates that the command should be applied to all of the cluster's data nodes.

- **HELP**  
Displays information on all available commands.
- **SHOW**  
Displays information on the cluster's status.

Beginning with MySQL Cluster NDB 6.2.8 and MySQL Cluster NDB 6.3.6, the output from this command indicates when the cluster is in single user mode.

### Note

In a cluster where multiple management nodes are in use, this command displays information only for data nodes that are actually connected to the current management server.

- `node_id START`

Brings online the data node identified by `node_id` (or all data nodes).

`ALL START` works on all data nodes only, and does not affect management nodes.

### Important

To use this command to bring a data node online, the data node must have been started using `ndbd --nostart` or `ndbd -n`.

- `node_id STOP [-a]`

Stops the data or management node identified by `node_id`. Note that `ALL STOP` works to stop all data nodes only, and does not affect management nodes.

A node affected by this command disconnects from the cluster, and its associated `ndbd` or `ndb_mgmd` process terminates.

The `-a` option causes the node to be stopped immediately, without waiting for the completion of any pending transactions.

### Warning

Use of the `-a` option also disables the safety check otherwise performed when `STOP` is invoked to insure that stopping the node does not cause an incomplete cluster. In other words, you should exercise extreme care when using the `-a` option with the `STOP` command, due to the fact that this option makes it possible for the cluster to undergo a forced shutdown because it no longer has a complete copy of all data stored in `NDB`.

- `node_id RESTART [-n] [-i] [-a]`

Restarts the data node identified by `node_id` (or all data nodes).

Using the `-i` option with `RESTART` causes the data node to perform an initial restart; that is, the node's file system is deleted and recreated. The effect is the same as that obtained from stopping the data node process and then starting it again using `ndbd --initial` from the system shell. Note that backup files and Disk Data files are not removed when this option is used.

Using the `-n` option causes the data node process to be restarted, but the data node is not actually brought online until the appropriate `START` command is issued. The effect of this option is the same as that obtained from stopping the data node and then starting it again using `ndbd --nostart` or `ndbd -n` from the system shell.

Using the `-a` causes all current transactions relying on this node to be aborted. No GCP check is done when the node rejoins the cluster.

- `node_id STATUS`

Displays status information for the data node identified by `node_id` (or for all data nodes).

Beginning with MySQL Cluster NDB 6.2.8 and MySQL Cluster NDB 6.3.6, the output from this command indicates when the cluster is in single user mode.

- `node_id REPORT report-type`

Displays a report of type `report-type` for the data node identified by `node_id`, or for all data nodes using `ALL`.

Currently, there are two accepted values for `report-type`:

- `BackupStatus` provides a status report on a cluster backup in progress
- `MemoryUsage` displays how much data memory and index memory is being used by each data node as shown in this example:

```
ndb_mgm> ALL REPORT MEMORY
Node 1: Data usage is 5%(177 32K pages of total 3200)
Node 1: Index usage is 0%(108 8K pages of total 12832)
Node 2: Data usage is 5%(177 32K pages of total 3200)
Node 2: Index usage is 0%(108 8K pages of total 12832)
```

In MySQL Cluster NDB 7.1.1 and later, this information is also available from the `ndbinfo.memoryusage` table; see [Section 17.5.8.6, “The `ndbinfo memoryusage` Table”](#).

`report-type` is case-insensitive and “fuzzy”; for `MemoryUsage`, you can use `MEMORY` (as shown in the prior example), `memory`, or even simply `MEM` (or `mem`). You can abbreviate `BackupStatus` in a similar fashion.

The `REPORT` command was introduced in MySQL Cluster NDB 6.2.3 and MySQL Cluster NDB 6.3.0.

- **`ENTER SINGLE USER MODE node_id`**

Enters single user mode, whereby only the MySQL server identified by the node ID `node_id` is permitted to access the database.

**Important**

Currently, it is not possible for data nodes to join a MySQL Cluster while it is running in single user mode. ([Bug#20395](#))

- **`EXIT SINGLE USER MODE`**

Exits single user mode, enabling all SQL nodes (that is, all running `mysqld` processes) to access the database.

**Note**

It is possible to use `EXIT SINGLE USER MODE` even when not in single user mode, although the command has no effect in this case.

- **`QUIT, EXIT`**

Terminates the management client.

This command does not affect any nodes connected to the cluster.

- **`SHUTDOWN`**

Shuts down all cluster data nodes and management nodes. To exit the management client after this has been done, use `EXIT` or `QUIT`.

This command does *not* shut down any SQL nodes or API nodes that are connected to the cluster.

- **`CREATE NODEGROUP nodeid[, nodeid, ...]`**

Creates a new MySQL Cluster node group and causes data nodes to join it.

This command is used after adding new data nodes online to a MySQL Cluster, and causes them to join a new node group and thus to begin participating fully in the cluster. The command takes as its sole parameter a comma-separated list of node IDs—these are the IDs of the nodes just added and started that are to join the new node group. The number of nodes must be the same as the number of nodes in each node group that is already part of the cluster (each MySQL Cluster node group must have the same number of nodes). In other words, if the MySQL Cluster has 2 node groups of 2 data nodes each, then the new node group must also have 2 data nodes.

The node group ID of the new node group created by this command is determined automatically, and always the next highest unused node group ID in the cluster; it is not possible to set it manually.

This command was introduced in MySQL Cluster NDB 6.4.0. For more information, see [Section 17.5.11, “Adding MySQL Cluster Data Nodes Online”](#).

- **`DROP NODEGROUP nodegroup_id`**

Drops the MySQL Cluster node group with the given `nodegroup_id`.

This command can be used to drop a node group from a MySQL Cluster. `DROP NODEGROUP` takes as its sole argument the node group ID of the node group to be dropped.

`DROP NODEGROUP` acts only to remove the data nodes in the effected node group from that node group. It does not stop data nodes, assign them to a different node group, or remove them from the cluster's configuration. A data node that does not belong to a node group is indicated in the output of the management client `SHOW` command with `no nodegroup` in place of the node group ID, like this (indicated using bold text):

```
id=3 @10.100.2.67 (5.1.47-ndb-7.1.8, no nodegroup)
```

Prior to MySQL Cluster NDB 7.0.4, the `SHOW` output was not updated correctly following `DROP NODEGROUP`. ([Bug#43413](#))

`DROP NODEGROUP` works only when all data nodes in the node group to be dropped are completely empty of any table data and table definitions. Since there is currently no way using `ndb_mgm` or in the `mysql` client to remove all data from a specific data node or node group, this means that the command succeeds only in the two following cases:

1. After issuing `CREATE NODEGROUP` in the `ndb_mgm` client, but before issuing any `ALTER ONLINE TABLE ... REORGANIZE PARTITION` statements in the `mysql` client.
2. After dropping all `NDBCLUSTER` tables using `DROP TABLE`.

`TRUNCATE TABLE` does not work for this purpose because this removes only the table data; the data nodes continue to store an `NDBCLUSTER` table's definition until a `DROP TABLE` statement is issued that causes the table metadata to be dropped.

`DROP NODEGROUP` was introduced in MySQL Cluster NDB 6.4.0. For more information, see [Section 17.5.11, “Adding MySQL Cluster Data Nodes Online”](#).

## 17.5.3. Online Backup of MySQL Cluster

The next few sections describe how to prepare for and then to create a MySQL Cluster backup using the functionality for this purpose found in the `ndb_mgm` management client. To distinguish this type of backup from a backup made using `mysqldump`, we sometimes refer to it as a “native” MySQL Cluster backup. (For information about the creation of backups with `mysqldump`, see [Section 4.5.4, “mysqldump — A Database Backup Program”](#).) Restoration of MySQL Cluster backups is done using the `ndb_restore` utility provided with the MySQL Cluster distribution; for information about `ndb_restore` and its use in restoring MySQL Cluster backups, see [Section 17.4.17, “ndb\\_restore — Restore a MySQL Cluster Backup”](#).

### 17.5.3.1. MySQL Cluster Backup Concepts

A backup is a snapshot of the database at a given time. The backup consists of three main parts:

- **Metadata.** The names and definitions of all database tables
- **Table records.** The data actually stored in the database tables at the time that the backup was made
- **Transaction log.** A sequential record telling how and when data was stored in the database

Each of these parts is saved on all nodes participating in the backup. During backup, each node saves these three parts into three files on disk:

- `BACKUP-backup_id.node_id.ctl`

A control file containing control information and metadata. Each node saves the same table definitions (for all tables in the cluster) to its own version of this file.

- `BACKUP-backup_id-0.node_id.data`

A data file containing the table records, which are saved on a per-fragment basis. That is, different nodes save different fragments during the backup. The file saved by each node starts with a header that states the tables to which the records belong. Following the list of records there is a footer containing a checksum for all records.

- `BACKUP-backup_id.node_id.log`

A log file containing records of committed transactions. Only transactions on tables stored in the backup are stored in the log. Nodes involved in the backup save different records because different nodes host different database fragments.

In the listing above, `backup_id` stands for the backup identifier and `node_id` is the unique identifier for the node creating the

file.

### 17.5.3.2. Using The MySQL Cluster Management Client to Create a Backup

Before starting a backup, make sure that the cluster is properly configured for performing one. (See [Section 17.5.3.3, “Configuration for MySQL Cluster Backups”](#).)

The `START BACKUP` command is used to create a backup:

```
START BACKUP [backup_id] [wait_option] [snapshot_option]

wait_option:
WAIT {STARTED | COMPLETED} | NOWAIT

snapshot_option:
SNAPSHOTSTART | SNAPSHOTEND
```

Successive backups are automatically identified sequentially, so the `backup_id`, an integer greater than or equal to 1, is optional; if it is omitted, the next available value is used. If an existing `backup_id` value is used, the backup fails with the error `BACKUP FAILED: FILE ALREADY EXISTS`. If used, the `backup_id` must follow `START BACKUP` immediately, before any other options are used.

Prior to MySQL Cluster NDB 6.2.17, 6.3.23, and 6.4.3, backup IDs greater than 2147483648 ( $2^{31}$ ) were not supported correctly. ([Bug#43042](#)) Beginning with these versions, the maximum possible backup ID is 4294967296 ( $2^{32}$ ).

#### Note

Prior to MySQL Cluster NDB 7.0.5, when starting a backup using `ndb_mgm -e "START BACKUP"`, the `backup_id` was required. ([Bug#31754](#))

The `wait_option` can be used to determine when control is returned to the management client after a `START BACKUP` command is issued, as shown in the following list:

- If `NOWAIT` is specified, the management client displays a prompt immediately, as seen here:

```
ndb_mgm> START BACKUP NOWAIT
ndb_mgm>
```

In this case, the management client can be used even while it prints progress information from the backup process.

- With `WAIT STARTED` the management client waits until the backup has started before returning control to the user, as shown here:

```
ndb_mgm> START BACKUP WAIT STARTED
Waiting for started, this may take several minutes
Node 2: Backup 3 started from node 1
ndb_mgm>
```

- `WAIT COMPLETED` causes the management client to wait until the backup process is complete before returning control to the user.

`WAIT COMPLETED` is the default.

Beginning with MySQL Cluster NDB 6.4.0, a `snapshot_option` can be used to determine whether the backup matches the state of the cluster when `START BACKUP` was issued, or when it was completed. `SNAPSHOTSTART` causes the backup to match the state of the cluster when the backup began; `SNAPSHOTEND` causes the backup to reflect the state of the cluster when the backup was finished. `SNAPSHOTEND` is the default, and matches the behavior found in previous MySQL Cluster releases.

#### Note

If you use the `SNAPSHOTSTART` option with `START BACKUP`, and the `CompressedBackup` parameter is enabled, only the data and control files are compressed—the log file is not compressed.

If both a `wait_option` and a `snapshot_option` are used, they may be specified in either order. For example, all of the following commands are valid, assuming that there is no existing backup having 4 as its ID:

```
START BACKUP WAIT STARTED SNAPSHOTSTART
START BACKUP SNAPSHOTSTART WAIT STARTED
START BACKUP 4 WAIT COMPLETED SNAPSHOTSTART
START BACKUP SNAPSHOTEND WAIT COMPLETED
START BACKUP 4 NOWAIT SNAPSHOTSTART
```

The procedure for creating a backup consists of the following steps:

1. Start the management client (`ndb_mgm`), if it not running already.
2. Execute the `START BACKUP` command. This produces several lines of output indicating the progress of the backup, as shown here:

```
ndb_mgm> START BACKUP
Waiting for completed, this may take several minutes
Node 2: Backup 1 started from node 1
Node 2: Backup 1 started from node 1 completed
 StartGCP: 177 StopGCP: 180
 #Records: 7362 #LogRecords: 0
 Data: 453648 bytes Log: 0 bytes
ndb_mgm>
```

3. When the backup has started the management client displays this message:

```
Backup backup_id started from node node_id
```

`backup_id` is the unique identifier for this particular backup. This identifier is saved in the cluster log, if it has not been configured otherwise. `node_id` is the identifier of the management server that is coordinating the backup with the data nodes. At this point in the backup process the cluster has received and processed the backup request. It does not mean that the backup has finished. An example of this statement is shown here:

```
Node 2: Backup 1 started from node 1
```

4. The management client indicates with a message like this one that the backup has started:

```
Backup backup_id started from node node_id completed
```

As is the case for the notification that the backup has started, `backup_id` is the unique identifier for this particular backup, and `node_id` is the node ID of the management server that is coordinating the backup with the data nodes. This output is accompanied by additional information including relevant global checkpoints, the number of records backed up, and the size of the data, as shown here:

```
Node 2: Backup 1 started from node 1 completed
 StartGCP: 177 StopGCP: 180
 #Records: 7362 #LogRecords: 0
 Data: 453648 bytes Log: 0 bytes
```

It is also possible to perform a backup from the system shell by invoking `ndb_mgm` with the `-e` or `--execute` option, as shown in this example:

```
shell> ndb_mgm -e "START BACKUP 6 WAIT COMPLETED SNAPSHOTSTART"
```

When using `START BACKUP` in this way, you must specify the backup ID.

Cluster backups are created by default in the `BACKUP` subdirectory of the `DataDir` on each data node. This can be overridden for one or more data nodes individually, or for all cluster data nodes in the `config.ini` file using the `BackupDataDir` configuration parameter as discussed in [Identifying Data Nodes](#). The backup files created for a backup with a given `backup_id` are stored in a subdirectory named `BACKUP-backup_id` in the backup directory.

To abort a backup that is already in progress:

1. Start the management client.
2. Execute this command:

```
ndb_mgm> ABORT BACKUP backup_id
```

The number `backup_id` is the identifier of the backup that was included in the response of the management client when the backup was started (in the message `Backup backup_id started from node management_node_id`).

3. The management client will acknowledge the abort request with `Abort of backup backup_id ordered`.

**Note**

At this point, the management client has not yet received a response from the cluster data nodes to this request, and the backup has not yet actually been aborted.

4. After the backup has been aborted, the management client will report this fact in a manner similar to what is shown here:

```
Node 1: Backup 3 started from 5 has been aborted. Error: 1321 - Backup aborted by user request: Permanent error: User requested abort
Node 3: Backup 3 started from 5 has been aborted. Error: 1323 - 1323: Permanent error: Internal error
Node 2: Backup 3 started from 5 has been aborted. Error: 1323 - 1323: Permanent error: Internal error
Node 4: Backup 3 started from 5 has been aborted. Error: 1323 - 1323: Permanent error: Internal error
```

In this example, we have shown sample output for a cluster with 4 data nodes, where the sequence number of the backup to be aborted is [3](#), and the management node to which the cluster management client is connected has the node ID [5](#). The first node to complete its part in aborting the backup reports that the reason for the abort was due to a request by the user. (The remaining nodes report that the backup was aborted due to an unspecified internal error.)

**Note**

There is no guarantee that the cluster nodes respond to an `ABORT BACKUP` command in any particular order.

The `Backup backup_id started from node management_node_id has been aborted` messages mean that the backup has been terminated and that all files relating to this backup have been removed from the cluster file system.

It is also possible to abort a backup in progress from a system shell using this command:

```
shell> ndb_mgm -e "ABORT BACKUP backup_id"
```

**Note**

If there is no backup having the ID `backup_id` running when an `ABORT BACKUP` is issued, the management client makes no response, nor is it indicated in the cluster log that an invalid abort command was sent.

### 17.5.3.3. Configuration for MySQL Cluster Backups

Five configuration parameters are essential for backup:

- **`BackupDataBufferSize`**

The amount of memory used to buffer data before it is written to disk.

- **`BackupLogBufferSize`**

The amount of memory used to buffer log records before these are written to disk.

- **`BackupMemory`**

The total memory allocated in a database node for backups. This should be the sum of the memory allocated for the backup data buffer and the backup log buffer.

- **`BackupWriteSize`**

The default size of blocks written to disk. This applies for both the backup data buffer and the backup log buffer.

- **`BackupMaxWriteSize`**

The maximum size of blocks written to disk. This applies for both the backup data buffer and the backup log buffer.

More detailed information about these parameters can be found in [Backup Parameters](#).

### 17.5.3.4. MySQL Cluster Backup Troubleshooting

If an error code is returned when issuing a backup request, the most likely cause is insufficient memory or disk space. You should check that there is enough memory allocated for the backup.

### Important

If you have set `BackupDataBufferSize` and `BackupLogBufferSize` and their sum is greater than 4MB, then you must also set `BackupMemory` as well. See [BackupMemory](#).

You should also make sure that there is sufficient space on the hard drive partition of the backup target.

NDB does not support repeatable reads, which can cause problems with the restoration process. Although the backup process is “hot”, restoring a MySQL Cluster from backup is not a 100% “hot” process. This is due to the fact that, for the duration of the restore process, running transactions get nonrepeatable reads from the restored data. This means that the state of the data is inconsistent while the restore is in progress.

## 17.5.4. Event Reports Generated in MySQL Cluster

In this section, we discuss the types of event logs provided by MySQL Cluster, and the types of events that are logged.

MySQL Cluster provides two types of event log:

- The *cluster log*, which includes events generated by all cluster nodes. The cluster log is the log recommended for most uses because it provides logging information for an entire cluster in a single location.

By default, the cluster log is saved to a file named `ndb_node_id_cluster.log`, (where `node_id` is the node ID of the management server) in the same directory where the `ndb_mgm` binary resides.

Cluster logging information can also be sent to `stdout` or a `syslog` facility in addition to or instead of being saved to a file, as determined by the values set for the `DataDir` and `LogDestination` configuration parameters. See [Section 17.3.2.5, “Defining a MySQL Cluster Management Server”](#), for more information about these parameters.

- Node logs* are local to each node.

Output generated by node event logging is written to the file `ndb_node_id_out.log` (where `node_id` is the node's node ID) in the node's `DataDir`. Node event logs are generated for both management nodes and data nodes.

Node logs are intended to be used only during application development, or for debugging application code.

Both types of event logs can be set to log different subsets of events.

Each reportable event can be distinguished according to three different criteria:

- Category*: This can be any one of the following values: `STARTUP`, `SHUTDOWN`, `STATISTICS`, `CHECKPOINT`, `NODERESTART`, `CONNECTION`, `ERROR`, or `INFO`.
- Priority*: This is represented by one of the numbers from 1 to 15 inclusive, where 1 indicates “most important” and 15 “least important.”
- Severity Level*: This can be any one of the following values: `ALERT`, `CRITICAL`, `ERROR`, `WARNING`, `INFO`, or `DEBUG`.

Both the cluster log and the node log can be filtered on these properties.

The format used in the cluster log is as shown here:

```
2007-01-26 19:35:55 [MgmSrvr] INFO -- Node 1: Data usage is 2%(60 32K pages of total 2560)
2007-01-26 19:35:55 [MgmSrvr] INFO -- Node 1: Index usage is 1%(24 8K pages of total 2336)
2007-01-26 19:35:55 [MgmSrvr] INFO -- Node 1: Resource 0 min: 0 max: 639 curr: 0
2007-01-26 19:35:55 [MgmSrvr] INFO -- Node 2: Data usage is 2%(76 32K pages of total 2560)
2007-01-26 19:35:55 [MgmSrvr] INFO -- Node 2: Index usage is 1%(24 8K pages of total 2336)
2007-01-26 19:35:55 [MgmSrvr] INFO -- Node 2: Resource 0 min: 0 max: 639 curr: 0
2007-01-26 19:35:55 [MgmSrvr] INFO -- Node 3: Data usage is 2%(58 32K pages of total 2560)
2007-01-26 19:35:55 [MgmSrvr] INFO -- Node 3: Index usage is 1%(25 8K pages of total 2336)
2007-01-26 19:35:55 [MgmSrvr] INFO -- Node 3: Resource 0 min: 0 max: 639 curr: 0
2007-01-26 19:35:55 [MgmSrvr] INFO -- Node 4: Data usage is 2%(74 32K pages of total 2560)
2007-01-26 19:35:55 [MgmSrvr] INFO -- Node 4: Index usage is 1%(25 8K pages of total 2336)
2007-01-26 19:35:55 [MgmSrvr] INFO -- Node 4: Resource 0 min: 0 max: 639 curr: 0
2007-01-26 19:39:42 [MgmSrvr] INFO -- Node 4: Node 9 Connected
2007-01-26 19:39:42 [MgmSrvr] INFO -- Node 1: Node 9 Connected
2007-01-26 19:39:42 [MgmSrvr] INFO -- Node 1: Node 9: API 5.1.47-ndb-7.1.8
2007-01-26 19:39:42 [MgmSrvr] INFO -- Node 2: Node 9 Connected
2007-01-26 19:39:42 [MgmSrvr] INFO -- Node 2: Node 9: API 5.1.47-ndb-7.1.8
2007-01-26 19:39:42 [MgmSrvr] INFO -- Node 3: Node 9 Connected
```

```
2007-01-26 19:39:42 [MgmSrvr] INFO -- Node 3: Node 9: API 5.1.47-ndb-7.1.8
2007-01-26 19:39:42 [MgmSrvr] INFO -- Node 4: Node 9: API 5.1.47-ndb-7.1.8
2007-01-26 19:59:22 [MgmSrvr] ALERT -- Node 2: Node 7 Disconnected
2007-01-26 19:59:22 [MgmSrvr] ALERT -- Node 2: Node 7 Disconnected
```

Each line in the cluster log contains the following information:

- A timestamp in `YYYY-MM-DD HH:MM:SS` format.
- The type of node which is performing the logging. In the cluster log, this is always `[MgmSrvr]`.
- The severity of the event.
- The ID of the node reporting the event.
- A description of the event. The most common types of events to appear in the log are connections and disconnections between different nodes in the cluster, and when checkpoints occur. In some cases, the description may contain status information.

#### 17.5.4.1. MySQL Cluster Logging Management Commands

The following management commands are related to the cluster log:

- `CLUSTERLOG ON`  
Turns the cluster log on.
- `CLUSTERLOG OFF`  
Turns the cluster log off.
- `CLUSTERLOG INFO`  
Provides information about cluster log settings.
- `node_id CLUSTERLOG category=threshold`  
Logs `category` events with priority less than or equal to `threshold` in the cluster log.
- `CLUSTERLOG FILTER severity_level`  
Toggles cluster logging of events of the specified `severity_level`.

The following table describes the default setting (for all data nodes) of the cluster log category threshold. If an event has a priority with a value lower than or equal to the priority threshold, it is reported in the cluster log.

Note that events are reported per data node, and that the threshold can be set to different values on different nodes.

Category	Default threshold (All data nodes)
STARTUP	7
SHUTDOWN	7
STATISTICS	7
CHECKPOINT	7
NODERESTART	7
CONNECTION	7
ERROR	15
INFO	7

The `STATISTICS` category can provide a great deal of useful data. See [Section 17.5.4.3, “Using CLUSTERLOG STATISTICS in the MySQL Cluster Management Client”](#), for more information.

Thresholds are used to filter events within each category. For example, a `STARTUP` event with a priority of 3 is not logged unless the threshold for `STARTUP` is set to 3 or higher. Only events with priority 3 or lower are sent if the threshold is 3.

The following table shows the event severity levels.

### Note

These correspond to Unix `syslog` levels, except for `LOG_EMERG` and `LOG_NOTICE`, which are not used or mapped.

<b>1</b>	<code>ALERT</code>	A condition that should be corrected immediately, such as a corrupted system database
<b>2</b>	<code>CRITICAL</code>	Critical conditions, such as device errors or insufficient resources
<b>3</b>	<code>ERROR</code>	Conditions that should be corrected, such as configuration errors
<b>4</b>	<code>WARNING</code>	Conditions that are not errors, but that might require special handling
<b>5</b>	<code>INFO</code>	Informational messages
<b>6</b>	<code>DEBUG</code>	Debugging messages used for <code>NDBCLUSTER</code> development

Event severity levels can be turned on or off (using `CLUSTERLOG FILTER`—see above). If a severity level is turned on, then all events with a priority less than or equal to the category thresholds are logged. If the severity level is turned off then no events belonging to that severity level are logged.

### Important

Cluster log levels are set on a per `ndb_mgmd`, per subscriber basis. This means that, in a MySQL Cluster with multiple management servers, using a `CLUSTERLOG` command in an instance of `ndb_mgm` connected to one management server affects only logs generated by that management server but not by any of the others. This also means that, should one of the management servers be restarted, only logs generated by that management server are affected by the resetting of log levels caused by the restart.

## 17.5.4.2. MySQL Cluster Log Events

An event report reported in the event logs has the following format:

```
datetime [string] severity -- message
```

For example:

```
09:19:30 2005-07-24 [NDB] INFO -- Node 4 Start phase 4 completed
```

This section discusses all reportable events, ordered by category and severity level within each category.

In the event descriptions, GCP and LCP mean “Global Checkpoint” and “Local Checkpoint”, respectively.

### CONNECTION Events

These events are associated with connections between Cluster nodes.

Event	Priority	Severity Level	Description
data nodes connected	8	<code>INFO</code>	Data nodes connected
data nodes disconnected	8	<code>INFO</code>	Data nodes disconnected
Communication closed	8	<code>INFO</code>	SQL node or data node connection closed
Communication opened	8	<code>INFO</code>	SQL node or data node connection opened

### CHECKPOINT Events

The logging messages shown here are associated with checkpoints.

Event	Priority	Severity Level	Description
LCP stopped in calc keep GCI	0	<code>ALERT</code>	LCP stopped
Local checkpoint fragment completed	11	<code>INFO</code>	LCP on a fragment has been completed
Global checkpoint completed	10	<code>INFO</code>	GCP finished
Global checkpoint started	9	<code>INFO</code>	Start of GCP: REDO log is written to disk

---

Local checkpoint completed	8	INFO	LCP completed normally
Local checkpoint started	7	INFO	Start of LCP: data written to disk

### STARTUP Events

The following events are generated in response to the startup of a node or of the cluster and of its success or failure. They also provide information relating to the progress of the startup process, including information concerning logging activities.

Event	Priority	Severity Level	Description
Internal start signal received STTORY	15	INFO	Blocks received after completion of restart
New REDO log started	10	INFO	GCI keep <i>X</i> , newest restorable GCI <i>Y</i>
New log started	10	INFO	Log part <i>X</i> , start MB <i>Y</i> , stop MB <i>Z</i>
Node has been refused for inclusion in the cluster	8	INFO	Node cannot be included in cluster due to misconfiguration, inability to establish communication, or other problem
data node neighbors	8	INFO	Shows neighboring data nodes
data node start phase <i>X</i> completed	4	INFO	A data node start phase has been completed
Node has been successfully included into the cluster	3	INFO	Displays the node, managing node, and dynamic ID
data node start phases initiated	1	INFO	NDB Cluster nodes starting
data node all start phases completed	1	INFO	NDB Cluster nodes started
data node shutdown initiated	1	INFO	Shutdown of data node has commenced
data node shutdown aborted	1	INFO	Unable to shut down data node normally

### NODERESTART Events

The following events are generated when restarting a node and relate to the success or failure of the node restart process.

Event	Priority	Severity Level	Description
Node failure phase completed	8	ALERT	Reports completion of node failure phases
Node has failed, node state was <i>X</i>	8	ALERT	Reports that a node has failed
Report arbitrator results	2	ALERT	There are eight different possible results for arbitration attempts: <ul style="list-style-type: none"><li>• Arbitration check failed—less than 1/2 nodes left</li><li>• Arbitration check succeeded—node group majority</li><li>• Arbitration check failed—missing node group</li><li>• Network partitioning—arbitration required</li><li>• Arbitration succeeded—affirmative response from node <i>X</i></li><li>• Arbitration failed - negative response from node <i>X</i></li><li>• Network partitioning - no arbitrator available</li><li>• Network partitioning - no arbitrator configured</li></ul>
Completed copying a fragment	10	INFO	
Completed copying of dictionary information	8	INFO	
Completed copying distribution information	8	INFO	
Starting to copy fragments	8	INFO	

Completed copying all fragments	8	INFO	
GCP takeover started	7	INFO	
GCP takeover completed	7	INFO	
LCP takeover started	7	INFO	
LCP takeover completed (state = <i>X</i> )	7	INFO	
Report whether an arbitrator is found or not	6	INFO	<p>There are seven different possible outcomes when seeking an arbitrator:</p> <ul style="list-style-type: none"> <li>• Management server restarts arbitration thread [state=<i>X</i>]</li> <li>• Prepare arbitrator node <i>X</i> [ticket=<i>Y</i>]</li> <li>• Receive arbitrator node <i>X</i> [ticket=<i>Y</i>]</li> <li>• Started arbitrator node <i>X</i> [ticket=<i>Y</i>]</li> <li>• Lost arbitrator node <i>X</i> - process failure [state=<i>Y</i>]</li> <li>• Lost arbitrator node <i>X</i> - process exit [state=<i>Y</i>]</li> <li>• Lost arbitrator node <i>X</i> &lt;error msg&gt; [state=<i>Y</i>]</li> </ul>

### STATISTICS Events

The following events are of a statistical nature. They provide information such as numbers of transactions and other operations, amount of data sent or received by individual nodes, and memory usage.

Event	Priority	Severity Level	Description
Report job scheduling statistics	9	INFO	Mean internal job scheduling statistics
Sent number of bytes	9	INFO	Mean number of bytes sent to node <i>X</i>
Received # of bytes	9	INFO	Mean number of bytes received from node <i>X</i>
Report transaction statistics	8	INFO	Numbers of: transactions, commits, reads, simple reads, writes, concurrent operations, attribute information, and aborts
Report operations	8	INFO	Number of operations
Report table create	7	INFO	
Memory usage	5	INFO	Data and index memory usage (80%, 90%, and 100%)

### ERROR Events

These events relate to Cluster errors and warnings. The presence of one or more of these generally indicates that a major malfunction or failure has occurred.

Event	Priority	Severity	Description
Dead due to missed heartbeat	8	ALERT	Node <i>X</i> declared “dead” due to missed heartbeat
Transporter errors	2	ERROR	
Transporter warnings	8	WARNING	
Missed heartbeats	8	WARNING	Node <i>X</i> missed heartbeat # <i>Y</i>
General warning events	2	WARNING	

### INFO Events

These events provide general information about the state of the cluster and activities associated with Cluster maintenance, such as logging and heartbeat transmission.

Event	Priority	Severity	Description
Sent heartbeat	12	INFO	Heartbeat sent to node <i>X</i>
Create log bytes	11	INFO	Log part, log file, MB
General information events	2	INFO	

### 17.5.4.3. Using `CLUSTERLOG STATISTICS` in the MySQL Cluster Management Client

The `NDB` management client's `CLUSTERLOG STATISTICS` command can provide a number of useful statistics in its output. Counters providing information about the state of the cluster are updated at 5-second reporting intervals by the transaction coordinator (TC) and the local query handler (LQH), and written to the cluster log.

**Transaction coordinator statistics.** Each transaction has one transaction coordinator, which is chosen by one of the following methods:

- In a round-robin fashion
- By communication proximity
- (*Beginning with MySQL Cluster NDB 6.3.4:*) By supplying a data placement hint when the transaction is started

#### Note

You can determine which TC selection method is used for transactions started from a given SQL node using the `ndb_optimized_node_selection` system variable.

All operations within the same transaction use the same transaction coordinator, which reports the following statistics:

- **Trans count.** This is the number transactions started in the last interval using this TC as the transaction coordinator. Any of these transactions may have committed, have been aborted, or remain uncommitted at the end of the reporting interval.

#### Note

Transactions do not migrate between TCs.

- **Commit count.** This is the number of transactions using this TC as the transaction coordinator that were committed in the last reporting interval. Because some transactions committed in this reporting interval may have started in a previous reporting interval, it is possible for `Commit count` to be greater than `Trans count`.
- **Read count.** This is the number of primary key read operations using this TC as the transaction coordinator that were started in the last reporting interval, including simple reads. This count also includes reads performed as part of unique index operations. A unique index read operation generates 2 primary key read operations—1 for the hidden unique index table, and 1 for the table on which the read takes place.
- **Simple read count.** This is the number of simple read operations using this TC as the transaction coordinator that were started in the last reporting interval. This is a subset of `Read count`. Because the value of `Simple read count` is incremented at a different point in time from `Read count`, it can lag behind `Read count` slightly, so it is conceivable that `Simple read count` is not equal to `Read count` for a given reporting interval, even if all reads made during that time were in fact simple reads.
- **Write count.** This is the number of primary key write operations using this TC as the transaction coordinator that were started in the last reporting interval. This includes all inserts, updates, writes and deletes, as well as writes performed as part of unique index operations.

#### Note

A unique index update operation can generate multiple PK read and write operations on the index table and on the base table.

- **AttrInfoCount.** This is the number of 32-bit data words received in the last reporting interval for primary key operations using this TC as the transaction coordinator. For reads, this is proportional to the number of columns requested. For inserts and updates, this is proportional to the number of columns written, and the size of their data. For delete operations, this is usually zero. Unique index operations generate multiple PK operations and so increase this count. However, data words sent to describe the PK operation itself, and the key information sent, are *not* counted here. Attribute information sent to describe columns to read for scans, or to describe ScanFilters, is also not counted in `AttrInfoCount`.
- **Concurrent Operations.** This is the number of primary key or scan operations using this TC as the transaction coordin-

ator that were started during the last reporting interval but that were not completed. Operations increment this counter when they are started and decrement it when they are completed; this occurs after the transaction commits. Dirty reads and writes—as well as failed operations—decrement this counter. The maximum value that `Concurrent Operations` can have is the maximum number of operations that a TC block can support; currently, this is `(2 * MaxNoOfConcurrentOperations) + 16 + MaxNoOfConcurrentTransactions`. (For more information about these configuration parameters, see the *Transaction Parameters* section of [Section 17.3.2.6, “Defining MySQL Cluster Data Nodes”](#).)

- **Abort count.** This is the number of transactions using this TC as the transaction coordinator that were aborted during the last reporting interval. Because some transactions that were aborted in the last reporting interval may have started in a previous reporting interval, `Abort count` can sometimes be greater than `Trans count`.
- **Scans.** This is the number of table scans using this TC as the transaction coordinator that were started during the last reporting interval. This does not include range scans (that is, ordered index scans).
- **Range scans.** This is the number of ordered index scans using this TC as the transaction coordinator that were started in the last reporting interval.

**Local query handler statistics (`Operations`).** There is 1 cluster event per local query handler block (that is, 1 per data node process). Operations are recorded in the LQH where the data they are operating on resides.

#### Note

A single transaction may operate on data stored in multiple LQH blocks.

The `Operations` statistic provides the number of local operations performed by this LQH block in the last reporting interval, and includes all types of read and write operations (insert, update, write, and delete operations). This also includes operations used to replicate writes—for example, in a 2-replica cluster, the write to the primary replica is recorded in the primary LQH, and the write to the backup will be recorded in the backup LQH. Unique key operations may result in multiple local operations; however, this does *not* include local operations generated as a result of a table scan or ordered index scan, which are not counted.

**Process scheduler statistics.** In addition to the statistics reported by the transaction coordinator and local query handler, each `ndbd` process has a scheduler which also provides useful metrics relating to the performance of a MySQL Cluster. This scheduler runs in an infinite loop; during each loop the scheduler performs the following tasks:

1. Read any incoming messages from sockets into a job buffer.
2. Check whether there are any timed messages to be executed; if so, put these into the job buffer as well.
3. Execute (in a loop) any messages in the job buffer.
4. Send any distributed messages that were generated by executing the messages in the job buffer.
5. Wait for any new incoming messages.

Process scheduler statistics include the following:

- **Mean Loop Counter.** This is the number of loops executed in the third step from the preceding list. This statistic increases in size as the utilization of the TCP/IP buffer improves. You can use this to monitor changes in performance as you add new data node processes.
- **Mean send size and Mean receive size.** These statistics enable you to gauge the efficiency of, respectively writes and reads between nodes. The values are given in bytes. Higher values mean a lower cost per byte sent or received; the maximum value is 64K.

To cause all cluster log statistics to be logged, you can use the following command in the `NDB` management client:

```
ndb_mgm> ALL CLUSTERLOG STATISTICS=15
```

#### Note

Setting the threshold for `STATISTICS` to 15 causes the cluster log to become very verbose, and to grow quite rapidly in size, in direct proportion to the number of cluster nodes and the amount of activity in the MySQL Cluster.

For more information about MySQL Cluster management client commands relating to logging and reporting, see [Section 17.5.4.1, “MySQL Cluster Logging Management Commands”](#).

## 17.5.5. MySQL Cluster Log Messages

This section contains information about the messages written to the cluster log in response to different cluster log events. It provides additional, more specific information on NDB transporter errors.

### 17.5.5.1. MySQL Cluster: Messages in the Cluster Log

The following table lists the most common NDB cluster log messages. For information about the cluster log, log events, and event types, see [Section 17.5.4, “Event Reports Generated in MySQL Cluster”](#). These log messages also correspond to log event types in the MGM API; see [The Ndb\\_logevent\\_type Type](#), for related information of interest to Cluster API developers.

<b>Log Message.</b> Node <i>mgm_node_id</i> : Node <i>data_node_id</i> Connected <b>Description.</b> The data node having node ID <i>node_id</i> has connected to the management server (node <i>mgm_node_id</i> ).	<b>Event Name.</b> Connected <b>Event Type.</b> Connection <b>Priority.</b> 8 <b>Severity.</b> INFO
<b>Log Message.</b> Node <i>mgm_node_id</i> : Node <i>data_node_id</i> Disconnected <b>Description.</b> The data node having node ID <i>data_node_id</i> has disconnected from the management server (node <i>mgm_node_id</i> ).	<b>Event Name.</b> Disconnected <b>Event Type.</b> Connection <b>Priority.</b> 8 <b>Severity.</b> ALERT
<b>Log Message.</b> Node <i>data_node_id</i> : Communication to Node <i>api_node_id</i> closed <b>Description.</b> The API node or SQL node having node ID <i>api_node_id</i> is no longer communicating with data node <i>data_node_id</i> .	<b>Event Name.</b> CommunicationClosed <b>Event Type.</b> Connection <b>Priority.</b> 8 <b>Severity.</b> INFO
<b>Log Message.</b> Node <i>data_node_id</i> : Communication to Node <i>api_node_id</i> opened <b>Description.</b> The API node or SQL node having node ID <i>api_node_id</i> is now communicating with data node <i>data_node_id</i> .	<b>Event Name.</b> CommunicationOpened <b>Event Type.</b> Connection <b>Priority.</b> 8 <b>Severity.</b> INFO
<b>Log Message.</b> Node <i>mgm_node_id</i> : Node <i>api_node_id</i> : API version <b>Description.</b> The API node having node ID <i>api_node_id</i> has connected to management node <i>mgm_node_id</i> using NDB API version <i>version</i> (generally the same as the MySQL version number).	<b>Event Name.</b> ConnectedApiVersion <b>Event Type.</b> Connection <b>Priority.</b> 8 <b>Severity.</b> INFO
<b>Log Message.</b> Node <i>node_id</i> : Global checkpoint <i>gci</i> started <b>Description.</b> A global checkpoint with the ID <i>gci</i> has been started; node <i>node_id</i> is the master responsible for this global checkpoint.	<b>Event Name.</b> GlobalCheckpointStarted <b>Event Type.</b> Checkpoint <b>Priority.</b> 9 <b>Severity.</b> INFO
<b>Log Message.</b> Node <i>node_id</i> : Global checkpoint <i>gci</i> completed <b>Description.</b> The global checkpoint having the ID <i>gci</i> has been completed; node <i>node_id</i> was the master responsible for this global checkpoint.	<b>Event Name.</b> GlobalCheckpointCompleted <b>Event Type.</b> Checkpoint <b>Priority.</b> 10 <b>Severity.</b> INFO

### 17.5.5.2. MySQL Cluster: NDB Transporter Errors

This section lists error codes, names, and messages that are written to the cluster log in the event of transporter errors.

Error Code	Error Name	Error Text
0x00	TE_NO_ERROR	NO ERROR
0x01	TE_ERROR_CLOSING_SOCKET	ERROR FOUND DURING CLOSING OF SOCKET
0x02	TE_ERROR_IN_SELECT_BEFORE_ACCEPT	ERROR FOUND BEFORE ACCEPT. THE TRANSPORTER WILL RETRY
0x03	TE_INVALID_MESSAGE_LENGTH	ERROR FOUND IN MESSAGE (INVALID MESSAGE LENGTH)
0x04	TE_INVALID_CHECKSUM	ERROR FOUND IN MESSAGE (CHECKSUM)

Error Code	Error Name	Error Text
0x05	<b>TE_COULD_NOT_CREATE_SOCKET</b>	ERROR FOUND WHILE CREATING SOCKET(CAN'T CREATE SOCKET)
0x06	<b>TE_COULD_NOT_BIND_SOCKET</b>	ERROR FOUND WHILE BINDING SERVER SOCKET
0x07	<b>TE_LISTEN_FAILED</b>	ERROR FOUND WHILE LISTENING TO SERVER SOCKET
0x08	<b>TE_ACCEPT_RETURN_ERROR</b>	ERROR FOUND DURING ACCEPT(ACCEPT RETURN ERROR)
0x0b	<b>TE_SHM_DISCONNECT</b>	THE REMOTE NODE HAS DISCONNECTED
0x0c	<b>TE_SHM_IPC_STAT</b>	UNABLE TO CHECK SHM SEGMENT
0x0d	<b>TE_SHM_UNABLE_TO_CREATE_SEGMENT</b>	UNABLE TO CREATE SHM SEGMENT
0x0e	<b>TE_SHM_UNABLE_TO_ATTACH_SEGMENT</b>	UNABLE TO ATTACH SHM SEGMENT
0x0f	<b>TE_SHM_UNABLE_TO_REMOVE_SEGMENT</b>	UNABLE TO REMOVE SHM SEGMENT
0x10	<b>TE_TOO_SMALL_SIGID</b>	SIG ID TOO SMALL
0x11	<b>TE_TOO_LARGE_SIGID</b>	SIG ID TOO LARGE
0x12	<b>TE_WAIT_STACK_FULL</b>	WAIT STACK WAS FULL
0x13	<b>TE_RECEIVE_BUFFER_FULL</b>	RECEIVE BUFFER WAS FULL
0x14	<b>TE_SIGNAL_LOST_SEND_BUFFER_FULL</b>	SEND BUFFER WAS FULL, AND TRYING TO FORCE SEND FAILS
0x15	<b>TE_SIGNAL_LOST</b>	SEND FAILED FOR UNKNOWN REASON(SIGNAL LOST)
0x16	<b>TE_SEND_BUFFER_FULL</b>	THE SEND BUFFER WAS FULL, BUT SLEEPING FOR A WHILE SOLVED
0x0017	<b>TE_SCI_LINK_ERROR</b>	THERE IS NO LINK FROM THIS NODE TO THE SWITCH
0x18	<b>TE_SCI_UNABLE_TO_START_SEQUENCE</b>	COULD NOT START A SEQUENCE, BECAUSE SYSTEM RESOURCES ARE EXUMED OR NO SEQUENCE HAS BEEN CREATED
0x19	<b>TE_SCI_UNABLE_TO_REMOVE_SEQUENCE</b>	COULD NOT REMOVE A SEQUENCE
0x1a	<b>TE_SCI_UNABLE_TO_CREATE_SEQUENCE</b>	COULD NOT CREATE A SEQUENCE, BECAUSE SYSTEM RESOURCES ARE EXEMPTED. MUST REBOOT
0x1b	<b>TE_SCI_UNRECOVERABLE_DATA_TFX_ERROR</b>	TRIED TO SEND DATA ON REDUNDANT LINK BUT FAILED
0x1c	<b>TE_SCI_CANNOT_INIT_LOCALSEGMENT</b>	CANNOT INITIALIZE LOCAL SEGMENT
0x1d	<b>TE_SCI_CANNOT_MAP_REMOTESEGMENT</b>	CANNOT MAP REMOTE SEGMENT
0x1e	<b>TE_SCI_UNABLE_TO_UNMAP_SEGMENT</b>	CANNOT FREE THE RESOURCES USED BY THIS SEGMENT (STEP 1)
0x1f	<b>TE_SCI_UNABLE_TO_REMOVE_SEGMENT</b>	CANNOT FREE THE RESOURCES USED BY THIS SEGMENT (STEP 2)
0x20	<b>TE_SCI_UNABLE_TO_DISCONNECT_SEGMENT</b>	CANNOT DISCONNECT FROM A REMOTE SEGMENT
0x21	<b>TE_SHM_IPC_PERMANENT</b>	SHM IPC PERMANENT ERROR
0x22	<b>TE_SCI_UNABLE_TO_CLOSE_CHANNEL</b>	UNABLE TO CLOSE THE SCI CHANNEL AND THE RESOURCES ALLOCATED

## 17.5.6. MySQL Cluster Single User Mode

*Single user mode* enables the database administrator to restrict access to the database system to a single API node, such as a MySQL server (SQL node) or an instance of [ndb\\_restore](#). When entering single user mode, connections to all other API nodes are closed gracefully and all running transactions are aborted. No new transactions are permitted to start.

Once the cluster has entered single user mode, only the designated API node is granted access to the database.

You can use the `ALL STATUS` command in the `ndb_mgm` client to see when the cluster has entered single user mode. Beginning with MySQL Cluster NDB 7.1.1, you can also check the `status` column of the `ndbinfo.nodes` table (see [Section 17.5.8.7, “The ndbinfo nodes Table”](#), for more information).

Example:

```
ndb_mgm> ENTER SINGLE USER MODE 5
```

After this command has executed and the cluster has entered single user mode, the API node whose node ID is `5` becomes the cluster's only permitted user.

The node specified in the preceding command must be an API node; attempting to specify any other type of node will be rejected.

#### Note

When the preceding command is invoked, all transactions running on the designated node are aborted, the connection is closed, and the server must be restarted.
